|----------------|-------|------|

## Chapter 1 About this Document

|     |                                 |    |
|-----|---------------------------------|----|
| 1.1 | Audience.....                   | 21 |
| 1.2 | Organization.....               | 21 |
| 1.3 | Suggested Reading.....          | 21 |
| 1.4 | Conventions.....                | 22 |
| 1.5 | Register Access.....            | 24 |
| 1.6 | Acronyms and Abbreviations..... | 26 |

## Chapter 2 Introduction

|     |                          |    |
|-----|--------------------------|----|
| 2.1 | Introduction.....        | 31 |
| 2.2 | Features.....            | 33 |
| 2.3 | Target Applications..... | 35 |
| 2.4 | Endianness Support.....  | 35 |

## Chapter 3 Memory Maps

|     |                              |    |
|-----|------------------------------|----|
| 3.1 | Memory system overview.....  | 37 |
| 3.2 | Arm Platform Memory Map..... | 37 |

## Chapter 4 Interrupts, DMA Events, and XBAR Assignments

|     |                                                          |    |
|-----|----------------------------------------------------------|----|
| 4.1 | Chip-specific Interrupt information.....                 | 45 |
| 4.2 | Overview.....                                            | 45 |
| 4.3 | CM7 interrupts.....                                      | 45 |
| 4.4 | DMA Mux.....                                             | 53 |
| 4.5 | PIT Channel Assignments For Periodic DMA Triggering..... | 61 |
| 4.6 | XBAR Resource Assignments.....                           | 61 |

## Chapter 5 Direct Memory Access Multiplexer (DMAMUX)

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 5.1            | Chip-specific DMAMUX information.....       | 75   |
| 5.2            | Introduction.....                           | 75   |
| 5.3            | External signal description.....            | 77   |
| 5.4            | Functional description.....                 | 77   |
| 5.5            | Initialization/application information..... | 82   |
| 5.6            | Memory map/register definition.....         | 85   |

## Chapter 6 Enhanced Direct Memory Access (eDMA)

|     |                                             |     |
|-----|---------------------------------------------|-----|
| 6.1 | Chip-specific eDMA information.....         | 89  |
| 6.2 | Introduction.....                           | 89  |
| 6.3 | Modes of operation.....                     | 93  |
| 6.4 | Functional description.....                 | 93  |
| 6.5 | Initialization/application information..... | 99  |
| 6.6 | Memory map/register definition.....         | 114 |

## Chapter 7 System Security

|      |                                                     |     |
|------|-----------------------------------------------------|-----|
| 7.1  | Chapter overview.....                               | 173 |
| 7.2  | Feature summary.....                                | 173 |
| 7.3  | High-Assurance Boot (HAB).....                      | 175 |
| 7.4  | Secure Non-Volatile Storage (SNVS) module.....      | 178 |
| 7.5  | Data Co-Processor (DCP).....                        | 180 |
| 7.6  | Standalone True Random Number Generator (TRNG)..... | 180 |
| 7.7  | On-Chip OTP Controller (OCOTP_CTRL).....            | 180 |
| 7.8  | Central Security Unit (CSU).....                    | 181 |
| 7.9  | System JTAG Controller (SJC).....                   | 181 |
| 7.10 | Bus Encryption Engine (BEE).....                    | 182 |

## Chapter 8 System Debug

|     |                                               |     |
|-----|-----------------------------------------------|-----|
| 8.1 | Overview.....                                 | 183 |
| 8.2 | Chip and Arm Platform Debug Architecture..... | 183 |

| Section number                                              | Title                                               | Page |
|-------------------------------------------------------------|-----------------------------------------------------|------|
| 8.3                                                         | Miscellaneous.....                                  | 191  |
| <b>Chapter 9<br/>System Boot</b>                            |                                                     |      |
| 9.1                                                         | Chip-specific Boot Information.....                 | 193  |
| 9.2                                                         | Overview.....                                       | 197  |
| 9.3                                                         | Boot modes.....                                     | 199  |
| 9.4                                                         | Device configuration.....                           | 203  |
| 9.5                                                         | Device initialization.....                          | 205  |
| 9.6                                                         | Boot devices.....                                   | 210  |
| 9.7                                                         | Program image.....                                  | 255  |
| 9.8                                                         | Plugin image.....                                   | 262  |
| 9.9                                                         | Serial Downloader.....                              | 263  |
| 9.10                                                        | Recovery devices.....                               | 272  |
| 9.11                                                        | SD/MMC manufacture mode.....                        | 272  |
| 9.12                                                        | High-Assurance Boot (HAB).....                      | 273  |
| <b>Chapter 10<br/>External Signals and Pin Multiplexing</b> |                                                     |      |
| 10.1                                                        | Overview.....                                       | 277  |
| <b>Chapter 11<br/>IOMUX Controller (IOMUXC)</b>             |                                                     |      |
| 11.1                                                        | Overview.....                                       | 303  |
| 11.2                                                        | Clocks.....                                         | 305  |
| 11.3                                                        | Functional description.....                         | 305  |
| 11.4                                                        | IOMUXC GPR Memory Map/Register Definition.....      | 308  |
| 11.5                                                        | IOMUXC SNVS Memory Map/Register Definition.....     | 357  |
| 11.6                                                        | IOMUXC SNVS GPR Memory Map/Register Definition..... | 376  |
| 11.7                                                        | IOMUXC Memory Map/Register Definition.....          | 380  |
| <b>Chapter 12<br/>General Purpose Input/Output (GPIO)</b>   |                                                     |      |
| 12.1                                                        | Chip-specific GPIO information.....                 | 997  |

| Section number | Title                            | Page |
|----------------|----------------------------------|------|
| 12.2           | Overview.....                    | 997  |
| 12.3           | Clocks.....                      | 1001 |
| 12.4           | GPIO Functional Description..... | 1001 |
| 12.5           | GPIO register descriptions.....  | 1009 |

## Chapter 13 Clock and Power Management

|      |                                                      |      |
|------|------------------------------------------------------|------|
| 13.1 | Introduction.....                                    | 1029 |
| 13.2 | Device Power Management Architecture Components..... | 1029 |
| 13.3 | Clock Management.....                                | 1032 |
| 13.4 | Power management.....                                | 1041 |
| 13.5 | ONOFF (Button).....                                  | 1056 |
| 13.6 | WAKEUP Pin.....                                      | 1057 |

## Chapter 14 Clock Controller Module (CCM)

|      |                                                |      |
|------|------------------------------------------------|------|
| 14.1 | Chip-specific CCM information.....             | 1059 |
| 14.2 | Overview.....                                  | 1059 |
| 14.3 | External Signals.....                          | 1062 |
| 14.4 | CCM Clock Tree.....                            | 1062 |
| 14.5 | System Clocks.....                             | 1065 |
| 14.6 | Functional Description.....                    | 1079 |
| 14.7 | CCM Memory Map/Register Definition.....        | 1092 |
| 14.8 | CCM Analog Memory Map/Register Definition..... | 1141 |

## Chapter 15 Crystal Oscillator (XTALOSC)

|      |                                                   |      |
|------|---------------------------------------------------|------|
| 15.1 | Chip-specific XTALOSC information.....            | 1181 |
| 15.2 | Overview.....                                     | 1181 |
| 15.3 | External Signals.....                             | 1182 |
| 15.4 | Crystal Oscillator 24 MHz.....                    | 1182 |
| 15.5 | Crystal Oscillator 32 kHz.....                    | 1184 |
| 15.6 | XTALOSC 24MHz Memory Map/Register Definition..... | 1186 |

| Section number                        | Title                                   | Page |
|---------------------------------------|-----------------------------------------|------|
| <b>Chapter 16</b>                     |                                         |      |
| <b>Power Management Unit (PMU)</b>    |                                         |      |
| 16.1                                  | Chip-specific PMU information.....      | 1199 |
| 16.2                                  | Overview.....                           | 1200 |
| 16.3                                  | Analog LDO Regulators.....              | 1201 |
| 16.4                                  | USB LDO Regulator.....                  | 1203 |
| 16.5                                  | SNVS Regulator.....                     | 1203 |
| 16.6                                  | PMU Memory Map/Register Definition..... | 1204 |
| <b>Chapter 17</b>                     |                                         |      |
| <b>General Power Controller (GPC)</b> |                                         |      |
| 17.1                                  | Chip-specific GPC information.....      | 1229 |
| 17.2                                  | Overview.....                           | 1229 |
| 17.3                                  | Clocks.....                             | 1230 |
| 17.4                                  | Power Gating Control (PGC).....         | 1230 |
| 17.5                                  | GPC Interrupt Controller (INTC).....    | 1233 |
| 17.6                                  | GPC Memory Map/Register Definition..... | 1234 |
| 17.7                                  | PGC Memory Map/Register Definition..... | 1240 |
| <b>Chapter 18</b>                     |                                         |      |
| <b>DCDC Converter (DCDC)</b>          |                                         |      |
| 18.1                                  | Chip-specific DCDC information.....     | 1249 |
| 18.2                                  | Introduction.....                       | 1249 |
| 18.3                                  | Features.....                           | 1249 |
| 18.4                                  | Block diagram.....                      | 1250 |
| 18.5                                  | Functional description.....             | 1250 |
| 18.6                                  | Application information.....            | 1251 |
| 18.7                                  | Memory Map and register definition..... | 1253 |
| <b>Chapter 19</b>                     |                                         |      |
| <b>Temperature Monitor (TEMPMON)</b>  |                                         |      |
| 19.1                                  | Chip-specific TEMPMON information.....  | 1265 |
| 19.2                                  | Overview.....                           | 1265 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 19.3           | Software Usage Guidelines.....              | 1267 |
| 19.4           | TEMPMON Memory Map/Register Definition..... | 1268 |

## Chapter 20 Secure Non-Volatile Storage (SNVS)

|      |                                       |      |
|------|---------------------------------------|------|
| 20.1 | Chip-specific SNVS information.....   | 1275 |
| 20.2 | SNVS introduction.....                | 1275 |
| 20.3 | SNVS Structure.....                   | 1277 |
| 20.4 | Runtime Procedures.....               | 1279 |
| 20.5 | Reset and Initialization of SNVS..... | 1282 |
| 20.6 | SNVS register descriptions.....       | 1285 |

## Chapter 21 System Reset Controller (SRC)

|      |                                                                          |      |
|------|--------------------------------------------------------------------------|------|
| 21.1 | Chip-specific SRC information.....                                       | 1315 |
| 21.2 | SRC Overview.....                                                        | 1315 |
| 21.3 | External Signals.....                                                    | 1316 |
| 21.4 | Clocks.....                                                              | 1316 |
| 21.5 | Top-level resets, power-up sequence and external supply integration..... | 1317 |
| 21.6 | Power-On Reset and power sequencing.....                                 | 1322 |
| 21.7 | Functional Description.....                                              | 1323 |
| 21.8 | SRC Memory Map/Register Definition.....                                  | 1328 |

## Chapter 22 Fusemap

|      |                                 |      |
|------|---------------------------------|------|
| 22.1 | Boot Fusemap.....               | 1343 |
| 22.2 | Lock Fusemap.....               | 1354 |
| 22.3 | Fusemap Descriptions Table..... | 1355 |

## Chapter 23 On-Chip OTP Controller (OCOTP\_CTRL)

|      |                                           |      |
|------|-------------------------------------------|------|
| 23.1 | Chip-specific OCOTP_CTRL information..... | 1367 |
| 23.2 | Overview.....                             | 1367 |
| 23.3 | Clocks.....                               | 1368 |

| Section number | Title                                         | Page |
|----------------|-----------------------------------------------|------|
| 23.4           | Top-Level Symbol and Functional Overview..... | 1369 |
| 23.5           | Fuse Map.....                                 | 1374 |
| 23.6           | OCOTP Memory Map/Register Definition.....     | 1374 |

## Chapter 24 External Memory Controllers

|      |                                                       |      |
|------|-------------------------------------------------------|------|
| 24.1 | Overview.....                                         | 1407 |
| 24.2 | Smart External Memory Controller (SEMC) Overview..... | 1407 |
| 24.3 | eMMC/eSD/SDIO.....                                    | 1408 |
| 24.4 | Quad Serial Peripheral Interface.....                 | 1409 |

## Chapter 25 Smart External Memory Controller

|      |                                         |      |
|------|-----------------------------------------|------|
| 25.1 | Chip-specific SEMC information.....     | 1411 |
| 25.2 | About this module.....                  | 1411 |
| 25.3 | Signals.....                            | 1415 |
| 25.4 | Functional description.....             | 1416 |
| 25.5 | Memory Map and register definition..... | 1453 |

## Chapter 26 Ultra Secured Digital Host Controller (uSDHC)

|      |                                           |      |
|------|-------------------------------------------|------|
| 26.1 | Chip-specific uSDHC information.....      | 1517 |
| 26.2 | Overview.....                             | 1517 |
| 26.3 | External Signals.....                     | 1521 |
| 26.4 | Clocks.....                               | 1523 |
| 26.5 | Functional Description.....               | 1523 |
| 26.6 | Initialization/Application of uSDHC.....  | 1546 |
| 26.7 | Commands for MMC/SD/SDIO.....             | 1571 |
| 26.8 | Software Restrictions.....                | 1577 |
| 26.9 | uSDHC Memory Map/Register Definition..... | 1579 |

## Chapter 27 FlexSPI Controller

|      |                                        |      |
|------|----------------------------------------|------|
| 27.1 | Chip-specific FlexSPI information..... | 1647 |
|------|----------------------------------------|------|

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 27.2           | Overview.....                           | 1648 |
| 27.3           | Glossary for FlexSPI module.....        | 1651 |
| 27.4           | External Signal Description.....        | 1652 |
| 27.5           | Functional description.....             | 1653 |
| 27.6           | Application information.....            | 1701 |
| 27.7           | Memory Map and register definition..... | 1720 |
| 27.8           | AHB Memory Map definition.....          | 1762 |

## Chapter 28 Arm Cortex M7 Platform

|      |                                              |      |
|------|----------------------------------------------|------|
| 28.1 | Chip-specific Arm Cortex M7 information..... | 1765 |
| 28.2 | Arm Cortex M7 Platform.....                  | 1766 |

## Chapter 29 Network Interconnect Bus System (NIC-301)

|      |                                         |      |
|------|-----------------------------------------|------|
| 29.1 | Chip-specific NIC-301 information.....  | 1769 |
| 29.2 | Overview .....                          | 1769 |
| 29.3 | External Signals.....                   | 1770 |
| 29.4 | Memory Map and Register Definition..... | 1770 |

## Chapter 30 On-Chip RAM Memory Controller (OCRAM)

|      |                                      |      |
|------|--------------------------------------|------|
| 30.1 | Chip-specific OCRAM information..... | 1779 |
| 30.2 | Overview.....                        | 1779 |
| 30.3 | Basic Functions.....                 | 1780 |
| 30.4 | Advanced Features.....               | 1781 |
| 30.5 | Programmable Registers.....          | 1783 |

## Chapter 31 FlexRAM

|      |                                         |      |
|------|-----------------------------------------|------|
| 31.1 | Chip-specific FlexRAM information.....  | 1785 |
| 31.2 | Overview.....                           | 1786 |
| 31.3 | Functional description.....             | 1787 |
| 31.4 | Memory Map and register definition..... | 1790 |

| Section number                         | Title                                      | Page |
|----------------------------------------|--------------------------------------------|------|
| <b>Chapter 32</b>                      |                                            |      |
| <b>AHB to IP Bridge (AIPSTZ)</b>       |                                            |      |
| 32.1                                   | Chip-specific AIPSTZ information.....      | 1797 |
| 32.2                                   | Overview.....                              | 1797 |
| 32.3                                   | Clocks.....                                | 1798 |
| 32.4                                   | Functional Description.....                | 1798 |
| 32.5                                   | Access Protections.....                    | 1799 |
| 32.6                                   | Access Support.....                        | 1800 |
| 32.7                                   | Initialization Information.....            | 1800 |
| 32.8                                   | AIPSTZ Memory Map/Register Definition..... | 1802 |
| <b>Chapter 33</b>                      |                                            |      |
| <b>Display And Camera Overview</b>     |                                            |      |
| 33.1                                   | Display and Camera Overview.....           | 1821 |
| <b>Chapter 34</b>                      |                                            |      |
| <b>CMOS Sensor Interface (CSI)</b>     |                                            |      |
| 34.1                                   | Chip-specific CSI information.....         | 1825 |
| 34.2                                   | Overview.....                              | 1825 |
| 34.3                                   | External Signals.....                      | 1826 |
| 34.4                                   | Clocks.....                                | 1828 |
| 34.5                                   | Principles of Operation.....               | 1828 |
| 34.6                                   | Interrupt Generation.....                  | 1835 |
| 34.7                                   | Data Packing Style.....                    | 1838 |
| 34.8                                   | CSI Memory Map/Register Definition.....    | 1842 |
| <b>Chapter 35</b>                      |                                            |      |
| <b>Enhanced LCD Interface (eLCDIF)</b> |                                            |      |
| 35.1                                   | Chip-specific eLCDIF information.....      | 1865 |
| 35.2                                   | Overview.....                              | 1865 |
| 35.3                                   | External Signals.....                      | 1866 |
| 35.4                                   | Clocks.....                                | 1867 |
| 35.5                                   | Functional Description.....                | 1867 |

| Section number | Title                                     | Page |
|----------------|-------------------------------------------|------|
| 35.6           | Behavior During Reset.....                | 1884 |
| 35.7           | LCDIF Memory Map/Register Definition..... | 1884 |

## Chapter 36 Pixel Pipeline (PXP)

|      |                                         |      |
|------|-----------------------------------------|------|
| 36.1 | Chip-specific PXP information.....      | 1913 |
| 36.2 | Overview.....                           | 1913 |
| 36.3 | Clocks.....                             | 1914 |
| 36.4 | Top-level architecture.....             | 1914 |
| 36.5 | Output Image Processing.....            | 1945 |
| 36.6 | Queuing PXP transactions.....           | 1946 |
| 36.7 | Error Handling.....                     | 1947 |
| 36.8 | PXP Memory Map/Register Definition..... | 1947 |

## Chapter 37 Audio Overview

|      |                     |      |
|------|---------------------|------|
| 37.1 | Audio Overview..... | 1985 |
|------|---------------------|------|

## Chapter 38 Synchronous Audio Interface (SAI)

|      |                                         |      |
|------|-----------------------------------------|------|
| 38.1 | Chip-specific SAI information.....      | 1991 |
| 38.2 | Introduction.....                       | 1992 |
| 38.3 | External signals.....                   | 1994 |
| 38.4 | Functional description.....             | 1995 |
| 38.5 | Memory map and register definition..... | 2005 |

## Chapter 39 Medium Quality Sound (MQS)

|      |                                    |      |
|------|------------------------------------|------|
| 39.1 | Chip-specific MQS information..... | 2041 |
| 39.2 | Overview.....                      | 2041 |
| 39.3 | External Signals.....              | 2043 |
| 39.4 | Interface Signals.....             | 2043 |
| 39.5 | Programming Considerations.....    | 2044 |

## Chapter 40

| Section number                                           | Title                                            | Page |
|----------------------------------------------------------|--------------------------------------------------|------|
| <b>Sony/Philips Digital Interface (SPDIF)</b>            |                                                  |      |
| 40.1                                                     | Chip-specific SPDIF information.....             | 2045 |
| 40.2                                                     | Overview .....                                   | 2045 |
| 40.3                                                     | External Signals.....                            | 2048 |
| 40.4                                                     | Clocks.....                                      | 2048 |
| 40.5                                                     | Functional Description.....                      | 2048 |
| 40.6                                                     | SPDIF Memory Map/Register Definition.....        | 2059 |
| <b>Chapter 41</b>                                        |                                                  |      |
| <b>10/100 /1000 -Mbps Ethernet MAC (ENET)</b>            |                                                  |      |
| 41.1                                                     | Chip-specific ENET information.....              | 2079 |
| 41.2                                                     | Introduction.....                                | 2079 |
| 41.3                                                     | Overview.....                                    | 2079 |
| 41.4                                                     | External Signals.....                            | 2084 |
| 41.5                                                     | Clocks.....                                      | 2092 |
| 41.6                                                     | Memory map/register definition.....              | 2092 |
| 41.7                                                     | Functional description.....                      | 2161 |
| <b>Chapter 42</b>                                        |                                                  |      |
| <b>Universal Serial Bus Controller (USB)</b>             |                                                  |      |
| 42.1                                                     | Chip-specific USB information.....               | 2223 |
| 42.2                                                     | Overview.....                                    | 2223 |
| 42.3                                                     | External Signals.....                            | 2226 |
| 42.4                                                     | Functional Description.....                      | 2227 |
| 42.5                                                     | USB Operation Model.....                         | 2231 |

| 42.7                                                     | USB Core Memory Map/Register Definition.....     | 2405 |
| <b>Chapter 43</b>                                        |                                                  |      |
| <b>Universal Serial Bus 2.0 Integrated PHY (USB-PHY)</b> |                                                  |      |
| 43.1                                                     | Chip-specific USB-PHY information.....           | 2483 |
| 43.2                                                     | USB PHY Overview.....                            | 2483 |
| 43.3                                                     | Operation.....                                   | 2483 |

| Section number | Title                                          | Page |
|----------------|------------------------------------------------|------|
| 43.4           | USB PHY Memory Map/Register Definition.....    | 2494 |
| 43.5           | USB Analog Memory Map/Register Definition..... | 2511 |

## Chapter 44 Flexible Controller Area Network (FLEXCAN)

|      |                                             |      |
|------|---------------------------------------------|------|
| 44.1 | Chip-specific FLEXCAN information.....      | 2533 |
| 44.2 | Overview.....                               | 2533 |
| 44.3 | External Signals.....                       | 2538 |
| 44.4 | Clocks.....                                 | 2539 |
| 44.5 | Message Buffer Structure.....               | 2539 |
| 44.6 | Rx FIFO Structure.....                      | 2544 |
| 44.7 | Functional Description.....                 | 2547 |
| 44.8 | Initialization/Application Information..... | 2574 |
| 44.9 | FLEXCAN Memory Map/Register Definition..... | 2575 |

## Chapter 45 Keypad Port (KPP)

|      |                                             |      |
|------|---------------------------------------------|------|
| 45.1 | Chip-specific KPP information.....          | 2619 |
| 45.2 | Overview .....                              | 2619 |
| 45.3 | Clocks.....                                 | 2621 |
| 45.4 | External Signals.....                       | 2621 |
| 45.5 | Functional Description.....                 | 2623 |
| 45.6 | Initialization/Application Information..... | 2631 |
| 45.7 | KPP Memory Map/Register Definition.....     | 2632 |

## Chapter 46 Low Power Inter-Integrated Circuit (LPI2C)

|      |                                      |      |
|------|--------------------------------------|------|
| 46.1 | Chip-specific LPI2C information..... | 2639 |
| 46.2 | Introduction.....                    | 2640 |
| 46.3 | Functional description.....          | 2646 |
| 46.4 | Memory Map and Registers.....        | 2658 |

## Chapter 47 Low Power Serial Peripheral Interface (LPSPI)

| Section number | Title                                | Page |
|----------------|--------------------------------------|------|
| 47.1           | Chip-specific LPSPI information..... | 2699 |
| 47.2           | Introduction.....                    | 2699 |
| 47.3           | Functional description.....          | 2702 |
| 47.4           | Memory Map and Registers.....        | 2713 |

## Chapter 48 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

|      |                                       |      |
|------|---------------------------------------|------|
| 48.1 | Chip-specific LPUART information..... | 2739 |
| 48.2 | Introduction.....                     | 2739 |
| 48.3 | Functional description.....           | 2743 |
| 48.4 | Register definition.....              | 2761 |

## Chapter 49 Flexible I/O (FlexIO)

|      |                                       |      |
|------|---------------------------------------|------|
| 49.1 | Chip-specific FlexIO information..... | 2789 |
| 49.2 | Introduction.....                     | 2790 |
| 49.3 | Functional description.....           | 2792 |
| 49.4 | Application Information.....          | 2804 |
| 49.5 | Memory Map and Registers.....         | 2823 |

## Chapter 50 Timers Overview

|      |               |      |
|------|---------------|------|
| 50.1 | Overview..... | 2855 |
|------|---------------|------|

## Chapter 51 General Purpose Timer (GPT)

|      |                                               |      |
|------|-----------------------------------------------|------|
| 51.1 | Chip-specific GPT information.....            | 2859 |
| 51.2 | Overview.....                                 | 2859 |
| 51.3 | External Signals.....                         | 2861 |
| 51.4 | Clocks.....                                   | 2864 |
| 51.5 | Functional Description.....                   | 2865 |
| 51.6 | Initialization/ Application Information ..... | 2870 |
| 51.7 | GPT Memory Map/Register Definition.....       | 2871 |

## Chapter 52

| Section number                        | Title                                             | Page |
|---------------------------------------|---------------------------------------------------|------|
| <b>Periodic Interrupt Timer (PIT)</b> |                                                   |      |
| 52.1                                  | Chip-specific PIT information.....                | 2885 |
| 52.2                                  | Introduction.....                                 | 2885 |
| 52.3                                  | Modes of operation.....                           | 2887 |
| 52.4                                  | Functional description.....                       | 2887 |
| 52.5                                  | Initialization and application information.....   | 2889 |
| 52.6                                  | Example configuration for chained timers.....     | 2890 |
| 52.7                                  | Example configuration for the Lifetime Timer..... | 2891 |
| 52.8                                  | PIT register descriptions.....                    | 2892 |

