14.7.3 CCM Clock Switcher Register (CCM\_CCSR)

The figure below represents the CCM Clock Switcher register (CCSR). The CCSR register contains bits to control the switcher sub-module dividers and multiplexers. The table below provides its field descriptions.

Address: 400F\_C000h base + Ch offset = 400F\_C00Ch

CCM\_CCSR field descriptions

| Field            | Description                                                  |
|------------------|--------------------------------------------------------------|
| 31–9<br>Reserved | This read-only field is reserved and always has the value 0. |
| 8<br>-           | This field is reserved.<br>Reserved                          |
| 7–3<br>Reserved  | This read-only field is reserved and always has the value 0. |
| 2<br>Reserved    | This read-only field is reserved and always has the value 0. |
| 1<br>-           | This field is reserved.<br>Reserved                          |

**14.7.6 CCM Bus Clock Multiplexer Register (CCM\_CBCMR)**

The figure below represents the CCM Bus Clock Multiplexer Register (CBCMR). The CBCMR register contains bits to control the multiplexers that generate the bus clocks. The table below provides its field descriptions.

**NOTE**

Any change on the above multiplexer will have to be done while the module that its clock is affected is not functional and the respective clock is gated in LPCG. If the change will be done during operation of the module, then it is not guaranteed that the modules operation will not be harmed.

**14.7.9 CCM Serial Clock Divider Register 1 (CCM\_CSCDR1)**

The figure below represents the CCM Serial Clock Divider Register 1 (CSCDR1). The CSCDR1 register contains bits to control the clock generation sub-module dividers. The table below provides its field descriptions.

**NOTE**

Any change on the above dividers will have to be done while the module that its clock is affected is not functional and the affected clock is gated. If the change will be done during operation of the module, then it is not guaranteed that the modules operation will not be harmed.

### 14.7.15 CCM Divider Handshake In-Process Register (CCM\_CDHIPR)

The figure below represents the CCM Divider Handshake In-Process Register (CDHIPR). The CDHIPR register contains read-only bits that indicate that CCM is in the process of updating dividers or muxes that might need handshake with modules.

Address: 400F\_C000h base + 48h offset = 400F\_C048h

## 14.7.17 CCM Interrupt Status Register (CCM\_CISR)

The figure below represents the CCM Interrupt Status Register (CISR). This is a write one to clear register. After an interrupt is generated, software should write one to clear it. The table below provides its field descriptions.

**NOTE**

CCM interrupt request 1 can be masked by CCM interrupt request 1 mask bit. CCM interrupt request 2 can be masked by CCM interrupt request 2 mask bit.

Address: 400F\_C000h base + 58h offset = 400F\_C058h

### 14.7.19 CCM Clock Output Source Register (CCM\_CCOSR)

The figure below represents the CCM Clock Output Source Register (CCOSR). The CCOSR register contains bits to control the clock that will be generated on the output `ipp_do_clk01`. The table below provides its field descriptions.

Address: 400F\_C000h base + 60h offset = 400F\_C060h

**14.7.21 CCM Clock Gating Register 0 (CCM\_CCGR0)**

CG(i) bits CCGR 0-6

These bits are used to turn on/off the clock to each module independently. The following table details the possible clock activity conditions for each module.

| CGR value | Clock Activity Description                                                |
|-----------|---------------------------------------------------------------------------|
| 00        | Clock is off during all modes. Stop enter hardware handshake is disabled. |
| 01        | Clock is on in run mode, but off in WAIT and STOP modes                   |
| 10        | Not applicable (Reserved).                                                |
| 11        | Clock is on during all modes, except STOP mode.                           |

Module should be stopped, before set its bits to "0"; clocks to the module will be stopped immediately.

The tables above show the register mappings for the different CGRs. The clock connectivity table should be used to match the "CCM output affected" to the actual clocks going into the modules.

The figure below represents the CCM Clock Gating Register 0 (CCM\_CCGR0). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 7 CGR registers. The number of registers required is according to the number of peripherals in the system.

## 14.7.24 CCM Clock Gating Register 3 (CCM\_CCGR3)

The figure below represents the CCM Clock Gating Register 3 (CCM\_CCGR3). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 8 CGR registers. The number of registers required is determined by the number of peripherals in the system.

**NOTE**

The OCRAM clock cannot be turned off when CM7 Cache is running. For details, refer to CCM\_CCGR3[CG14] bitfield.

Address: 400F\_C000h base + 74h offset = 400F\_C074h

## 14.7.28 CCM Module Enable Override Register (CCM\_CMEOR)

The follow figure represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. This bit will be applicable only for modules whose clock enable signals are used. The following table provides its field descriptions.

Address: 400F\_C000h base + 88h offset = 400F\_C088h

|       |    |                        |    |                        |    |    |                    |    |              |               |               |    |    |    |    |    |

## 14.8 CCM Analog Memory Map/Register Definition

This section describes the registers for the analog PLLs. The registers which have the same description are grouped within { }. The register offsets for the various PLLs are:

- ARM PLL: {0h000, 0h004, 0h008, 0h00C}.
- USB1 PLL: {0h010, 0h014, 0h018, 0h01C}, {0h0F0, 0h0F4, 0h0F8, 0h0FC}.
- System PLL: {0h030, 0h034, 0h038, 0h03C}, 0h040, 0h050, 0h060, {0h100, 0h104, 0h108, 0h10C}.
- Audio / Video PLL: {0h070, 0h074, 0h078, 0h07C}, 0h080, 0h090, {0h0A0, 0h0A4, 0h0A8, 0h0AC}, 0h0B0, 0h0C0

### 14.8.1 Analog ARM PLL control Register (CCM\_ANALOG\_PLL\_ARMn)

The control register provides control for the system PLL.

Address: 400D\_8000h base + 0h offset + (4d × i), where i=0d to 3d

CCM\_ANALOG\_PLL\_ARMn field descriptions

| Field         | Description                                                      |
|---------------|------------------------------------------------------------------|
| 31<br>LOCK    | 1 - PLL is currently locked.<br>0 - PLL is not currently locked. |

### 14.8.2 Analog USB1 480MHz PLL Control Register (CCM\_ANALOG\_PLL\_USB1*n*)

The control register provides control for USBPHY0 480MHz PLL.

Address: 400D\_8000h base + 10h offset + (4d × i), where i=0d to 3d

## CCM Analog Memory Map/Register Definition

**CCM\_ANALOG\_PLL\_USB1n field descriptions**

| Field                   | Description                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>LOCK              | 1 - PLL is currently locked.<br>0 - PLL is not currently locked.                                                                                                                                                                                                                                                                 |
| 30–17<br>-              | Always set to zero (0).                                                                                                                                                                                                                                                                                                          |
| 16<br>BYPASS            | Bypass the PLL.                                                                                                                                                                                                                                                                                                                  |
| 15–14<br>BYPASS_CLK_SRC | Determines the bypass source.<br>0x0 <b>REF_CLK_24M</b> — Select the 24MHz oscillator as source.<br>0x1 <b>CLK1</b> — Select the CLK1_N / CLK1_P as source.                                                                                                                                                                      |
| 13<br>ENABLE            | Enable the PLL clock output.                                                                                                                                                                                                                                                                                                     |
| 12<br>POWER             | Powers up the PLL. This bit will be set automatically when USBPHY0 remote wakeup event happens.                                                                                                                                                                                                                                  |
| 11–7<br>-               | Always set to zero (0).                                                                                                                                                                                                                                                                                                          |
| 6<br>EN_USB_CLKS        | Powers the 9-phase PLL outputs for USBPHYn. Additionally, the UTMI clock gate must be deasserted in the USBPHYn to enable USBn operation (clear CLKGATE bit in USBPHYn_CTRL). This bit will be set automatically when USBPHYn remote wakeup event occurs.<br><br>0 PLL outputs for USBPHYn off.<br>1 PLL outputs for USBPHYn on. |
| 5–2<br>-                | Always set to zero (0).                                                                                                                                                                                                                                                                                                          |
| 1<br>DIV_SELECT         | This field controls the PLL loop divider. 0 - Fout=Fref*20; 1 - Fout=Fref*22.                                                                                                                                                                                                                                                    |

### 14.8.3 Analog USB2 480MHz PLL Control Register (CCM\_ANALOG\_PLL\_USB2n)

The control register provides control for USBPHY1 480MHz PLL.

Address: 400D\_8000h base + 20h offset + (4d × i), where i=0d to 3d

**CCM\_ANALOG\_PLL\_SYS\_NUM field descriptions**

| Field      | Description                                                       |
|------------|-------------------------------------------------------------------|
| 31–30<br>- | Always set to zero (0).                                           |
| A          | 30 bit numerator (A) of fractional loop divider (signed integer). |

### 14.8.7 Denominator of 528MHz System PLL Fractional Loop Divider Register (CCM\_ANALOG\_PLL\_SYS\_DENOM)

This register contains the denominator of 528MHz PLL fractional loop divider.

Address: 400D\_8000h base + 60h offset = 400D\_8060h

CCM\_ANALOG\_PLL\_SYS\_DENOM field descriptions

| Field      | Description                                                           |
|------------|-----------------------------------------------------------------------|
| 31–30<br>- | Always set to zero (0).                                               |
| B          | 30 bit denominator (B) of fractional loop divider (unsigned integer). |

### 14.8.8 Analog Audio PLL control Register (CCM\_ANALOG\_PLL\_AUDIO<sub>n</sub>)

The control register provides control for the audio PLL.

Address: 400D\_8000h base + 70h offset + (4d × i), where i=0d to 3d

### CCM\_ANALOG\_PLL\_AUDION field descriptions

| Field                    | Description                                                                                                                                                                                                     |

### 14.8.15 480MHz Clock (PLL3) Phase Fractional Divider Control Register (CCM\_ANALOG\_PFD\_480<sub>n</sub>)

The PFD\_480 control register provides control for PFD clock generation.

This register controls the 4-phase fractional clock dividers. The fractional clock frequencies are a product of the values in these registers.

Address: 400D\_8000h base + F0h offset + (4d × i), where i=0d to 3d

**CCM\_ANALOG\_PFD\_480n field descriptions**

| Field              | Description                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>PFD3_CLKGATE | IO Clock Gate. If set to 1, the 3rd fractional divider clock (reference ref_pfd3) is off (power savings). 0: ref_pfd3 fractional divider clock is enabled.<br>Need to assert this bit before PLL is powered down                                                                                                    |
| 30<br>PFD3_STABLE  | This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, |

### 14.8.16 528MHz Clock (PLL2) Phase Fractional Divider Control Register (CCM\_ANALOG\_PFD\_528n)

The PFD\_528 control register provides control for PFD clock generation.

This register controls the 3-phase fractional clock dividers. The fractional clock frequencies are a product of the values in these registers.

