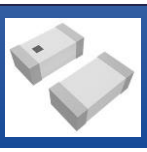
UWB 6.24-8.24GHz Chip Antenna



AANI-CH-0136

Request Samples | Check Inventory

3.2 x 1.6 x 1.1 mm
RoHS/RoHS II Compliant
MSL Level = 1

Features

- Miniaturized in Size: 3.2 x 1.6 x 1.1 mm
- Low Return Loss of: ≤ -15.1 dB
- Peak Gain: 3.9 dBi
- Average Total Efficiency: -1.3 dB (74%)
- Linear Polarization
- Surface Mount (SMD)
- Integration: PCB Corner Mount

Applications

- UWB Channels: 5,6,8,9 (6.24-8.24 GHz)
- Real-Time Location Systems (RTLS)
- Secure Ranging (Two-Way, TDOA, etc.)
- Indoor Navigation
- Asset Tracking for Smart Homes & Mining
- Smart Access Control
- Secure Keyless Entry

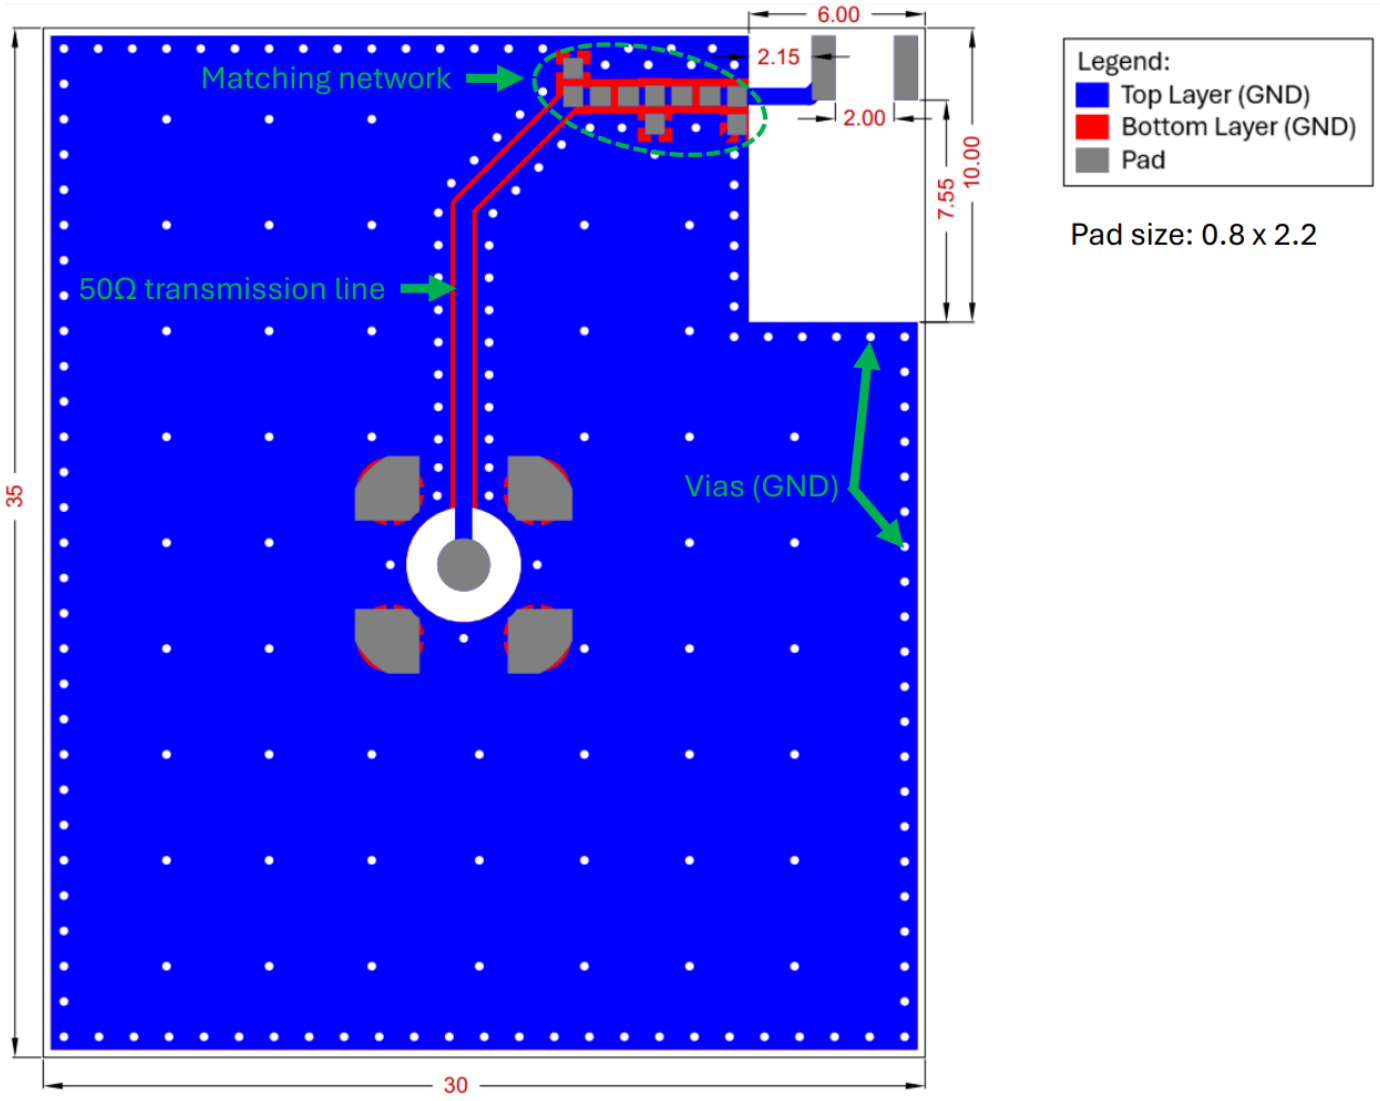
Recommended PCB layout

If there are several layers in the PCB, there is an advantage to add vias for smooth interconnection of the ground areas to avoid splits in the ground plane. It is also important that the ground clearance is respected through **all layers** of the PCB. It is recommended to implement a matching network to optimize the antenna impedance in your application.



Unit: mm

Transmission Line

The transmission line should be kept as short as possible and be designed to have a characteristic impedance of 50Ω. Abracon recommends using a Co-Planar Waveguide with Ground (CPWG), which dimensions can be derived by any trusted calculator, using the correct input for PCB materials and layer stack-up.