## Chapter 53 Quad Timer (TMR)

|       |                                    |      |
|-------|------------------------------------|------|
| 53.1  | Chip-specific TMR information..... | 2901 |
| 53.2  | Overview.....                      | 2901 |
| 53.3  | Features.....                      | 2902 |
| 53.4  | Modes of Operation.....            | 2903 |
| 53.5  | Block Diagram.....                 | 2903 |
| 53.6  | Functional Description.....        | 2904 |
| 53.7  | Resets.....                        | 2921 |
| 53.8  | Clocks.....                        | 2921 |
| 53.9  | Interrupts.....                    | 2922 |
| 53.10 | DMA.....                           | 2923 |
| 53.11 | Memory Map and Registers.....      | 2924 |

## Chapter 54 Enhanced Flex Pulse Width Modulator (eFlexPWM)

|      |                                        |      |
|------|----------------------------------------|------|
| 54.1 | Chip-specific FlexPWM information..... | 2945 |
| 54.2 | Introduction.....                      | 2945 |
| 54.3 | Signal Descriptions.....               | 2948 |
| 54.4 | Functional Description.....            | 2950 |
| 54.5 | Resets.....                            | 2985 |
| 54.6 | Interrupts.....                        | 2986 |

| Section number | Title                          | Page |
|----------------|--------------------------------|------|
| 54.7           | DMA.....                       | 2987 |
| 54.8           | PWM register descriptions..... | 2989 |

## Chapter 55 Quadrature Encoder/Decoder (ENC)

|      |                                    |      |
|------|------------------------------------|------|
| 55.1 | Chip-specific ENC information..... | 3059 |
| 55.2 | Introduction.....                  | 3059 |
| 55.3 | Signal Descriptions.....           | 3063 |
| 55.4 | Functional Description.....        | 3064 |
| 55.5 | Speed Measurement Method .....     | 3066 |
| 55.6 | Resets.....                        | 3075 |
| 55.7 | Clocks.....                        | 3075 |
| 55.8 | Interrupts.....                    | 3075 |
| 55.9 | Memory Map and Registers.....      | 3076 |

## Chapter 56 Watchdog Timer (WDOG1-2)

|      |                                                |      |
|------|------------------------------------------------|------|
| 56.1 | Chip-specific WDOG information.....            | 3099 |
| 56.2 | Overview.....                                  | 3099 |
| 56.3 | External signals.....                          | 3101 |
| 56.4 | Clocks.....                                    | 3101 |
| 56.5 | Watchdog mechanism and system integration..... | 3102 |
| 56.6 | Functional description.....                    | 3102 |
| 56.7 | Initialization.....                            | 3110 |
| 56.8 | WDOG Memory Map/Register Definition.....       | 3111 |

## Chapter 57 RTWDOG (WDOG3)

|      |                                         |      |
|------|-----------------------------------------|------|
| 57.1 | Chip-specific RTWDOG information.....   | 3119 |
| 57.2 | Introduction.....                       | 3119 |
| 57.3 | Functional description.....             | 3121 |
| 57.4 | Application Information.....            | 3128 |
| 57.5 | Memory map and register definition..... | 3129 |

| Section number                                    | Title                                     | Page |
|---------------------------------------------------|-------------------------------------------|------|
| <b>Chapter 58</b>                                 |                                           |      |
| <b>External Watchdog Monitor (EWM)</b>            |                                           |      |
| 58.1                                              | Chip-specific EWM information.....        | 3137 |
| 58.2                                              | Introduction.....                         | 3138 |
| 58.3                                              | EWM Signal Descriptions.....              | 3140 |
| 58.4                                              | Functional Description.....               | 3141 |
| 58.5                                              | Memory Map/Register Definition.....       | 3144 |
| <b>Chapter 59</b>                                 |                                           |      |
| <b>On Chip Cross Triggers Overview</b>            |                                           |      |
| 59.1                                              | Overview.....                             | 3153 |
| <b>Chapter 60</b>                                 |                                           |      |
| <b>Inter-Peripheral Crossbar Switch A (XBARA)</b> |                                           |      |
| 60.1                                              | Chip-specific XBAR information.....       | 3155 |

| 66.5 | Memory Map and register definition..... | 3294 |

## Chapter 67 Analog Comparator (ACMP)

| Section number | Title                                | Page |
|----------------|--------------------------------------|------|
| 67.1           | Chip-specific CMP information.....   | 3317 |
| 67.2           | Introduction.....                    | 3317 |
| 67.3           | Functional description.....          | 3322 |
| 67.4           | CMP interrupts.....                  | 3335 |
| 67.5           | DMA support.....                     | 3335 |
| 67.6           | Digital-to-analog converter.....     | 3336 |
| 67.7           | DAC functional description.....      | 3336 |
| 67.8           | DAC resets.....                      | 3337 |
| 67.9           | DAC clocks.....                      | 3337 |
| 67.10          | DAC interrupts.....                  | 3337 |
| 67.11          | Memory map/register definitions..... | 3337 |

# Chapter 1

## About this Document

### 1.1 Audience

The reference manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, input/output (I/O) devices, industry standard communication, and device interface protocols.

### 1.2 Organization

The reference manual describes the chip at a system level and provides an architectural overview. It also describes the system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

### 1.3 Suggested Reading

This section lists additional resources that provide background for the information in the reference manual, as well as general information about the architecture.

**Table 1-1. Suggested Reading**

| Type             | Description                                                                                                      | Resource                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| Fact Sheet       | The Fact Sheet is an overview of the product key features and its uses.                                          | <a href="#">i.MX RT Series Crossover Processor Fact Sheet</a> |
| Reference Manual | The Reference Manual contains a comprehensive description of the structure and function (operation) of a device. | <a href="#">This document</a>                                 |
| Data Sheet       | The Data Sheet includes electrical characteristics and signal connections.                                       | <a href="#">i.MX RT1050 Data Sheet - Industrial Products</a>  |

## 1.4 Conventions

The reference manual uses the following notational conventions:

### cleared / set

When a bit has a value of zero, it is said to be cleared; when it has a value of one, it is said to be set.

### mnemonics

Instruction mnemonics are shown in lowercase bold.

### italics

Italics indicate variable command parameters, for example, **bcctrx**.

The book titles in the text are set in italics.

### 15

An integer in decimal.

### 0x

the prefix to denote a hexadecimal number.

### 0b

The prefix to denote a binary number. Binary values of 0 and 1 are written without a prefix.

### n'H4000CA00

The n-bit hexadecimal number.

**BLK\_REG\_NAME**

The register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (\_).

**BLK\_REG[FIELD]**

The fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.

**BLK\_REG[ *n* ]**

The bit number *n* within the BLK.REG register.

**BLK\_REG[ *l:r* ]**

The register bit ranges. The ranges are indicated by the left-most bit number *l* and the right-most bit number *r*, separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.

**x, U**

In some contexts, such as signal encodings, an unitalicized x indicates a "don't care" or "uninitialized". The binary value can be 1 or 0.

***x***

An italicized *x* indicates an alphanumeric variable.

***n, m***

Italicized *n* or *m* represent integer variables.

**!**

Binary logic operator NOT.

**&&**

Binary logic operator AND.

**||**

Binary logic operator OR.

**^ or <O+>**

Binary logic operator XOR. For example, A <O+> B.

**|**

Bit-wise OR. For example, 0b0001 | 0b1000 yields the value of 0b1001.

**&**

Bit-wise AND. For example, 0b0001 and 0b1000 yields the value of 0b0000.

**{A,B}**

Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n* + *m*)-bit value. For example, {0, REG<sub>m</sub> [14:0]} yeilds a 16-bit value with 0 in the most significant bit.

**- or grey fill**

Indicates a reserved bit field in a register. Although these bits can be written to with ones or zeros, they always read zeros.

**>>**

Shift right logical one position.

**<<**

Shift left logical one position.

<=

Assignment.

==

Compare equal.

!=

Compare not equal.

>

Greater than.

<

Less than.

## 1.5 Register Access

### 1.5.1 Register Diagram Field Access Type Legend

This figure provides the interpretation of the notation used in the register diagrams for a number of common field access types:

**Figure 1-1. Register Field Conventions**

#### NOTE

For reserved register fields, the software should mask off the data in the field after a read (the software can't rely on the contents of data read from a reserved field) and always write all zeros.

### 1.5.2 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all the bits set to 1 perform the associated operation on the primary register, while the bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one-bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read-modify-write operations. When an atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

A set of SCT registers is offered for registers in many modules on this device, as described in this manual. In a module memory map table, the suffix `_SET`, `_CLR`, or `_TOG` is added to the base name of the register. For example, the `CCM_ANALOG_PLL_ARM` register has three other registers called `CCM_ANALOG_PLL_ARM_SET`, `CCM_ANALOG_PLL_ARM_CLR`, and `CCM_ANALOG_PLL_ARM_TOG`.

In the sub-section that describes one of these sets of registers, a short-hand convention is used to denote that a register has the SCT register set. There is an italicized *n* appended to the end of the short register name. Using the above example, the name used for this register is `CCM_ANALOG_PLL_ARMn`. When you see this designation, there is a SCT register set associated with the register, and you can verify this by checking it in the memory map table. The address offset for each of these registers is given in the form of the following example:

Address: `20C_8000h` base + `0h` offset +  $(4d \times i)$ , where  $i=0d$  to  $3d$

## Acronyms and Abbreviations

In this example, the address for each of the base registers and their three SCT registers can be calculated as:

| Register               | Address   |
|------------------------|-----------|
| CCM_ANALOG_PLL_ARM     | 20C_8000h |
| CCM_ANALOG_PLL_ARM_SET | 20C_8004h |
| CCM_ANALOG_PLL_ARM_CLR | 20c_8008h |
| CCM_ANALOG_PLL_ARM_TOG | 20C_800Ch |

## 1.6 Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

### Acronyms and Abbreviated Terms

| Term    | Meaning                                   |
|---------|-------------------------------------------|
| ACMP    | Analog Comparator                         |
| ADC     | Analog-to-Digital Converter               |
| AHB     | Advanced High-performance Bus             |
| AIPS    | Arm IP Bus                                |
| ALU     | Arithmetic Logic Unit                     |
| AMBA    | Advanced Microcontroller Bus Architecture |
| APB     | Advanced Peripheral Bus                   |
| ASRC    | Asynchronous Sample Rate Converter        |
| AXI     | Advanced eXtensible Interface             |
| BEE     | Bus Encryption Engine                     |
| BIST    | Built-In Self Test                        |
| CA/CM   | Arm Cortex-A/Cortex-M                     |
| CAN     | Controller Area Network                   |
| CCM     | Clock Controller Module                   |
| CM7     | ARM Cortex M7 Core                        |
| CPU     | Central Processing Unit                   |
| CSI     | CMOS Sensor Interface                     |
| CSU     | Central Security Unit                     |
| CTI     | Cross Trigger Interface                   |
| D-cache | Data cache                                |
| DAP     | Debug Access Port                         |
| DCP     | Data Co-Processor                         |
| DDR     | Double data rate                          |
| DMA     | Direct memory access                      |

*Table continues on the next page...*

| Term                    | Meaning                                                                        |
|-------------------------|--------------------------------------------------------------------------------|
| DPLL                    | Digital phase-locked loop                                                      |
| DRAM                    | Dynamic random access memory                                                   |
| ECC                     | Error correcting codes                                                         |

# Chapter 2

## Introduction

### 2.1 Introduction

The i.MX RT1050 is a new processor family featuring NXP's advanced implementation of the high performance Arm Cortex<sup>®</sup>-M7 Core. It offers high-performance processing optimized for lowest power consumption and best real-time response.

This device provides various memory interfaces, including SDRAM, Raw NAND FLASH, NOR FLASH, SD/eMMC, Quad SPI (FlexSPI), and a wide range of other interfaces for connecting peripherals, such as WLAN, Bluetooth<sup>™</sup>, displays, camera sensors, and GPS. Same as other i.MX processors, this i.MX RT series also has rich audio and video features, including LCD display, basic 2D graphics, camera interface, SPDIF and I2S audio interface.

#### 2.1.1 Block Diagram

The functional block diagram is shown in the figure below. This diagram provides a view of the chip's major functional components and core complexes.

Figure 2-1. Simplified Block Diagram

## 2.2 Features

The i.MX RT1050 processors are based on Arm®Cortex®-M7 Platform, which have the following features:

Single Arm Cortex-M7 with:

- 32 KB L1 Instruction Cache
- 32 KB L1 Data Cache
- Single-precision and double-precision FPU (Floating Point Unit)

On Chip Memory:

- Boot ROM (96 KB)
- On-chip RAM, configurable RAM up to 512KB shared with M7 TCM

External Memory Interfaces:

- 8/16-bit SDRAM, up to SDRAM-166
- 8-bit SLC NAND FLASH, with ECC handled in SW
- SD/eMMC
- Single/Dual channel Quad SPI FLASH with XIP support
- Parallel NOR FLASH with XIP support
- SPI NOR/NAND FLASH

Graphics:

- Generic 2D Graphics engine (PXP)
  - BitBlit
  - Flexible image composition options – alpha, chroma key
  - Image rotation (90, 180, 270 degree rotation)
  - Porter-Daff operation
  - Image size
  - Color space conversion
  - Multiple pixel format support (RGB, YUV444, YUV422, YUV420, YUV400)
  - Standard 2D-DMA operation

Display Interface:

- Parallel RGB LCD interface
  - Support 8/16/24 bit interface
  - Support upto WXGA resolution
  - Smart LCD Display with 8/16-bit MPU/8080 interface
  - Support Index color with 256 entry × 24bit color LUT

Camera Sensor Interface:

- Support 8/16/24-bit CSI Input

### Audio:

- S/PDIF Input and Output
- 3x SAI (synchronous audio interface) modules supporting I2S, AC97, TDM, and codec/DSP interfaces
- MQS interface for medium quality audio via GPIO pads

### Connectivity:

- 2x USB 2.0 OTG controller with integrated PHY interface
- 2x Ultra Secure Digital Host Controller (uSDHC) interfaces
- 10M/100M Ethernet controller with support for IEEE1588
- 8x Universal asynchronous receiver/transmitter (UARTs) modules
- 4x I2C modules
- 4x SPI modules
- 2x FlexCAN modules
- 2x FlexIO modules

### Timers:

- 2x General Programmable Timer (GPT)
- 4-channel Periodical Interrupt Timer (PIT)
- 4x Quad Timer (QTimer)
- 4x FlexPWM

### Analog:

- 2x Analog-Digital-Converters (ADC) (upto 20 channels)
- 4x Analog Comparators (ACMP)

### Security:

- High Assurance Boot (HAB)
- Data Co-Processor (DCP)
  - AES-128, ECB, and CBC mode
  - SHA-1 and SHA-256
  - CRC-32
- Bus Encryption Engine (BEE)
  - AES-128, ECB, and CTR mode
  - On-the-fly QSPI Flash decryption
- True Random Number Generator (TRNG)
- Secure Non-volatile Storage (SNVS)
  - Secure real-time clock (RTC)
  - Zero Master Key (ZMK)
- Secure JTAG Controller (SJC)

### System Debug:

- Arm CoreSight debug and trace architecture

- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Cross Triggering Interface (CTI)
- Support for 5-pin (JTAG) and SWD debug interfaces

#### Power Management:

- Full PMIC integration, including on-chip DCDC and LDO
- Temperature sensor with programmable trim points
- GPC hardware power management controller

## 2.3 Target Applications

This processor can be used in areas such as industrial HMI, IoT, motor control and home appliances, etc.

The architecture's flexibility enables it to be used in a wide variety of other general embedded applications too. This processor provides all interfaces necessary to connect peripherals such as WLAN, Bluetooth<sup>™</sup>, GPS, camera sensors, and multiple displays.

## 2.4 Endianness Support

The chip supports only the Little Endian mode.

## Chapter 3 Memory Maps

### 3.1 Memory system overview

This section introduces the memory architecture of the chip.

#### NOTE

Accessing the reserved memory regions can result in unpredictable behavior.

### 3.2 Arm Platform Memory Map

The chip memory map has been provided in the following tables.

**Table 3-1. System memory map (CM7)**

| Start Address | End Address | Size  | Description                                                                   |
|---------------|-------------|-------|-------------------------------------------------------------------------------|
| E010_0000     | FFFF_FFFF   | 511MB | Reserved                                                                      |
| E000_0000     | E00F_FFFF   | 1MB   | CM7 PPB                                                                       |
| 8000_0000     | DFFF_FFFF   | 1.5GB | SEMC external memories (SDRAM, NOR, PSRAM, NAND and 8080) shared memory space |
| 7FC0_0000     | 7FFF_FFFF   | 4MB   | FlexSPI RX FIFO                                                               |
| 7F80_0000     | 7FBF_FFFF   | 4MB   | FlexSPI TX FIFO                                                               |
| 6000_0000     | 7F7F_FFFF   | 504MB | FlexSPI/ FlexSPI ciphertext                                                   |
| 4800_0000     | 5FFF_FFFF   | 384MB | Reserved                                                                      |
| 4400_0000     | 47FF_FFFF   | 64MB  | Reserved                                                                      |
| 4200_0000     | 43FF_FFFF   | 32MB  | Reserved                                                                      |
| 4180_0000     | 41FF_FFFF   | 8MB   | Reserved                                                                      |
| 4170_0000     | 417F_FFFF   | 1MB   | GPV Reserved                                                                  |
| 4160_0000     | 416F_FFFF   | 1MB   | GPV Reserved                                                                  |
| 4150_0000     | 415F_FFFF   | 1MB   | GPV Reserved                                                                  |
| 4140_0000     | 414F_FFFF   | 1MB   | "cpu" configuration port                                                      |

### 4.2 Overview

This section describes the assignments of interrupts from the Arm domain and from the DMA events.

### 4.3 CM7 interrupts

The Nested Vectored Interrupt Controller (NVIC) collects interrupt request sources and provides an interface to the Cortex-M7 core.

This table describes the Cortex-M7 interrupt sources:

**Table 4-2. CM7 domain interrupt summary**

| IRQ | Module  | Logic | Description                               |
|-----|---------|-------|-------------------------------------------|
| 0   | eDMA    | OR    | eDMA Channel 0 Transfer Complete          |
|     |         |       | eDMA Channel 16 Transfer Complete         |
| 1   |         | OR    | eDMA Channel 1 Transfer Complete          |
|     |         |       | eDMA Channel 17 Transfer Complete         |
| 2   |         | OR    | eDMA Channel 2 Transfer Complete          |
|     |         |       | eDMA Channel 18 Transfer Complete         |
| 3   |         | OR    | eDMA Channel 3 Transfer Complete          |
|     |         |       | eDMA Channel 19 Transfer Complete         |
| 4   |         | OR    | eDMA Channel 4 Transfer Complete          |
|     |         |       | eDMA Channel 20 Transfer Complete         |
| 5   |         | OR    | eDMA Channel 5 Transfer Complete          |

## 4.5 PIT Channel Assignments For Periodic DMA Triggering

This table shows the PIT channel to DMA channel correspondence.

**Table 4-4. PIT Channel Assignments For Periodic DMA Triggering**

| DMA Channel Number | PIT Channel   |
|--------------------|---------------|
| eDMA Channel 0     | PIT Channel 0 |
| eDMA Channel 1     | PIT Channel 1 |
| eDMA Channel 2     | PIT Channel 2 |
| eDMA Channel 3     | PIT Channel 3 |

## 4.6 XBAR Resource Assignments

This table shows the XBAR resource assignments in the chip.

### NOTE

ADC\_ETC0\_COCO0 ... ADC\_ETC1\_COCO3 in the table are corresponding to coco0 ... coco7, also ADC\_ETC\_TRIG00 ... ADC\_ETC\_TRIG13 corresponding to trg0 ... trg7, see the figure "ADC\_ETC block diagram" in the ADC\_ETC chapter.

**Table 4-5. XBAR1 Input Assignments**

| Assigned Input     | XBAR1 Input | Gate |
|--------------------|-------------|------|
| LOGIC LOW          | XBAR1_IN00  | -    |
| LOGIC HIGH         | XBAR1_IN01  | -    |

On this device, only 32-bit write is supported for the DMA\_CH\_MUX registers.

## 5.2 Introduction

### 5.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 32 DMA channels. This process is illustrated in the following figure.

**Figure 5-1. DMAMUX block diagram**

## 5.2.2 Features

The DMAMUX module provides these features:

- Up to 128 peripheral slots can be routed to 32 channels.
- 32 independently selectable DMA channel routers.
  - Each channel output can be individually configured to be Always On and not depend on any of the peripheral slots.
  - The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots.
- On every memory map configuration change for a any channel, this module signals to the DMA Controller to reset the internal state machine for that channel and it can accept a new request based on the new configuration.

### 5.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0 to 3.

## 5.3 External signal description

The DMAMUX has no external pins.

## 5.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

### **5.4.1 DMA channels with periodic triggering capability**

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

#### **Note**

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

**Figure 5-2. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 5-3. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 5-4. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

## 5.4.2 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, each DMA Channel can be individually configured to function as an Always Enabled source. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the always enabled channel provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA channel can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and configured as "always enabled" channel. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

**NOTE**

When a channel is configured as "Always Enabled", then the peripheral DMA sources for that channel are ignored; i.e. SOURCE field has no effect.

## 5.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 5.5.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 5.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

**NOTE**

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC0000005 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1 with no periodic triggering capability :

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x80000005 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);
```

```
In File main.c:
#include "registers.h"
:
```

```

:
*CHCFG1 = 0x00000000;
*CHCFG1 = 0x80000005;

```

### To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

### To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00000000 to CHCFG8.
3. Write 0x80000007 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```

In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000 /* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

```

```

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00000000;
*CHCFG8 = 0x80000007;

```

### 5.5.2.1 Configuration options

Table 5-2. Channel Configuration Options

| ENBL | TRIG | A_ON | Function                                                | Mode                   |
|------|------|------|---------------------------------------------------------|------------------------|
| 0    | X    | X    | DMA channel is disabled                                 | Disabled Mode          |
| 1    | 0    | 0    | DMA channel is enabled with no triggering (transparent) | Normal Mode            |
| 1    | 1    | 0    | DMA channel is enabled with triggering                  | Periodic Trigger Mode  |
| 1    | 0    | 1    | DMA channel is always enabled                           | Always On Mode         |
| 1    | 1    | 1    | DMA channel is always enabled with triggering           | Always On Trigger Mode |

## 5.6 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

### 5.6.1 DMA\_CH\_MUX register descriptions

#### 5.6.1.1 DMA\_CH\_MUX memory map

DMAMUX base address: 400E\_C000h

| Offset   | Register                                                            | Width<br>(In bits) | Access | Reset value |
|----------|---------------------------------------------------------------------|--------------------|--------|-------------|
| 0h - 7Ch | <a href="#">Channel a Configuration Register (CHCFG0 - CHCFG31)</a> | 32                 | RW     | 0000_0000h  |

#### 5.6.1.2 Channel a Configuration Register (CHCFG0 - CHCFG31)

##### 5.6.1.2.1 Offset

For a = 0 to 31:

| Register | Offset        |
|----------|---------------|
| CHCFGa   | 0h + (a × 4h) |

### 5.6.1.2.2 Function

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

#### NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

### 5.6.1.2.3 Diagram

### 6.2 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

### 6.2.1 eDMA system block diagram

The following figure illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 6-1. eDMA system block diagram

### 6.2.2 Block parts

The eDMA module comprises two major modules: the eDMA engine and the transfer-control descriptor local memory.

Table 6-2 describes the eDMA engine submodules.

Table 6-2. eDMA engine submodules

| Submodule    | Function                                                                                                                                                                                                                                |

Table continues on the next page...

**Table 6-2. eDMA engine submodules (continued)**

| Submodule                                 | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | <p>All channels provide the same functionality. This structure enables preemption of data transfers associated with an active channel (after completion of a read/write sequence) if the eDMA engine asserts a higher priority channel activation.</p> <p>After eDMA activates a channel, it runs until the minor loop completes, unless preempted by a higher priority channel. This provides a mechanism (enabled by <a href="#">DCHPRI<sub>n</sub>[ECP]</a>) in which the eDMA engine can preempt a large data move operation to minimize the time another channel stalls.</p> <p>When the eDMA engine selects a channel to execute, it reads the contents of the channel TCD from local memory and loads it into one of the following:</p> <ul style="list-style-type: none"> <li>• The address path channel x registers (normal start)</li> <li>• The address path channel y registers (preemption start)</li> </ul> <p>After the minor loop execution completes, the address path hardware writes the new values for the TCD<sub>n</sub>{SADDR, DADDR, CITER} back to local memory. If the major iteration count completes, the eDMA engine performs additional processing, including:</p> <ul style="list-style-type: none"> <li>• Final address pointer updates</li> <li>• Reloading the TCD<sub>n</sub>_CITER field</li> <li>• A possible fetch of the next TCD<sub>n</sub> from memory as part of a scatter/gather operation.</li> </ul> |
| Data path                                 | <p>The Data path block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase). The data path module implements the second stage of the pipeline (data phase).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Programming model/<br>channel arbitration | <p>This block implements:</p> <ul style="list-style-type: none"> <li>• The first section of the eDMA programming model</li> <li>• Channel arbitration logic</li> </ul> <p>The programming model registers connect to the chip's internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs also connect to this block (via control logic).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Control                                   | <p>The Control block provides all control functions for the eDMA engine. For data transfers in which the source size (SSIZE) and destination size (DSIZE) are equal, the eDMA engine performs a series of source read/destination write operations until it has transferred the number of bytes specified in the minor loop byte count (NBYTES). For TCDs in which the source and destination sizes are not equal, the eDMA engine executes multiple accesses of the smaller size data for each reference of the larger size. For example, if the source size (SSIZE) references 16-bit data and the destination size (DSIZE) is 32-bit data, eDMA performs two reads, then one 32-bit write.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

[Table 6-3](#) explains the partitioning of the TCD local memory.