Address: 400D\_8000h base + 100h offset + (4d × i), where i=0d to 3d

Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state. |
| PFD0_FRAC          | This field controls the fractional divide value. The resulting frequency shall be $528 \times 18 / \text{PFD0\_FRAC}$ where PFD0_FRAC is in the range 12-35.                                                                                                                                                                                                                                                                                                                                                                      |

### 14.8.17 Miscellaneous Register 0 (CCM\_ANALOG\_MISC0n)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 400D\_8000h base + 150h offset + (4d × i), where i=0d to 3d

## CCM Analog Memory Map/Register Definition

### CCM\_ANALOG\_MISC0n field descriptions

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                        |

| 3<br>REFTOP_<br>SELFBIASOFF | Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap.<br><b>NOTE:</b> Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit.<br><b>NOTE:</b> Not related to CCM. See <a href="#">Power Management Unit (PMU)</a><br><br>0 Uses coarse bias currents for startup<br>1 Uses bandgap-based bias currents for best performance. |
| 2–1<br>-                    | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0<br>REFTOP_PWD             | Control bit to power-down the analog bandgap reference circuitry.<br><b>NOTE:</b> A note of caution, the bandgap is necessary for correct operation of most of the LDO, PLL, and other analog functions on the die.<br><b>NOTE:</b> Not related to CCM. See <a href="#">Power Management Unit (PMU)</a>                                                                                                                                                                                                                                                                                                                                                      |

### 14.8.18 Miscellaneous Register 1 (CCM\_ANALOG\_MISC1n)

This register defines the control and status bits for miscellaneous analog blocks. The LVDS1 and LVDS2 controls below control the behavior of the anack1/1b LVDS IO.

Address: 400D\_8000h base + 160h offset + (4d × i), where i=0d to 3d

| Bit   | 31         | 30         | 29           | 28          | 27            | 26       | 25       | 24 | 23 | 22 | 21 | 20            | 19 | 18 | 17 | 16                  |

### 15.2 Overview

This block comprises both the 24 MHz and 32 kHz implementation of a biased amplifier that when combined with a suitable external quartz crystal and external load capacitors, implements an oscillator.

The block includes means to:

- Accept an external clock source.
- Detect if the crystal frequency is close to 24 MHz or 32 kHz.
- Reduce the operating current via software after the oscillator has started (24 MHz specific feature)
- Supply another ~32 kHz clock source based off an independent internal oscillator if there is no oscillation sensed on the RTC\_XTAL bumps(contacts) (32 kHz specific

feature). The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator.

- Automatically switch to the external oscillation source when sensed on the RTC\_XTAL bumps(contacts) (32 kHz specific feature).

## 15.3 External Signals

The table found here describes the external signals of XTALOSC:

**Table 15-2. XTALOSC External Signals**

| Signal      | Description                      | Pad           | Mode      | Direction |
|-------------|----------------------------------|---------------|-----------|-----------|
| REF_CLK_32K | 32 kHz reference clock           | GPIO_AD_B0_00 | ALT2      | O         |
| REF_CLK_24M | 24 MHz reference clock           | GPIO_AD_B0_01 | ALT2      | O         |
|             |                                  | GPIO_AD_B0_03 | ALT6      |           |
|             |                                  | GPIO_AD_B0_13 | ALT7      |           |
| XTALI       | Crystal oscillator input signal  | XTALI         | No Muxing | O         |
| XTALO       | Crystal oscillator output signal | XTALO         | No Muxing | O         |

## 15.4 Crystal Oscillator 24 MHz

### 15.4.1 Oscillator Configuration (24 MHz)

The basic block diagram of the 24 MHz module configured as a crystal oscillator is shown below.

**Figure 15-1. Oscillator Configuration (24 MHz)**

This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. However, care should be taken as many of the serial IO modules depend on the fixed frequency of 24 MHz. Please consult the sections of the document pertaining to the USB, ENET interfaces, for example. After a healthy oscillation is established, then the bias current of the oscillator can generally be reduced to save power. This is accomplished through the XTALOSC24M\_MISC0[OSC\_I] bits, defined in the MISC0 register later in this chapter. Restore the XTALOSC24M\_MISC0[OSC\_I] bits before going into a power mode where the XTALOSC24 is powered down or oscillator startup may become an issue. The power down of the XTALOSC24 module is controlled by the CCM. See this section of the manual for more details.

### 15.4.2 Bypass Configuration (24 MHz)

If it is desired to drive the chip with an external clock source, then the 24 MHz oscillator could be driven in one of three configurations using a nominal 1.1V source.

1. A single ended external clock source can be used to overdrive the output of the amplifier (XTALO). Since the oscillation sensing amplifier is differential, the

XTALI pin should be externally floating and capacitively loaded. The combination of the internal biasing resistor and the external capacitor will filter the signal applied to the XTALO pin and develop a rough reference for the sensing amplifier to compare to.

2. A single ended external clock source can be used to drive XTALI. In this configuration, XTALO should be left externally floating.
3. A differential external clock source can be used to drive both XTALI and XTALO.

Generally, configuration 2 is anticipated to be the most used configuration, but all three configurations may be utilized.

### **15.4.3 RC Oscillator (24 MHz)**

A lower-power RC oscillator module is available on-chip as a possible alternative to the 24 MHz crystal oscillator after a successful power-up sequence.

The 24 MHz RC oscillator is a self-tuning circuit that will output the programmed frequency value by using the RTC clock as its reference. This oscillator is intended for normal operation and not fast boot.

While the power consumption of this RC oscillator is much lower than the 24 MHz crystal oscillator, one limitation of this RC oscillator module is that its clock frequency is not as accurate. Therefore, care should be observed when using this oscillator as the reference for the on-chip PLLs as their output clock frequency will be lower/higher than when using the 24 MHz crystal oscillator clock.

### **15.4.4 Crystal Frequency Detection(24 MHz)**

A submodule exists that gives a fairly crude (relative to the accuracy of a crystal) estimation of whether the clock frequency is correct.

This function may be enabled by setting the XTALOSC24M\_MISC0[OSC\_XTALOK\_EN] bit. It is disabled at system reset. When the oscillator is stable and the correct frequency is detected, the XTALOSC24M\_MISC0[OSC\_XTALOK] bit will be set. Note that the correct frequency will be observed before the oscillator fully blooms(the oscillation waveform build-up is completed).

## **15.5 Crystal Oscillator 32 kHz**

### 15.5.1 Oscillator Configuration (32 kHz)

The basic block diagram of the 32 kHz module configured as a crystal oscillator is shown below.

**Figure 15-2. Oscillator Configuration (32 kHz)**

This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. Generally, RTC oscillators are either implemented with 32 kHz or 32.768 kHz crystals. Please consult the Security Reference Manual for appropriate frequency selection and configuration. Care must be taken to limit external leakage as this may debias the amplifier and degrade the gain.

The internal oscillator is automatically multiplexed in the clocking system when the system detects a loss of clock. The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator. The internal oscillator is not precise relative to a crystal. While it will provide a clock to the system, it generally will not be precise enough for long term time keeping. The internal oscillator is anticipated to be useful for quicker startup times and tampering prevention, but should not be used as the exclusive source for the 32 kHz clocks. An external 32 kHz clock source must be used for production systems.

## 15.5.2 Bypass Configuration (32 kHz)

If it is desired to drive the chip with an external clock source, then the 32 kHz oscillator could be driven in one of three configurations using a nominal 1.1V source.

1. A single ended external clock source can be used to overdrive the output of the amplifier (RTC\_XTALO). Since the oscillation sensing amplifier is differential, the RTC\_XTALI pin should be externally floating and capacitively loaded. The combination of the internal biasing resistor and the external capacitor will filter the signal applied to the RTC\_XTALO pin and develop a rough reference for the sensing amplifier to compare to.
2. A single ended external clock source can be used to drive RTC\_XTALI. In this configuration, RTC\_XTALO should be left externally floating.
3. A differential external clock source can be used to drive both RTC\_XTALI and RTC\_XTALO.

Generally, configuration 2 is anticipated to be the most used configuration, but all three configurations may be utilized.

## 15.6 XTALOSC 24MHz Memory Map/Register Definition

### NOTE

The register content is mixed with analog functions not related to the oscillator function. These bits are noted.

**XTALOSC24M memory map**

### 15.6.1 Miscellaneous Register 0 (XTALOSC24M\_MISC0n)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 400D\_8000h base + 150h offset + (4d × i), where i=0d to 3d

### XTALOSC24M\_MISC0n field descriptions

| Field                  | Description                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>VID_PLL_PREDIV   | Predivider for the source clock of the PLL's.<br><b>NOTE:</b> Not related to oscillator.<br>0 Divide by 1<br>1 Divide by 2                                                                                                                                                                                                                        |
| 30<br>XTAL_24M_PWD     | This field powers down the 24M crystal oscillator if set true.                                                                                                                                                                                                                                                                                    |
| 29<br>RTC_XTAL_SOURCE  | This field indicates which chip source is being used for the rtc clock.<br>0 Internal ring oscillator<br>1 RTC_XTAL                                                                                                                                                                                                                               |
| 28–26<br>CLKGATE_DELAY | This field specifies the delay between powering up the XTAL 24MHz clock and releasing the clock to the digital logic inside the analog block.<br><b>NOTE:</b> Do not change the field during a low power event. This is not a field that the user would normally need to modify.<br>000 0.5ms<br>001 1.0ms<br>010 2.0ms<br>011 3.0ms<br>100 4.0ms |

| Field       | Description                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------|
| 2<br>BYPASS | Bypasses any calculated RC tuning value and uses the programmed register value.                                         |
| 1<br>ENABLE | Enables the tuning logic to calculate new RC tuning values. Disabling essentially freezes the state of the calculation. |
| 0<br>START  | Start/stop bit for the RC tuning calculation logic. If stopped the tuning logic is reset.                               |

## 15.6.4 XTAL OSC Configuration 1 Register (XTALOSC24M\_OSC\_CONFIG1n)

This register is used to configure the 24MHz RC oscillator.

Address: 400D\_8000h base + 2B0h offset + (4d × i), where i=0d to 3d

|       |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |              |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |
|-------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15           | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |
| R     | COUNT_RC_CUR |    |    |    |    |    |    |    |    |    |    |    | -  |    |    |    | COUNT_RC_TRG |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |
| W     | COUNT_RC_CUR |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | COUNT_RC_TRG |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |
| Reset | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0            | 0  | 0  | 0  | 0  | 0  | 0 | 1 | 0 | 1 | 1 | 1 | 0 | 1 | 1 | 1 | 0 |

### XTALOSC24M\_OSC\_CONFIG1n field descriptions

| Field                 | Description                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 31–20<br>COUNT_RC_CUR | The current tuning value in use.                                                                                                           |
| 19–12<br>-            | Reserved                                                                                                                                   |
| COUNT_RC_TRG          | The target count used to tune the RC OSC frequency. Essentially the number of desired RC OSC clock cycles is within one 32kHz clock cycle. |

### 15.6.5 XTAL OSC Configuration 2 Register (XTALOSC24M\_OSC\_CONFIG2n)

This register is used to configure the 1MHz clock generated from the 24MHz RC oscillator.

