

MAX40006

Micropower, Rail-to-Rail, 300kHz Op Amp with Shutdown in a Tiny, 6-Bump WLP

General Description

The MAX40006 op amp features a maximized ratio of gain bandwidth (GBW) to supply current and is ideal for battery-powered applications such as handsets, tablets, notebooks, and portable medical equipment. This CMOS op amp features an ultra-low input-bias current of 1pA, rail-to-rail input and output, low supply current of 4.5 μ A, and operates from a single 1.7V to 5.5V supply. For additional power conservation, the IC also features a low-power shutdown mode that reduces supply current to 0.1 μ A and puts the amplifier's outputs in a high-impedance state. This device is unity-gain stable with a 300kHz GBW product.

The MAX40006 is available in a space-saving, 0.73mm x 1.07mm, 6-bump wafer-level package (WLP), as well as a 6-pin SOT-23 package. The device is specified over the -40°C to +125°C automotive operating temperature range.

Applications

- Portable Media Players
- Tablet/Notebook Computers
- Electronic Toys
- Portable Medical Devices
- Wearable Fitness Devices

Pin Configurations

Benefits and Features

- 300kHz GBW
- Ultra-Low 4.5 μ A Supply Current
- Single 1.7V to 5.5V Supply Voltage Range
- Ultra-Low 1pA Input Bias Current
- Rail-to-Rail Input and Output Voltage Ranges
- Low $\pm 200\mu$ V Input Offset Voltage
- Low 0.1 μ A Shutdown Current
- High-Impedance Output During Shutdown
- Unity-Gain Stable
- Available in Tiny, 0.73mm x 1.07mm, 6-Bump WLP and SOT-23 Packages
- -40°C to +125°C Temperature Range

Ordering Information appears at end of data sheet.

Typical Operating Characteristic

Absolute Maximum Ratings

V_{DD} to GND -0.3V to +6V
 IN+, IN-, SHDN, OUT to GND -0.3V to ($V_{DD} + 0.3V$)
 Differential Input Voltage (IN+, IN-) $\pm(V_{DD} + 0.3V)$
 Output Short Circuit Duration to either Supply Continuous
 Continuous Current into any input/output $\pm 10mA$
 Continuous Power Dissipation ($T_A = +70^\circ C$)
 6-Bump WLP (Derate 10.19mW/ $^\circ C$ above $+70^\circ C$) 815mW
 6-Pin SOT (Derate 4.3mW/ $^\circ C$ above $+70^\circ C$) 347.8mW

Operating Temperature Range $-40^\circ C$ to $+125^\circ C$
 Junction Temperature $+150^\circ C$
 Storage Temperature Range $-65^\circ C$ to $+150^\circ C$
 Lead Temperature (soldering, 10s) $+300^\circ C$
 Soldering Temperature (reflow) $260^\circ C$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 1)

WLP

Junction-to-Ambient Thermal Resistance (θ_{JA}) 98.06 $^\circ C/W$

SOT23

Junction-to-Ambient Thermal Resistance (θ_{JA}) 230 $^\circ C/W$ Junction-to-Ambient Thermal Resistance (θ_{JC}) 76 $^\circ C/W$

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Electrical Characteristics

$V_{DD} = 3.6V$, $V_{GND} = 0V$, $V_{CM} = V_{DD}/2$, $V_{OUT} = V_{DD}/2$, $R_L = \infty$, $V_{SHDN} = V_{DD}$, $T_A = T_{MIN}$ to T_{MAX} . Typical values are at $T_A = +25^\circ C$, unless otherwise noted. (Note 2)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
POWER SUPPLY VOLTAGE						
Supply Voltage Range	V_{DD}		1.7		5.5	V
Supply Current	I_{DD}	$V_{DD} = 3.6V$, $T_A = +25^\circ C$		4.5	5	μA

MAX40006

Micropower, Rail-to-Rail, 300kHz Op Amp
with Shutdown in a Tiny, 6-Bump WLP

Pin Configurations

Functional Block Diagram

Pin Description

PIN		NAME	FUNCTION
WLP	SOT23		
A1	3	IN+	Noninverting Input
A2	4	IN-	Inverting Input
A3	1	OUT	Output
B1	5	$\overline{\text{SHDN}}$	Active Low Shutdown Input
B2	6	VDD	Positive Supply Voltage
B3	2	GND	Ground

Detailed Description

Featuring a maximized ratio of GBW-to-supply current, low operating supply voltage, low input bias current, and rail-to-rail inputs and outputs, the MAX40006 is an excellent choice for precision or general-purpose, low-current, low-voltage, battery-powered applications. This CMOS device consumes an ultra-low 4.5μA (typ) supply current and has a 200μV (typ) offset voltage. For additional power conservation, the IC features a low-power shutdown mode that reduces supply current to 0.1μA (typ) and puts the amplifier's output in a high-impedance state. This device is unity-gain stable with a 300kHz GBW product, driving capacitive loads up to 30pF. The capacitive load can be increased to 250pF when the amplifier is configured for a minimum gain of 10V/V. Applications that require greater capacitive-drive capability should use an isolation resistor between the output and the capacitive load (Figure 2). Also, in unity-gain applications with relatively small R_L (approximately 5kΩ), the capacitive load can be increased up to 200pF.