**Table 6-3. Transfer control descriptor memory**

| Submodule         | Description                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory controller | The Memory controller logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. If simultaneous accesses occur, the eDMA engine receives priority and the peripheral transaction stalls. |
| Memory array      | The Memory array provides TCD storage for the transfer profile for each channel.                                                                                                                                                                                                    |

## 6.2.3 Features

The eDMA module is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. Use it for applications where you statically know the size of the data to be transferred and do not define the size within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch (AXBS) for bus mastering the data movement
- TCD supports two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion notification via programmable interrupt requests
  - One interrupt per channel. eDMA engine can generate an interrupt when major iteration count completes
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller

- Programmable support for scatter/gather DMA processing
- Support for complex data structures

### NOTE

In the discussion of this module,  $n$  is the channel number.

## 6.3 Modes of operation

eDMA operates in the following modes:

**Table 6-4. Modes of operation**

| Mode   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal | <p>In Normal mode, eDMA transfers data from a source to a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA.</p> <p>A <i>service request</i> initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD.</p> <ul style="list-style-type: none"> <li>• The <i>minor loop</i> is the sequence of read and write operations that transfers the NBYTES of data for a service request.</li> <li>• Each service request executes one iteration of the major loop, transferring NBYTES of data.</li> </ul> |
| Debug  | <p>DMA operation is configurable in Debug mode via <a href="#">Control (CR)</a></p> <ul style="list-style-type: none"> <li>• If CR[EDBG] = 0, eDMA continues to operate normally when the chip is in debug mode.</li> <li>• If CR[EDBG] = 1, eDMA stops transferring data when the chip enters debug mode. If a channel is active when eDMA enters Debug mode, eDMA continues operation until the channel retires.</li> </ul>                                                                                                                                                           |
| Wait   | <p>Before entering Wait mode, eDMA attempts to complete any transfer that is in progress. After the transfer completes, the chip enters Wait mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 6.4 Functional description

The operation of the eDMA is described in the following subsections.

### 6.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

**Figure 6-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $TCDn\_CSR[START]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration executes, using either the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $TCDn$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

**Figure 6-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) execute sequentially through the required source reads and destination writes to perform the data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 6-4. eDMA operation, part 3

## 6.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on 0-modulo transfer size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### NOTE

When two channels have the same priority, a channel priority error exists and is reported in the Error Status register. However, the channel number is not reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control register. If all channel priorities within a group are not unique, the DMA is halted after the CPE error is recorded. The DMA remains halted and does not process any channel service requests. After all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the HALT bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[ELINK] bit does not equal the TCDn\_BITER[ELINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion, when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the

data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be canceled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the canceled channel number and ECX is set. The TCD of a canceled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is canceled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

### **NOTE**

The cancel transfer request enables you to stop a large data transfer when the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must manage the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor because the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 6.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting DCHPRIn[ECP]. Channel preemption enables the executing channel's data transfers to temporarily be suspended in favor of starting a higher priority channel. After the preempting channel has completed its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preemption ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This enables a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

## 6.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 6.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRIn registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
  - Software: setting TCDn\_CSR[START]
  - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels in the programming model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in [Table 6-5](#), for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal, unless a configuration error is detected. Transfers from the source, as defined by `TCDn_SADDR`, to the destination, as defined by `TCDn_DADDR`, continue until the number of bytes specified by `TCDn_NBYTES` have been transferred.

When the transfer is complete, the eDMA engine's local `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_CITER` are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post-processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 6-5. TCD control and status fields**

| TCDn_CSR field name | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| START               | Control bit to start channel explicitly when using a software-initiated DMA service (automatically cleared by hardware) |
| ACTIVE              | Status bit indicating the channel is currently in execution                                                             |
| DONE                | Status bit indicating major loop completion (cleared by software when using a software-initiated DMA service)           |
| DREQ                | Control bit to disable DMA request at end of major loop completion when using a hardware-initiated DMA service          |
| BWC                 | Control bits for throttling bandwidth control of a channel                                                              |
| ESG                 | Control bit to enable scatter/gather feature                                                                            |
| INTHALF             | Control bit to enable interrupt when major loop is half complete                                                        |
| INTMAJOR            | Control bit to enable interrupt when major loop completes                                                               |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 6-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 6-6. Memory array terms

## 6.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group after that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting are associated with the selected channel.

## 6.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 6.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

### 6.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

## 6.5.4 DMA transfer examples

This section presents examples of how to perform DMA transfers with the eDMA.

### 6.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $TCDn\_CITER = TCDn\_BITER = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete,  $TCDn\_CSR[DONE]$  is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has an 8-bit memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INTMAJOR] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCDn\_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCDn\_SADDR = 0x1000, TCDn\_DADDR = 0x2000, TCDn\_CITER = 1 (TCDn\_BITER).
7. The eDMA engine writes: TCDn\_CSR[ACTIVE] = 0, TCDn\_CSR[DONE] = 1, INT[n] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

### 6.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, the eDMA peripheral, requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCDn data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCDn\_SADDR = 0x1010, TCDn\_DADDR = 0x2010, TCDn\_CITER = 1.
7. eDMA engine writes: TCDn\_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
12. eDMA engine reads channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:

- a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD<sub>n</sub>\_SADDR = 0x1000, TCD<sub>n</sub>\_DADDR = 0x2000, TCD<sub>n</sub>\_CITER = 2 (TCD<sub>n</sub>\_BITER).
  15. eDMA engine writes: TCD<sub>n</sub>\_CSR[ACTIVE] = 0, TCD<sub>n</sub>\_CSR[DONE] = 1, INT[n] = 1.
  16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

### 6.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of zero for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 2<sup>4</sup> byte (16-byte) size queue.

**Table 6-6. Modulo example**

| Transfer number | Address    |
|-----------------|------------|
| 1               | 0x12345670 |
| 2               | 0x12345674 |
| 3               | 0x12345678 |
| 4               | 0x1234567C |

*Table continues on the next page...*

**Table 6-6. Modulo example (continued)**

| Transfer number | Address    |
|-----------------|------------|
| 5               | 0x12345670 |
| 6               | 0x12345674 |

## 6.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

### 6.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests. The first is to read the `TCDn_CITER` field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test `TCDn_CSR[START]` and `TCDn_CSR[ACTIVE]`. The minor-loop-complete condition is indicated by both bits reading zero after `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCDn_CSR bits |        |      | State                                            |
|-------|---------------|--------|------|--------------------------------------------------|
|       | START         | ACTIVE | DONE |                                                  |
| 1     | 1             | 0      | 0    | Channel service request via software             |
| 2     | 0             | 1      | 0    | Channel is executing                             |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using service requests initiated by hardware, that is, peripherals, is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCD <sub>n</sub> _CSR bits |        |      | State                                                              |
|-------|----------------------------|--------|------|--------------------------------------------------------------------|
|       | START                      | ACTIVE | DONE |                                                                    |
| 1     | 0                          | 0      | 0    | Channel service request via hardware (peripheral request asserted) |
| 2     | 0                          | 1      | 0    | Channel is executing                                               |
| 3a    | 0                          | 0      | 0    | Channel has completed the minor loop and is idle                   |
| 3b    | 0                          | 0      | 1    | Channel has completed the major loop and is idle                   |

For both activation types, the major-loop-complete status is explicitly indicated via the TCD<sub>n</sub>\_CSR[DONE] bit.

The TCD<sub>n</sub>\_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 6.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD<sub>n</sub>\_SADDR, TCD<sub>n</sub>\_DADDR, and TCD<sub>n</sub>\_NBYTES values if read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 6.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD<sub>n</sub>\_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD<sub>n</sub>\_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

## 6.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD<sub>n</sub>\_CSR[START] bit of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD<sub>n</sub>\_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_ELINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12\_CSR[START] bit.
2. Minor loop done → set TCD12\_CSR[START] bit.
3. Minor loop done → set TCD12\_CSR[START] bit.
4. Minor loop done, major loop done → set TCD7\_CSR[START] bit.

When minor loop linking is enabled (TCD<sub>n</sub>\_CITER[ELINK] = 1), the TCD<sub>n</sub>\_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCD<sub>n</sub>\_CITER[ELINK] = 0), the TCD<sub>n</sub>\_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD<sub>n</sub>\_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

### Note

The TCD<sub>n</sub>\_CITER[ELINK] bit and the TCD<sub>n</sub>\_BITER[ELINK] bit must be equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

**Table 6-7. Channel linking parameters**

| Desired link behavior     | TCD control field name | Description                                                                    |
|---------------------------|------------------------|--------------------------------------------------------------------------------|
| Link at end of minor loop | CITER[ELINK]           | Enable channel-to-channel linking on minor loop completion (current iteration) |
|                           | CITER[LINKCH]          | Link channel number when linking at end of minor loop (current iteration)      |
| Link at end of major loop | CSR[MAJOR_ELINK]       | Enable channel-to-channel linking on major loop completion                     |
|                           | CSR[MAJOR_LINKCH]      | Link channel number when linking at end of major loop                          |

## 6.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 6.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 6.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting [TCDn\\_CSR\[MAJORELINK\]](#) during channel execution (see the diagram in [TCD structure](#)). This field is read from the TCD local memory at the end of channel execution, thus enabling you to enable the feature during channel execution.

Because you can change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic channel link by enabling [TCDn\\_CSR\[MAJORELINK\]](#) at the same time the eDMA engine is retiring the channel. [TCDn\\_CSR\[MAJORELINK\]](#) would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write one to TCDn\_CSR[MAJORELINK].
2. Read back TCDn\_CSR[MAJORELINK].
3. Test the TCDn\_CSR[MAJORELINK] request status:
  - If TCDn\_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
  - If TCDn\_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces TCDn\_CSR[MAJORELINK] to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

### NOTE

You must clear [TCDn\\_CSR\[DONE\]](#) before writing TCDn\_CSR[MAJORELINK]. The eDMA engine automatically clears TCDn\_CSR[DONE] after a channel begins execution.

### 6.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It enables a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because you are able to change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the [TCDn\\_CSR\[ESG\]](#) bit at the same time the eDMA engine is retiring the channel. The ESG bit would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the MAJORLINKCH field and the ESG bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD MAJOR[ELINK] and ESG bits to zero on any writes to a channel's TCD word 7 if that channel's TCD[DONE] bit is set, indicating the major loop is complete.

**NOTE**

The user must clear the [TCDn\\_CSR\[DONE\]](#) bit before writing the MAJORELINK or ESG bits. The TCDn\_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

**6.5.7.3.1 Method 1 (channel not using major loop channel linking)**

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When [TCDn\\_CSR\[MAJORELINK\]](#) is zero, TCDn\_CSR[MAJORLINKCH] is not used by the eDMA. In this case, MAJORLINKCH may be used for other purposes. This method uses the MAJORLINKCH field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in TCDn\_CSR[MAJORLINKCH] for each TCD associated with a channel using dynamic scatter/gather.
2. Write one to [TCDn\\_CSR\[DREQ\]](#).

Should a dynamic scatter/gather attempt fail, setting the DREQ bit prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST\_SGA final offset value.

3. Write the [TCDn\\_DLASTSGA](#) register with the scatter/gather address.
4. Write one to TCDn\_CSR[ESG].
5. Read back the 16-bit TCD control/status field.
6. Test the ESG request status and MAJORLINKCH value in the TCDn\_CSR register:

If ESG = 1, the dynamic link attempt was successful.

If ESG = 0 and MAJORLINKCH (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If ESG = 0 and MAJORLINKCH (ID) changed, the dynamic link attempt was successful (the new TCD's ESG value cleared the ESG bit).

**6.5.7.3.2 Method 2 (channel using major loop channel linking)**

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD[DLAST\_SGA] field as a TCD identification (ID).

1. Write one to [TCDn\\_CSR\[DREQ\]](#).

Should a dynamic scatter/gather attempt fail, setting TCDn\_CSR[DREQ] prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST\_SGA final offset value.

2. Write the **TCDn\_DLAST\_SGA** register with the scatter/gather address.
3. Write one to TCDn\_CSR[ESG].
4. Read back TCDn\_CSR[ESG].
5. Test the ESG request status:

If ESG = 1, the dynamic link attempt was successful.

If ESG = 0, read the 32-bit TCDn\_DLAST\_SGA field.

If ESG = 0 and TCDn\_DLAST\_SGA did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If ESG = 0 and TCDn\_DLAST\_SGA changed, the dynamic link attempt was successful (the new TCD's ESG value cleared the ESG bit).

## 6.5.8 Suspend/resume a DMA channel with active hardware service requests

The DMA enables you to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. After the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), ADC, or other module.

### 6.5.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status register (DMA\_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

### 6.5.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the relevant ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the SPI\_TXFIFO has an empty slot. The DMA transfers the next command and data to the TXFIFO upon the request. You must suspend the DMA/SPI transfer loop and perform the following steps:

1. Disable the DMA service request at the source by writing zero to SPI\_RSER[TFFF\_RE]. Confirm that SPI\_RSER[TFFF\_RE] is zero.
2. Ensure there is no DMA service request from the SPI by verifying that DMA\_HRS[HRS<sub>n</sub>] is zero for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

## 6.6 Memory map/register definition

The eDMA programming model consists of registers that provide:

- Control and status functions
- Channel configuration functions
- TCD definition functions

### 6.6.1 TCD memory

Each channel requires a 32-byte TCD to define the desired data movement operation. The channel descriptors are in local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD<sub>n</sub> definition comprises 11 registers of 16 or 32 bits.

### 6.6.2 TCD initialization

Before activating a channel, you must initialize its TCD with the appropriate transfer profile.

## 6.6.3 TCD structure

## 6.6.4 Reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- The eDMA ignores writes to reserved bits in a register.
- Reading or writing a reserved memory location generates a bus error.

## 6.6.5 DMA register descriptions

### 6.6.5.1 DMA memory map

DMA base address: 400E\_8000h

| Offset | Register                     | Width<br>(In bits) | Access | Reset value               |
|--------|------------------------------|--------------------|--------|---------------------------|
| 0h     | <a href="#">Control (CR)</a> | 32                 | RW     | <a href="#">Table 6-7</a> |

Table continues on the next page...

**Memory map/register definition**

| Offset | Register                                   | Width<br>(In bits) | Access | Reset value |
|--------|--------------------------------------------|--------------------|--------|-------------|
| 4h     | Error Status (ES)                          | 32                 | RO     | 0000_0000h  |
| Ch     | Enable Request (ERQ)                       | 32                 | RW     | 0000_0000h  |
| 14h    | Enable Error Interrupt (EEI)               | 32                 | RW     | 0000_0000h  |
| 18h    | Clear Enable Error Interrupt (CEEI)        | 8                  | WORZ   | 00h         |
| 19h    | Set Enable Error Interrupt (SEEI)          | 8                  | WORZ   | 00h         |
| 1Ah    | Clear Enable Request (CERQ)                | 8                  | WORZ   | 00h         |
| 1Bh    | Set Enable Request (SERQ)                  | 8                  | WORZ   | 00h         |
| 1Ch    | Clear DONE Status Bit (CDNE)               | 8                  | WORZ   | 00h         |
| 1Dh    | Set START Bit (SSRT)                       | 8                  | WORZ   | 00h         |
| 1Eh    | Clear Error (CERR)                         | 8                  | WORZ   | 00h         |
| 1Fh    | Clear Interrupt Request (CINT)             | 8                  | WORZ   | 00h         |
| 24h    | Interrupt Request (INT)                    | 32                 | W1C    | 0000_0000h  |
| 2Ch    | Error (ERR)                                | 32                 | W1C    | 0000_0000h  |
| 34h    | Hardware Request Status (HRS)              | 32                 | RO     | 0000_0000h  |

### 6.6.5.2 Control (CR)

### 6.6.5.2.1 Offset

| Register | Offset |
|----------|--------|
| CR       | 0h     |

### 6.6.5.2.2 Function

This register defines the basic operating configuration of the eDMA module. eDMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

You can configure arbitration within a group to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, eDMA selects and executes the highest-priority channel that requests service. The channel priority registers assign the priorities (see the [Channel Priority \(DCHPRI0 - DCHPRI31\)](#) registers). For round-robin arbitration, the eDMA engine ignores channel priorities and cycles through channels within each group from high to low channel number without regard to priority.

#### NOTE

For correct operation, you must write to this register only when the eDMA channels are inactive—that is, when  $TCDn\_CSR[ACTIVE] = 0$ .

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the  $GRPnPRI$  fields of the Control register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error is reported. For group round robin arbitration, eDMA ignores the group priorities and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address-offset values to be added to the final source address ( $TCDn\_SADDR$ ) or destination address ( $TCDn\_DADDR$ ) when the minor loop completes. When you enable minor loop offsets, eDMA adds the minor loop offset ( $MLOFF$ ) value to the final source address ( $TCDn\_SADDR$ ), to the final destination address ( $TCDn\_DADDR$ ), or to both, before it writes the addresses back into the TCD. If the major loop is complete, eDMA ignores the minor loop offset, and uses the major loop address offsets ( $TCDn\_SLAST$  and  $TCDn\_DLAST\_SGA$ ) to compute the next  $TCDn\_SADDR$  and  $TCDn\_DADDR$  values.

Enabling minor loop mapping ( $EMLM = 1$ ) redefines  $TCDn$  word2. eDMA uses a portion of  $TCDn$  word2 for multiple fields:

- A source enable field (SMLOE) to specify the minor loop offset is to be applied to the source address (TCDn\_SADDR) when the minor loop completes
- A destination enable field (DMLOE) to specify the minor loop offset to be applied to the destination address (TCDn\_DADDR) when the minor loop completes
- The sign extended minor loop offset value (MLOFF).

eDMA uses the same offset value (MLOFF) for both source and destination minor loop offsets. When you enable either minor loop offset (SMLOE = 1 or DMLOE = 1), the NBYTES field reduces in size to 10 bits. When you disable both minor loop offsets (SMLOE = 0 and DMLOE = 0), the NBYTES field is a 30-bit vector.

When you disable minor loop mapping (EMLM = 0), the NBYTES field contains all 32 bits of TCDn word2.

When the value of this field is 1, TCDn.word2 includes:</p> <ul style="list-style-type: none"> <li>• Individual enable fields</li> <li>• An offset field</li> <li>• The NBYTES field.</li> </ul> <p>The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field reduces in size when either offset is enabled.</p> <p>0b - Disabled<br/>1b - Enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 6<br>CLM      | <p>Continuous Link Mode</p> <p>When the value of this field is 0, a minor loop channel link made to itself goes through channel arbitration before being activated again. When the value of this field is 1, a minor loop channel link made to itself does not go through channel arbitration before being activated again. When the minor loop completes, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.</p> <p><b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.</p> <p>0b - Continuous link mode is off</p> |

### 6.6.5.3 Error Status (ES)

#### 6.6.5.3.1 Offset

| Register | Offset |
|----------|--------|
| ES       | 4h     |

### 6.6.5.3.2 Function

The ES register provides information concerning the most-recently recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor
  - An illegal priority register setting in fixed arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error field that is 1 when a transfer is canceled via the corresponding cancel transfer control field

See [Fault reporting and handling](#) for more details.

TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or TCDn_CITER[CITER] = 0, or TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK].                                                                                                                                         |
| 2<br>SGE       | Scatter/Gather Configuration Error<br>When 1, this field indicates the most-recently recorded error was a configuration error detected in the TCDn_DLASTSGA field. eDMA checks This field at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32-byte boundary.<br>0b - No scatter/gather configuration error.<br>1b - The most-recently recorded error was a configuration error detected in the TCDn_DLASTSGA field. |
| 1<br>SBE       | Source Bus Error<br>0b - No source bus error.<br>1b - The most-recently recorded error was a bus error on a source read.                                                                                                                                                                                                                                                                                                                                                                             |
| 0<br>DBE       | Destination Bus Error<br>0b - No destination bus error.<br>1b - The most-recently recorded error was a bus error on a destination write.                                                                                                                                                                                                                                                                                                                                                             |

#### 6.6.5.4 Enable Request (ERQ)

### 6.6.5.4.1 Offset

| Register | Offset |
|----------|--------|
| ERQ      | Ch     |

### 6.6.5.4.2 Function

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request field must be set to 1 before a channel's hardware service request is accepted. The state of the DMA enable request field does not affect a channel service request made explicitly through software or a linked channel request.

#### NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

### 6.6.5.5 Enable Error Interrupt (EEI)

### 6.6.5.5.1 Offset

| Register | Offset |
|----------|--------|
| EEI      | 14h    |

### 6.6.5.5.2 Function

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI registers. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable field must be set to 1 before an error interrupt request for a given channel is sent to the interrupt controller.

### 6.6.5.6 Clear Enable Error Interrupt (CEEI)

#### 6.6.5.6.1 Offset

| Register | Offset |
|----------|--------|
| CEEI     | 18h    |

6.6.5.6.2 Function

The CEEI provides a simple memory-mapped mechanism to write 0 to a given field in the EEI register to disable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI register to be written to 0. Writing 1 to the CAEE field provides a global clear to 0 function, forcing the EEI contents to be written to 0, disabling all DMA request inputs.

If the NOP field is written with 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

6.6.5.6.3 Diagram

6.6.5.6.4 Fields

| Field       | Function                                                                                                                                 |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation, ignore the other fields in this register                                     |
| 6<br>CAEE   | Clear All Enable Error Interrupts<br>0b - Write 0 only to the EEI field specified in the CEEI field<br>1b - Write 0 to all fields in EEI |
| 5<br>—      | Reserved                                                                                                                                 |
| 4-0<br>CEEI | Clear Enable Error Interrupt<br>Writes 0 to the corresponding field in EEI                                                               |

6.6.5.7 Set Enable Error Interrupt (SEEI)

### 6.6.5.7.1 Offset

| Register | Offset |
|----------|--------|
| SEEI     | 19h    |

### 6.6.5.7.2 Function

The SEEI register provides a simple memory-mapped mechanism to write 1 to a given field in the EEI register to enable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI to be written to 1. Writing 1 to the SAE field provides a global set to 1 function, forcing the entire EEI register contents to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 6.6.5.7.3 Diagram

### 6.6.5.7.4 Fields

| Field       | Function                                                                                                                                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation, ignore the other fields in this register                                    |
| 6<br>SAEE   | Set All Enable Error Interrupts<br>0b - Write 1 only to the EEI field specified in the SEEI field<br>1b - Writes 1 to all fields in EEI |
| 5<br>—      | Reserved                                                                                                                                |
| 4-0<br>SEEI | Set Enable Error Interrupt<br>Writes 1 to the corresponding field in EEI                                                                |

6.6.5.8 Clear Enable Request (CERQ)

6.6.5.8.1 Offset

| Register | Offset |
|----------|--------|
| CERQ     | 1Ah    |

6.6.5.8.2 Function

The CERQ provides a simple memory-mapped mechanism to write 0 to a given field in the ERQ register to disable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be written with 0. Setting the CAER field provides a global clear to 0 function, forcing the entire contents of the ERQ register to be written with 0, disabling all DMA request inputs.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

| 4-0<br>CERQ | Clear Enable Request<br>Writes 0 to the corresponding field in ERQ.                                                              |

### 6.6.5.9 Set Enable Request (SERQ)

#### 6.6.5.9.1 Offset

| Register | Offset |
|----------|--------|
| SERQ     | 1Bh    |

#### 6.6.5.9.2 Function

The SERQ provides a simple memory-mapped mechanism to write 1 to a given field in the ERQ register to enable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be set. Writing 1 to the SAER field provides a global set to 1 function, forcing the entire contents of ERQ register to be 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register returns all zeroes.