Address: 400D\_8000h base + 2C0h offset + (4d × i), where i=0d to 3d

| Bit   | 31            | 30 | 29 | 28 | 27           | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |  |        |  |           |  |
|-------|---------------|----|----|----|--------------|----|----|----|----|----|----|----|----|----|----|----|--|--------|--|-----------|--|
| R     | CLK_1M_ERR_FL |    |    |    |              |    |    |    | -  |    |    |    |    |    |    |    |  | MUX_1M |  | ENABLE_1M |  |
| W     |               |    |    |    |              |    |    |    |    |    |    |    |    |    |    |    |  |        |  |           |  |
| Reset | 0             | 0  | 0  | 0  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  |  |        |  |           |  |
| Bit   | 15            | 14 | 13 | 12 | 11           | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |  |        |  |           |  |
| R     |               |    |    |    | COUNT_1M_TRG |    |    |    |    |    |    |    |    |    |    |    |  |        |  |           |  |
| W     |               |    |    |    |              |    |    |    |    |    |    |    |    |    |    |    |  |        |  |           |  |
| Reset | 0             | 0  | 0  | 0  | 0            | 0  | 1  | 0  | 1  | 1  | 1  | 0  | 0  | 0  | 1  | 0  |  |        |  |           |  |

**XTALOSC24M\_OSC\_CONFIG2n field descriptions**

| Field               | Description                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>CLK_1M_ERR_FL | Flag indicates that the count_1m count wasn't reached within 1 32kHz period. This is intended as feedback to software that the HW_ANADIG_OSC_CONFIG2_COUNT_1M_TRG value is too high for the RC Osc frequency. |
| 30–18<br>-          | Reserved.                                                                                                                                                                                                     |
| 17<br>MUX_1M        | Mux the corrected or uncorrected 1MHz clock to the output. 0 - free 1MHz clock; 1 - locked 1MHz clock.                                                                                                        |

*Table continues on the next page...*

**XTALOSC24M\_OSC\_CONFIG2*n* field descriptions (continued)**

| Field            | Description                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16<br>ENABLE_1M  | Enable the 1MHz clock output. 0 - disabled; 1 - enabled.                                                                                                                       |
| 15-12<br>-       | Reserved                                                                                                                                                                       |
| COUNT_1M_<br>TRG | The target count used to tune the 1MHz clock frequency. Essentially the number of desired RC OSC clock cycles used to generate the 1MHz clock is within one 32kHz clock cycle. |

# Chapter 16

## Power Management Unit (PMU)

### 16.1 Chip-specific PMU information

Table 16-1. Reference links to related information

#### NOTE

The following bitfields are not applicable on this device, and those corresponding bits are **Reserved**:

- in PMU\_REG\_CORE $n$  register:
  - RAMP\_RATE
  - REG2\_TARG
  - REG1\_TARG
  - REG0\_TARG
- in PMU\_MISC1 $n$  register: IRQ\_DIG\_BO.
- in PMU\_MISC2 $n$  register:
  - REG2\_STEP\_TIME
  - REG1\_STEP\_TIME
  - REG0\_STEP\_TIME
  - REG2\_OK
  - REG2\_ENABLE\_BO
  - REG1\_ENABLE\_BO

- REG0\_ENABLE\_BO
- REG2\_BO\_STATUS
- REG1\_BO\_STATUS
- REG0\_BO\_STATUS
- REG2\_BO\_OFFSET
- REG1\_BO\_OFFSET
- REG0\_BO\_OFFSET

## 16.2 Overview

The power management unit (PMU) is designed to simplify the external power interface. The power system can be split into the input power sources and their characteristics, the integrated power transforming and controlling elements, and the final load interconnection and requirements.

A typical power system uses the PMU is depicted in the following diagram.

**Figure 16-1. Power system overview**

Using four LDO regulators, the number of external supplies is greatly reduced. Not counting the backup coin and USB inputs, the number of external supplies is reduced to two. Missing from this external supply total is the number of necessary external supplies to power the desired memory interface; that number varies depending on the type of external memory selected. Other supplies may also be necessary to supply the voltage to the different I/O power segments if their I/O voltages have to be different from what is provided above.

## 16.3 Analog LDO Regulators

There are two analog regulators described here.

### 16.3.1 LDO 1P1

The LDO\_1P1 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8 V–3.3 V) to produce a nominal 1.1 V output voltage.

The output of the regulator can be programmed in 25 mV steps from 0.8 V to 1.4 V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken.

Current limiting can be enabled by setting the PMU\_REG\_1P1[ENABLE\_ILIMIT] bit to allow for in-rush current requirements during startup if needed. Active pulldown can also be enabled by setting the PMU\_REG\_1P1[ENABLE\_PULLDOWN] bit for systems requiring this feature.

### 16.3.2 LDO 2P5

The LDO\_2P5 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8V-3.3V) to produce a nominal 2.5V output voltage.

The output of the regulator can be programmed in 25mV steps from 2.0V to 2.75V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brown-out detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded to take the necessary steps.

Current-limiting can be enabled by setting the REG\_PMU\_2P5[ENABLE\_ILIMIT] bit to allow for in-rush current requirements during start-up if needed. Active-pulldown can also be enabled by setting the REG\_PMU\_2P5[ENABLE\_PULLDOWN] bit for systems requiring this feature.

### 16.3.3 Low Power Operation

The 1.1 V and 2.5 V LDO includes an alternate, self-biased, low-precision, weak regulator which can be enabled for applications needing to keep the 1.1 V and 2.5 V output voltage alive during low-power modes where the main regulator and its associated global bandgap reference module are disabled.

The output of this weak regulator is not programmable and is a function of its input power supply as well as load current. The low-power mode is enabled by setting high the PMU\_REG\_1P1[ENABLE\_WEAK\_LINREG] and PMU\_REG\_2P5[ENABLE\_WEAK\_LINREG] bit of the regulator. It is recommended that the following sequence be followed to enable this mode:

1. Throttle down the 1.1 V / 2.5 V attached load to its low-power maintain state.
2. Disable the main 1.1 V / 2.5 V regulator driver by clearing the PMU\_REG\_1P1[ENABLE\_LINREG] / PMU\_REG\_2P5[ENABLE\_LINREG] bit.
3. Enable the weak 1.1 V / 2.5 V regulator by setting the PMU\_REG\_1P1[ENABLE\_WEAK\_LINREG] / PMU\_REG\_2P5[ENABLE\_WEAK\_LINREG] bit.

To go back to full-power operation, reverse the steps outlined above. Note that the external decoupling cap is supporting the power supply between steps 2 and 3. Therefore step 3 should happen appropriately in time relative to the discharge of the supporting capacitor.

## 16.4 USB LDO Regulator

The USB\_LDO module on the chip implements a programmable linear-regulator function from the USB VBUS voltages (typically 5 V) to produce a nominal 3.0 V output voltage.

The output of the regulator can be programmed in 25 mV steps, from 2.625V to 3.4 V . The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 4.7  $\mu$ F, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken. This regulator has a built-in power mux which allows the user to choose to run the regulator from either VBUS supply when both are present. If only one of the VBUS voltages is present, then the regulator automatically selects this supply. Current limit is also included to help the system meet in-rush current targets.

Upon attachment of VBUS, this regulator starts up in a low-power, self-preservation mode to prevent over-voltage conditions on the chip. It is expected that the user transition to full regulation by enabling the regulator and disabling the in-rush current limits via its control registers. Upon VBUS removal, it is further expected that the regulator controls are returned to their reset state.

## 16.5 SNVS Regulator

The SNVS regulator takes the SNVS\_IN supply and generates the SNVS\_CAP supply, which powers the real time clock and SNVS blocks.

The SNVS\_LDO is a non-programmable linear-regulator function, producing a nominal 1.1V output voltage.

## 16.6 PMU Memory Map/Register Definition

The register definitions that affect the behavior of the digital LDO regulators follow.

### NOTE

Some of the registers are collections of bits that affect multiple components on the chip. Those that are not pertinent to this chapter have comments in the related register bitfields.

If a full description is desired, please consult the full register programming reference in the related block.

### 16.6.1 Regulator 1P1 Register (PMU\_REG\_1P1n)

This register defines the control and status bits for the 1.1V regulator. This regulator is designed to power the digital portions of the analog cells.

Address: 400D\_8000h base + 110h offset + (4d × i), where i=0d to 3d

| 1<br>ENABLE_BO     | Control bit to enable the brownout circuitry in the regulator.                                                                                                                                                                                                                                                                                                    |
| 0<br>ENABLE_LINREG | Control bit to enable the regulator output to be set by the programmed target voltage setting and internal bandgap reference.                                                                                                                                                                                                                                     |

### 16.6.3 Regulator 2P5 Register (PMU\_REG\_2P5n)

This register defines the control and status bits for the 2.5V regulator.

Address: 400D\_8000h base + 130h offset + (4d × i), where i=0d to 3d

## PMU Memory Map/Register Definition

### PMU\_REG\_2P5n field descriptions

| Field                    | Description                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–19<br>-               | This field is reserved.                                                                                                                                                                                                                                                                                                                                         |
| 18<br>ENABLE_WEAK_LINREG | Enables the weak 2p5 regulator. This low power regulator is used when the main 2p5 regulator is disabled to keep the 2.5V output roughly at 2.5V. Scales directly with the value of VDDHIGH_IN.                                                                                                                                                                 |
| 17<br>OK_VDD2P5          | Status bit that signals when the regulator output is ok. 1 = regulator output > brownout target                                                                                                                                                                                                                                                                 |
| 16<br>BO_VDD2P5          | Status bit that signals when a brownout is detected on the regulator output.                                                                                                                                                                                                                                                                                    |

| 11110 | Target core voltage = 1.450V               |
| 11111 | Power FET switched full on. No regulation. |

### 16.6.5 Miscellaneous Register 0 (PMU\_MISC0n)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 400D\_8000h base + 150h offset + (4d × i), where i=0d to 3d

## PMU Memory Map/Register Definition

### PMU\_MISC0n field descriptions

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                       |

**16.6.7 Miscellaneous Control Register (PMU\_MISC2n)**

This register defines the control for miscellaneous PMU Analog blocks.

**NOTE**

This register is shared with CCM.

PMU Memory Map/Register Definition

Address: 400D\_8000h base + 170h offset + (4d × i), where i=0d to 3d

### 17.2 Overview

The General Power Control (GPC) block includes the sub-blocks listed here.

- CPU [Power Gating Control \(PGC\)](#)

Each sub-block has its own IP registers.

GPC determines wake-up IRQ for exiting WAIT/STOP mode (with or without CPU power gating).

Figure 17-1. GPC Block Diagram

17.3 Clocks

The table found here describes the clock sources for GPC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 17-2. GPC Clocks

| Clock name | Clock Root   | Description             |
|------------|--------------|-------------------------|
| ipg_clk    | ipg_clk_root | Peripheral clock        |
| ipg_clk_s  | ipg_clk_root | Peripheral access clock |
| pgc_clk    | ipg_clk_root | PGC peripheral clock    |
| sys_clk    | ipg_clk_root | Module clock            |

17.4 Power Gating Control (PGC)

Power Gating (PGC) is applied to the Arm CPU and FlexRAM optionally in STOP low power mode, after all essential CPU registers data are saved by Arm dormant procedure.

