1. The optimum core supply voltage is determined by the individual chip manufacturing process variation. The system software reads an index stored in the on-chip OTP memory and controls the VDD regulator output voltage. The nominal regulation of the VDD regulator should be within ±3%. For details refer to the *PV Compensation Application Note*.

2. For normal operation only, not applicable during power up/down.

3. The important parameter is maximum junction temperature. The maximum junction temperature needs to be observed in addition to the ambient temperature limits.

3. VDD_CPU and SOC_VDD_CORE are recommended to ramp up relatively close to each other. No specific sequence is required between them.
4. SOC_VDDIO1P8/SOC_AVDD1P8/SM_VDDIO1P8/SM_AVDD1P8 starts ramping up (T3) after SOC_VDD_CORE reaches its 100% of 0.8V (T2).
5. SM_FE_AVDD3P3 starts ramping (T5) after the other SM/SOC rails have reached their thresholds (T4).