### 6.6.5.9.4 Fields

| Field       | Function                                                                                                                       |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation, ignore the other fields in this register                           |
| 6<br>SAER   | Set All Enable Requests<br>0b - Write 1 to only the ERQ field specified in the SERQ field<br>1b - Write 1 to all fields in ERQ |
| 5<br>—      | Reserved                                                                                                                       |
| 4-0<br>SERQ | Set Enable Request<br>Writes 1 to the corresponding field in ERQ.                                                              |

### 6.6.5.10 Clear DONE Status Bit (CDNE)

#### 6.6.5.10.1 Offset

| Register | Offset |
|----------|--------|
| CDNE     | 1Ch    |

#### 6.6.5.10.2 Function

The CDNE provides a simple memory-mapped mechanism to write 0 to the DONE field in the TCD of the given channel. The data value on a register write causes the DONE field in the corresponding TCD to be written with 0. Writing 1 to the CADN field provides a global clear function, forcing all DONE fields to be written with 0.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 6.6.5.10.3 Diagram

### 6.6.5.10.4 Fields

| Field       | Function                                                                                                                                            |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation; all other fields in this register are ignored.                                          |
| 6<br>CADN   | Clears All DONE fields<br>0b - Writes 0 to only the TCDn_CSR[DONE] field specified in the CDNE field<br>1b - Writes 0 to all bits in TCDn_CSR[DONE] |
| 5<br>—      | Reserved                                                                                                                                            |
| 4-0<br>CDNE | Clear DONE field<br>Writes 0 to the corresponding field in TCDn_CSR[DONE]                                                                           |

## 6.6.5.11 Set START Bit (SSRT)

### 6.6.5.11.1 Offset

| Register | Offset |
|----------|--------|
| SSRT     | 1Dh    |

### 6.6.5.11.2 Function

The SSRT register provides a simple memory-mapped mechanism to write 1 to the START field in the TCD of the given channel. The data value on a register write causes the START field in the corresponding TCD to be written with 1. Writing 1 to the SAST field provides a global set to 1 function, forcing all START fields to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 6.6.5.11.3 Diagram

### 6.6.5.11.4 Fields

| Field       | Function                                                                                                                                                                   |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation; all other fields in this register are ignored.                                                                 |
| 6<br>SAST   | Set All START fields (activates all channels)<br>0b - Write 1 to only the TCDn_CSR[START] field specified in the SSRT field<br>1b - Write 1 to all bits in TCDn_CSR[START] |
| 5<br>—      | Reserved                                                                                                                                                                   |
| 4-0<br>SSRT | Set START field<br>Sets the corresponding field in TCDn_CSR[START]                                                                                                         |

## 6.6.5.12 Clear Error (CERR)

### 6.6.5.12.1 Offset

| Register | Offset |
|----------|--------|
| CERR     | 1Eh    |

### 6.6.5.12.2 Function

The CERR provides a simple memory-mapped mechanism to write 0 to a given field in the ERR register to disable the error condition field for a given channel. The given value on a register write causes the corresponding field in the ERR register to be written with 0. Writing 1 to the CAEI field provides a global clear to 0 function, forcing the ERR register contents to be written with 0, clearing all channel error indicators. If the NOP field is 1, the command is ignored. This enables you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

### 6.6.5.12.3 Diagram

### 6.6.5.12.4 Fields

| Field       | Function                                                                                                                          |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation; all other fields in this register are ignored.                        |
| 6<br>CAEI   | Clear All Error Indicators<br>0b - Write 0 to only the ERR field specified in the CERR field<br>1b - Write 0 to all fields in ERR |
| 5<br>—      | Reserved                                                                                                                          |
| 4-0<br>CERR | Clear Error Indicator<br>Writes 0 to the corresponding field in ERR                                                               |

### 6.6.5.13 Clear Interrupt Request (CINT)

#### 6.6.5.13.1 Offset

| Register | Offset |
|----------|--------|
| CINT     | 1Fh    |

### 6.6.5.13.2 Function

The CINT register provides a simple, memory-mapped mechanism to clear a given field in the INT register to disable the interrupt request for a given channel. The given value on a register write causes the corresponding field in the INT register to be cleared. Setting the CAIR field provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests.

If the NOP field is 1, the command is ignored. This enables you to set a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

| 4-0<br>CINT | Clear Interrupt Request<br>Clears the corresponding field in INT                                                        |

## 6.6.5.14 Interrupt Request (INT)

### 6.6.5.14.1 Offset

| Register | Offset |
|----------|--------|
| INT      | 24h    |

### 6.6.5.14.2 Function

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to write 0 to the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A 0 in any bit position has no effect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

## 6.6.5.15 Error (ERR)

### 6.6.5.15.1 Offset

| Register | Offset |
|----------|--------|
| ERR      | 2Ch    |

### 6.6.5.15.2 Function

The ERR register provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the EEI register, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to reset the appropriate bit to 0, negating the error-interrupt request. Typically, a write to the CERR in the interrupt service routine is used for this purpose. The normal DMA channel completion indicators (setting the TCD DONE field to 1 and the possible generation of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a 1 in any bit position clears the corresponding channel's error status. A 0 in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be reset to 0.

## 6.6.5.16 Hardware Request Status (HRS)

### 6.6.5.16.1 Offset

| Register | Offset |
|----------|--------|
| HRS      | 34h    |

### 6.6.5.16.2 Function

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals, as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

#### NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Each HRS field for its respective channel is 1 when a hardware request is present on the channel. After the request is completed and channel is free, the HRS field is automatically changed to 0 by hardware.

## 6.6.5.17 Enable Asynchronous Request in Stop (EARS)

### 6.6.5.17.1 Offset

| Register | Offset |
|----------|--------|
| EARS     | 44h    |

### 6.6.5.17.2 Function

The EARS register is used to enable or disable the DMA requests in [Enable Request \(ERQ\)](#) by AND'ing the bits of these two registers.

## 6.6.5.18 Channel Priority (DCHPRI0 - DCHPRI31)

### 6.6.5.18.1 Offset

| Register | Offset |
|----------|--------|
| DCHPRI3  | 100h   |
| DCHPRI2  | 101h   |
| DCHPRI1  | 102h   |
| DCHPRI0  | 103h   |
| DCHPRI7  | 104h   |
| DCHPRI6  | 105h   |
| DCHPRI5  | 106h   |
| DCHPRI4  | 107h   |
| DCHPRI11 | 108h   |
| DCHPRI10 | 109h   |
| DCHPRI9  | 10Ah   |
| DCHPRI8  | 10Bh   |
| DCHPRI15 | 10Ch   |
| DCHPRI14 | 10Dh   |
| DCHPRI13 | 10Eh   |
| DCHPRI12 | 10Fh   |
| DCHPRI19 | 110h   |
| DCHPRI18 | 111h   |

*Table continues on the next page...*

| Register | Offset |
|----------|--------|
| DCHPRI17 | 112h   |
| DCHPRI16 | 113h   |
| DCHPRI23 | 114h   |
| DCHPRI22 | 115h   |
| DCHPRI21 | 116h   |
| DCHPRI20 | 117h   |
| DCHPRI27 | 118h   |
| DCHPRI26 | 119h   |
| DCHPRI25 | 11Ah   |
| DCHPRI24 | 11Bh   |
| DCHPRI31 | 11Ch   |
| DCHPRI30 | 11Dh   |
| DCHPRI29 | 11Eh   |
| DCHPRI28 | 11Fh   |

### 6.6.5.18.2 Function

When fixed-priority channel arbitration is enabled ( $CR[ERCA] = 0$ ), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRI<sub>n</sub> register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRI<sub>n</sub> registers. The group priority is assigned in the DMA control register.

### 6.6.5.18.3 Diagram

### 6.6.5.18.4 Register reset values

| Register | Reset value |
|----------|-------------|
| DCHPRI0  | 00h         |
| DCHPRI1  | 01h         |
| DCHPRI2  | 02h         |
| DCHPRI3  | 03h         |
| DCHPRI4  | 04h         |
| DCHPRI5  | 05h         |
| DCHPRI6  | 06h         |
| DCHPRI7  | 07h         |
| DCHPRI8  | 08h         |
| DCHPRI9  | 09h         |
| DCHPRI10 | 0Ah         |
| DCHPRI11 | 0Bh         |
| DCHPRI12 | 0Ch         |
| DCHPRI13 | 0Dh         |
| DCHPRI14 | 0Eh         |
| DCHPRI15 | 0Fh         |
| DCHPRI16 | 10h         |
| DCHPRI17 | 11h         |
| DCHPRI18 | 12h         |
| DCHPRI19 | 13h         |
| DCHPRI20 | 14h         |
| DCHPRI21 | 15h         |
| DCHPRI22 | 16h         |
| DCHPRI23 | 17h         |
| DCHPRI24 | 18h         |
| DCHPRI25 | 19h         |
| DCHPRI26 | 1Ah         |
| DCHPRI27 | 1Bh         |
| DCHPRI28 | 1Ch         |

## 6.6.5.19 TCD Source Address (TCD0\_SADDR - TCD31\_SADDR)

### 6.6.5.19.1 Offset

For n = 0 to 31:

| Register   | Offset            |
|------------|-------------------|
| TCDn_SADDR | 1000h + (n × 20h) |

### 6.6.5.19.2 Function

This register contains the source address of the transfer.

### 6.6.5.19.3 Diagram

### 6.6.5.19.4 Fields

| Field         | Function                                                      |
|---------------|---------------------------------------------------------------|
| 31-0<br>SADDR | Source Address<br>Memory address pointing to the source data. |

### 6.6.5.20 TCD Signed Source Address Offset (TCD0\_SOFF - TCD31\_SOFF)

#### 6.6.5.20.1 Offset

For  $n = 0$  to 31:

| Register  | Offset                   |
|-----------|--------------------------|
| TCDn_SOFF | $1004h + (n \times 20h)$ |

#### 6.6.5.20.2 Diagram

#### 6.6.5.20.3 Fields

| Field        | Function                                                                                                                                                  |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0<br>SOFF | Source address signed offset<br>Sign-extended offset applied to the current source address to form the next-state value as each source read is completed. |

### 6.6.5.21 TCD Transfer Attributes (TCD0\_ATTR - TCD31\_ATTR)

#### 6.6.5.21.1 Offset

For  $n = 0$  to 31:

## Memory map/register definition

| Register  | Offset            |
|-----------|-------------------|
| TCDn_ATTR | 1006h + (n × 20h) |

### 6.6.5.21.2 Diagram

|       |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| 15-11<br>SMOD | <p>Source Address Modulo</p> <p>Any non-zero value in this field defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.</p> <p>00000b - Source address modulo feature is disabled<br/>00001-11111b - Value defines address range used to set up circular data queue</p> |

## 6.6.5.22 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0\_NBYTES\_MLNO - TCD31\_NBYTES\_MLNO)

### 6.6.5.22.1 Offset

For  $n = 0$  to 31:

| Register         | Offset                     |
|------------------|----------------------------|
| TCDn_NBYTES_MLNO | 1008h + ( $n \times 20$ h) |

### 6.6.5.22.2 Function

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if minor loop mapping is disabled ([CR\[EMLM\]](#) = 0).

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

### 6.6.5.22.3 Diagram

### 6.6.5.22.4 Fields

| Field          | Function                  |
|----------------|---------------------------|
| 31-0<br>NBYTES | Minor Byte Transfer Count |

| Field | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption.</p> <p>After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.</p> <p><b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.</p> |

### 6.6.5.23 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0\_NBYTES\_MLOFFNO - TCD31\_NBYTES\_MLOFFNO)

#### 6.6.5.23.1 Offset

For n = 0 to 31:

| Register            | Offset            |
|---------------------|-------------------|
| TCDn_NBYTES_MLOFFNO | 1008h + (n × 20h) |

#### 6.6.5.23.2 Function

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled ([CR\[EMLM\]](#) = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE = 1 or DMLOE = 1, refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, refer to the TCD\_NBYTES\_MLNO register description.

| 29-0<br>NBYTES | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br><br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

### 6.6.5.24 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0\_NBYTES\_MLOFFYES - TCD31\_NBYTES\_MLOFFYES)

#### 6.6.5.24.1 Offset

For n = 0 to 31:

| Register                 | Offset            |
|--------------------------|-------------------|
| TCDn_NBYTES_MLOFF<br>YES | 1008h + (n × 20h) |

### 6.6.5.24.2 Function

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled ([CR\[EMLM\]](#) = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE = 0 and DMLOE = 0, refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, refer to the TCD\_NBYTES\_MLNO register description.

### 6.6.5.25 TCD Last Source Address Adjustment (TCD0\_SLAST - TCD31\_SLAST)

#### 6.6.5.25.1 Offset

For  $n = 0$  to 31:

| Register   | Offset                   |
|------------|--------------------------|
| TCDn_SLAST | $100Ch + (n \times 20h)$ |

#### 6.6.5.25.2 Diagram

### 6.6.5.25.3 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>SLAST | <p>Last Source Address Adjustment</p> <p>Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.</p> <p>This register uses two's complement notation; the overflow bit is discarded.</p> |

### 6.6.5.26 TCD Destination Address (TCD0\_DADDR - TCD31\_DADDR)

#### 6.6.5.26.1 Offset

For n = 0 to 31:

| Register   | Offset            |
|------------|-------------------|
| TCDn_DADDR | 1010h + (n × 20h) |

#### 6.6.5.26.2 Function

This register contains the destination address of the transfer.

#### 6.6.5.26.3 Diagram

#### 6.6.5.26.4 Fields

| Field | Function            |
|-------|---------------------|
| 31-0  | Destination Address |

| Field | Function                                         |
|-------|--------------------------------------------------|
| DADDR | Memory address pointing to the destination data. |

### 6.6.5.27 TCD Signed Destination Address Offset (TCD0\_DOFF - TCD31\_DOFF)

#### 6.6.5.27.1 Offset

For  $n = 0$  to 31:

| Register  | Offset                   |
|-----------|--------------------------|
| TCDn_DOFF | $1014h + (n \times 20h)$ |

#### 6.6.5.27.2 Diagram

#### 6.6.5.27.3 Fields

| Field | Function                                                                                                                             |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| 15-0  | Destination Address Signed Offset                                                                                                    |
| DOFF  | Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed. |

### 6.6.5.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0\_CITER\_ELINKNO - TCD31\_CITER\_ELINKNO)

#### 6.6.5.28.1 Offset

For  $n = 0$  to 31:

| Register           | Offset            |
|--------------------|-------------------|
| TCDn_CITER_ELINKNO | 1016h + (n × 20h) |

### 6.6.5.28.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as [TCD Current Minor Loop Link, Major Loop Count \(Channel Linking Enabled\) \(TCD0\\_CITER\\_ELINKYES - TCD31\\_CITER\\_ELINKYES\)](#), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 0, this register is defined as follows.

### 6.6.5.28.3 Diagram

### 6.6.5.28.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>ELINK   | <p>Enable channel-to-channel linking on minor-loop complete</p> <p>As the channel completes the minor loop, this field enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel.</p> <p>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported.<br/> 0b - Channel-to-channel linking is disabled<br/> 1b - Channel-to-channel linking is enabled</p>                                                                                            |
| 14-0<br>CITER | <p>Current Major Iteration Count</p> <p>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations. It optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.</p> <p><b>NOTE:</b></p> <ol style="list-style-type: none"> <li>When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</li> <li>If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</li> </ol> |

### 6.6.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0\_CITER\_ELINKYES - TCD31\_CITER\_ELINKYES)

#### 6.6.5.29.1 Offset

For  $n = 0$  to 31:

| Register            | Offset            |
|---------------------|-------------------|
| TCDn_CITER_ELINKYES | 1016h + (n × 20h) |

#### 6.6.5.29.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as [TCD Current Minor Loop Link, Major Loop Count \(Channel Linking Disabled\) \(TCD0\\_CITER\\_ELINKNO - TCD31\\_CITER\\_ELINKNO\)](#), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 1, this register is defined as follows.

| 2<br>INTHALF  | Enable an interrupt when major counter is half complete.<br><br>If the value of this field is 1, the channel generates an interrupt request by setting the appropriate field in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.<br><br><b>NOTE:</b> If BITER = 1, do not use INTHALF. Use INTMAJOR instead.<br>0b - Half-point interrupt is disabled<br>1b - Half-point interrupt is enabled |
| 1<br>INTMAJOR | Enable an interrupt when major iteration count completes.<br><br>If the value of this field is 1, the channel generates an interrupt request by setting the appropriate field in the INT when the current major iteration count reaches zero.<br>0b - End of major loop interrupt is disabled<br>1b - End of major loop interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                  |
| 0<br>START    | Channel Start<br><br>If the value of this field is 1, the channel is requesting service. eDMA hardware automatically writes 0 to this field after the channel begins execution.<br>0b - Channel is not explicitly started<br>1b - Channel is explicitly started via a software initiated service request                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 6.6.5.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCDn\_BITER\_ELINKNO - TCD31\_BITER\_ELINKNO)

#### 6.6.5.32.1 Offset

For n = 0 to 31:

| Register           | Offset            |
|--------------------|-------------------|
| TCDn_BITER_ELINKNO | 101Eh + (n × 20h) |

#### 6.6.5.32.2 Function

If TCDn\_BITER[ELINK] is 0, the TCDn\_BITER register is defined as follows.

### 6.6.5.33 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0\_BITER\_ELINKYES - TCD31\_BITER\_ELINKYES)

#### 6.6.5.33.1 Offset

For n = 0 to 31:

| Register            | Offset            |
|---------------------|-------------------|
| TCDn_BITER_ELINKYES | 101Eh + (n × 20h) |

### 6.6.5.33.2 Function

If TCDn\_BITER[ELINK] is 1, the TCDn\_BITER register is defined as follows.

# Chapter 7

## System Security

### 7.1 Chapter overview

This chapter provides an overview of the following chip security components, explaining the purpose and features of each of them.

- High Assurance Boot (HAB)
- Secure Non-Volatile Storage (SNVS) with the security monitor, key storage, and real-time clock
- Data co-processor (DCP) with cryptographic acceleration, with Cryptographic Hash Engine, Public Key Cryptography Engine and Random Number Generation
- Hardware encryption and hash algorithm engine for AES128 and SHA-1/256
- True Random Number Generator (TRNG)
- On-chip One-Time Programmable Element Controller (OCOTP\_CTRL) with on-chip electrical fuse arrays
- Central Security Unit (CSU)
- System JTAG Controller (SJC) with secure debug
- Bus Encryption Engine (BEE) for on-the-fly FlexSPI(QSPI) Flash decryption

### 7.2 Feature summary

This figure shows a simplified diagram of the security subsystem:

**Figure 7-1. Security subsystem (simplified)**

All platforms built using this chip share a general need for security, though the specific security requirements vary greatly from platform to platform. For example, portable consumer devices need to protect a different type and cost of assets than automotive or industrial platforms. Each market must be protected against different kinds of attacks. The platform designers need an appropriate set of counter measures to meet the security needs of their specific platform.

To help the platform designers to meet the requirements of each market, the chip incorporates a range of security features. Most of these features provide protection against specific kinds of attack, and can be configured for different levels according to the required degree of protection. These features are designed to work together or independently. They can be also integrated with the appropriate software to create defensive layers. In addition, the chip includes a general-purpose accelerator that enhances the performance of selected industry-standard cryptographic algorithms.

The security features include:

- Secure High-Assurance Boot
  - Security library embedded in the tamper-proof on-chip ROM
  - Authenticated boot, which protects against unauthorized software
    - Verification of the code signature during boot
    - RSA-1024/2048/3072/4096 keys anchored to the OTP fingerprint (SHA-256)
  - Encrypted boot which protects the software confidentiality

- Runs every time the chip is reset
- Image version control/image revocation (on-chip OTP-based)
- Secure storage
  - Off-chip storage protection using AES-128 and the chip's unique hardware-only key
- Hardware cryptographic accelerators
  - Symmetric: AES-128,
  - Hash message digest: SHA-1, SHA-256,
- True and pseudorandom number generator
- On-chip secure real-time clock with autonomous power domain
- Secure debugging
  - Configurable protection against unauthorized JTAG manipulation
  - Three security levels + a complete JTAG disable
  - Support for JTAG port secure reopening for field return debugging
- Universal unique ID
- Electrical fuses (OTP Memory)
- Hardware bus encryption
  - AES-128 encryption, supporting ECB and CTR modes
  - Non-secured access filtering

## 7.3 High-Assurance Boot (HAB)

The HAB, which is the high-assurance boot feature in the system boot ROM, detects and prevents the execution of unauthorized software (malware) during the boot sequence.

When the unauthorized software is permitted to gain control of the boot sequence, it can be used for a variety of goals, such as exposing stored secrets, circumventing access controls to sensitive data, services, or networks, or for re-purposing the platform. The unauthorized software can enter the platform during upgrades or re-provisioning, or when booting from the USB connections or removable devices.

The HAB protects against unauthorized software by:

- Using digital signatures to recognize the authentic software. This enables you to boot the device to a known initial state and run the software signed by the device manufacturer.
- Using code encryption to protect the confidential software during off-chip storage. When activated, the HAB decrypts the software loaded into the RAM before execution.

### **7.3.1 HAB process flow**

The following figure shows the flow for creating and verifying digital signatures. The top half of this figure shows the signing process, which is performed off-chip. The bottom half shows the verification process performed on-chip during every system boot.

**Figure 7-2. Code signing and authentication processes**

The original software is programmed into the flash memory (or any other boot device) along with the signature. The HAB uses a public key to recover the reference hash value from the signature; it then compares the reference hash value to the current hash value

calculated from the software in the flash. If the contents of the flash are modified either intentionally or unintentionally, the two hash values do not match and the verification fails.

### 7.3.2 HAB feature summary

The HAB features:

- Enforced internal boot via on-chip masked ROM
- Authentication of software loaded from any boot device (including the USB download)
- Authenticated decryption of software loaded from any boot device (including USB download) using the AES keys (128-bit)
- CMS PKCS#1 signature verification using the RSA public keys (from 1024-bit to 4096-bit), and the SHA-256 hash algorithm
- Public Key Infrastructure (PKI) support using X.509v3 certificates
- Root public key fingerprint in the manufacturer-programmable on-chip fuses
- Multiple root public keys with revocation by fuses
- Initialization of other security components
- Authenticated USB download fall-over on any security failure
- Open configuration for development purposes and non-secure platforms
- Closed configuration for shipping secure platforms

On the chip, the HAB is integrated with these security features:

- The HAB initializes the SNVS security monitor state machine. A successful secure boot with the HAB is required for the platform software to gain access to use the DCP master secret key selected by SNVS.
- The HAB reads the root public key fingerprint, revocation mask, and security configuration from the OCOTP\_CTRL.
- The HAB initializes the CSU.
- The HAB can use the DCP to accelerate hash calculations.

## 7.4 Secure Non-Volatile Storage (SNVS) module

- Provides a non-volatile real-time clock maintained by a coin-cell battery during system power down for use in both the secure and non-secure.
- Protects the secure real-time clock against rollback attacks in time-sensitive protocols such as DRM and PKI
- Deters replay attacks in time-independent protocols such as certificate or firmware revocations

- Handles security violation detection and reporting, to defend sensitive data and operations against compromise, both at run-time and during system power-down
- Controls the access to the OTP master secret key used by the DCP to protect confidential data in the off-chip storage
- Provides non-volatile highly protected storage for an alternative master secret key

### 7.4.1 SNVS architecture

The SNVS is partitioned into two sections: a low-power part (SNVS\_LP) and a high-power part (SNVS\_HP).

The SNVS\_LP block is in the always-powered-up domain. It is isolated from the rest of the logic by isolation cells which are library-instantiated cells that insure that the powered-up logic is not corrupted when the power goes down in the rest of the chip.

The SNVS\_LP has these functional units:

- Zeroizable Master Key
- Secure non-rollover real-time counter with alarm
- Non-rollover monotonic counter
- Power glitch detector
- General-purpose register
- Control and status registers

The SNVS\_HP is in the chip power-supply domain. The SNVS\_HP provides an interface between the SNVS\_LP and the rest of the system. The access to the SNVS\_LP registers can be gained through the SNVS\_HP only when it is powered up according to the access permission policy.

The SNVS\_HP has these functional units:

- IP bus interface
- SNVS\_LP interface
- System Security Monitor (SSM)
- Zeroizable Master Key programming mechanism
- Master Key control block
- Non-secure real-time counter with alarm
- Control and status registers

## 7.5 Data Co-Processor (DCP)

For security purposes, the Data Co-Processor (DCP) provides hardware acceleration for the cryptographic algorithms. The features of DCP include:

- Encryption Algorithms: AES-128 (ECB and CBC modes)
- Hashing Algorithms: SHA-1 and SHA-256
- CRC-32
- Key selection from the SNVS, DCP internal key storage, or general memory
- Internal Memory for storing up to four AES-128 keys—when a key is written to a key slot it can be read only by the DCP AES-128 engine
- IP slave interface
- DMA

## 7.6 Standalone True Random Number Generator (TRNG)

The SA-TRNG is hardware accelerator module that generates a 512-bit entropy as needed by an entropy consuming module or by other post processing functions. A typical entropy consumer is a pseudo random number generator (PRNG) which can be implemented to achieve both true randomness and cryptographic strength random numbers using the SA-TRNG output as its entropy seed. The PRNG is not part of this module.

## 7.7 On-Chip OTP Controller (OCOTP\_CTRL)

The OCOTP\_CTRL provides the primary user-visible mechanism for interfacing with the on-chip fuses. These fuses' uses include:

- Unique chip identifiers
- Mask revision numbers
- Cryptographic keys
- Security configuration
- Boot characteristics
- Various control signals requiring permanent non-volatility

The OCOTP\_CTRL provides:

- Shadow cache of fuse values, loaded at reset, before the system boot
- Ability to read and override the fuse values in the shadow cache (does not affect the fuse element)

- Ability to read the fuses directly (ignoring the shadow cache)
- Ability to write (program) the fuses by software or JTAG
- Fuses and shadow cache bits enforce read-protect, override-protect, and write-protect
- Lock fuses for selected fuse fields
- Scan protection
- Volatile software-accessible signals which can be used for software control of hardware elements (not requiring non-volatility).

## 7.8 Central Security Unit (CSU)

Central Security Unit (CSU) sets access control policies between the bus masters and bus slaves, enabling the peripherals to be separated into distinct security domains. This protects against the indirect unauthorized access to data which occurs when the software programs a DMA bus master to access addresses that the software itself is prohibited from accessing directly. Configuring the DMA bus master privileges in the CSU consistently with the software privileges defends against such indirect unauthorized access.