If any of the unmasked interrupts appears, CPU is powered up and clock restore request (exit from STOP mode) is sent to CCM.

**PGC power down sequence:**

- CCM sends power down request when the chip is about to enter stop mode. The user should define which modules will be powered down (CTRL registers of corresponding PGC module, bit 0).

**PGC power up sequence:**

- One of the power up irq is asserted.
- Power up request is asserted in GPC and in CCM.
- The Power Gated modules are powered up, according to PGC settings of appropriate module.

The Power Gated modules require reset after powering up. The next figure describes GPC-SRC handshake procedure for reset after power gating.

**Figure 17-2. GPC-SRC handshake for reset after power gating**

### 17.4.1 Overview

The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems.

The sequence timing is programmable using the PGC control registers. [Figure 17-3](#) shows PGC as part of the SoC's overall power management scheme.

Figure 17-3. PGC Block Diagram

### 17.4.1.1 Features

Key features of the PGC include:

- Provides the ability to switch off power to a target subsystem.
- Generates power-up and power-down control sequences.
- Provides programmable registers to adjust the timing of the power control signals.

## 17.5 GPC Interrupt Controller (INTC)

The INTC (Interrupt Controller) detects an interrupt and generates the wakeup signal. It supports up to 160 interrupts.

### 17.5.1 Interrupt Controller features

The features of the GPC INTC are listed below.

Features:

- Supports up to 160 interrupts
- Provides an option to mask/unmask each interrupt
- Detects interrupts and generates the wake up signal
- 32-bits IP bus interface
- All registers are byte-accessible

## 17.6 GPC Memory Map/Register Definition

Detailed descriptions of each register can be found below.

Writes to GPC registers only takes effect in supervisor mode.

**GPC memory map**

| Absolute address (hex) | Register name                             | Width (in bits) | Access | Reset value | Section/ page                |

| Reset | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### GPC\_IMR3 field descriptions

| Field | Description                                                |
|-------|------------------------------------------------------------|
| IMR3  | IRQ[95:64] masking bits: 1-irq masked, 0-irq is not masked |

## 17.6.5 IRQ masking register 4 (GPC\_IMR4)

IMR4 Register - masking of irq[127:96].

Address: 400F\_4000h base + 14h offset = 400F\_4014h

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | IMR4 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### GPC\_IMR4 field descriptions

| Field | Description                                                 |
|-------|-------------------------------------------------------------|
| IMR4  | IRQ[127:96] masking bits: 1-irq masked, 0-irq is not masked |

17.6.6 IRQ status resister 1 (GPC\_ISR1)

ISR1 Register - status of irq [31:0].

Address: 400F\_4000h base + 18h offset = 400F\_4018h

GPC\_ISR1 field descriptions

| Field | Description                 |
|-------|-----------------------------|
| ISR1  | IRQ[31:0] status, read only |

17.6.7 IRQ status resister 2 (GPC\_ISR2)

ISR2 Register - status of irq [63:32].

Address: 400F\_4000h base + 1Ch offset = 400F\_401Ch

GPC\_ISR2 field descriptions

| Field | Description                  |
|-------|------------------------------|
| ISR2  | IRQ[63:32] status, read only |

### 17.6.8 IRQ status resister 3 (GPC\_ISR3)

ISR3 Register - status of irq [95:64].

Address: 400F\_4000h base + 20h offset = 400F\_4020h

GPC\_ISR3 field descriptions

| Field | Description                  |
|-------|------------------------------|
| ISR3  | IRQ[95:64] status, read only |

### 17.6.9 IRQ status resister 4 (GPC\_ISR4)

ISR4 Register - status of irq [127:96].

Address: 400F\_4000h base + 24h offset = 400F\_4024h

GPC\_ISR4 field descriptions

| Field | Description                   |
|-------|-------------------------------|
| ISR4  | IRQ[127:96] status, read only |

## 17.6.10 IRQ masking register 5 (GPC\_IMR5)

IMR5 Register - masking of irq[159:128].

Address: 400F\_4000h base + 34h offset = 400F\_4034h

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | IMR5 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### GPC\_IMR5 field descriptions

| Field | Description                                                  |
|-------|--------------------------------------------------------------|
| IMR5  | IRQ[159:128] masking bits: 1-irq masked, 0-irq is not masked |

## 17.6.11 IRQ status resister 5 (GPC\_ISR5)

ISR5 Register - status of irq [159:128].

Address: 400F\_4000h base + 38h offset = 400F\_4038h

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### GPC\_ISR5 field descriptions

| Field | Description                    |
|-------|--------------------------------|
| ISR4  | IRQ[159:128] status, read only |

## 17.7 PGC Memory Map/Register Definition

The PGC registers can be accessed only in supervisor mode.

Attempts to access registers when not in supervisor mode or attempts to access an unimplemented address location might trigger a bus transfer error. In this case, software should take appropriate action (such as ignore the error, log the error, or initiate a soft reset).

All PGC registers are byte-accessible.

### NOTE

PGC MEGA is used to control the power gate of PDRAM1 domain . PGC CPU is used to control the power gate of PDM7 domain (CM7 CPU). FlexRAM PDRAM0 domain is further controlled by GPC\_CNTR[PDRAM0\_PGE] bit.

### PGC memory map

| Absolute address (hex) | Register name                                                  | Width (in bits) | Access | Reset value | Section/ page               |
|------------------------|----------------------------------------------------------------|-----------------|--------|-------------|-----------------------------|

### PGC\_MEGA\_SR field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–1<br>Reserved | This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 0<br>PSR         | Power status. When in functional (or software-controlled debug) mode, PGC hardware sets PSR as soon as any of the power control output changes its state to one (isolation or power off occurs). Write one to clear this bit. Software should clear this bit after power up; otherwise, PSR continues to reflect the power status of the initial power down.<br><br>0 The target subsystem was not powered down for the previous power-down request.<br>1 The target subsystem was powered down for the previous power-down request. |

## 17.7.5 PGC CPU Control Register (PGC\_CPU\_CTRL)

The PGCR enables the response to a power-down request.

Address: 400F\_4000h base + 2A0h offset = 400F\_42A0h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

### 18.2 Introduction

This module is a synchronous buck mode DCDC converter with a single output.

### 18.3 Features

The DCDC module includes the following features:

- Buck mode, a single output
- PSWITCH pin to control DCDC to enable or bypass DCDC
- Continuous conduction mode (CCM) and discontinuous conduction mode (DCM) operation
- Power-save mode operation
- Over current protection

## Block diagram

- Over voltage protection
- Low voltage detection
- Internal oscillator to support the case when the crystal oscillator is not present as in the block diagram

## 18.4 Block diagram

Figure 18-1. DCDC block diagram

## 18.5 Functional description

The DCDC converter is a synchronous step down converter with a single output. In run mode, it can operate in the continuous conduction mode or discontinuous conduction mode, depending on the level of the load current. The load current level is about 50mA in a typical case, but it depends on the exact value of inductance, input voltage level and output target. If DCM mode is enabled, the DCDC can switch to DCM mode automatically if the current of the inductance goes to zero. The current does not need to be monitored to switch modes. Discontinuous conduction mode must be enabled by the register configuration.

The DCDC can also be configured to operate in power-save mode when the load current is less than 50 mA. During the power-save mode, the converter operates with reduced switching frequency in PFM mode and with a minimum quiescent current to maintain high efficiency.

DCM and CCM both work in run mode, in which the DCDC regulates the output continuously.

PFM is Pulse Frequency Modulation. In PFM, which is also named Pulse Mode, the DCDC is idle until the output drops to the low threshold. The DCDC then starts to charge the output to the high threshold. After it reaches the high threshold, the DCDC is idle again.

The DCDC also includes the following three protection functions:

- Over current protection. In run mode, DCDC will shut down when detecting abnormal large current in the P-type power switch. In power save mode, DCDC will stop charging inductor when detecting large current in the P-type power switch. The threshold is also different in run mode and in power save mode: the former is 1 A–2 A, and the latter is 200 mA–250 mA.
- Over voltage protection. DCDC will shut down when detecting the output voltage is too high.
- Low voltage detection. DCDC will shut down when detecting the input voltage is too low.

Another function of DCDC is that it can detect the peak current in the P-channel switch. When the peak current exceeds the threshold, DCDC will give an alert signal, and the threshold can be configured. By this way, DCDC can roughly detect the current loading.

## 18.6 Application information

### 18.6.1 Turn on DCDC

The below conditions must be met to enable the DCDC:

- Power snvs\_1p0 and clk32k in snvs\_1p0 are available
- DCDC\_IN powered up
- After DCDC\_IN powered up, delay about 1ms reset time to enable DCDC
- PSWITCH and PMIC\_ON\_REQ are both high to enable DCDC

The sequence is:

1. Power snvs1p0 and clk32k
2. PMIC\_ON\_REQ = 1

3. DCDC\_IN powered up
4. Delay 1ms reset time
5. PSWITCH = 1
6. DCDC is now enabled

OR:

1. Power snvs\_1p0 and clk32k
2. DCDC\_IN powered up
3. Delay 1ms reset time
4. PSWITCH = 1
5. PMIC\_ON\_REQ = 1
6. DCDC is now enabled

Only if when PSWITCH and PMIC\_ON\_REQ are both high, DCDC can be enabled, PMIC\_ON\_REQ can be before or after DCDC\_IN , just to assure delay about 1ms reset time to enable DCDC after DCDC\_IN power up,

#### NOTE

For safety purpose, over-voltage detector needs to be enabled, i.e. PWD\_HIGH\_VOLT\_DET=1'b0.

### 18.6.2 Target Voltage Adjustment

DISABLE\_STEP=0x0

set TRG

#### NOTE

If setting disable\_step=0, the overshoot will be low when changing the target, but the settling time is longer. If setting disable\_step=1, the settling time is shorter, but the overshoot might be higher. The following settings can speed up the settling time: pwd\_cmp\_offset=0x0; loopctrl\_en\_rcscale=0x4.

### 18.6.3 Continuous Conduction Mode

pwd\_zcd=0x1

pwd\_cmp\_offset=0x0

loopctrl\_en\_rcscale=0x3

## 18.6.4 Discontinuous Conduction Mode

`pwd_zcd=0x0`

`pwd_cmp_offset=0x0`

`loopctrl_en_rcscale=0x4`

`DCM_SET_CTRL=1'b1`

### NOTE

Because discontinuous conduction mode can increase the efficiency of DCDC in case of low current loading, it is always recommended.

## 18.6.5 Power Saving Mode

Before entering this mode, set the target value of run mode the same as power saving mode, because DCDC will switch back to run mode if it detects the current loading is larger than about 50 mA (the threshold can be configured).