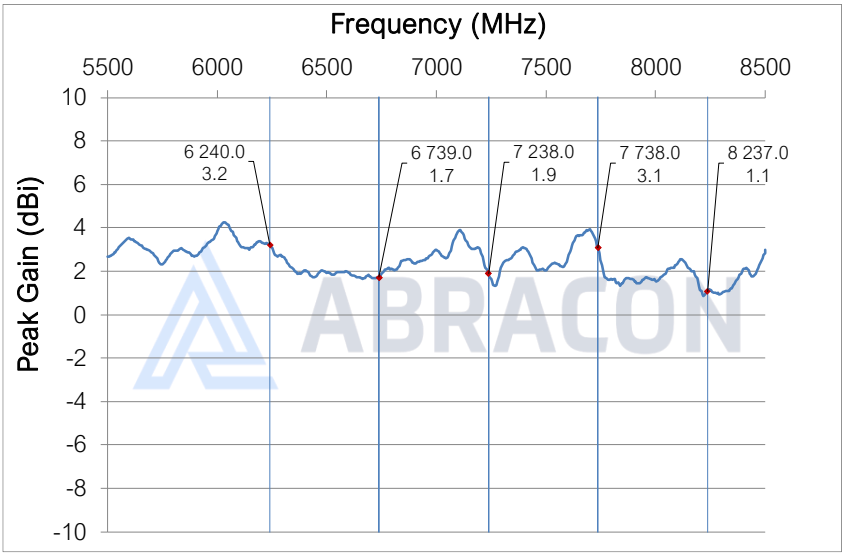
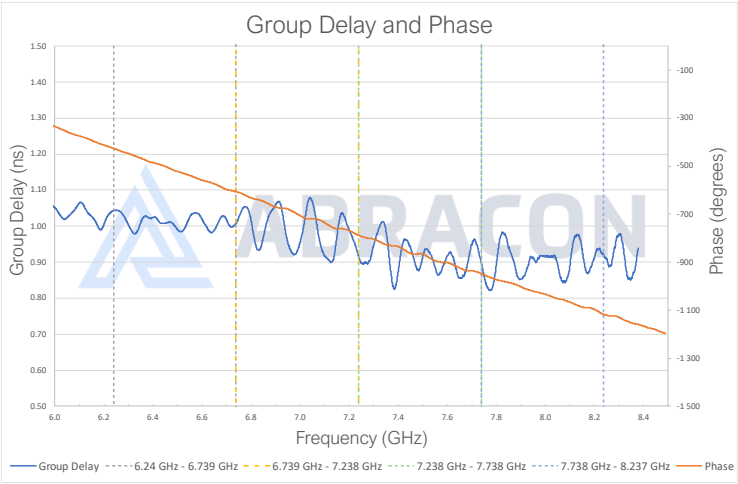
Radiation Characteristics – Maximum Gain



Radiation Characteristics – Group Delay

Two identical antennas were placed a distance d_{sep} apart in an anechoic chamber. The Group Delay, τ_{GD}, is then calculated from the transmission S-parameter (S12) by $\tau_{GD} = -\frac{1}{2 \cdot 360}\frac{\Delta\phi}{\Delta f}$, where $\Delta\phi$ is the change of phase over an aperture Δf. The maximum variation in group delay per channel, $\Delta_{\max}\tau_{GD}$, can be found in the table below.



Used Parameters	
Distance $\mathbf{d_{sep}}$ (cm)	Aperture $\mathbf{\Delta f}$ (MHz)
50	220

Maximum Group Delay Variation			
UWB Ch.	Freq. Low (GHz)	Freq. High (GHz)	$\mathbf{\Delta_{max}\tau_{GD}}$ (ps)
5	6.240	6.739	66
6	6.739	7.238	180
8	7.238	7.738	186
9	7.738	8.237	162

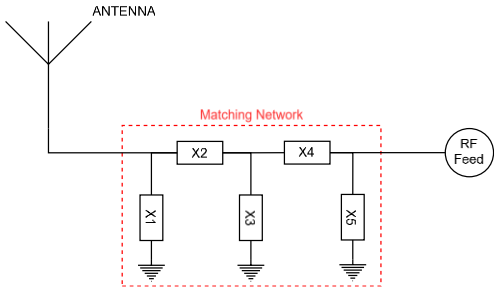
Evaluation Board Outline & Matching Circuit

The evaluation board (Abracon AANI-CH-0136-EVB) is developed to simplify antenna testing and evaluation. It has an arbitrary size of 35 x 30 mm and includes an SMA connector. The purpose is to give a reference design for an optimal antenna implementation. The evaluation board can also be used to test other implementations by cutting and soldering the PCB into any device.

The evaluation board has a matching circuit implemented next to the antenna. This is aimed to enable optimization possibilities for the user. The component positions are sized for 0402 (1005 metric) SMD components.