The CSU provides:

- Configuration of peripheral access permissions for peripherals that are unable to control their own access permissions
- Configuration of bus master privileges for bus masters that are unable to control their own privileges
- Optional locking of the individual CSU settings until the next power-on reset

## 7.9 System JTAG Controller (SJC)

The JTAG port provides debug access to hardware blocks, including the Arm processor and the system bus. This enables program control and manipulation as well as visibility to the chip peripherals and memory.

The JTAG port must be accessible during initial platform development, manufacturing tests, and general troubleshooting. Given its capabilities, JTAG manipulation is a known attack vector for accessing sensitive data and gaining control over software execution. The System JTAG Controller (SJC) protects against the whole range of attacks based on unauthorized JTAG manipulation. It also provides a JTAG port that conforms to the IEEE 1149.1 and IEEE 1149.6 (AC) standards for BSR (boundary-scan) testing.

The SJC provides these security levels:

- The JTAG Disabled-JTAG use is permanently blocked.
- The No-Debug-All security sensitive JTAG features are permanently blocked.
- The Secure JTAG-JTAG use is restricted (as in the No-Debug level) unless a secret-key challenge/response protocol is successfully executed.
- The JTAG Enabled-JTAG use is unrestricted.

The security levels are selected via the e-fuse configuration.

### 7.9.1 Scan protection

The chip includes further scan protection logic for those SJC modes where the JTAG use is allowed. This ensures that the access to critical security values is protected as follows:

- The chip is reset when entering the scan mode.
- All modules are reset two clock cycles before receiving the scan-enable indication.
- The chip cannot exit the scan mode without a reset.
- The security modules (including SNVS, CSU, and OCOTP\_CTRL) have an additional scan-protection logic to protect the sensitive internal data and functionality.

See the "System JTAG Controller (SJC)" chapter in the Security Reference Manual for more information on the SJC.

## 7.10 Bus Encryption Engine (BEE)

The Bus Encryption Engine (BEE) is implemented as an on-the-fly decryption engine, which is used for decrypting cypher context of FlexSPI. The main features of the BEE are:

- Standard AXI interconnection
- On-the-fly AES-128 decryption, supporting ECB and CTR modes
- Aliased memory space support. Address remapping for up to two individual regions
- Independent AES Key management for those two individual regions
- Bus access pattern optimization with the aid of the local store and forward buffer
- Non-secured access filtering based on the security label of the access
- Illegal access check and filtering

See the "Bus Encryption Engine (BEE)" chapter in the Security Reference Manual for more information on BEE.

# Chapter 8

## System Debug

### 8.1 Overview

This section describes the hardware and software debug and application development features and resources of the chip. It describes the following:

- Core/platform-specific resources
- Resources associated with complex IP blocks
- Chip-wide resources
- Interface to the external debug and development tools

The debug and trace architecture is designed around the following:

- Arm CoreSight architecture, adapted to SoC (for core debug), including a cross-trigger subsystem for cross-domain triggering of debug resources
- JTAG port used to interact with core under the debug by means of SJC, the system JTAG controller port
- DAP, the debug access port that supports the interface to the Arm RealView Debugging tools and other third-party tools
- TPIU, a trace port interface unit that efficiently accesses the program trace information from the system
- Various chip-wide resources, such as debug features built into the IP blocks and critical signal visibility available through alternate pin functions or observability muxes

### 8.2 Chip and Arm Platform Debug Architecture

The Arm Debug architecture is based on the CoreSight architecture by Arm. The CoreSight architecture provides a system-wide solution to real-time debug and trace.

The CoreSight architecture is embodied in a set of CoreSight components and compliant processors that form the CoreSight systems. Its architecture maintains the traditional requirements of debug and trace:

- To access the debug functionality without software interaction
- To connect to a running system without performing a reset

Full access to the processor debug capability is available by the Arm debug register map through the Advanced Peripheral Bus (APB) slave port. The core includes a Processor Debug Unit which stops program execution, examines and alters the processor and coprocessor state, examines and alters the memory and input/output peripheral state, and restarts the processor core.

### 8.2.1 Debug Features

- EmbeddedICE-RT logic
  - Support for both the monitor-mode and halt-mode debugging:
  - Core run/halt control, debug status/control
  - Breakpoint/watchpoint control
  - Core-mapped and memory-mapped resource examination/modification
- Data communication channel between the Arm core and the host debugger via JTAG or SWD and the Debug Access Port (DAP) module

The chip includes Arm CoreSight components for debug and trace solutions.

### 8.2.2 Debug system components

The CoreSight components include:

- ETM (Embedded Trace Macrocell) supporting instruction trace
- ITM (Instrumentation Trace Macrocell)
- TPIU (Trace Port Interface)
- Cross Triggering logic for event routing, including CTIs

Other related IPs and functionality:

- Flash Patch and Breakpoint unit (FPB)

### 8.2.2.1 AMBA Trace Bus (ATB)

ATB transfers trace data through the chip CoreSight infrastructure. The trace sources are ATB masters and the sinks are ATB slaves. The Arm (via PTM) cores are the data generators. Link components such as the Trace Funnel and Replicator provide both the master and slave interfaces.

The ATB protocol supports:

- Stalling of trace sources to enable the CoreSight components to funnel and combine the sources into a single trace stream
- Association of the trace data with the generating source using trace source IDs. The CoreSight system can trace up to 111 different items at any time
- Capture and transfer of multiple byte bus widths, currently to 32 bits
- A flushing mechanism to force the historic trace to drain from any sources, links, or sinks up to the point that the request is initiated

### 8.2.2.2 CoreSight trace port interface (TPIU)

#### TPIU (Cortex-M7)

TPIU is one of the CoreSight trace sink components. It acts as a bridge between the on-chip trace data and a data stream that is then driven out the trace port.

TPIU uses the ATB interface to accept trace data from a trace source, either directly or by using a trace funnel. TPIU has 4 bit port connected to the chip pad.

The APB interface is the programming interface for the TPIU configuration.

The features of the sub-blocks are as follows:

- **Formatter**—Inserts source ID signals into the data packet stream so that the trace data can be re-associated with the trace source.
- **Asynchronous FIFO**—Enables trace data to be driven out at a speed that is not dependent on the on-chip bus clock.
- **Register Bank**—Contains the management, control and status registers for triggers, flushing behavior and external control.
- **Trace out**—The Trace out block serializes the formatted data before it goes off-chip.
- **Pattern Generator**—The Pattern Generator unit provides a simple set of defined bit sequences or patterns that can be output over the Trace Port and be detected by the TPA or other associated Trace Capture Device (TCD). The TCD can use these patterns to indicate if it is possible to increase or decrease the trace port clock speed.

The TPIU accepts trace data from a trace source, either direct from a trace source or using a Trace Funnel. The APB interface is the programming interface for the TPIU. The Trace Clock driving the data out to external pins can be obtained from either an on chip or off chip source, selectable via a mux.

The output of the TPIU is connected via external pins (MPS of TRACEDATA (ARM\_TRACEEn), which can be 1, 2, or 4 bits). The system may utilize double data rate pins to either use a lower clock speed than that of the 32-bit ATB interface, or use fewer than 4 data pins for the output, based on the ability of the technology used. Given the speed of the ATB, 4 data pins with double data rate is recommended, with the external interface running at half the speed of the ATB. The speed of the external interface is from TRACECLKIN (TRACE\_CLK\_ROOT), and should be selectable via an on chip or off chip clock. TRACECLK (ARM\_TRACE\_CLK) is equal to TRACECLKIN / 2, and is divided in the TPIU to clock trace data at the trace capture unit.

TPIU used to be part of the Arm platform sub blocks in previous versions of i.MX products, placing the TPIU off platform allows future debug trace sources from the chip level to connect to the TPIU by means of a funnel.

For more information, see Arm Cortex M7 Integration and Implementation Manual.

### 8.2.2.3 Coresight Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from any CoreSight-compliant component trace source with an ATB master port, such as a trace source or a trace funnel. It is included in this device to remove dependencies from the trace pin pad speed, and enable low cost trace solutions. The TraceRAM size is 2 KB.

Figure 8-1. ETB Block Diagram

The ETB contains the following blocks:

- **Formatter**—Inserts source ID signals into the data packet stream so that trace data can be re-associated with its trace source after the data is read back out of the ETB.
- **Control**—Control registers for trace capture and flushing.
- **APB interface**—Read, write, and data pointers provide access to ETB registers. In addition, the APB interface supports wait states through the use of a PREADYDBG signal output by the ETB. The APB interface is synchronous to the ATB domain.
- **Register bank**—Contains the management, control, and status registers for triggers, flushing behavior, and external control.
- **Trace RAM interface**—Controls reads and writes to the Trace RAM.

### 8.2.2.3.1 Performance Profiling with the ETB

To create a performance profile (for example, gprof) for the target application, a means to collect trace over a long period of time is needed. The ETB buffer is too small to capture a meaningful profile in just one take. What is needed is to collect and concatenate data from the ETB buffer for multiple sequential runs. Using the ETB packet counter, the trace analysis tool can capture multiple sequential runs by executing code until the ETB is almost full, and halting or executing an interrupt handler to allow the buffer to be emptied, and then continuing executing code. The target halts or executes an interrupt handler when the buffer is almost full to empty the data and then the debugger runs the target again.

### 8.2.2.3.2 ETB Counter Control

The ETB packet counter is controlled by the ETB counter control register, ETB reload register, and ETB counter value register implemented in the Miscellaneous Control Module (MCM) accessible via the Private Peripheral Bus. Via the ETB counter control register the ETB control logic can be configured to cause an MCM Alert Interrupt, an NMI Interrupt, or cause a Debug halt when the down counter reaches 0. Other features of the ETB control logic include:

- Down counter to count as many as 512 x 32-bit packets.
- Reload request transfers reload value to counter.
- ATB valid and ready signals used to form counter decrement.
- The counter disarms itself when the count reaches 0.

The counter decrement enable will allow the counter to decrement at the rising edge of ATCLK when,

- The counter enable bit is set.
- The counter is armed.
- ATVALID and ATREADY are asserted.

**Figure 8-2. Count Decrement Enable**

#### 8.2.2.4 Embedded Trace Macrocell (ETM)

Instruction trace, also known as ETM (Embedded Trace Macrocell) trace, is a continuously collected sequence of every executed instruction for a selected portion of the application. ETM generates trace packets and sends them to the trace bus. ETM does not actually output every address or instruction that the processor has reached or executed; it usually generates compressed information about the program flow and outputs full addresses only if needed (for example, if a branch has taken place). Because the debugger knows the application code image, the debugger can then reconstruct the full instruction sequence from the trace data.

For more information about ETM, refer to *Arm® CoreSight™ ETM-M7 Revision r0p1 Technical Reference Manual*.

#### 8.2.2.5 Instrumentation Trace Macrocell

The ITM (Instrumentation Trace Macrocell) generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

- Synchronization: DWT provides periodic requests to make ITM generate synchronization packet. Trace capture hardware uses it to identify the alignment of packet bytes in the bit-stream.
- Software Trace: Application software can write console messages directly to ITM stimulus ports, and output them to the host as trace packets.
- Hardware trace: The DWT generates these packets, and the ITM outputs them.
- Timestamping: ITM can generate timestamp packets that are inserted in to the trace stream, to help the host debugger to find out the timing of events. Timestamps are generated relative to packets. The ITM receives a 64-bit counter to generate the timestamp.

Trace data from ITM will be forwarded to TPIU and streamed out via the trace port.

For more information about ITM, refer to *Armv7-M Architecture Reference Manual*.

## 8.2.3 Chip-Specific SJC Features

### NOTE

The application note [AN12419: Secure JTAG for i.MXRT10xx](#) describes how the Secure JTAG on the i.MX RT10xx MCU family can be used.

### 8.2.3.1 JTAG Disable Mode

In addition to different JTAG security modes that are implemented internally in the JTAG Controller, there is an option to disable the SJC functionality by e-fuse configuration.

This creates additional JTAG mode "JTAG Disabled" with highest level of JTAG protection. In this mode all JTAG features are disabled. Specifically, the following debug features are disabled in addition to the features that were already disabled in "No Debug" JTAG mode:

- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

### 8.2.3.2 JTAG ID

**Table 8-1. i.MX JTAG ID**

| Device      | Silicon revision     | JTAG ID    |
|-------------|----------------------|------------|
| i.MX RT1050 | Rev 1.1 (Silicon A1) | 188C_301Dh |

### 8.2.4 System JTAG controller main features

- IEEE P1149.1, 1149.6 (standard JTAG) interface to off-chip test and development equipment
  - Includes an SJC-only mode for true IEEE P1149.1 compliance, used primarily for board-level implementation of boundary scan.
  - Supports IEEE P1149.6 extensions to the JTAG standard for AC testing of selected I/O signals.
- Debug-related control and status; putting selected cores into reset and/or debug mode and monitoring individual core status signals by means of JTAG
- System status, such as the state of the PLLs (locked or not locked)
- levels of security, ranging from no security to no JTAG accessibility to the chip

### 8.2.5 TAP Port

The SJC supports the following standard JTAG pins:

- TRSTB
- TDI
- TDO
- TCK
- TMS

### 8.2.6 SJC main blocks

- Interface to the outside world via the standard JTAG pins
- Interface to the external Debug\_Event pin
- A master TAP controller which implements the standard JTAG state machine
- Implementation of the mandatory and optional IEEE P1149.1 (JTAG) instructions
  - Mandatory: "EXTEST", "SAMPLE/PRELOAD", and "BYPASS"
  - Optional: "ID\_CODE" (SOC JTAG ID register), "HIGHZ"
- The ExtraDebug registers, which implement a variety of control and status features
  - Three 32-bit insecure general purpose status registers

- Two 32-bit secure status registers - one predefined, one general purpose.
- Control and status registers for debug, core, charge pump, and PLL.
- Four levels of fuse-defined security, ranging from no security to no access.

Both predefined and user-defined control and status functions are supported by the SJC.

## 8.3 Miscellaneous

The Miscellaneous function described in this section provide useful general capabilities.

### 8.3.1 Clock/Reset/Power

CDBGPWRUPREQ and CDBGPWRUPACK are the handshake signals between the DAP and the clock control module to ensure debug power and clocks are turned on. If the debug components are always powered on, the handshake becomes a mechanism to turn debug clocks on. Similarly, there is a register bit in the CCM which allows internal software to turn debug clocks on as well because the CDBGPWRUPREQ is in the TCLK domain and is inaccessible to software.

The debug components can receive resets from the following sources:

- Debug Reset (CDBGIRSTREQ bit within the SWJ-DP CTRL/STAT register of the DAP) in the TCLK domain. This allows the debug tools to reset the debug logic.
- System POR reset

# Chapter 9

## System Boot

### 9.1 Chip-specific Boot Information

This device has various peripherals supported by the ROM bootloader.

**Table 9-1. ROM Bootloader Peripheral PinMux**

| Peripheral | Instance | Port (IO function) | PAD           | Mode | Use                                                                                                                                                                                                                                                                               |
|------------|----------|--------------------|---------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPUART     | 1        | LPUART1_TX         | GPIO_AD_B0_12 | ALT2 | Can be used for serial downloader mode. Refer to <a href="#">Serial Downloader</a> for more information.                                                                                                                                                                          |
|            |          | LPUART1_RX         | GPIO_AD_B0_13 | ALT2 |                                                                                                                                                                                                                                                                                   |
| LPSP1      | 1        | LPSP11_SCK         | GPIO_SD_B0_00 | ALT4 | Serial NOR/EEPROM connected to one of the LPSP1 ports can be used as a recovery device. Refer to <a href="#">Recovery devices</a> for more information.<br><br><b>Note:</b> recovery device boot is disabled by default. Fuses must be blown to enable and configure this option. |
|            |          | LPSP11_SDO         | GPIO_SD_B0_02 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP11_SDI         | GPIO_SD_B0_03 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP11_PCS0        | GPIO_SD_B0_01 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            | 2        | LPSP12_SCK         | GPIO_SD_B1_07 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP12_SDO         | GPIO_SD_B1_08 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP12_SDI         | GPIO_SD_B1_09 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP12_PCS0        | GPIO_SD_B1_06 | ALT4 |                                                                                                                                                                                                                                                                                   |
|            | 3        | LPSP13_SCK         | GPIO_AD_B0_00 | ALT7 |                                                                                                                                                                                                                                                                                   |
|            |          | LPSP13_SDO         | GPIO_AD_B0_01 | ALT7 |                                                                                                                                                                                                                                                                                   |

| SEMC NOR   | N/A      | SEMC_DATA00        | GPIO_EMC_00 | ALT0 | Parallel NOR flash connected to the SEMC is a primary boot option. Refer to <a href="#">Parallel NOR flash Boot over SEMC</a> for more information.<br><br><b>Note:</b> By default SEMC_CSX0 is used as the chip select. Other chip selects can be used, but fuses must be blown to select these configurations (GPIO overrides cannot be used to configure this option). |

|               |          | FLEXSPI_A_DATA3    | GPIO_SD_B1_11 | ALT1 |     |
| FlexSPI RESET |          | GPIO1_IO29         | GPIO_AD_B1_13 | ALT5 |     |

**NOTE**

ROM does not support boot from FLEXSPI\_B port directly. ROM always seeks a valid Flash Configuration Block from the FLEXSPI\_A port and then re-configures the FLEXSPI controller using the valid parameters in the block read-out. This reconfiguration can include, but is not limited to, FLEXSPI\_B port support.

## 9.2 Overview

The boot process begins at any Reset where the hardware reset logic forces the Arm core to begin execution starting from the on-chip boot ROM.

The boot ROM code uses the state of the internal register BOOT\_MODE[1:0] as well as the state of various eFUSES and/or GPIO settings to determine the boot flow behavior of the device.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial downloader support (USB OTG and UART)
- Device Configuration Data (DCD) and plugin
- Digital signature and encryption based High-Assurance Boot (HAB)
- Wake-up from the low-power modes
- Encrypted XIP on Serial NOR via FlexSPI interface powered by Bus Encryption Engine (BEE) and Data Co-Processor (DCP) controller

The boot ROM supports boot device as below:

- Serial NOR Flash via FlexSPI
- Serial NAND Flash via FlexSPI
- Parallel NOR Flash via SEMC
- RAWNAND Flash via SEMC

- SD/MMC
- SPI NOR/EEPROM via LPSPI

The boot ROM uses the state of the `BOOT_MODE` and eFUSEs to determine the boot device. For development purposes, the eFUSEs used to determine the boot device may be overridden using the GPIO pin inputs.

The boot ROM code also allows to download the programs to be run on the device. An example is a provisioning program that can make further use of the serial connection to provide a boot device with a new image. Typically, the provisioning program is downloaded to the internal RAM and allows to program the boot devices, such as the FlexSPI NOR flash. The ROM serial downloader uses a high-speed USB in a non-stream mode connection.

The boot ROM allows waking up from the low-power modes. On reset, the ROM checks the power gating status register. When waking from the low-power mode, the core skips loading an image from the boot device and jumps to the address saved in `PERSISTENT_ENTRY0`.

The Device Configuration Data (DCD) feature allows the boot ROM code to obtain the SOC configuration data from an external program image residing on the boot device. As an example, the DCD can be used to program the SDRAM controller for optimal settings, improving the boot performance. The DCD is restricted to the memory areas and peripheral addresses that are considered essential for the boot purposes (see [Write data command](#)).

A key feature of the boot ROM is the ability to perform a secure boot, also known as a High-Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the ROM code. The HAB uses a combination of hardware and software together with the Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized programs. Before the HAB allows the user image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as a part of the final program image. If configured to do so, the ROM verifies the signatures using the public keys included in the program image. In addition to supporting the digital signature verification to authenticate the program images, the encrypted boot is also supported. The encrypted boot can be used to prevent the cloning of the program image directly off the boot device. A secure boot with HAB can be performed on all boot devices supported on the chip in addition to the serial downloader. The HAB library in the boot ROM also provides the API functions, allowing the additional boot chain components (bootloaders) to extend the secure boot chain. The out-of-fab setting for the `SEC_CONFIG` is the open configuration, in which the ROM/HAB performs the image authentication, but all authentication errors are ignored and the image is still allowed to execute.

## 9.3 Boot modes

During reset, the chip checks the power gating controller status register.

During boot, the core's behavior is defined by the boot mode pin settings, as described in [Boot mode pin settings](#). When waking up from the low-power boot mode, the core skips the clock settings. The boot ROM checks that the PERSISTENT\_ENTRY0 (see [Persistent bits](#)) is a pointer to a valid address space (OCRAM). If the PERSISTENT\_ENTRY0 is a pointer to a valid range, it starts the execution using the entry point from the PERSISTENT\_ENTRY0 register. If the PERSISTENT\_ENTRY0 is a pointer to an invalid range, the core performs the system reset.

### 9.3.1 Boot mode pin settings

The device has four boot modes (one is reserved for NXP use). The boot mode is selected based on the binary value stored in the internal BOOT\_MODE register.

The BOOT\_MODE is initialized by sampling the BOOT\_MODE0 and BOOT\_MODE1 inputs on the rising edge of the POR\_B. After these inputs are sampled, their subsequent state does not affect the contents of the BOOT\_MODE internal register. The state of the internal BOOT\_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC\_SBMR2). The available boot modes are: Boot From Fuses, serial boot via USB, and Internal Boot. See this table for settings:

**Table 9-2. Boot MODE pin settings**

| BOOT_MODE[1:0] | Boot Type         |
|----------------|-------------------|
| 00             | Boot From Fuses   |
| 01             | Serial Downloader |
| 10             | Internal Boot     |
| 11             | Reserved          |

### 9.3.2 High-level boot sequence

The figure found here show the high-level boot ROM code flow.

Figure 9-1. Boot flow

### 9.3.3 Boot From Fuses mode (BOOT\_MODE[1:0] = 00b)

A value of 00b in the BOOT\_MODE[1:0] register selects the Boot From Fuses mode.

This mode is similar to the Internal Boot mode described in [Internal Boot mode \(BOOT\\_MODE\[1:0\] = 0b10\)](#) with one difference. In this mode, the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT\_FUSE\_SEL eFUSE value. If BT\_FUSE\_SEL = 0, indicating that the boot device (for example, flash) was not programmed yet, the boot flow jumps directly to the Serial Downloader. If BT\_FUSE\_SEL = 1, the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSES may be configured incorrectly for the hardware on the platform. In such case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using the Boot From Fuses mode addresses this problem.

Setting the BT\_FUSE\_SEL=0 forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a program image and blow the BT\_FUSE\_SEL and the other boot configuration eFUSES. After the reset, the boot ROM code determines that the BT\_FUSE\_SEL is blown (BT\_FUSE\_SEL = 1) and the ROM code performs an internal boot according to the new eFUSE settings. This allows the user to set BOOT\_MODE[1:0]=00b on a production device and burn the fuses on the same device (by forcing the entry to the Serial Downloader), without changing the value of the BOOT\_MODE[1:0] or the pullups/pulldowns on the BOOT\_MODE pins.

### 9.3.4 Serial Downloader (BOOT\_MODE[1:0] = 01b)

The Serial Downloader provides a means to download a Program Image to the chip over USB or UART serial connection. In this mode, typically a host PC can communicate to the ROM bootloader using serial download protocol. Serial downloader and the protocol are discussed in [Serial Downloader](#).

### 9.3.5 Internal Boot mode (BOOT\_MODE[1:0] = 0b10)

A value of 0b10 in the BOOT\_MODE[1:0] register selects the Internal Boot mode. In this mode, the processor continues to execute the boot code from the internal boot ROM.

The boot code performs the hardware initialization, loads the program image from the chosen boot device, performs the image validation using the HAB library (see [Boot security settings](#)), and then jumps to an address derived from the program image. If an error occurs during the internal boot, the boot code jumps to the Serial Downloader (see [Serial Downloader \(BOOT\\_MODE\[1:0\] = 01b\)](#)). A secure boot using the HAB is possible in all the three boot modes.

When set to the Internal Boot, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using the General Purpose I/O (GPIO) pins. The GPIO Boot Select FUSE (BT\_FUSE\_SEL) determines whether the ROM uses the GPIO pins for a selected number of configuration parameters or eFUSES in this mode.

- If BT\_FUSE\_SEL = 1, all boot options are controlled by the eFUSES described in [Boot eFUSE descriptions](#).
- If BT\_FUSE\_SEL = 0, the specific boot configuration parameters may be set using the GPIO pins rather than eFUSES. The fuses that can be overridden when in this mode are indicated in the GPIO column of [Boot eFUSE descriptions](#). [GPIO boot overrides](#) provides the details of the GPIO pins.

The use of the GPIO overrides is intended for development since these pads are used for other purposes in the deployed products. NXP recommends controlling the boot configuration by the eFUSES in the deployed products and reserving the use of the GPIO mode for the development and testing purposes only.

### 9.3.6 Boot security settings

The internal boot modes use one of three security configurations.

- Closed: This level is intended for use with shipping-secure products. All HAB functions are executed and the security hardware is initialized (the Security Controller or SNVS enters the Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, and the boot flow is aborted with the control being passed to the serial downloader. At this level, the execution does not leave the internal ROM unless the target executable image is authenticated.
- Open: This level is intended for use in non-secure products or during the development phases of a secure product. All HAB functions are executed as for a closed device. The security hardware is initialized (except for the SNVS which is left in the Non-Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, but have no influence on the boot flow which continues as if the errors did not occur. This configuration is useful for a secure product development because the program image runs even if the authentication data is missing or incorrect, and the error log can be examined to determine the cause of the authentication failure.
- Field Return: This level is intended for the parts returned from the shipped products.