`PMIC_STBY_REQ=0x1`

## 18.7 Memory Map and register definition

This section includes the DCDC module memory map and detailed descriptions of all registers.

### 18.7.1 DCDC register descriptions

#### 18.7.1.1 DCDC memory map

DCDC base address: 4008\_0000h

| Offset | Register                               | Width<br>(In bits) | Access | Reset value |

### 18.7.1.3 DCDC Register 1 (REG1)

#### 18.7.1.3.1 Offset

| Register | Offset |
|----------|--------|
| REG1     | 4h     |

#### 18.7.1.3.2 Function

DCDC register 1

This register controls various high-level functions of the DCDC

| 11-9<br>LOOPCTRL_EN<br>_RCSCALE  | Enable RC Scale<br><br>This enables the analog circuit of the DCDC to respond faster under transient load conditions. A larger number for this bit field means a faster transient response.<br><br>In order for a faster transient response to be implemented, the offset comparators must be turned on (PWD_CMP_OFFSET = 0). This means about 80uA additional current consumption is needed.<br><br>It is recommended set LOOPCTRL_EN_RCSCALE > 0 if big steps of current loading is required in a real application. LOOPCTRL_EN_RCSCALE = 0x3 is recommended for CCM and LOOPCTRL_EN_RCSCALE = 0x4 for DCM.<br><br>However, the DCDC can be more stable with LOOPCTRL_EN_RCSCALE = 0, and the offset comparators are also powered down by default. This results in lower current consumption. If big steps of current loading is not required, it is recommended that the default value of 0 is used.<br><br>The value of this bit field doesn't match an RC constant directly. |
| 8-6<br>LOOPCTRL_DC<br>_FF        | Two's complement feed forward step in duty cycle in the switching DC-DC converter. Each time this field makes a transition from 0x0, the loop filter of the DC-DC converter is stepped once by a value proportional to the change. This can be used to force a certain control loop behavior, such as improving response under known heavy load transients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 19.2 Overview

The temperature sensor module implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

The module features alarm functions that can raise independent interrupt signals if the temperature is above two high-temperature thresholds and below a low temperature threshold. These temperature thresholds are programmable and designated as low, high and panic temperature. The panic threshold is a special programmable threshold in that if the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, the hardware will assume that software no longer has control over the thermal situation and will initiate a reset of the chip.

In order to avoid false panic temperature initiated resets, the panic alarm will not fire until the temperature panic condition has been met for four consecutive conversion cycles. A self-repeating mode can also be programmed which executes a temperature sensing operation based on a programmed delay.

Since the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the application's needs. For example, at start-up software can set the low temperature threshold to the minimum temperature code and the high temperature threshold to a maximum operating temperature for the system.

The system can then use this module to monitor the on-die temperature and take appropriate actions such as throttling back the core frequency when a the high temperature interrupt is set. After the high temperature interrupt is set then the system can program the low temperature threshold to a desired cool down temperature. The system would then switch to monitoring the low temperature alarm and wait for its interrupt to be set. With this scheme, after the low temperature interrupt is set then software could be assured that the temperature has cooled down to a safe level and the process could be repeated.

The high-level implementation of the temperature sensor is shown in the figure below.

**Figure 19-1. High Level Temp Sensor System Diagram**

As shown in the figure above, the temperature sensor uses and assumes that the bandgap reference, 480MHz PLL and 32KHz RTC modules are properly programmed and fully settled for correct operation.

### 19.3 Software Usage Guidelines

During normal system operation software can use the temperature sensor counter output (TEMP\_CNT) in conjunction with the fused temperature calibration data to determine the on-die operational temperature or to set an over-temperature interrupt alarm to within a couple of °C.

Based on calibration, two sets of temperature and counter values will be available via fuses on the device. These data points will correspond to the points ( $N_1$ ,  $T_1$ ) and ( $N_2$ ,  $T_2$ ) in the curve below.

**Figure 19-2. Temperature Measurement Cycle**

After a temperature measurement cycle, software should use the calibration points in conjunction with the temperature code value in the TEMPMON\_TEMPSENSE0[TEMP\_CNT] bitfield to calculate the temperature for the device using the following equation:

$$T_{\text{meas}} = T_2 - (N_{\text{meas}} - N_2) * ((T_2 - T_1) / (N_1 - N_2))$$

Likewise, to determine the alarm counter value to be written in the TEMPMON\_TEMPSENSE0 register for a temperature based interrupt, the above equation can be solved for the  $N_{\text{meas}}$  value that should be used based on the desired temperature trigger.

The temperature calibration point fuse values are available in the OCOTP\_ANA1 register. The temperature calibration values are fused individually for each part in the product testing process. The fields of this register are described in the following table.

**Table 19-2. OCOTP\_ANA1 Temperature Sensor Calibration Data**

| Bit Range | Bit Mask   | Name       | Description                                                                                              |
|-----------|------------|------------|----------------------------------------------------------------------------------------------------------|
| [31:20]   | FFF0_0000h | ROOM_COUNT | Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at room temperature (25.0 °C).         |
| [19:8]    | 000F_FF00h | HOT_COUNT  | Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at the hot temperature, i.e. HOT_TEMP. |
| [7:0]     | 0000_00FFh | HOT_TEMP   | The hot temperature test point. Each LSB equals 1 °C.                                                    |

The points on the calibration curve are as follows.

- $(N_1, T_1) = (\text{ROOM\_COUNT}, 25.0)$
- $(N_2, T_2) = (\text{HOT\_COUNT}, \text{HOT\_TEMP})$
- $(N_{\text{meas}}, T_{\text{meas}}) = (\text{TEMP\_CNT}, T_{\text{meas}})$

Substituting the fields from OCOTP\_ANA1 into the earlier equation results in the following:

$$T_{\text{meas}} = \text{HOT\_TEMP} - (N_{\text{meas}} - \text{HOT\_COUNT}) * ((\text{HOT\_TEMP} - 25.0) / (\text{ROOM\_COUNT} - \text{HOT\_COUNT}))$$

## 19.4 TEMPMON Memory Map/Register Definition

### TEMPMON memory map

#### NOTE

Tamper Detection feature and ZMK hardware programming are not applicable on this device.

### 20.2 SNVS introduction

SNVS is a companion module to the DCP module.

SNVS incorporates both security and non-security functionality. The SNVS non-security functionality is described in this document, but the SNVS security functionality is described only in the Security Reference Manual.

#### SNVS non-security functions:

- Realtime Counter (RTC) - a software accessible realtime counter
  - RTC can be set to the value in the SRTC

- Periodic Interrupt - a hardware-generated interrupt that occurs periodically at software-specified frequency
- General Purpose Register - a set of registers used to hold 128 bits of data specified by software
  - If the SNVS\_LP power input is connected to an uninterrupted power supply, e.g. a coin cell battery, the GPR value is maintained when main SoC is powered off
- Chip power-on/power-off - If the SNVS\_LP power input is connected to an uninterrupted power supply and the Power On button input signal is connected to a power button external to the chip, logic within SNVS\_LP can be used to wake the chip from a power down.

## 20.2.1 SNVS feature list

The following table summarizes the features of SNVS:

**Table 20-2. SNVS feature list**

| Feature                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Links for Further Information                           |

## 20.2.2 SNVS functional description

SNVS implements several non-security features that involve software interaction:

- reading or writing the Realtime Counter (RTC) (This is a non-privileged operation.) - software can also instruct SNVS to load the current SRTC value into the RTC
- reading or writing the General Purpose Register (GPR) (Note that there may be a significant delay when reading or writing registers in the LP section if the LP clock is different from the HP clock.)

The following sections describe in more detail the operation of SNVS.

## 20.3 SNVS Structure

SNVS is organized as two major sub-modules:

- Low-Power Section of SNVS (SNVS\_LP)

The SNVS\_LP section provides hardware that enables secure storage and protection of sensitive data. The SNVS module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general purpose security information.

The SNVS\_LP block implements the following functional units:

- Control and Status Registers
- General Purpose Registers

When the LP section is powered by a backup battery the state of these registers is maintained even when the main chip power is off. (see [SNVS power domains](#))

- High-Power Section of SNVS (SNVS\_HP)

The SNVS\_HP section contains all SNVS status and configuration registers. It implements all features that enable system communication and provisioning of the SNVS\_LP section.

The SNVS\_HP provides an interface between SNVS\_LP and the rest of the system.

The SNVS\_HP block implements the following functional units:

- IP Bus Interface
- SNVS\_LP Interface
- Zeroizable Master Key Programming Mechanism
- Real Time Counter with Alarm Control and Status Registers
- Control and status registers

SNVS\_HP is in the chip's power supply domain and thus receives power along with the rest of the chip.

The following figure illustrates the structure of SNVS.

### 20.3.1 SNVS power domains

In some versions of SNVS (including this version), the LP (Low Power) section is implemented in an independent power domain from the HP (High Power) section, and most other logic on the chip. Throughout the SNVS documentation whenever mention is made of "always-on" logic, this assumes a version of SNVS that implements an independent power domain for the LP section, and that the power for this section is supplied by an uninterrupted power supply. The purpose for the independent power domain is so that data can be retained and certain logic can remain functional even when the main chip logic is powered down. But this is possible only if the LP domain remains powered via an uninterrupted power supply when the main chip power domain is powered off. Usually this uninterrupted power supply would be a coin-cell battery, with possibly some power management logic to power the LP section from main power (and perhaps recharge the coin cell battery) when main power is on, and switch to coin-cell power when the main power is off. In versions of SNVS with an independent LP power domain the LP section can be electrically isolated from the rest of the chip logic to ensure that its logic does not get corrupted when the main chip is powered down. If the battery runs down or is removed, an LP POR will occur when the LP section next powers up. Note that some OEMs may choose to connect LP power to HP/main chip power and dispense with a coin cell battery. In that case the SNVS will operate the same as an SNVS without an independent LP power domain. No state will be retained in the LP section when the chip is powered down, and an LP POR will occur whenever there is an HP POR.

### 20.3.2 SNVS clock sources

The SNVS has the following clock sources:

- System peripheral clock input. This clock is used by the SNVS's internal logic, for example, the Security State Machine. This clock can be gated outside of the module when the SNVS indicates that it is not in use.
- HP RTC clock. This clock is used by SNVS\_HP real-time counter. This clock does not need to be synchronous with other clocks.

## 20.4 Runtime Procedures

SNVS implements a number of features that are intended to be accessed by software at runtime (as opposed to accessed at boot time). These features include:

- Real Time Clock (see [SNVS\\_HP Real Time Counter](#))
- Secure Real Time Clock (see [SNVS\\_LP Secure Real Time Counter \(SRTC\)](#))

- General Purpose Register (see [Using the General-Purpose Register](#))
- Monotonic Counter (see [Using the Monotonic Counter \(MC\)](#))

Procedures for using these features are described in the following sections.