Input Differential Voltage Protection

During normal operation, the inverting and noninverting inputs of the device are at essentially the same voltage. However, either due to fast input voltage transients or other fault conditions, these inputs can be forced to be at two different voltages. Internal back-to-back diodes protect the inputs from an excessive differential voltage (see [Functional Block Diagram](#)). Therefore, V_{IN+} and V_{IN-} can be any voltage within the range shown in the [Absolute Maximum Ratings](#) section. Note the protection time is still dependent on the package thermal limits. If the input signal is fast enough to create the internal diodes' forward bias condition, the input signal current must be limited to 5mA or less. If the input signal current is not inherently limited, an input series resistor can be used to limit the signal input current. Care should be taken in choosing the input series resistor value, since it degrades the input noise performance of the amplifier.

Rail-to-Rail Inputs and Outputs

The MAX40006 has a parallel-connected n-channel and p-channel differential input stage that allows an input common-mode voltage range that extends 50mV beyond the positive and negative supply rails. This device is capable of driving the output to within 5mV of both supply rails with a 100kΩ load. This device can drive a 5kΩ load with swings to within 70mV of the rails. Figure 1 shows the output voltage swing of the amplifier, configured as a unity-gain buffer, and powered from a single 3V supply.

Low Input Bias Current

The MAX40006 features ultra-low 1pA (typ) input bias current. The variation in the input bias current is minimal with changes in the input voltage due to very high input impedance (in the order of 1GΩ).

Applications Information

Driving Capacitive Loads

The amplifier is unity-gain stable for loads up to 30pF. However, the capacitive load can be increased to 250pF when the amplifier is configured for a minimum gain of 10V/V. Applications that require greater capacitive-drive capability should use an isolation resistor between the output and the capacitive load (Figure 2). Also, in unity-gain applications with relatively small R_L (approximately 5kΩ), the capacitive load can be increased up to 200pF.

Figure 2. Using a Resistor to Isolate a Capacitive Load from the Op Amp

Power-Supply Considerations

The MAX40006 is optimized for single 1.7V to 5.5V supply operation. A high amplifier power-supply rejection ratio of 80dB (typ) allows the devices to be powered directly from a battery, simplifying design and extending battery life.

Power-Up Settling Time

The MAX40006 settling time depends primarily on the output voltage and is slew rate limited. [Figure 3](#) shows the MAX40006 in a noninverting voltage follower configuration with the input held at midsupply. The output settles in approximately 35 μ s for $V_{DD} = 3V$ (see the [Typical Operating Characteristics](#) for power-up settling time).

Power-Supply Bypassing and Layout

To minimize noise, bypass V_{DD} with a 0.1 μ F capacitor to ground, as close to the pin as possible.

Good layout techniques optimize performance by decreasing the amount of stray capacitance and inductance to the op amps' inputs and outputs. Minimize stray capacitance and inductance by placing external components close to the IC.

Figure 3. Power-Up Test Configuration

Shutdown

The shutdown input ($\overline{\text{SHDN}}$) is an active-low input. For normal operating conditions, connect $\overline{\text{SHDN}}$ to a logic-high or V_{DD} . Drive $\overline{\text{SHDN}}$ low to place the device in shut down and reduce the supply current to 0.1 μ A. The MAX40006's output is high impedance in shutdown mode; however, due to the back-to-back diode protection circuit at the inputs and the feedback path, the output sees a voltage of one diode drop below the noninverting input voltage in unity buffer configuration (see [Figure 4](#)). The device typically enters shutdown in 2 μ s and exits in 35 μ s. [Figure 5](#) and [Figure 6](#) show the output voltage behavior during into and out of the shutdown mode in unity buffer configuration with $V_{DD} = 5V$, $V_{IN+} = 2.5V$ and 0V, respectively. [Figure 7](#) and [Figure 8](#) show the output with 1M Ω in the feedback path, limiting the leakage current from the positive input due to the internal back-to-back diodes in shutdown mode.