## 9.4 Device configuration

This section describes the external inputs that control the behavior of the Boot ROM code.

This includes the boot device selection (FlexSPI NOR, FlexSPI NAND, Parallel NOR, SD, MMC, and so on), boot device configuration (SD bus width, speed, and so on), and other. In general, the source for this configuration comes from the eFUSES embedded inside the chip. However, certain configuration parameters can be sourced from the GPIO pins, allowing further flexibility during the development process.

### 9.4.1 Boot eFUSE descriptions

This table is a comprehensive list of the configuration parameters that the ROM uses.

**Table 9-3. Boot eFUSE descriptions**

| Fuse            | Configuration | Definition                                                                                                                                                                                                                                                                                                                                                                             | GPIO <sup>1</sup> | Shipped value | Settings <sup>2</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BT_FUSE_SEL     | OEM           | In the Internal Boot mode BOOT_MODE[1:0] = 10, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by the GPIO pins or the eFUSE settings in the On-Chip OTP Controller (OCOTP).<br><br>In the Boot From Fuse mode BOOT_MODE[1:0] = 00, the BT_FUSE_SEL fuse indicates whether the bit configuration eFuses are programmed. | NA                | 0             | If BOOT_MODE[1:0] = 0b10: <ul style="list-style-type: none"> <li>• 0—The bits of the SBMR are overridden by the GPIO pins.</li> <li>• 1—The specific bits of the SBMR are controlled by the eFUSE settings.</li> </ul> If BOOT_MODE[1:0] = 0b00 <ul style="list-style-type: none"> <li>• 0—The BOOT configuration eFuses are not programmed yet. | WDOG_ENABLE    | OEM                   | Watchdog reset counter enable                      | No                | 0                | 0—The watchdog reset counter is disabled during the serial downloader.<br>1—The watchdog reset counter is enabled during the serial downloader.                                                 |
| PAD_SETTINGS   | OEM                   | Override values for the SD/MMC and NAND boot modes | No                | 0                | Override these IO PAD settings: <ul style="list-style-type: none"> <li>PAD_SETTINGS[0]—Slew Rate</li> <li>PAD_SETTINGS[3:1]—Drive Strength</li> <li>PAD_SETTINGS[5:4]—Speed Settings</li> </ul> |

1. This setting can be overridden by the GPIO settings when the BT\_FUSE\_SEL fuse is intact. See [GPIO Boot Overrides](#) for the corresponding GPIO pin.
2. 0 = intact fuse and 1= blown fuse

## 9.4.2 GPIO boot overrides

This table provides a list of the GPIO boot overrides:

**Table 9-4. GPIO Boot Overrides**

| Package Pin              | Direction on reset | eFuse               |
|--------------------------|--------------------|---------------------|
| GPIO_AD_B0_04/BOOT_MODE0 | Input              | Boot Mode selection |
| GPIO_AD_B0_05/BOOT_MODE1 | Input              |                     |
| GPIO_B0_04               | Input              | BOOT_CFG1[0]        |
| GPIO_B0_05               | Input              | BOOT_CFG1[1]        |
| GPIO_B0_06               | Input              | BOOT_CFG1[2]        |

*Table continues on the next page...*

**Table 9-4. GPIO Boot Overrides (continued)**

| Package Pin | Direction on reset | eFuse        |
|-------------|--------------------|--------------|
| GPIO_B0_07  | Input              | BOOT_CFG1[3] |
| GPIO_B0_08  | Input              | BOOT_CFG1[4] |
| GPIO_B0_09  | Input              | BOOT_CFG1[5] |
| GPIO_B0_10  | Input              | BOOT_CFG1[6] |
| GPIO_B0_11  | Input              | BOOT_CFG1[7] |
| GPIO_B0_12  | Input              | BOOT_CFG2[0] |
| GPIO_B0_13  | Input              | BOOT_CFG2[1] |
| GPIO_B0_14  | Input              | BOOT_CFG2[2] |
| GPIO_B0_15  | Input              | BOOT_CFG2[3] |

**NOTE**

Refer to the Fusemap chapter for more information on fuses mapped to the GPIO pins.

The input pins provided are sampled at boot, and can be used to override the corresponding eFUSE values, depending on the setting of the BT\_FUSE\_SEL fuse.

### 9.4.3 Device Configuration Data (DCD)

The DCD is the configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various on-chip peripherals. See [Device Configuration Data \(DCD\)](#) for more details on DCD.

## 9.5 Device initialization

This section describes the details of the ROM and provides the initialization details.

This includes details on:

- The ROM memory map
- The RAM memory map
- On-chip blocks that the ROM must use or change the POR register default values
- Clock initialization
- Enabling the L1 I/D cache
- Exception handling and interrupt handling

### 9.5.1 Internal ROM/RAM memory map

These figures show the internal ROM and RAM memory map:

Figure 9-2. Internal ROM and RAM memory map

**NOTE**

The entire OCRAM region can be used freely after the boot.

### 9.5.2 Boot block activation

The boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow.

The ROM configures and uses the following blocks (listed in an alphabetical order) during the boot process. Note that the blocks actually used depend on the boot mode and the boot device selection:

| Block   | Description                                                                           |
|---------|---------------------------------------------------------------------------------------|
| CCM     | Clock Control Module                                                                  |
| FlexSPI | Flexible SPI Interface which supports serial NOR, Serial NAND and serial RAM devices  |
| OCOTP   | On Chip One Time Programmable Controller containing the eFUSEs                        |
| IOMUXC  | I/O Multiplexer Control which allows the GPIO use to override the eFUSE boot settings |

Table continues on the next page...

| Block     | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| IOMUX GPR | I/O Multiplexer control General Purpose Registers                                      |
| LPSPi     | Low Power SPI interface which supports serial NOR/EEPROM devices                       |
| SEMC      | Smart External Memory Controller which supports parallel NOR and RAWNAND (SLC) devices |
| SNVS      | Secure Non-Volatile Storage                                                            |
| SRC       | System Reset Controller                                                                |
| USB       | Used for Serial download of a boot device provisioning program                         |
| uSDHC     | Ultra-Secure Digital Host Controller                                                   |
| WDOG 1    | WatchDog Timer                                                                         |
| TRNG      | True Random Number Generator                                                           |
| PIT       | Periodic Interrupt Timer                                                               |

### 9.5.3 Clocks at boot time

The table below shows the various clocks and their sources used by the ROM.

**Table 9-5. Normal Frequency Clock Configurations**

| BOOT_FREQ(0x460[2]) | LPB_BOOT(0x470[22:21]) | Core Clock Frequency(MHz) |
|---------------------|------------------------|---------------------------|
| 0                   | 0                      | 396                       |
|                     | 1                      | 198                       |
|                     | 2                      | 99                        |
|                     | 3                      | 49.5                      |
| 1                   | 0                      | 528                       |
|                     | 1                      | 264                       |
|                     | 2                      | 132                       |
|                     | 3                      | 66                        |

Following reset, the Arm core has access to all peripherals. The ROM code will disable the clocks associated with the following Clock Gate Enables. See the [CCM Chapter's System Clocks section](#) for information about the CCM output clocks' system-level connectivity.

**Table 9-6. List of Disabled Clock Gate Enables**

## 9.5.4 Enabling Caches

The boot ROM includes a feature that enables the caches to improve the boot speed.

L1 instruction cache is enabled at the start of image download. And, the L1 data cache is enabled at the start of image authentication.

By default, the L1-ICache and DCache are enabled by ROM. However, there are fuse bits that can be programmed for ROM not to enable the L1 I/DCache at boot.

The Cache features are controlled by the BT\_ICACHE\_DISABLE fuse and BT\_DCACHE\_DISABLE fuses. By default, both fuses are not blown meaning the ROM uses the L1-ICache and L1-DCache of the Arm core. This improves the performance of the HAB signature verification software.

## 9.5.5 Exception handling

The exception vectors (interrupt vectors/vector table) are located at the start of ROM. During the boot phase, CPU loads the SP and PC from exception vectors and then boot to ROM.

After booting, the program image can relocate the vectors as required.

## 9.5.6 Interrupt handling during boot

No special interrupt-handling routines are required during the boot process. The interrupts are disabled during the boot ROM execution and may be enabled in a later boot stage.

## 9.5.7 Persistent bits

Some modes of the boot ROM require the registers that keep their values after a warm reset. The SRC General-Purpose registers are used for this purpose.

See this table for persistent bits list and description:

**Table 9-7. Persistent bits**

| Bit name                | Bit location     | Description                                                                                                 |
|-------------------------|------------------|-------------------------------------------------------------------------------------------------------------|
| PERSIST_SECONDARY_BOOT  | SRC_GPR10[30]    | This bit identifies which image must be used—primary and secondary. Used only for eMMC/SD/FlexSPI NOR boot. |
| PERSISTENT_ENTRY0[31:0] | SRC_GPR1[31:0]   | Holds the entry function for the CPU0 to wake up from the low-power mode.                                   |
| PERSISTENT_ARG0[31:0]   | SRC_GPR2[31:0]   | Holds the argument of entry function for the CPU0 to wake up from the low-power mode.                       |
| PERSIST_REDUNDANT_BOOT  | SRC_GPR10[27:26] | This field identifies which image must be used - 0/1/2/3. Used for both SPI NAND and SLC raw NAND devices.  |

## 9.6 Boot devices

The chip supports the following boot flash devices:

- Serial NOR flash via FlexSPI Interface
- Serial NAND Flash via FlexSPI Interface
- Parallel NOR flash with the Smart External Memory Controller (SEMC), located on CS0, 16-bit bus width.
- NAND Flash with SEMC interface, located on CS0, 8-bit/16-bit bus width.
- SD/MMC/eSD/SDXC/eMMC4.4 via uSDHC interface, supporting high capacity cards
- Serial NOR/EEPROM boot via LPSPI

The selection of the external boot device type is controlled by the BOOT\_CFG1[7:4] eFUSEs. See this table for more details:

**Table 9-8. Boot device selection**

| BOOT_CFG1[7:4] | Boot device                  |
|----------------|------------------------------|
| 0000b          | Serial NOR boot via FlexSPI  |
| 01xxb          | SD Boot via uSDHC            |
| 10xxb          | eMMC/MMC boot via uSDHC      |
| 001xb          | SLC NAND boot via SEMC       |
| 0001b          | Parallel NOR boot via SEMC   |
| 11xxb          | Serial NAND boot via FlexSPI |

## NOTE

A user can use the LPSPI to boot from Serial NOR/EEPROM. Booting from Serial NOR/EEPROM via an LPSPI port is not intended as the primary device, but as a recovery boot device if the primary boot device fails.

In order to enable a recovery boot device, EEPROM\_RECOVERY\_EN fuse must be set to 1, and other fuses listed in [Serial NOR/EEPROM eFUSE configuration](#) must be properly set.

## 9.6.1 Serial NOR Flash Boot via FlexSPI

### 9.6.1.1 Serial NOR eFUSE Configuration

**Table 9-9. Fuse definition for Serial NOR over FlexSPI**

### 9.6.1.2 FlexSPI Serial NOR Flash Boot Operation

The Boot ROM attempts to boot from Serial NOR flash if the BOOT\_CFG1 [7:4] fuses are programmed to 0b'0000 as shown in the Serial NOR eFUSE Configuration table, then the ROM will initialize FlexSPI interface. FlexSPI interface initialization is a two-step process.

1. The ROM expects the 512-byte FlexSPI NOR configuration parameters (as explained in the next section) to be present at offset 0x400 in Serial NOR flash attached to FLEXSPI\_A\_SS0\_B. The ROM reads these configuration parameters using the read command specified by BOOT\_CFG2[2:0] with serial clock operating at 30 MHz.
2. ROM configures FlexSPI interface with the parameters provided in configuration block read from Serial NOR flash and starts the boot procedure. Refer to [Table 9-17](#) for details regarding FlexSPI configuration parameters and to the FlexSPI NOR boot flow chart for detailed boot flow chart of FlexSPI NOR.

Both booting an XIP and non XIP image are supported from Serial NOR Flash. For XIP boot, the image has to be built for FlexSPI address space; and for non XIP, the image can be built to execute from internal RAM.

**NOTE**

A non-XIP image's execute address space should NOT be overlapped with the reserved OCRAM region described in the section "Internal ROM/RAM memory map". And it is also highly recommended to avoid using address space near 0x00000000, typically up to 0x00000003.

**9.6.1.3 FlexSPI NOR boot flow chart****Figure 9-3. FlexSPI NOR boot flow**

## 9.6.2 Serial NAND Flash Boot over FlexSPI

The boot ROM supports a number of Serial NAND Flash devices from different vendors. The Embedded Error Correction and Control (ECC) module in SPI NAND devices are used to detect and correct the errors.

### 9.6.2.1 Serial NAND eFUSE Configuration

The boot ROM determines the configuration of external Serial NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins during boot. See below table for parameters details.

**Table 9-10. Fuse definition for Serial NAND over FlexSPI**

| Fuse           | Config | Definitions                                                       | GPIO | Shipped Value | Settings                                                                           |
|----------------|--------|-------------------------------------------------------------------|------|---------------|------------------------------------------------------------------------------------|
| BOOT_CFG1[1:0] | OEM    | Search Stride for FCB and DBBT<br>Search strides in terms of page | Yes  | 0             | 0 - 64<br>1 - 128<br>2 - 256<br>3 - 32                                             |
| BOOT_CFG1[3:2] | OEM    | Hold Time before access to Serial NAND                            | Yes  | 0             | 0 - Hold time determined by Read Status command<br>1 - 500us<br>2 - 1ms<br>3 - 3ms |

| 0x6E0[13:8]  | OEM    | SPI NAND Boot - Page Read Time (in terms of micro seconds) | No   | 0             |                                                                                                 |
| 0x6E0[23:16] | OEM    | Page Read Command                                          | No   | 0             | Available only if it is not 0                                                                   |
| 0x6F0[31:24] | OEM    | Cache Read command                                         | No   | 0             | Available only if it is not 0                                                                   |

**NOTE**

BOOT\_CFGx sampled on GPIO pins depends on BT\_FUSE\_SEL setting.

### 9.6.2.2 FlexSPI NAND Flash Boot Flow and Boot Control Blocks (BCB)

There are two BCB data structures:

- FCB
- DBBT

As part of the NAND media initialization, the ROM driver uses safe NAND timings to search for a Firmware Configuration Block (FCB) that contains the optimum NAND timings, page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The built-in HW ECC in Serial NAND device is used during data read, the FCB data structure is protected using CRC checksum. Driver reads raw 2048 bytes of first sector and runs through CRC check that determines whether FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters into serial download mode.

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. DBBT is searched in DBBT Search Area just like how FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

Figure 9-4 shows the state diagram of FCB search.

**Figure 9-4. FCB Search Flow**

After FCB is found, the boot ROM searches for the Discovered Bad Blocks Table (DBBT). If DBBTSearchStartPage is 0 in the FCB, then ROM assumes that there are no bad blocks in the NAND device boot area. See Figure 9-5 for the DBBT search flow.

**Figure 9-5. DBBT Search Flow**

The BCB search and load function also monitors the ECC correction threshold and sets the `PERSIST_BLOCK_REWRITE` persistent bit if the threshold exceeds the maximum ECC correction ability.

If during primary image read there is a page with a number of errors higher than ECC can correct, the boot ROM will turn on `PERSIST_SECONDARY_BOOT` bit and perform SW reset (After SW reset, secondary image is used).

If during secondary image read there is a page with number of errors higher than ECC can correct, the boot ROM goes to serial loader.

### 9.6.2.3 Firmware Configuration Block

The FCB is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Serial NAND block. The search area should span over at least two Serial NAND blocks. The location information for DBBT search area and images are all specified in the FCB. The following table shows the Flash Control Block Structure.

**Table 9-11. Flash Control Block Structure**

| Name                | Offset | Size Bytes                  | Description                                                                                                                                                                                                                                                              |       |      |             |           |   |                             |           |   |                        |

**NOTE**

1. The “crcChecksum” is calculated with an MPEG2 variant of CRC-32. See [Table 9-12](#) for more details.
2. The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
3. The “spiNandConfigBlock” is FlexSPI NAND configuration block which consists of common FlexSPI memory configuration block and Serial NAND specified configuration parameters.

**Table 9-12. CRC-32 variant algorithm**

| Property    | Description |
|-------------|-------------|
| Width       | 32 bits     |
| Polynomial  | 0x04C11DB7  |
| Init Value  | 0xFFFFFFFF  |
| Reflect in  | False       |
| Reflect Out | False       |
| XOR Out     | 0x00000000  |

| Reserved          | 0x014  | 12              | Must be filled with 0x00s                                                                                                                                                                                                                                                                                                                                                   |
| Bad Block entries | 0x020  | 1024<br>(256*4) | Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs. |

**NOTE**

1. Maximum badBlockNumber is 256.
2. The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

**9.6.2.5 Bad block handling in ROM**

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

**9.6.3 Serial NOR and NAND configuration based on FlexSPI interface**

The ROM SW supports Serial NOR and Serial NAND based on FlexSPI module, using a 448-bytes common FlexSPI configuration block and several specified parameters for Serial NOR and Serial NAND respectively. See the following sections for more details.

### 9.6.3.1 FlexSPI Configuration Block

FlexSPI Configuration block consists of parameters regarding specific Flash devices including read command sequence, quad mode enablement sequence (optional), etc.

**Table 9-14. FlexSPI Configuration block**

| lutCustomSeq           | 0x180  | 48          | Customized LUT sequence, see below table for details.                                                                                                                                                                                                                                                                  |
|                        | 0x1B0  | 16          | Reserved for future use                                                                                                                                                                                                                                                                                                |

**Note:**

1. To customize the LUT sequence for some specific device, users need to enable “lutCustomSeqEnable” and fill in corresponding “lutCustomSeq” field specified by command index below.
2. For Serial (SPI) NOR, the pre-defined LUT index is as follows:

**Table 9-15. LUT sequence definition for Serial NOR**

| Command Index | Name        | Index in lookup table | Description                   |
|---------------|-------------|-----------------------|-------------------------------|
| 0             | Read        | 0                     | Read command Sequence         |
| 1             | ReadStatus  | 1                     | Read Status command           |
| 2             | WriteEnable | 3                     | Write Enable command sequence |

**Table 9-15. LUT sequence definition for Serial NOR  
(continued)**

| Command Index | Name                              | Index in lookup table | Description                                                                |
|---------------|-----------------------------------|-----------------------|----------------------------------------------------------------------------|
| 3             | EraseSector                       | 5                     | Erase Sector Command                                                       |
| 4             | PageProgram                       | 9                     | Page Program Command                                                       |
| 5             | ChipErase                         | 11                    | Full Chip Erase                                                            |
| 6             | Dummy                             | 15                    | Dummy Command as needed                                                    |
| 7-12          | Reserved                          | 2,4,6,7,8,10,12,13,14 | All reserved indexes can be freely used for other purpose                  |
| 13            | NOR_CMD_LUT_SEQ_IDX_READ_SFDP     | 13                    | Read SFDP sequence in lookupTable id stored in config block                |
| 14            | NOR_CMD_LUT_SEQ_IDX_RESTORE_NOCMD | 14                    | Restore 0-4-4/0-8-8 mode sequence id in lookupTable stored in config block |

3. For Serial (SPI) NAND, the pre-defined LUT index is as follows:

**Table 9-16. LUT sequence definition for Serial NAND**

| Command Index | Name             | Index in lookup table | Description                                                |
|---------------|------------------|-----------------------|------------------------------------------------------------|
| 0             | ReadFromCache    | 0                     | Read from cache                                            |
| 1             | ReadStatus       | 1                     | Read Status                                                |
| 2             | WriteEnable      | 3                     | Write Enable                                               |
| 3             | BlockErase       | 5                     | Erase block                                                |
| 4             | ProgramLoad      | 9                     | Program Load                                               |
| 5             | ReadPage         | 11                    | Read page to cache                                         |
| 6             | ReadEccStatus    | 13                    | Read ECC Status                                            |
| 7             | ProgramExecute   | 14                    | Program Execute                                            |
| 8             | ReadFromCacheOdd | 4                     | Read from Cache while page in odd plane                    |
| 9             | ProgramLoadOdd   | 10                    | Program Load for pages within odd blocks                   |
|               | Reserved         | 2,6,7,8,12,15         | All reserved indexes can be freely used for other purposes |

**NOTE**

1. All the pre-defined LUT indexes are only applicable to boot stage. User application can use the whole 16 LUT entries freely based on their requirement.
2. The FlexSPI NOR ROM APIs occupy LUT index 0-5. User application should **NOT** use these LUT indexes if the ROM API is called in their application frequently.

**9.6.3.2 Serial NOR configuration block (512 bytes)****Table 9-17. Serial NOR configuration block**

| Name               | Offset | Size (Bytes) | Description                                                                                                                                                                                                       |
|--------------------|--------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 9.6.4 Parallel NOR flash Boot over SEMC

The Smart External Memory Controller (SEMC) works in an asynchronous mode, and supports Muxed Address/Data scheme.

### 9.6.4.1 Parallel NOR eFUSE Configuration

The boot ROM determines the configuration of external Parallel NOR flash by parameters, either provided by eFUSE, or sampled on GPIO pins during boot. See below table for parameters details.

**Table 9-19. Fuse definition for Parallel NOR over SEMC**

| Fuse           | Config | Definitions                       | GPIO | Shipped Value | Settings                                                                   |

#### 9.6.4.2 SEMC Parallel NOR Flash Boot Operation

The Boot ROM attempts to boot from Parallel NOR flash if the BOOT\_CFG [7:4] fuses are programmed to 0b'0000 as shown in the Parallel NOR eFUSE Configuration table. ROM supports booting from both XIP and non-XIP images from Parallel NOR Flash. For XIP boot, the image has to be built for SEMC address space and for non XIP the image can be built to execute from Internal RAM.

#### 9.6.5 Parallel NAND flash Boot over SEMC

The boot ROM supports a number of Parallel SLC NAND flash devices from different vendors. Both the Error Correction and Control (ECC) module in NAND device and software ECC algorithm (SECDED) in boot ROM can be used to detect the errors, based on the fuse settings.

### 9.6.5.1 Parallel NAND eFUSE Configuration

The boot ROM determines the configuration of external Parallel NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins, during boot. See below table for parameters details:

**Table 9-20. Fuse definition for Parallel NAND over SEMC**

| Fuse           | Config | Definitions                                      | GPIO | Shipped Value | Settings                                                                                                                                                                                                     |
|----------------|--------|--------------------------------------------------|------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 9.6.5.2 Parallel NAND Flash Boot Control Blocks (BCB)

There are two BCB data structures:

- Firmware Configuration Block (FCB)
- Discovered Bad Blocks Table (DBBT)

As part of the Parallel NAND media initialization, the ROM driver uses proper Parallel NAND parameters specified by FUSE to search for an FCB that contains the complete Parallel NAND parameters, page address of DBBT Search Area and Image info, including image copies, start page address and image size in terms of pages for each image.

FCB data structure is protected using Embedded ECC module in Parallel NAND devices or software ECC in ROM. The ROM driver reads 2048 bytes of first sector and checks the ECC check status to determine whether FCB data is valid or not.

If the FCB is found, the complete NAND parameters (Parallel NAND configuration block) are loaded for further reads, if the ECC fails, or the fingerprint does not match, or the CRC checksum does not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next FCB until Search Count pages have been read.

If search fails to find a valid FCB, the Parallel NAND driver responds with an error and the boot ROM enters into Recovery boot mode (Secondary boot, if it is enabled, or Serial download mode).

The FCB contains the page address of DBBT Search Area, and the info for images. DBBT is searched in DBBT Search area just like how FCB is searched. After the FCB is read, the DBBT is loaded, then the boot image is loaded using starting page address from FCB.

### 9.6.5.3 Firmware Configuration Block (FCB)

The FCB is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Parallel NAND block. The search area should span over at least two Parallel NAND blocks. The location information for DBBT search area and images are all specified in the FCB. Below Table shows the FCB Structure.

| Name                    | offset | Size (Bytes) | Description                                        |
|-------------------------|--------|--------------|----------------------------------------------------|
| bcbHeader               | 0x000  | 12           | See <a href="#">Table 9-21</a> for details         |
| DBBTSearchAreaStartPage | 0x00c  | 4            | Start Page address for bad block table search area |

*Table continues on the next page...*

|                |       |     |                                                                        |
|----------------|-------|-----|------------------------------------------------------------------------|
| searchStride   | 0x010 | 2   | Search stride for DBBT and FCB search. Not used by ROM Max value is 8. |
| searchCount    | 0x012 | 2   | Copies of DBBT and FCB. Not used by ROM, max value is 8.               |
| firmwareCopies | 0x014 | 4   | Firmware copies<br>Valid range 1-4.                                    |
| -              | 0x018 | 40  | Reserved                                                               |
| firmwareTable  | 0x040 | 64  | For details see <a href="#">Table 9-22</a>                             |
| -              | 0x080 | 128 | Reserved                                                               |
| nandConfig     | 0x100 | 256 | Parallel NAND configuration block over SEMC                            |
| -              | 0x200 | 512 | Reserved                                                               |

**Table 9-21. Header Description**

| Field       | Size | Description                  |
|-------------|------|------------------------------|
| crcChecksum | 4    | Checksum                     |
| fingerprint | 4    | 0x4E46_4342<br>ASCII: "NFCB" |
| version     | 4    | 0x0000_0001                  |

**Table 9-22. Table Descriptions**

| Field           | Size | Description                 |
|-----------------|------|-----------------------------|
| startPage       | 4    | Start page of this firmware |
| pagesInFirmware | 4    | Pages in this firmware      |

**NOTE**

- The “crcChecksum” is calculated with an MPEG2 variant of CRC-32.
- The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
- The “nandConfig” is SEMC NAND configuration block which consists of common SEMC memory configuration block and Parallel NAND specified configuration parameters. See [Parallel NAND eFUSE Configuration](#) for more details.