## 20.4.1 Using SNVS Timer Facilities

SNVS incorporates timer facilities that can optionally generate an interrupt at a specified time. As described in the following sections, SNVS\_HP incorporates a Real Time Counter that is available for general use, and SNVS\_LP incorporates a Secure Real Time Counter intended for security applications.

### 20.4.1.1 SNVS\_HP Real Time Counter

SNVS\_HP implements a real time counter that can be read or written by any application; it has no privileged software access restrictions. When the chip is powered down the RTC is not active and it is reset at chip POR. The RTC can be used to generate a functional interrupt request either at a specific time, or at a specific frequency, or both. To generate an interrupt request at a specific time HPTA\_EN is set to 0, the desired time is written to HPTA\_MS and HPTA\_LS and then HPTA\_EN is set to 1. HPTA\_EN, HPTA\_MS and HPTA\_LS can be written by any software that has access to SNVS registers; there are no privileged access restrictions. The counter can be synchronized to the SNVS\_LP SRTC by writing to the HP\_TS bit of SNVS\_HP Control Register. This is particularly useful if the SNVS\_LP is powered from an uninterrupted power source (e.g. a coin cell battery) because the RTC can then be set from a chip-internal time source.

### 20.4.1.2 RTC/SRTC control bits setting

All SNVS registers are programmed from the register bus, consequently any software-initiated changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC/SRTC clock after they are programmed. To avoid IP clock and RTC/SRTC clock synchronization issues, the following values can be changed only when the corresponding function is disabled.

**Table 20-3. RTC/SRTC synchronized values list**

| Function             | Value/register                | Control bit setting                            |
|----------------------|-------------------------------|------------------------------------------------|
| HP section           |                               |                                                |
| HP Real Time Counter | HPRTCMR and HPRTCLR Registers | RTC_EN = 0 : HPRTCMR/HPRTCLR can be programmed |

*Table continues on the next page...*

**Table 20-3. RTC/SRTC synchronized values list (continued)**

| Function                    | Value/register                | Control bit setting                                                                                                   |
|-----------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------|
|                             |                               | RTC_EN = 1 : HPRTCMR/HPRTCLR <b>cannot</b> be programmed                                                              |
| HP Time Alarm               | HPTAMR and HPTALR Registers   | HPTA_EN = 0 : HPTAMR/HPTALR <b>can</b> be programmed<br>HPTA_EN = 1 : HPTAMR/HPTALR <b>cannot</b> be programmed       |
| LP section                  |                               |                                                                                                                       |
| LP Secure Real Time Counter | LPRTCMR and LPRTCLR Registers | SRTC_ENV = 0 : LPRTCMR/LPRTCLR <b>can</b> be programmed<br>SRTC_ENV = 1 : LPRTCMR/LPRTCLR <b>cannot</b> be programmed |
| LP Time Alarm               | LPTAR Register                | LPTA_EN = 0 : LPTAR <b>can</b> be programmed<br>LPTA_EN = 1 : LPTAR <b>cannot</b> be programmed                       |

Use the following steps to program synchronized values:

1. Check the enable bit value. If set, clear it.
2. Verify that the enable bit is cleared. There are two reasons to verify the enable bit's setting:
  - Enable bit clearing does not happen immediately; it takes three IP clock cycles and two RTC/SRTC clock cycles to change the enable bit's value.
  - If the enable bit is locked for programming, it cannot be cleared.
3. Program the desired value.
4. Set the enable bit; it takes three IP clock cycles and two RTC/SRTC clock cycles for the bit to set.

### NOTE

Incrementing the value programmed into RTC/SRTC registers by two compensates for the two RTC/SRTC clock cycle delay that is required to enable the counter.

#### 20.4.1.3 Reading RTC and SRTC values

Software should follow the following procedure to ensure that it has read correct data from the RTC (HPRTCMR and HPRTCLR) and SRTC (LPSRTCMR and LPSRTCLR) registers:

- Read the most-significant half and the least-significant half of the RTC/SRTC and then read both halves again. If the values read are the same both times, the value is correct.
- If the two consecutive pairs of reads yield different results, perform two more reads.

The worst case scenario may require three sessions of two consecutive pairs of reads.

There are several reasons that the values may be incorrectly read initially:

- Synchronization issues between the RTC/SRTC clock and the system clock
- Since the counter continues to increment, there may be a carry from the least-significant 32-bits to the most-significant bits in between reading the two halves of the counter

## **20.4.2 Using Other SNVS Registers**

The sections below describe how to use the General Purpose Register, Monotonic Counter. The sections below describe how to use the General Purpose Register and the Monotonic Counter.

### **20.4.2.1 Using the General-Purpose Register**

SNVS implements a 128-bit general-purpose register allows software to store a small amount of data. To maintain backward compatibility with versions of SNVS that implement only a 32-bit general purpose register, the most-significant word of the general purpose register is aliased to the legacy address. The data in the GPR will be retained during system power-down mode as long as the SNVS\_LP remains powered by an uninterrupted power source (e.g. coin cell battery).

## **20.5 Reset and Initialization of SNVS**

SNVS is implemented in two sections (HP and LP) that both must be initialized by software following POR. If the SNVS\_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS\_HP is powered-down, but SNVS\_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS\_LP keeps its registers' values and monitors the SNVS\_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS\_LP is disabled and both SNVS\_HP and SNVS\_LP are powered from the main SoC power.

Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS\_HP and SNVS\_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS\_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS\_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS\_LP is disabled and both SNVS\_HP and SNVS\_LP are powered from the main SoC power. Signals between the SNVS\_HP and SNVS\_LP sections are enabled and all SNVS functions are operational. The SNVS\_HP section is powered from the main SoC power, so it must be initialized whenever the device is powered on. If the SNVS\_LP section is powered from the main SoC power rather than from an uninterrupted power source, the SNVS\_LP section must also be initialized at SoC POR.

Initializing the LP section The following steps should be completed to properly initialize the SNVS LP section (required only on LP POR, i.e. when the battery is replaced):

1. Program the Power Glitch Detector and clear the power glitch record in the LP status register
2. If the SRTC will be used, set the Secure Real Time Clock
3. If the ZMK will be used, provision the ZMK
4. If the Monotonic Counter will be used, burn an additional Monotonic Counter Era bit in the fuse bank and reset the Monotonic Counter

Initializing the HP section The following steps should be completed to properly initialize the SNVS HP section (following successful completion of secure boot):

1. Perform normal or secure boot to put the SNVS into a functional state (Non-secure, Trusted, Secure)
2. At SNVS\_LP POR a power glitch violation will be asserted. Therefore at the first HP POR following an LP POR software should write the proper initialization value (41736166h) into the LPPGDR and clear the power glitch record in the LP status register. See [Power glitch detector \(PGD\)](#) for more details.
3. Transition SSM from trusted state to secure state (if not already done by HAB).
4. Enable security violations and interrupts in HPSVCR and HPSICR registers
5. Program SNVS general functions/configurations
6. Select Master Key (OTPMK, ZMK or XOR of the two. Default is OTPMK.)
7. Set lock bits. The ms bit of the SNVS\_HP lock register should be set before starting any functional operation. Setting this bit prevents further changes to the Master Key selection.

Figure 20-1. Relationship Between the Registers

## 20.5.1 Initialization Checklists

SNVS is implemented in two sections (HP and LP) that both must be initialized by software following POR. If the SNVS\_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS\_HP is powered-down, but SNVS\_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS\_LP keeps its registers' values and monitors the SNVS\_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS\_LP is disabled and both SNVS\_HP and SNVS\_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS\_HP and SNVS\_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS\_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS\_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS\_LP is disabled and both

SNVS\_HP and SNVS\_LP are powered from the main SoC power. Signals between the SNVS\_HP and SNVS\_LP sections are enabled and all SNVS functions are operational. The SNVS\_HP section is powered from the main SoC power, so it must be initialized whenever the device is powered on. If the SNVS\_LP section is powered from the main SoC power rather than from an uninterrupted power source, the SNVS\_LP section must also be initialized at SoC POR.

## 20.6 SNVS register descriptions

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and register table. The register table provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. Non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS\_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.

The LP register values are set only on LP POR and are unaffected by System (HP) POR. The HP registers are set only on System POR and are unaffected by LP POR.

The following table shows the SNVS main memory map.

### NOTE

For more information on security-related bitfields, see the Security Reference Manual for mxrt.

## 20.6.4 SNVS\_HP Control Register (HPCR)

### 20.6.4.1 Offset

| Register | Offset |
|----------|--------|
| HPCR     | 8h     |

### 20.6.4.2 Function

The SNVS\_HP Control Register contains various control bits of the HP section of SNVS. This is *not* a privileged write register.

### 20.6.4.3 Diagram

### 20.6.4.4 Fields

| Field | Function  |
|-------|-----------|
| 31-28 | Reserved. |

## 20.6.5 SNVS\_HP Status Register (HPSR)

### 20.6.5.1 Offset

| Register | Offset |
|----------|--------|
| HPSR     | 14h    |

### 20.6.5.2 Function

The HP Status Register reflects the internal state of the SNVS. This is *not* a privileged write register.

20.6.5.3 Diagram

1. The value of Low Power Disable is determined by the *no\_battery* input signal to SNVS.

20.6.5.4 Fields

| Field | Function                                                                   |

## 20.6.6 SNVS\_HP Real Time Counter MSB Register (HPRTCMR)

### 20.6.6.1 Offset

| Register | Offset |
|----------|--------|
| HPRTCMR  | 24h    |

### 20.6.6.2 Function

The SNVS\_HP Real Time Counter MSB register contains the 15 most-significant bits of the HP Real Time Counter. This is *not* a privileged write register.

20.6.6.3 Diagram

20.6.6.4 Fields

| Field       | Function                                                                                                                                              |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15<br>—  | Reserved                                                                                                                                              |
| 14-0<br>RTC | HP Real Time Counter<br>The most-significant 15 bits of the RTC. This register can be programmed only when RTC is not active (RTC_EN bit is not set). |

20.6.7 SNVS\_HP Real Time Counter LSB Register (HPRTCLR)

20.6.7.1 Offset

| Register | Offset |
|----------|--------|
| HPRTCLR  | 28h    |

20.6.7.2 Function

The SNVS\_HP Real Time Counter LSB register contains the 32 least-significant bits of the HP real time counter. This is *not* a privileged write register.

### 20.6.7.3 Diagram

### 20.6.7.4 Fields

| Field | Function                                                                                                        |
|-------|-----------------------------------------------------------------------------------------------------------------|
| 31-0  | HP Real Time Counter                                                                                            |
| RTC   | least-significant 32 bits. This register can be programmed only when RTC is not active (RTC_EN bit is not set). |

## 20.6.8 SNVS\_HP Time Alarm MSB Register (HPTAMR)

### 20.6.8.1 Offset

| Register | Offset |
|----------|--------|
| HPTAMR   | 2Ch    |

### 20.6.8.2 Function

The SNVS\_HP Time Alarm MSB register contains the most-significant bits of the SNVS\_HP Time Alarm value. This is *not* a privileged write register.