The antenna requires a matching circuit to fine-tune the resonant frequency and achieve optimal balance. The evaluation board is pre-tuned for optimal performance in the 6.24-8.24 GHz range using the components listed below (equivalents may be used):



X1 = Not mounted

X2 = 0.7 pF (Murata GJM1555C1HR70WB01)

X3 = 1.7 nH (Murata LQW15AN1N7C00)

X4 = 0 Ω (KOA Speer RK73Z1ETTP)

X5 = Not mounted

However, it is common that the resonant frequency will shift during implementation in an arbitrary device. Therefore, this matching may be changed with other values/components/brands for compensation of such effects. This is further described in the General Implementation Guidelines section below.

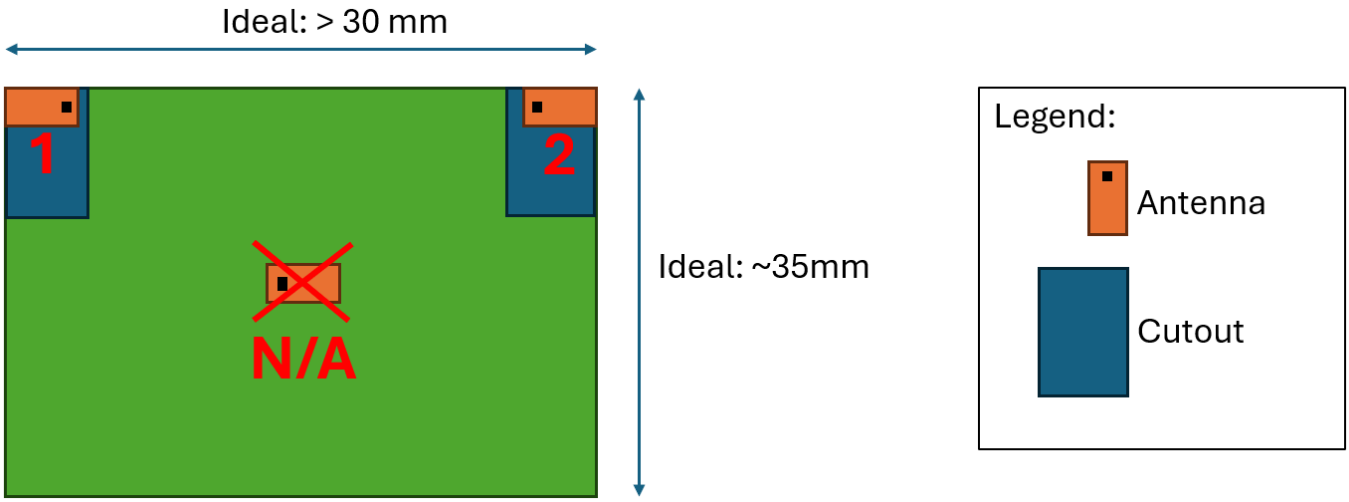
General Implementation Guidelines

The antenna can be positioned in different ways, although there are some positions which are more beneficial. The illustration below shows a typical PCB with examples on different antenna positions:

- Both options are optimal.
- The antenna must be placed along the PCB edge, i.e., it cannot be placed in the middle (see “N/A”).



The rectangular copper cutout in the footprint must extend through all layers of the PCB stack-up, ensuring there is **no copper on any layer in this area**. Additionally, a robust via structure around the cutout and along the edge of the ground plane is highly recommended for optimal performance.

It is important to note that plastic and metal parts in close proximity to antennas may significantly affect antenna tuning and performance. For instance, a plastic housing above the antenna often causes the resonant frequency to shift downward. Since such effects are challenging to predict without detailed design information, it is recommended to measure the antenna performance in the final device after implementation. To compensate for potential frequency shifts, implementing a matching network on the antenna feed is advisable.

Another general consideration for surface-mounted antennas relates to PCB population. Electrical components placed near the antenna may impact its tuning and radiation performance. To mitigate this, components in the surrounding area should be positioned below a topographical slope. This slope should begin at the PCB level near the antenna's designated keep-out zone and gradually increase in height as distance from the antenna grows.