## 9.6.5.4 Discovered Bad Blocks Table (DBBT)

| -              | 0x014  | 12              | Reserved                                                                                                                                                                                                                                                                                                                                                                    |
| badBlockTable  | 0x020  | 1024<br>(256*4) | Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs. |

**Table 9-24. Header Description**

| Field       | Size | Description                  |
|-------------|------|------------------------------|
| crcChecksum | 4    | Checksum                     |
| fingerprint | 4    | 0x4442_4254<br>ASCII: "DBBT" |
| version     | 4    | 0x0000_0001                  |

### NOTE

- Maximum bad block number is 256.
- The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

## 9.6.5.5 Bad block handling in ROM

During firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block is checked.

## 9.6.6 Parallel NOR and NAND configuration based on SEMC interface

The ROM SW supports Parallel NOR and Parallel NAND based on SEMC module, using an 80-bytes common SEMC configuration block and several specified parameters for Parallel NOR and Parallel NAND respectively. See below sections for more details.

### 9.6.6.1 SEMC Configuration Block

SEMC Configuration block consists of all parameters related to specific Flash devices.

**Table 9-25. SEMC control block structure**

## 9.6.7 Expansion device

The ROM supports booting from the MMC/eMMC and SD/eSD compliant devices.

### 9.6.7.1 Expansion device eFUSE configuration

The SD/MMC/eSD/eMMC/SDXC boot can be performed using the USDHC ports. The port can be configured based on either the setting of the BOOT\_CFG1[1] (Port Select) fuse or its corresponding GPIO overrides.

All USDHC ports support the fast boot. See this table for details:

**Table 9-30. USDHC eFuse Descriptions**

| 0X6D0[5:0]   | OEM | PAD_SETTINGS                     | Yes | 000000  | Override number                                |

The boot code supports these standards:

- MMCv4.4 or less
- eMMCv4.4 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST\_BOOT
- SDXCv3.0

The MMC/SD/eSD/SDXC/eMMC can be connected to any of the USDHC blocks and can be booted by copying 4 KB of data from the MMC/SD/eSD/eMMC device to the internal RAM. After checking the Image Vector Table header value (0xD1) from program image, the ROM code performs a DCD check. After a successful DCD extraction, the ROM code extracts from the Boot Data Structure the destination pointer and length of image to be copied to the RAM device from where the code execution occurs.

The maximum image size to load into the SD/MMC boot is 32 MB. This is due to a limited number of uSDHC ADMA Buffer Descriptors allocated by the ROM.

### NOTE

The initial 4 KB of the program image must contain the IVT, DCD, and the Boot Data structures.

**Table 9-31. SD/MMC frequencies**

|                         | SD     | MMC | MMC (DDR mode) |
|-------------------------|--------|-----|----------------|
| Identification (KHz)    | 347.22 |     |                |
| Normal-speed mode (MHz) | 25     | 20  | 25             |
| High-speed mode (MHz)   | 50     | 40  | 50             |
| UHSI SDR50 (MHz)        | 100    |     |                |
| UHSI SDR104 (MHz)       | 200    |     |                |

**NOTE**

The boot ROM code reads the application image length and the application destination pointer from the image.

**9.6.7.2 MMC and eMMC boot**

This table provides the MMC and eMMC boot details.

**Table 9-32. MMC and eMMC boot details**

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal boot mode                                       | <p>During the initialization (normal boot mode), the MMC frequency is set to 347.22 KHz. When the MMC card enters the identification portion of the initialization, the voltage validation is performed, and the ROM boot code checks the high-voltage settings and the card capacity. The ROM boot code supports both the high-capacity and low-capacity MMC/eMMC cards. After the initialization phase is complete, the ROM boot code switches to a higher frequency (20 MHz in the normal boot mode or 40 MHz in the high-speed mode). The eMMC is also interfaced via the USDHC and follows the same flow as the MMC.</p> <p>The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in the BOOT_PARTITION_ENABLE field or the user partition was mentioned, the ROM boots from the user partition.</p> |
| eMMC4.3 or eMMC4.4 device supporting special boot mode | <p>If using an eMMC4.3 or eMMC4.4 device that supports the special boot mode, it can be initiated by pulling the CMD line low. If the BOOT ACK is enabled, the eMMC4.3/eMMC4.4 device sends the BOOT ACK via the DATA lines and the ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. The eMMC4.3/eMMC4.4 device with the "boot mode" feature can only be supported via the ESDHCV3-3 and with or without the BOOT ACK. If the BOOT ACK is enabled, the ROM waits 50 ms to get the BOOT ACK and if the BOOT ACK is received by the ROM. If BOOT ACK is disabled ROM waits 1 second for data. If the BOOT ACK or data was received, the eMMC4.3/eMMC4.4 is booted in the "boot mode", otherwise the eMMC4.3/eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by the BOOT_CFG1[4] (fast boot) fuse. The BOOT ACK is selected by the BOOT_CFG2[1].</p>                                                                           |
| eMMC4.4 device                                         | <p>If using the eMMC4.4 device, the Double Data Rate (DDR) mode can be used. This mode can be selected by the BOOT_CFG2[7:5] (bus width) fuse.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 9.6.7.3 SD, eSD, and SDXC

After the normal boot mode initialization begins, the SD/eSD/SDXC frequency is set to 347.22 kHz. During the identification phase, the SD/eSD/SDXC card voltage validation is performed. During the voltage validation, the boot code first checks with the high-voltage settings; if that fails, it checks with the low-voltage settings.

The capacity of the card is also checked. The boot code supports the high-capacity and low-capacity SD/eSD/SDXC cards after the voltage validation card initialization is done.

During the card initialization, the ROM boot code attempts to set the boot partition for all SD, eSD, and SDXC devices. If this fails, the boot code assumes that the card is a normal SD or SDXC card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, the boot code switches to a higher frequency (25 MHz in the normal-speed mode or 50 MHz in the high-speed mode). The ROM also supports the FAST\_BOOT mode booting from the eSD card. This mode can be selected by the BOOT\_CFG1[0] (Fast Boot).

For the UHSI cards, the clock speed fuses can be set to SDR50 or SDR104 on USDHC1, USDHC2 ports. This enables the voltage switch process to set the signaling voltage to 1.8 V during the voltage validation. The bus width is fixed at a 4-bit width and a sampling point tuning process is needed to calibrate the number of the delay cells. If the SD Loopback Clock eFuse is set, the feedback clock comes directly from the loopback SD clock, instead of the card clock (by default). The SD clock speed can be selected by the BOOT\_CFG1[5:4], and the SD Loopback Clock is selected by the BOOT\_CFG1[2].

The UHSI calibration start value (MMC\_DLL\_DLY[6:0]) and the step value SD\_CALIBRATION\_STEP[1:0] can be set to optimize the sample point tuning process.

If the SD Power Cycle Enable eFuse is 1, the ROM sets the SD\_RST pad low, waits for 5 ms, and then sets the SD\_RST pad high. If the SD\_RST pad is connected to the SD power supply enable logic on board, it enables the power cycle of the SD card. This may be crucial in case the SD logic is in the 1.8 V states and must be reset to the 3.3 V states.

The SDR50 and SDR104 boots are not supported on the USDHC1 and USDHC2 ports because there are no reset signals for those ports when connected in the IOMUX.

### 9.6.7.4 IOMUX configuration for SD/MMC

**Table 9-33. IOMUX configuration for SD/MMC**

| Signal  | USDHC1             | USDHC2             |
|---------|--------------------|--------------------|
| CLK     | GPIO_SD_B0_01.alt0 | GPIO_SD_B1_04.alt0 |
| CMD     | GPIO_SD_B0_00.alt0 | GPIO_SD_B1_05.alt0 |
| DATA0   | GPIO_SD_B0_02.alt0 | GPIO_SD_B1_03.alt0 |
| DATA1   | GPIO_SD_B0_03.alt0 | GPIO_SD_B1_02.alt0 |
| DATA2   | GPIO_SD_B0_04.alt0 | GPIO_SD_B1_01.alt0 |
| DATA3   | GPIO_SD_B0_05.alt0 | GPIO_SD_B1_00.alt0 |

### 9.6.7.5 Redundant boot support for expansion device

The ROM supports the redundant boot for an expansion device. The primary or secondary image is selected, depending on the PERSIST\_SECONDARY\_BOOT setting. (see [Table 9-7](#)).

If the PERSIST\_SECONDARY\_BOOT is 0, the boot ROM uses address 0x0 for the primary image.

If the PERSIST\_SECONDARY\_BOOT is 1, the boot ROM reads the secondary image table from address 0x200 on the boot media and uses the address specified in the table.

**Table 9-34. Secondary image table format**

|                        |
|------------------------|
| Reserved (chipNum)     |
| Reserved (driveType)   |
| tag                    |
| firstSectorNumber      |
| Reserved (sectorCount) |

Where:

- The tag is used as an indication of the valid secondary image table. It must be 0x00112233.
- The firstSectorNumber is the first 512-byte sector number of the secondary image.

For the secondary image support, the primary image must reserve the space for the secondary image table. See this figure for the typical structures layout on an expansion device.

**Figure 9-13. Expansion device structures layout**

For the Closed mode, if there are failures during primary image authentication, the boot ROM turns on the PERSIST\_SECONDARY\_BOOT bit (see [Table 9-7](#)) and performs the software reset. (After the software reset, the secondary image is used.)

## 9.6.8 Serial NOR/EEPROM through LPSPI

The chip supports booting from serial memory devices, such as EEPROM and serial flash, using the LPSPI.

These ports are available for serial boot: LPSPI interfaces.

### 9.6.8.1 Serial NOR/EEPROM eFUSE configuration

The boot ROM code determines the type of device using the following parameters, provided by the eFUSE settings, during boot.

**Table 9-35. Serial NOR/EEPROM boot eFUSE descriptions**

| Fuse                          | Config | Definition                | GPIO | Shipped value | Settings                                                                                                             |
|-------------------------------|--------|---------------------------|------|---------------|----------------------------------------------------------------------------------------------------------------------|
| EEPROM_RECOVERY_EN(0x6D0[24]) | OEM    | EEPROM recovery enable    | No   | 0             | 0 - Disabled<br>1 - Enabled                                                                                          |
| LPSPI_PORT_SEL(0x6D0[26:25])  | OEM    | Port select               | No   | 00            | 00 - LPSPI1<br>01 - LPSPI2<br>10 - LPSPI3 (if applicable in the device)<br>11 - LPSPI4 (if applicable in the device) |
| LPSPI_ADDR(0x6D0[27])         | OEM    | SPI addressing (SPI only) | No   | 0             | 0 - 3B (24-bit)<br>1 - 2B (16-bit)                                                                                   |
| LPSPI_SPEED(0x6D0[29:28])     | OEM    | LPSPI Speed select        | No   | 00            | 00 - 20 MHz<br>01 - 10 MHz<br>10 - 5 MHz<br>11 - 2 MHz                                                               |

The LPSPI<sub>n</sub> block can be used as a boot device using the LPSPI interface for the serial ROM boot. The SPI interface is configured to operate at speed specified by LPSPI\_SPED\_SEL fuse field.

The boot ROM copies 4 KB of data from the serial ROM device to the internal RAM. After checking the Image Vector Table header value (0xD1) from the program image, the ROM code performs a DCD check. After a successful DCD extraction, the ROM code extracts the destination pointer and length of image from the Boot Data Structure to be copied to the RAM device from where the code execution occurs.

**NOTE**

The Initial 4 KB of program image must contain the IVT, DCD, and the Boot Data Structures.

## 9.7 Program image

This section describes the data structures that are required to be included in the user's program image. The program image consists of:

- Image vector table—a list of pointers located at a fixed address that the ROM examines to determine where the other components of the program image are located.
- Boot data—a table that indicates the program image location, program image size in bytes, and the plugin flag.
- Device configuration data—IC configuration data.
- User code and data.

### 9.7.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot.

The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to the Chip. The IVT offset from the base address for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

**Table 9-36. Image Vector Table Offset and Initial Load Region Size**

| Boot Device Type                       | Image Vector Table Offset |
|----------------------------------------|---------------------------|
| FlexSPI NOR/SEMC NOR                   | 4 Kbyte = 0x1000 bytes    |
| SD/MMC/eSD/eMMC/SDXC                   | 1 Kbyte = 0x400 bytes     |
| SPI NOR/EEPROM/SEMC NAND/ FlexSPI NAND | 1 Kbyte = 0x400 bytes     |

Figure 9-14. Image Vector Table

### 9.7.1.1 Image vector table structure

The IVT has the following format where each entry is a 32-bit word:

Table 9-37. IVT format

|                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| header                                                                                                                                                                                                                                         |
| entry: Absolute address of the first instruction to execute from the image                                                                                                                                                                     |
| reserved1: Reserved and should be zero                                                                                                                                                                                                         |
| dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See <a href="#">Device Configuration Data (DCD)</a> for further details on the DCD.                                        |
| boot data: Absolute address of the boot data                                                                                                                                                                                                   |
| self: Absolute address of the IVT. Used internally by the ROM                                                                                                                                                                                  |
| csf: Absolute address of the Command Sequence File (CSF) used by the HAB library. See <a href="#">High-Assurance Boot (HAB)</a> for details on the secure boot using HAB. This field must be set to NULL if a CSF is not provided in the image |
| reserved2: Reserved and should be zero                                                                                                                                                                                                         |

**NOTE**

The DCD is not supported in the BootROM, in this device. It must be set to 0x00.

Figure 9-15 shows the IVT header format:

|     |        |         |
|-----|--------|---------|
| Tag | Length | Version |
|-----|--------|---------|

**Figure 9-15. IVT header format**

where:

Tag: A single byte field set to 0xD1

Length: a two byte field in big endian format containing the overall length of the IVT, in bytes, including the header. (the length is fixed and must have a value of 32 bytes)

Version: A single byte field set to 0x40 or 0x41

### 9.7.1.2 Boot data structure

The boot data must follow the format defined in the table found here, each entry is a 32-bit word.

**Table 9-38. Boot data format**

|        |                                                 |
|--------|-------------------------------------------------|
| start  | Absolute address of the image                   |
| length | Size of the program image                       |
| plugin | Plugin flag (see <a href="#">Plugin image</a> ) |

## 9.7.2 Device Configuration Data (DCD)

Upon reset, the chip uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving the optimal system performance and there are even some peripherals that must be configured before they can be used.

The DCD is a configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various peripherals on the chip.

For example, some components (such as SDRAM) require some sequence of register programming as a part of the configuration before it is ready to be used. The DCD feature can be used to program the SEMC register to the optimal settings.

The ROM determines the location of the DCD table based on the information located in the Image Vector Table (IVT). See [Image Vector Table and Boot Data](#) for more details. The DCD table shown below is a big-endian byte array of the allowable DCD commands. The maximum size of the DCD is limited to 1768 B.

|        |
|--------|
| Header |
| [CMD]  |
| [CMD]  |
| ...    |

Figure 9-16. DCD data format

The DCD header is 4 B with the following format:

|     |        |         |
|-----|--------|---------|
| Tag | Length | Version |
|-----|--------|---------|

Figure 9-17. DCD header format

where:

Tag: A single-byte field set to 0xD2  
Length: a two-byte field in the big-endian format containing the overall length of the DCD (in bytes) including the header  
Version: A single-byte field set to 0x41

9.7.2.1 Write data command

The write data command is used to write a list of given 1-, 2- or 4-byte values (or bitmasks) to a corresponding list of target addresses.

The Value/Mask fields are always 32-bits. If the parameter field specifies a smaller size, then the extra bytes must be zero.

The format of the write data command (in a big-endian byte array) is shown in this table:

**Table 9-39. Write data command format**

| Tag | Length       | Parameter |
|-----|--------------|-----------|
|     | Address      |           |
|     | Value/Mask   |           |
|     | [Address]    |           |
|     | [Value/Mask] |           |
|     | ...          |           |
|     | [Address]    |           |
|     | [Value/Mask] |           |

where:

Tag: a single-byte field set to 0xCC

Length: a two-byte field in a big-endian format, containing the length of the Write Data Command (in bytes) including the header

Address: the target address to which the data must be written

Value/Mask: the data value (or bitmask) to be written to the preceding address

The parameter field is a single byte divided into the bitfields, as follows:

**Table 9-40. Write data command parameter field**

| 7     | 6 | 5 | 4 | 3 | 2     | 1 | 0 |
|-------|---|---|---|---|-------|---|---|
| flags |   |   |   |   | bytes |   |   |

where

bytes: the width of the target locations in bytes (either 1, 2, or 4)

flags: control flags for the command behavior

Data Mask = bit 3: if set, only specific bits may be overwritten at the target address (otherwise all bits may be overwritten)

Data Set = bit 4: if set, the bits at the target address are overwritten with this flag (otherwise it is ignored)

One or more target address and value/bitmask pairs can be specified. The same bytes' and flags' parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

**Table 9-41. Interpretation of write data command flags**

| "Mask" | "Set" | Action               | Interpretation |
|--------|-------|----------------------|----------------|
| 0      | 0     | *address = val_msk   | Write value    |
| 0      | 1     | *address = val_msk   | Write value    |
| 1      | 0     | *address &= ~val_msk | Clear bitmask  |
| 1      | 1     | *address  = val_msk  | Set bitmask    |

**NOTE**

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values are larger or any of the bitmasks are wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within the allowed region, none of the values are written. The list of allowable blocks and target addresses for the chip are provided below.

**Table 9-42. Valid DCD address ranges**

| Address range                                     | Start address | Last address |
|---------------------------------------------------|---------------|--------------|
| IOMUX Control SNVS GPR(IOMUXC_SNVS_GPR) registers | 0x400A_4000   | 0x400A_7FFF  |
| IOMUX Control SNVS (IOMUXC_SNVS) registers        | 0x400A_8000   | 0x400A_BFFF  |
| IOMUX Control GPR(IOMUXC_GPR) registers           | 0x400A_C000   | 0x400A_FFFF  |
| CCM Analog (ANATOP) registers                     | 0x400D_8000   | 0x400D_BFFF  |
| CCM registers                                     | 0x400F_C000   | 0x400F_FFFF  |
| SEMC registers                                    | 0x402F_0000   | 0x402F_3FFF  |

**9.7.2.2 Check data command**

The check data command is used to test for a given 1-, 2-, or 4-byte bitmasks from a source address.

The check data command is a big-endian byte array with the format shown in this table:

**Table 9-43. Check data command format**

| Tag | Length  | Parameter |
|-----|---------|-----------|
|     | Address |           |
|     | Mask    |           |
|     | [Count] |           |

where:

Tag: a single-byte field set to 0xCF

Length: a two-byte field in the big-endian format containing the length of the check data command (in bytes) including the header

Address: the source address to test

Mask: the bit mask to test

Count: an optional poll count; If the count is not specified, this command polls indefinitely until the exit condition is met. If count = 0, this command behaves as for the NOP.

The parameter field is a single byte divided into bitfields, as follows:

**Table 9-44. Check data command parameter field**

|       |   |   |   |   |       |   |   |
|-------|---|---|---|---|-------|---|---|
| 7     | 6 | 5 | 4 | 3 | 2     | 1 | 0 |
| flags |   |   |   |   | bytes |   |   |

where

bytes: the width of target locations in bytes (either 1, 2, or 4)

flags: control flags for the command behavior

Data Mask = bit 3: if set, only the specific bits may be overwritten at a target address (otherwise all bits may be overwritten)

Data Set = bit 4: if set, the bits at the target address are overwritten with this flag (otherwise it is ignored)

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

**Table 9-45. Interpretation of check data command flags**

| "Mask" | "Set" | Action                       | Interpretation |
|--------|-------|------------------------------|----------------|
| 0      | 0     | $(*address \& mask) == 0$    | All bits clear |
| 0      | 1     | $(*address \& mask) == mask$ | All bits set   |
| 1      | 0     | $(*address \& mask) != mask$ | Any bit clear  |
| 1      | 1     | $(*address \& mask) != 0$    | Any bit set    |

## NOTE

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

### 9.7.2.3 NOP command

This command has no effect.

The format of the NOP command is a big-endian four-byte array, as shown in this table:

**Table 9-46. NOP command format**

|     |        |           |
|-----|--------|-----------|
| Tag | Length | Undefined |
|-----|--------|-----------|

where:

Tag: a single-byte field set to 0xC0

Length: a two-byte field in big endian containing the length of the NOP command in bytes (fixed to a value of 4)

Undefined: this byte is ignored and can be set to any value.

## 9.8 Plugin image

The ROM supports a limited number of boot devices. When using other devices as a boot source (for example, Ethernet or USB), the supported boot device must be used (typically serial flash) as a firmware to provide the missing boot drivers. Additionally, the plugin can be customized to support boot drivers, which is more flexible when performing the device initialization, such as condition judging, delay assertion, or to apply custom settings to the boot device and memory system.

In addition to the standard images, the chip also supports plugin images. The plugin images return the execution to the ROM whereas the standard image does not.

The boot ROM detects the image type using the plugin flag of the boot data structure (see [Boot data structure](#)). If the plugin flag is 1, then the ROM uses the image as a plugin function. The function must initialize the boot device and copy the program image to the final location. At the end, the plugin function must return with the program image parameters. (See [High-level boot sequence](#) for details about the boot flow).

The boot ROM authenticates the plugin image before running the plugin function and then authenticates the program image.

The plugin function must follow the API described below:

```
typedef BOOLEAN (*plugin_download_f)(void **start, size_t *bytes, UINT32 *ivt_offset);
```

### ARGUMENTS PASSED:

- start - the image load address on exit.
- bytes - the image size on exit.
- ivt\_offset - the offset (in bytes) of the IVT from the image start address on exit.

### RETURN VALUE:

- 1 - success
- 0 - failure

## 9.9 Serial Downloader

The Serial Downloader provides a means to download a program image to the chip over the USB and UART serial connection.

In this mode, the ROM programs the WDOG1 for a time-out specified by the fuse WDOG Time-out Select (See the Fusemap chapter for details) if the WDOG\_ENABLE eFuse is 1 and continuously polls for the USB and UART connection. If no activity is found on the USB OTG1 and UART and the watchdog timer expires, the Arm core is reset.

### NOTE

After the downloaded image is loaded, it is responsible for managing the watchdog resets properly.

This figure shows the USB and UART boot flow:

Figure 9-18. Serial Downloader boot flow

## 9.9.1 USB

The USB support is composed of the USB1 (USB OTG1 core controller, compliant with the USB 2.0 specification) and the USBPHY (HS USB transceiver).

The ROM supports the USB1 port for boot purposes. The other USB ports on the chip are not supported for boot purposes.

The USB Driver is implemented as a USB HID class. A collection of four HID reports are used to implement the SDP protocol for data transfers, as described in [Table 9-47](#).

**Table 9-47. USB HID reports**

| Report ID (first byte) | Transfer endpoint | Direction      | Length       | Description                                                                                                 |
|------------------------|-------------------|----------------|--------------|-------------------------------------------------------------------------------------------------------------|
| 1                      | control OUT       | Host to device | 17 B         | SDP command from the host to the device.                                                                    |
| 2                      | control OUT       | Host to device | Up to 1025 B | Data associated with the report 1 SDP command.                                                              |
| 3                      | interrupt         | Device to host | 5 B          | HAB security configuration. The device sends 0x12343412 in the closed mode and 0x56787856 in the open mode. |
| 4                      | interrupt         | Device to host | Up to 65 B   | Data in response to the SDP command in report 1.                                                            |

### 9.9.1.1 USB configuration details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for the USB device driver are listed in the following table.

**Table 9-48. VID/PID and strings for USB device driver**

| Descriptor                        | Value                     |
|-----------------------------------|---------------------------|
| VID                               | 0x1FC9<br>(NXP vendor ID) |
| PID <sup>1</sup>                  | 0x0130                    |
| String Descriptor1 (manufacturer) | NXP Semiconductors        |
| String Descriptor2 (product)      | S Blank                   |

*Table continues on the next page...*

**Table 9-48. VID/PID and strings for USB device driver (continued)**

| Descriptor         | Value     |
|--------------------|-----------|
| String Descriptor4 | NXP Flash |
| String Descriptor5 | NXP Flash |

1. Allocation based on the BPN (Before Part Number)

### 9.9.1.2 IOMUX configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX. The UTMI PHY interface uses the dedicated contacts on the IC. See the chip data sheet for details.