## 20.6.8.3 Diagram

## 20.6.8.4 Fields

| Field           | Function                                                                                                                                  |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15<br>—      | Reserved.                                                                                                                                 |
| 14-0<br>HPTA_MS | HP Time Alarm, most-significant 15 bits.<br>This register can be programmed only when HP time alarm is disabled (HPTA_EN bit is not set). |

## 20.6.9 SNVS\_HP Time Alarm LSB Register (HPTALR)

### 20.6.9.1 Offset

| Register | Offset |
|----------|--------|
| HPTALR   | 30h    |

### 20.6.9.2 Function

The SNVS\_HP Time Alarm LSB register contains the 32 least-significant bits of the SNVS\_HP Time Alarm value. This is *not* a privileged write register.

20.6.9.3 Diagram

20.6.9.4 Fields

| Field   | Function                                                                                      |
|---------|-----------------------------------------------------------------------------------------------|
| 31-0    | HP Time Alarm, 32 least-significant bits.                                                     |
| HPTA_LS | This register can be programmed only when HP time alarm is disabled (HPTA_EN bit is not set). |

20.6.10 SNVS\_LP Lock Register (LPLR)

20.6.10.1 Offset

20.6.10.2 Function

The SNVS\_LP Lock Register contains lock bits for the SNVS\_LP registers. This is a privileged write register.

## 20.6.11 SNVS\_LP Control Register (LPCR)

### 20.6.11.1 Offset

| Register | Offset |
|----------|--------|
| LPCR     | 38h    |

### 20.6.11.2 Function

The SNVS\_LP Control Register contains various control bits of the LP section of SNVS. This is a privileged write register.

20.6.12 SNVS\_LP Status Register (LPSR)

20.6.12.1 Offset

| Register | Offset |
|----------|--------|
| LPSR     | 4Ch    |

20.6.12.2 Function

The SNVS\_LP Status Register reflects the internal state and behavior of the SNVS\_LP. This is a privileged write register.

### 20.6.13 SNVS\_LP Secure Monotonic Counter MSB Register (LPSMCMR)

#### 20.6.13.1 Offset

| Register | Offset |
|----------|--------|
| LPSMCMR  | 5Ch    |

#### 20.6.13.2 Function

The SNVS\_LP Secure Monotonic Counter MSB Register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

|                     | monotonic counter remains monotonic (i.e. never decreasing). The action is to blow an additional MC_ERA_BITS fuse. Since the MC_ERA_BITS field forms the most-significant field of the monotonic counter, blowing an additional fuse guarantees that the new monotonic counter value is higher than any previous value. Typically this would be necessary only when the coin cell battery is changed. Since the Monotonic Counter is reset on an LP Software Reset, an excessive number of MC_ERA_BITS fuses may be consumed if LP Software Reset is used repeatedly. |

## 20.6.14 SNVS\_LP Secure Monotonic Counter LSB Register (LPSMCLR)

### 20.6.14.1 Offset

| Register | Offset |
|----------|--------|
| LPSMCLR  | 60h    |

### 20.6.14.2 Function

The SNVS\_LP Secure Monotonic Counter LSB Register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

20.6.15 SNVS\_LP General Purpose Register 0 (legacy alias) (LPGPR0\_legacy\_alias)

20.6.15.1 Offset

| Register            | Offset |
|---------------------|--------|
| LPGPR0_legacy_alias | 68h    |

### 20.6.15.2 Function

The SNVS\_LP General Purpose Register is a 128-bit read/write register located in SNVS\_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 4 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is aliased at its original offset of 68h. The GPR will be automatically zeroized when a tamper event occurs, unless GPR zeroization is disabled via the GPR\_Z\_DIS bit in the LP Control Register.

## 20.6.16.4 Fields

| Field | Function                                                             |
|-------|----------------------------------------------------------------------|
| 31-0  | General Purpose Register                                             |
| GPR   | When GPR_SL or GPR_HL bit is set, the register cannot be programmed. |

## 20.6.17 SNVS\_LP General Purpose Registers 0 .. 3 (LPGPR0 - LPGPR3)

### 20.6.17.1 Offset

For a = 0 to 3:

| Register | Offset          |
|----------|-----------------|
| LPGPRa   | 100h + (a × 4h) |

### 20.6.17.2 Function

The SNVS\_LP General Purpose Register is a 128-bit read/write register located in SNVS\_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 4 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is aliased at its original offset of 68h. The GPR will be automatically zeroized when a tamper event occurs, unless GPR zeroization is disabled via the GPR\_Z\_DIS bit in the LP Control Register.

### 20.6.17.3 Diagram

## 20.6.17.4 Fields

| Field | Function                                                             |
|-------|----------------------------------------------------------------------|
| 31-0  | General Purpose Register                                             |
| GPR   | When GPR_SL or GPR_HL bit is set, the register cannot be programmed. |

## 20.6.18 SNVS\_HP Version ID Register 1 (HPVIDR1)

### 20.6.18.1 Offset

| Register | Offset |
|----------|--------|
| HPVIDR1  | BF8h   |

### 20.6.18.2 Function

The SNVS\_HP Version ID Register 1 is a non-privileged read-only register that contains the current version of the SNVS. The version consists of a module ID, a major version number, and a minor version number.

### 20.6.18.3 Diagram

|       |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

### 21.2 SRC Overview

The System Reset Controller (SRC) controls the reset and boot operation of the SoC.

It is responsible for the generation of all reset signals and boot decoding.

The reset controller determines the source and the type of reset, such as POR, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is issued through SRC\_ONOFF signal and the entire chip is reset.

#### 21.2.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the resets sources and the nature of the reset
- Latches the SRC\_BOOT\_MODE pins and common configuration signals from the internal fuse

## 21.3 External Signals

The following table describes the external signals of SRC.

**Table 21-2. SRC External Signals**

| Signal         | Description                | Pad           | Mode             | Direction |
|----------------|----------------------------|---------------|------------------|-----------|
| SRC_BT_CFG0    | Boot configuration signals | GPIO_B0_04    | ALT6             | I         |
| SRC_BT_CFG1    |                            | GPIO_B0_05    | ALT6             | I         |
| SRC_BT_CFG2    |                            | GPIO_B0_06    | ALT6             | I         |
| SRC_BT_CFG3    |                            | GPIO_B0_07    | ALT6             | I         |
| SRC_BT_CFG4    |                            | GPIO_B0_08    | ALT6             | I         |
| SRC_BT_CFG5    |                            | GPIO_B0_09    | ALT6             | I         |
| SRC_BT_CFG6    |                            | GPIO_B0_10    | ALT6             | I         |
| SRC_BT_CFG7    |                            | GPIO_B0_11    | ALT6             | I         |
| SRC_BT_CFG8    |                            | GPIO_B0_12    | ALT6             | I         |
| SRC_BT_CFG9    |                            | GPIO_B0_13    | ALT6             | I         |
| SRC_BT_CFG10   |                            | GPIO_B0_14    | ALT6             | I         |
| SRC_BT_CFG11   |                            | GPIO_B0_15    | ALT6             | I         |
| SRC_POR_B      | Power on reset signal      | POR_B         | No Muxing (ALT0) | I         |
| SRC_ONOFF      | ON/OFF signal              | ONOFF         | No Muxing (ALT0) | I         |
| SRC_BOOT_MODE0 | Boot mode signals          | GPIO_AD_B0_04 | ALT0             | I         |
| SRC_BOOT_MODE1 |                            | GPIO_AD_B0_05 | ALT0             | I         |

## 21.4 Clocks

The table found here describes the clock sources for SRC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 21-3. SRC Clocks**

| Clock name | Clock Root   | Description             |
|------------|--------------|-------------------------|
| ipg_clk    | ipg_clk_root | Peripheral clock        |
| ipg_clk_s  | ipg_clk_root | Peripheral access clock |

## 21.5 Top-level resets, power-up sequence and external supply integration

Information found here defines chip resets, power-up sequence, and external supply integration.

### 21.5.1 Reset and Power-up Flow

The chip presumes the following reset and power-up flow:

Note: PMIC\_ON\_REQ acts as an active high-signal  
 1 or high Z = ON  
 0 = OFF

**Figure 21-1. Chip reset scheme under PMU control**

**Figure 21-2. Chip reset scheme under external PMIC control**

Figure 21-3. Chip on/off state flow diagram

## 21.5.2 Finite-State Machine (FSM)

Figure 21-4. FSM

## 21.5.3 Power mode transitions

Table 21-4. Power mode transitions

| Power mode                  | Configuration with external PMIC                                                                                                                                                         | Configuration with internal PMIC                                                                                                                                                                                                                       |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ON, first time              | <ol style="list-style-type: none"> <li>1. Either coin cell or SoC power supply is connected to SNVS.</li> <li>2. When button is pressed, PMIC powers on.</li> </ol>                      | <ol style="list-style-type: none"> <li>1. Either coin cell or SoC power supply is connected to SNVS, PMIC_ON_REQ goes to '1'.</li> <li>2. Drive DCDC_PSWITCH to high, 1 ms after DCDC_IN is powered.</li> <li>3. DCDC regulator is enabled.</li> </ol> |
| Normal ON to OFF, by button | <ol style="list-style-type: none"> <li>1. Button is pressed for a short duration on the external PMIC.</li> <li>2. Interrupt request (irq) is sent to SoC from external PMIC.</li> </ol> | <ol style="list-style-type: none"> <li>1. SoC button is pressed for a short duration.</li> <li>2. Interrupt request (irq) is sent to SoC from FSM.</li> <li>3. Alarm timer is set up by software routine and started.</li> </ol>                       |

Table continues on the next page...

**Table 21-4. Power mode transitions (continued)**

| Power mode                     | Configuration with external PMIC                                                                                                                                                                                                                                                          | Configuration with internal PMIC                                                                                                                                                                                                                                                    |

## 21.6 Power-On Reset and power sequencing

This module generates an internal POR\_B signal that is logically AND'ed with any externally applied SRC\_POR\_B signal. The internal POR\_B signal will be held low until all of the following conditions are met:

- 4ms after the external power supply VDDHIGH\_IN is valid
- 1ms after the VDD\_SOC\_IN supply is valid

The 4ms and 1ms delays are derived from counting the 32 kHz RTC clock cycles; the accuracy depends on the accuracy of the RTC. When the RTC crystal is either absent or in the process of powering up, an internal ring oscillator will be the source of RTC, which is not as accurate as the crystal.

### 21.6.1 External POR using SRC\_POR\_B

If the external SRC\_POR\_B signal is used to control the processor POR, SRC\_POR\_B must remain low (asserted) until the VDD\_SOC supplies are stable.

## 21.6.2 Internal POR

If the external SRC\_POR\_B signal is not used (always held high or left unconnected), the processor defaults to the internal POR function (PMU controls generation of the POR based on the power supplies).

## 21.7 Functional Description

### 21.7.1 Reset Control

This section details the reset control of this device.