## 9.9.2 Serial Download Protocol (SDP)

The 16-byte SDP command from the host to device is sent using the HID report 1. This table describes the 16-byte SDP command data structure:

**Table 9-49. 16-byte SDP command data structure**

| BYTE offset | Size | Name         | Description                                                                                                                                                                                                                                                                                                                        |
|-------------|------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | 2    | COMMAND TYPE | These commands are supported for the ROM: <ul style="list-style-type: none"> <li>• 0x0101 READ_REGISTER</li> <li>• 0x0202 WRITE_REGISTER</li> <li>• 0x0404 WRITE_FILE</li> <li>• 0x0505 ERROR_STATUS</li> <li>• 0x0A0A DCD_WRITE</li> <li>• 0x0B0B JUMP_ADDRESS</li> </ul>                                                         |
| 2           | 4    | ADDRESS      | Only relevant for these commands:<br>READ_REGISTER, WRITE_REGISTER, WRITE_FILE, DCD_WRITE, and JUMP_ADDRESS.<br><br>For the READ_REGISTER and WRITE_REGISTER commands, this field is the address to a register. For the WRITE_FILE and JUMP_ADDRESS commands, this field is an address to the internal or external memory address. |
| 6           | 1    | FORMAT       | Format of access, 0x8 for an 8-bit access, 0x10 for a 16-bit access, and 0x20 for a 32-bit access. Only relevant for the READ_REGISTER and WRITE_REGISTER commands.                                                                                                                                                                |
| 7           | 4    | DATA COUNT   | Size of the data to read or write in bytes. Only relevant for the WRITE_FILE, READ_REGISTER, WRITE_REGISTER, and DCD_WRITE commands. For the WRITE_FILE and DCD_WRITE commands, the DATA COUNT is in the byte units.                                                                                                               |
| 11          | 4    | DATA         | The value to write. Only relevant for the WRITE_REGISTER command.                                                                                                                                                                                                                                                                  |
| 15          | 1    | RESERVED     | Reserved                                                                                                                                                                                                                                                                                                                           |

### 9.9.2.1 SDP commands

The SDP commands are described in the following sections.

#### 9.9.2.1.1 READ\_REGISTER

The transaction for the READ\_REGISTER command consists of these reports: Report1 for the command, Report3 for the security configuration, and Report4 for the response or the register value.

The register to read is specified in the ADDRESS field of the SDP command. The first device sends Report3 with the security configuration followed by the Report4 with the bytes read at a given address. If the count is greater than 64, multiple reports with the report id 4 are sent until the entire data requested by the host is sent. The STATUS is either 0x12343412 for the closed parts and 0x56787856 for the open or field return parts.

Report1, Command, Host to Device:

|   |                                                                         |
|---|-------------------------------------------------------------------------|
| 1 | Valid values for the READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT |
|---|-------------------------------------------------------------------------|

ID 16-byte SDP command

Report3, Response, Device to Host:

|   |                                                  |
|---|--------------------------------------------------|
| 3 | Four bytes indicating the security configuration |
|---|--------------------------------------------------|

ID 4 bytes status

Report4, Response, Device to Host: first response report

|   |                |
|---|----------------|
| 4 | Register value |
|---|----------------|

ID 4 bytes of data containing the register value. If the number of bytes requested is less than 4, the remaining bytes must be ignored by the host.

Multiple reports of the report id 4 are sent until the entire requested data is sent.

Report4, Response, Device to Host: last response report

|   |                |
|---|----------------|
| 4 | Register value |
|---|----------------|

ID 64 bytes of data containing the register value. If the number of bytes requested is less than 64, the remaining bytes must be ignored by the host.

9.9.2.1.2 WRITE\_REGISTER

The transaction for the WRITE\_REGISTER command consists of these reports: Report1 for the command, Report3 for the security configuration and Report4 for the write status.

The host sends Report1 with the WRITE\_REGISTER command. The register to write is specified in the ADDRESS field of the SDP command of Report1, with the FORMAT field set to the data type (number of bits to write, either 8, 16, or 32) and the value to write in the DATA field of the SDP command. The device writes the DATA to the register address and returns the WRITE\_COMPLETE code using Report4 and the security configuration using Report3 to complete the transaction.

Report1, Command, Host to Device:

|   |                                                                               |
|---|-------------------------------------------------------------------------------|
| 1 | Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT and DATA |
|---|-------------------------------------------------------------------------------|

ID 16-byte SDP command

Report3, Response, Device to Host:

|   |                                               |
|---|-----------------------------------------------|
| 3 | 4 bytes indicating the security configuration |
|---|-----------------------------------------------|

ID 4 bytes status

Report4, Response, Device to Host:

|   |                                    |
|---|------------------------------------|
| 4 | WRITE_COMPLETE (0x128A8A12) status |
|---|------------------------------------|

ID 64 bytes data with the first 4 bytes to indicate that the write is completed with code 0x128A8A12. On failure, the device reports the HAB error status.

9.9.2.1.3 WRITE\_FILE

The transaction for the WRITE\_FILE command consists of these reports: Report1 for the command phase, Report2 for the data phase, Report3 for the HAB mode, and Report4 to indicate that the data are received in full.

The size of each Report2 is limited to 1024 bytes (limitation of the USB HID protocol). Hence, multiple Report2 packets are sent by the host in the data phase until the entire data is transferred to the device. When the entire data (DATA\_COUNT bytes) is received, the device sends Report3 with the HAB mode and Report4 with 0x88888888, indicating that the file download completed.

Report1, Host to Device:

|   |                                                          |
|---|----------------------------------------------------------|
| 1 | Valid values for WRITE_FILE COMMAND, ADDRESS, DATA_COUNT |
|---|----------------------------------------------------------|

ID 16-byte SDP command

=====Optional Begin=====

Host sends the ERROR\_STATUS command to query if the HAB rejected the address

===== Optional End=====

Report2, Host to Device:

|   |           |
|---|-----------|
| 2 | File data |
|---|-----------|

ID Max 1024 bytes data per report

Report2, Host to Device:

|   |           |
|---|-----------|
| 2 | File data |
|---|-----------|

ID Max 1024 bytes data per report

Report3, Device to Host:

|   |                                           |
|---|-------------------------------------------|
| 3 | 4 bytes indicating security configuration |
|---|-------------------------------------------|

ID 4 bytes status

Report4, Response, Device to Host:

|   |                              |
|---|------------------------------|
| 4 | COMPLETE (0x88888888) status |
|---|------------------------------|

ID 64 bytes data with the first four bytes to indicate that the file download completed with code 0x88888888. On failure, the device reports the HAB error status.

9.9.2.1.4 ERROR\_STATUS

The transaction for the SDP command ERROR\_STATUS consists of three reports.

Report1 is used by the host to send the command; the device sends global error status in four bytes of Report4 after returning the security configuration in Report3. When the device receives the ERROR\_STATUS command, it returns the global error status that is updated for each command. This command is useful to find out whether the last command resulted in a device error or succeeded.

Report1, Command, Host to Device:

|   |                      |
|---|----------------------|
| 1 | ERROR_STATUS COMMAND |
|---|----------------------|

ID 16-byte SDP Command

Report3, Response, Device to Host:

|   |                                                  |
|---|--------------------------------------------------|
| 3 | Four bytes indicating the security configuration |
|---|--------------------------------------------------|

ID 4 bytes status

Report4, Response, Device to Host:

|   |                         |
|---|-------------------------|
| 4 | Four bytes Error status |
|---|-------------------------|

ID first 4 bytes status in 64 bytes Report4

9.9.2.1.5 DCD\_WRITE

The SDP command DCD\_WRITE is used by the host to send multiple register writes in one shot. This command is provided to speed up the process of programming the register writes (such as to configure an external RAM device).

The command goes with Report1 from the host with COMMAND TYPE set to DCD\_WRITE, ADDRESS which is used as a temporary location of the DCD data, and DATA\_COUNT to the number of bytes sent in the data out phase. In the data phase, the host sends the data for a number of registers using Report2. The device completes the transaction with Report3 indicating the security configuration and Report4 with the WRITE\_COMPLETE code 0x12828212.

Report1, Command, Host to Device:

|   |                                        |
|---|----------------------------------------|
| 1 | DCD_WRITE COMMAND, ADDRESS, DATA_COUNT |
|---|----------------------------------------|

ID 16-byte SDP Command

Report2, Data, Host to Device:

|   |                 |
|---|-----------------|
| 2 | DCD binary data |
|---|-----------------|

ID Max 1024 bytes per report

Report3, Response, Device to Host:

|   |                                                  |
|---|--------------------------------------------------|
| 3 | Four bytes indicating the security configuration |
|---|--------------------------------------------------|

ID 4 bytes status

Report4, Response, Device to Host:

|   |                                    |
|---|------------------------------------|
| 4 | WRITE_COMPLETE (0x128A8A12) status |
|---|------------------------------------|

ID 64 bytes report with the first four bytes to indicate that the write completed with the code 0x128A8A12. On failure, the device reports the HAB error status.

See [Device Configuration Data \(DCD\)](#) for the DCD format description.

### 9.9.2.1.6 JUMP\_ADDRESS

The SDP command JUMP\_ADDRESS is the last command that the host can send to the device. After this command, the device jumps to the address specified in the ADDRESS field of the SDP command and starts to execute.

This command usually follows after the WRITE\_FILE command. The command is sent by the host in the command-phase of the transaction using Report1. There is no data phase for this command, but the device sends the status Report3 to complete the transaction. If the authentication fails, it also sends Report4 with the HAB error status.

Report1, Command, Host to Device:

|   |                               |
|---|-------------------------------|
| 1 | JUMP_ADDRESS COMMAND, ADDRESS |
|---|-------------------------------|

ID 16-byte SDP Command

Report3, Response, Device to Host:

## Recovery devices

|   |                                                  |
|---|--------------------------------------------------|
| 3 | Four bytes indicating the security configuration |
|---|--------------------------------------------------|

ID 4 bytes status

This report is sent by the device only in case of an error jumping to the given address, or if the device reports error in Report4, Response, Device to Host:

|   |                             |
|---|-----------------------------|
| 4 | Four bytes HAB error status |
|---|-----------------------------|

ID 4 bytes status, 64 bytes report length

### 9.10 Recovery devices

The chip supports recovery devices. If the primary boot device fails, the boot ROM tries to boot from the recovery device using one of the LPSPI ports.

To enable the recovery device, the `EEPROM_RECOVERY_EN` fuse must be set. Additionally, the serial EEPROM fuses must be set as described in [Serial NOR/EEPROM through LPSPI](#).

### 9.11 SD/MMC manufacture mode

When the internal boot and recover boot (if enabled) failed, the boot goes to the SD/MMC manufacture mode before the serial download mode. In the manufacture mode, one bit bus width is used despite of the fuse setting.

Figure 9-19. SD/MMC manufacture boot flow

## 9.12 High-Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying the areas of code or data in the programmable memory to make it behave in an incorrect manner. The HAB also prevents the attempts to gain access to features which must not be available.

The integration of the HAB feature with the ROM code ensures that the chip does not enter an operational state if the existing hardware security blocks detected a condition that may be a security threat or if the areas of memory deemed to be important were modified. The HAB uses the RSA digital signatures to enforce these policies.

**Figure 9-20. Secure boot components**

The figure above illustrates the components used during a secure boot using HAB. The HAB interfaces with the SNVS to make sure that the system security state is as expected. The HAB also uses the hardware block to accelerate the SHA-256 message digest operations performed during the signature verifications. The HAB also includes a software implementation of SHA-256 for cases where a hardware accelerator cannot be used. The RSA key sizes supported are 1024, 2048, 3072 and 4096 bits. The RSA signature verification operations are performed by a software implementation contained in the HAB library. The main features supported by the HAB are:

- X.509 public key certificate support
- CMS signature format support

#### **NOTE**

NXP provides the reference Code Signing Tool (CST) for key generation and code signing for use with the HAB library. The CST can be found by searching for "IMX\_CST\_TOOL" at <http://www.nxp.com>.

#### **NOTE**

For further details on using the secure boot feature using HAB, contact your local NXP representative.

### **9.12.1 HAB API vector table addresses**

For devices that perform a secure boot, the HAB library may be called by the boot stages that execute after the ROM code.

The HAB API vector table for this device is at address 0x0020\_0300.

**NOTE**

For additional information on the secure boot including the HAB API, contact your local NXP representative.

# Chapter 10

## External Signals and Pin Multiplexing

### 10.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

#### 10.1.1 Muxing Options

**NOTE**

System STOP/WAIT status can be observed on pin. See [CCM\\_WAIT](#) and [CCM\\_STOP](#) in the table below.

**Table 10-1. Muxing Options**

| Instance | Port     | Pad           | Mode |
|----------|----------|---------------|------|
| ADC1     | ADC1_IN0 | GPIO_AD_B1_11 | -    |
|          | ADC1_IN1 | GPIO_AD_B0_12 | -    |
|          | ADC1_IN2 | GPIO_AD_B0_13 | -    |
|          | ADC1_IN3 | GPIO_AD_B0_14 | -    |
|          | ADC1_IN4 | GPIO_AD_B0_15 | -    |
|          | ADC1_IN5 | GPIO_AD_B1_00 | -    |
|          | ADC1_IN6 | GPIO_AD_B1_01 | -    |
|          | ADC1_IN7 | GPIO_AD_B1_02 | -    |
|          | ADC1_IN8 | GPIO_AD_B1_03 | -    |
|          | ADC1_IN9 | GPIO_AD_B1_04 | -    |

*Table continues on the next page...*

**Table 10-1. Muxing Options (continued)**

|       |           |               |   |
|-------|-----------|---------------|---|
|       | ADC1_IN10 | GPIO_AD_B1_05 | - |
|       | ADC1_IN11 | GPIO_AD_B1_06 | - |
|       | ADC1_IN12 | GPIO_AD_B1_07 | - |
|       | ADC1_IN13 | GPIO_AD_B1_08 | - |
|       | ADC1_IN14 | GPIO_AD_B1_09 | - |
|       | ADC1_IN15 | GPIO_AD_B1_10 | - |
| ADC2  | ADC2_IN0  | GPIO_AD_B1_11 | - |
|       | ADC2_IN1  | GPIO_AD_B1_12 | - |
|       | ADC2_IN2  | GPIO_AD_B1_13 | - |
|       | ADC2_IN3  | GPIO_AD_B1_14 | - |
|       | ADC2_IN4  | GPIO_AD_B1_15 | - |
|       | ADC2_IN5  | GPIO_AD_B1_00 | - |
|       | ADC2_IN6  | GPIO_AD_B1_01 | - |
|       | ADC2_IN7  | GPIO_AD_B1_02 | - |
|       | ADC2_IN8  | GPIO_AD_B1_03 | - |
|       | ADC2_IN9  | GPIO_AD_B1_04 | - |

# Chapter 11

## IOMUX Controller (IOMUXC)

### 11.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

[Figure 11-1](#) illustrates the IOMUX/IOMUXC connectivity in the system.

Figure 11-1. IOMUX SoC Level Block Diagram

### 11.1.1 Features

The IOMUXC features are:

- 32-bit software mux control registers (IOMUXC\_SW\_MUX\_CTL\_PAD\_<PAD NAME> or IOMUXC\_SW\_MUX\_CTL\_GRP\_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX\_MODE fields of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC\_SW\_PAD\_CTL\_PAD\_<PAD NAME> or IOMUXC\_SW\_PAD\_CTL\_GRP\_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - several (GPR0 to GPR $n$ ) 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX\_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

## 11.2 Clocks

The table found here describes the clock sources for IOMUXC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 11-1. IOMUXC Clocks**

| Clock name | Clock Root   | Description             |
|------------|--------------|-------------------------|
| ipg_clk_s  | ipg_clk_root | Peripheral access clock |

## 11.3 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC\_REGISTERS includes all of the IOMUXC registers (see [Features](#)).
- IOMUXC\_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux\_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux\_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in [Figure 11-2](#).

Figure 11-2. IOMUX Cell Block Diagram

### 11.3.1 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

### 11.3.2 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (`ipp_ibe==1'b1`) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC\_SW\_MUX\_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

### 11.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC\_SW\_MUX\_CTL\_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC\_SW\_MUX\_CTL\_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

Figure 11-3. Daisy chain illustration

## 11.4 IOMUXC GPR Memory Map/Register Definition

IOMUXC\_GPR memory map

| Absolute address (hex) | Register name                                     | Width (in bits) | Access | Reset value | Section/page                |

|            | <p>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.</p> <p>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.</p> <p>10 <b>Medium</b> — 100MHz</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 7–6<br>SPEED | <p>Speed Field</p> <p>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.</p> <p>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.</p> <p>10 <b>Medium</b> — 100MHz</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 13<br>PUE    | Pull / Keep Select Field<br>Control signal to enable internal pull-up/down resistors or pad keeper functionality.<br>Select one out of next values for pad: ONOFF<br>0 <b>PUE_0_Keeper</b> — Keep the previous output value when the output driver is disabled.<br>1 <b>PUE_1_Pull</b> — Pull-up or pull-down (determined by PUS field).                                                                                                                                                                                                                                                                          |
| 12<br>PKE    | Pull / Keep Enable Field<br>Select one out of next values for pad: ONOFF<br>The pull/keeper function for a given pin is controlled by the PKE, PUE and PUS bits. The pull/keeper can be enabled by the pull/keep enable (PKE) bit. When the pull/keeper is enabled, the PUE (pull-up enable) bit selects either a pull-up/pull-down resistor on the output or a keeper device (keep the previous output value).<br>When the pull/keeper is disabled, PUE and PUS have no functionality.<br>0 <b>PKE_0_Pull_Keeper_Disabled</b> — Pull/Keeper Disabled<br>1 <b>PKE_1_Pull_Keeper_Enabled</b> — Pull/Keeper Enabled |
| 11<br>ODE    | Open Drain Enable Field<br>Select one out of next values for pad: ONOFF<br>If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0.<br>0 <b>ODE_0_Open_Drain_Disabled</b> — Open Drain Disabled (Output is CMOS)<br>1 <b>ODE_1_Open_Drain_Enabled</b> — Open Drain Enabled (Output is Open Drain)                                    |

Field</p> <p>Controls signals to select pull-up or pull-down internal resistance strength.</p> <p>Select one out of next values for pad: WAKEUP</p> <p>00 <b>PUS_0_100K_Ohm_Pull_Down</b> — 100K Ohm Pull Down<br/> 01 <b>PUS_1_47K_Ohm_Pull_Up</b> — 47K Ohm Pull Up<br/> 10 <b>PUS_2_100K_Ohm_Pull_Up</b> — 100K Ohm Pull Up<br/> 11 <b>PUS_3_22K_Ohm_Pull_Up</b> — 22K Ohm Pull Up</p>                                                                                                                                                                                                                         |
| 13<br>PUE    | <p>Pull / Keep Select Field</p> <p>Control signal to enable internal pull-up/down resistors or pad keeper functionality.</p> <p>Select one out of next values for pad: WAKEUP</p> <p>0 <b>PUE_0_Keeper</b> — Keep the previous output value when the output driver is disabled.<br/> 1 <b>PUE_1_Pull</b> — Pull-up or pull-down (determined by PUS field).</p>                                                                                                                                                                                                                                                                              |
| 12<br>PKE    | <p>Pull / Keep Enable Field</p> <p>Select one out of next values for pad: WAKEUP</p> <p>The pull/keeper function for a given pin is controlled by the PKE, PUE and PUS bits. The pull/keeper can be enabled by the pull/keep enable (PKE) bit. When the pull/keeper is enabled, the PUE (pull-up enable) bit selects either a pull-up/pull-down resistor on the output or a keeper device (keep the previous output value).</p> <p>When the pull/keeper is disabled, PUE and PUS have no functionality.</p> <p>0 <b>PKE_0_Pull_Keeper_Disabled</b> — Pull/Keeper Disabled<br/> 1 <b>PKE_1_Pull_Keeper_Enabled</b> — Pull/Keeper Enabled</p> |
| 11<br>ODE    | <p>Open Drain Enable Field</p> <p>Select one out of next values for pad: WAKEUP</p> <p>If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0.</p> <p>0 <b>ODE_0_Open_Drain_Disabled</b> — Open Drain Disabled (Output is CMOS)<br/> 1 <b>ODE_1_Open_Drain_Enabled</b> — Open Drain Enabled (Output is Open Drain)</p>                                        |
| 10–8<br>-    | <p>This field is reserved.<br/> Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 7–6<br>SPEED | <p>Speed Field</p> <p>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.</p> <p>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.</p>                                                                                         |

## IOMUXC\_SW\_PAD\_CTL\_PAD\_GPIO\_EMC\_00 field descriptions (continued)

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13<br>PUE    | <p>Pull / Keep Select Field</p> <p>Control signal to enable internal pull-up/down resistors or pad keeper functionality.</p> <p>Select one out of next values for pad: GPIO_EMC_00</p> <p>0 <b>PUE_0_Keeper</b> — Keep the previous output value when the output driver is disabled.</p> <p>1 <b>PUE_1_Pull</b> — Pull-up or pull-down (determined by PUS field).</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12<br>PKE    | <p>Pull / Keep Enable Field</p> <p>The pull/keeper function for a given pin is controlled by the PKE, PUE and PUS bits. The pull/keeper can be enabled by the pull/keep enable (PKE) bit. When the pull/keeper is enabled, the PUE (pull-up enable) bit selects either a pull-up/pull-down resistor on the output or a keeper device (keep the previous output value).</p> <p>When the pull/keeper is disabled, PUE and PUS have no functionality.</p> <p>Select one out of next values for pad: GPIO_EMC_00</p> <p>0 <b>PKE_0_Pull_Keeper_Disabled</b> — Pull/Keeper Disabled</p> <p>1 <b>PKE_1_Pull_Keeper_Enabled</b> — Pull/Keeper Enabled</p>                                                                                                                        |
| 11<br>ODE    | <p>Open Drain Enable Field</p> <p>If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0.</p> <p>Select one out of next values for pad: GPIO_EMC_00</p> <p>0 <b>ODE_0_Open_Drain_Disabled</b> — Open Drain Disabled (Output is CMOS)</p> <p>1 <b>ODE_1_Open_Drain_Enabled</b> — Open Drain Enabled (Output is Open Drain)</p>                                                                                                                                                               |
| 10–8<br>-    | <p>This field is reserved.</p> <p>Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 7–6<br>SPEED | <p>Speed Field</p> <p>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.</p> <p>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.</p> <p>Select one out of next values for pad: GPIO_EMC_00</p> <p>00 <b>Low</b> — 50MHz</p> <p>01 <b>Medium</b> — 100MHz - 150MHz</p> <p>10 <b>Medium</b> — 100MHz - 150MHz</p> <p>11 <b>Maximum</b> — 150MHz - 200MHz</p> |

| 12<br>PKE    | Pull / Keep Enable Field<br>The pull/keeper function for a given pin is controlled by the PKE, PUE and PUS bits. The pull/keeper can be enabled by the pull/keep enable (PKE) bit. When the pull/keeper is enabled, the PUE (pull-up enable) bit selects either a pull-up/pull-down resistor on the output or a keeper device (keep the previous output value).<br>When the pull/keeper is disabled, PUE and PUS have no functionality.<br>Select one out of next values for pad: GPIO_EMC_06<br>0 <b>PKE_0_Pull_Keeper_Disabled</b> — Pull/Keeper Disabled<br>1 <b>PKE_1_Pull_Keeper_Enabled</b> — Pull/Keeper Enabled                                                                                                                |
| 11<br>ODE    | Open Drain Enable Field<br>If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0.<br>Select one out of next values for pad: GPIO_EMC_06<br>0 <b>ODE_0_Open_Drain_Disabled</b> — Open Drain Disabled (Output is CMOS)<br>1 <b>ODE_1_Open_Drain_Enabled</b> — Open Drain Enabled (Output is Open Drain)                                                                                                                                                   |

| 7–6<br>SPEED | Speed Field<br>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.<br>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.<br>Select one out of next values for pad: GPIO_EMC_06<br>00 <b>Low</b> — 50MHz<br>01 <b>Medium</b> — 100MHz - 150MHz<br>10 <b>Medium</b> — 100MHz - 150MHz<br>11 <b>Maximum</b> — 150MHz - 200MHz |

| 12<br>PKE    | Pull / Keep Enable Field<br>The pull/keeper function for a given pin is controlled by the PKE, PUE and PUS bits. The pull/keeper can be enabled by the pull/keep enable (PKE) bit. When the pull/keeper is enabled, the PUE (pull-up enable) bit selects either a pull-up/pull-down resistor on the output or a keeper device (keep the previous output value).<br>When the pull/keeper is disabled, PUE and PUS have no functionality.<br>Select one out of next values for pad: GPIO_EMC_11<br>0 <b>PKE_0_Pull_Keeper_Disabled</b> — Pull/Keeper Disabled<br>1 <b>PKE_1_Pull_Keeper_Enabled</b> — Pull/Keeper Enabled                                                                                                                |
| 11<br>ODE    | Open Drain Enable Field<br>If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0.<br>Select one out of next values for pad: GPIO_EMC_11<br>0 <b>ODE_0_Open_Drain_Disabled</b> — Open Drain Disabled (Output is CMOS)<br>1 <b>ODE_1_Open_Drain_Enabled</b> — Open Drain Enabled (Output is Open Drain)                                                                                                                                                   |
| 10–8<br>-    | This field is reserved.<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 7–6<br>SPEED | Speed Field<br>SPEED is a selectable bit field that sets electrical characteristics of a pin in a given frequency range. This field provides additional 2-bit slew rate control. These options can either increase the output driver current in the higher frequency range, or reduce the switching noise in the lower frequency range.<br>The operational frequency on GPIO pads is dependent on slew rate (SRE), speed (SPEED), and supply voltage (OVDD). See Operating Frequency table in the GPIO block guide for more details.<br>Select one out of next values for pad: GPIO_EMC_11<br>00 <b>Low</b> — 50MHz<br>01 <b>Medium</b> — 100MHz - 150MHz<br>10 <b>Medium</b> — 100MHz - 150MHz<br>11 <b>Maximum</b> — 150MHz - 200MHz |