#### 21.7.1.1 Reset inputs and outputs

The reset control logic receives reset requests from all potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block, whereas the resets requiring qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:

**Figure 21-5. SRC inputs and outputs**

The reset types and modules they affect are shown in [Table 21-5](#). As there is no chip POR, the POR\_B is used to reset the entire chip including test logic and JTAG modules.

### NOTE

All resets are expected to be active low except jtag\_sw\_rst.

**Table 21-5. SRC reset functionality**

| SoC Modules                       | POR | COLD |
|-----------------------------------|-----|------|
| System modules (PLLs, fuses, etc) | yes | yes  |
| Functional modules                | yes | yes  |
| Arm                               | yes | yes  |
| IOMUXC                            | yes | no   |
| Arm debug                         | yes | no   |
| SJC                               | yes | no   |

The reset priorities are POR (strongest) and COLD (weakest). If a stronger reset is asserted during the sequence of a weaker reset, then the weaker sequence will be overridden, and the stronger reset sequence will commence. There is no priority within a reset type (POR, etc). If a reset is asserted during the reset sequence of the same type, the reset sequence will be interrupted and restarted.

The following lists the functionality of each of these reset outputs:

- `system_early_rst_b` - Resets the system modules that need to start first as CCM, OCOTP\_CTRL, FUSEBOX, etc.
- `system_rst_b` - Resets functional modules
- `arm_rst_b` - Resets Arm module (on regular system reset)
- `arm_por_rst_b` - Resets Arm POR input
- `arm_dbg_rst_b` - Reset debug logic of Arm
- `test_logic_rst_b` - Reset test logic (IOMUXC, DAP)
- `sjc_por_rst_b` - Reset to SJC

### NOTE

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or by negation of the reset source (if it came from an external source to the chip). In the latter case, the reset source is assumed to be held for at least 2 XTALI clocks so it can be sampled by SRC.

## 21.7.1.2 Reset Handling

### 21.7.1.2.1 POR (SRC\_POR\_B)

`SRC_POR_B` is an external reset signal. When the chip is powered up, the reset signal is passed through the `POR_B` pin indicating power-up sequence. The SRC resets the entire chip including the JTAG (SJC) module. All SRC registers will be reset during the POR sequence.

As soon as `SRC_POR_B` occurs, all resets are asserted and the entire chip is reset by SRC. The `SRC_POR_B` is stretched for 2 XTALI cycles and the stretching sequence takes place after 2 XTALI clocks of `POR_B` pin deassertion.

The `sjc_por_rst_b` signal is deasserted together with `SRC_POR_B` signal. The output is also deasserted after the stretching of `SRC_POR_B` has deasserted.

After the above resets deassert, `system_early_rst_b` reset is deasserted after 2 XTALI clocks. The `system_early_rst_b` is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

When the system root clocks are ready, the CCM will assert `system_clk_ready` signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation.

SRC then enables `OCOTP_CTRL` and fusebox clocks, so that fuses can be loaded to `OCOTP_CTRL`.

- SRC will prepare the boot information
- After 8 ipg cycles, resets to all modules will be de-asserted
- After 8 ipg cycles, system clocks will be enabled (`en_system_clk`).

### **21.7.1.2.2 COLD RESET**

The sequence is similar to `SRC_POR_B` except the memory repair operation is not performed.

After the reset source deasserts, `system_early_rst_b` reset is deasserted after at least 2 XTALI clocks. The `system_early_rst_b` is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

After the system root clocks are ready, the CCM will assert `system_clk_ready` signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation. See CCM for more information.

After `system_clk_ready` arrives at the SRC, it will enable `OCOTP_CTRL` and fusebox clocks, so that fuses can be loaded to `OCOTP_CTRL`. `OCOTP_CTRL` will notify with `iim_ready_flag` when the fusebox loading finishes.

- SRC will prepare the boot information
- After 8 ipg cycles resets to all modules will be deasserted
- After 8 ipg cycles, system clocks will be enabled (`en_system_clk`).

## **21.7.2 Parallel Reset Requests**

SRC will follow the following rules in the case of parallel reset requests:

1. The order of strength of resets is POR - strongest, COLD - weakest
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. The following cases fall into this category:
  - POR reset request in the middle of cold reset process - the cold will be stopped and the POR sequence will start.

3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:
  - COLD reset requests in the middle of POR reset process - the POR process will continue without interference.
4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:
  - POR reset request in the middle of POR reset process - the POR process will start over.
  - COLD reset request in the middle of COLD reset process - the COLD process will start over.

## 21.7.3 Boot Mode Control

### 21.7.3.1 BOOT\_MODE Pin Latching

The exact boot sequence is controlled by the values of the BOOT\_MODE pins on this device.

The value of the BOOT\_MODE pins will be latched after the OCOTP\_CTRL asserts the fuse read completion flag. After latching, the values of the BOOT\_MODE pins are used to determine the booting options of the core as described in the SRC\_SBMRx registers.

The boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio\_bt\_sel e-fuse defines the source to be used to derive the boot information. When gpio\_bt\_sel is set, e-fuses are used. When cleared, GPIO signals are used.

The boot information is provided in SRC\_SBMR1 register. The figure below shows the selection of boot mode information.

**Figure 21-6. Boot mode information**

## 21.8 SRC Memory Map/Register Definition

### SRC memory map

| Absolute address (hex) | Register name                             | Width (in bits) | Access | Reset value | Section/ page               |

## 21.8.1 SRC Control Register (SRC\_SCR)

The Reset control register (SCR), contains bits that control operation of the reset controller.

Address: 400F\_8000h base + 0h offset = 400F\_8000h

## SRC\_SCR field descriptions

| Field                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 10–7<br>mask_wdog_rst   | Mask wdog_rst_b source. If these 4 bits are coded from A to 5 then, the wdog_rst_b input to SRC will be masked and the wdog_rst_b will not create a reset to the chip.<br><br><b>NOTE:</b> During the time the WDOG event is masked using SRC logic, it is likely that the WDOG Reset Status Register (WRSR) bit 1 (which indicates a WDOG timeout event) will get asserted. software / OS developer must prepare for this case. Re-enabling the WDOG is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module.<br><br>(Hardware reset is the only way to cause the de-assertion of that bit). |

**21.8.2 SRC Boot Mode Register 1 (SRC\_SBMR1)**

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip. The reset value is configuration dependent (depending on boot/fuses/IO pads).

If SRC\_GPR10[28] bit is set, this bit instructs the ROM code to use the SRC\_GPR9 register as if it is SBMR1. This allows software to override the fuse bits and boot from an alternate boot source.

### 21.8.3 SRC Reset Status Register (SRC\_SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp\_reset\_b. This is a read-write register.

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3<br>ipp_user_reset_b   | Indicates whether the reset was the result of the ipp_user_reset_b qualified reset.<br>0 Reset is not a result of the ipp_user_reset_b qualified as COLD reset event.<br>1 Reset is a result of the ipp_user_reset_b qualified as COLD reset event.                                                                                                                                                                                 |
| 2<br>csu_reset_b        | Indicates whether the reset was the result of the csu_reset_b input.<br>0 Reset is not a result of the csu_reset_b event.<br>1 Reset is a result of the csu_reset_b event.                                                                                                                                                                                                                                                          |
| 1<br>lockup_sysresetreq | Indicates a reset has been caused by CPU lockup or software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register of the Arm core. SW needs to write a value to SRC_GPR5 before writing the SYSRESETREQ bit and use the SRC_GPR5 value to distinguish if the reset is caused by SYSRESETREQ or CPU lockup.<br>0 Reset is not a result of the mentioned case.<br>1 Reset is a result of the mentioned case. |
| 0<br>ipp_reset_b        | Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence)<br>0 Reset is not a result of ipp_reset_b pin.<br>1 Reset is a result of ipp_reset_b pin.                                                                                                                                                                                                                                                             |

### 21.8.4 SRC Boot Mode Register 2 (SRC\_SBMR2)

The Boot Mode register (SBMR), contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depends on the values of pins/fuses during reset sequence, hence the question mark on their default value.

Address: 400F\_8000h base + 1Ch offset = 400F\_801Ch

| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25        | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-------|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|----|----|
| R     | 0  |    |    |    |    |    | BMOD[1:0] |    | 0  |    |    |    |    |    |    |    |
| W     |    |    |    |    |    |    |           |    |    |    |    |    |    |    |    |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5           | 4 | 3 | 2 | 1 | 0               |  |
|-------|----|----|----|----|----|----|---|---|---|---|-------------|---|---|---|---|-----------------|--|
| R     | 0  |    |    |    |    |    |   |   |   |   | BT_FUSE_SEL |   |   | 0 | 0 | SEC_CONFIG[1:0] |  |
| W     |    |    |    |    |    |    |   |   |   |   |             |   |   |   |   |                 |  |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0           | 0 | 0 | 0 | 0 | 0               |  |

## SRC\_SBMR2 field descriptions

| Field              | Description                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–26<br>Reserved  | This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                   |
| 25–24<br>BMOD[1:0] | BMOD[1:0] shows the latched state of the BOOT_MODE1 and BOOT_MODE0 signals on the rising edge of POR_B. See the Boot mode pin settings section of System Boot.                                                                                                                 |
| 23–5<br>Reserved   | This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                   |
| 4<br>BT_FUSE_SEL   | BT_FUSE_SEL (connected to gpio bt_fuse_sel) shows the state of the BT_FUSE_SEL fuse. See Fusemap for additional information on this fuse.                                                                                                                                      |
| 3<br>Reserved      | This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                   |
| 2<br>Reserved      | This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                   |
| SEC_CONFIG[1:0]    | SECONFIG[1] shows the state of the SECONFIG[1] fuse. See Fusemap for additional information on this fuse. SECONFIG[0] shows the state of the SECONFIG[0] fuse. This fuse is shown as reserved in Fusemap (address 0x440[1]) because it does not have a user-relevant function. |

## 21.8.5 SRC General Purpose Register 1 (SRC\_GPR1)

## NOTE

This register is used by the ROM code and should not be used by application software.

Address: 400F\_8000h base + 20h offset = 400F\_8020h

|       |                   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|-------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     |                   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     | PERSISTENT_ENTRY0 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |   |

## SRC\_GPR1 field descriptions

| Field             | Description                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| PERSISTENT_ENTRY0 | Holds entry function for core0 for waking-up from low power mode. The SRC ensures that the register value will persist across system resets. |

## 21.8.6 SRC General Purpose Register 2 (SRC\_GPR2)

### NOTE

This register is used by the ROM code and should not be used by application software.

Address: 400F\_8000h base + 24h offset = 400F\_8024h

|       |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31              | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | PERSISTENT_ARG0 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### SRC\_GPR2 field descriptions

| Field           | Description                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| PERSISTENT_ARG0 | Holds argument of entry function for core0 for waking-up from low power mode. The SRC ensures that the register value will persist across system resets. |

## 21.8.7 SRC General Purpose Register 3 (SRC\_GPR3)

### NOTE

This register is used by the ROM code and should not be used by application software.

Address: 400F\_8000h base + 28h offset = 400F\_8028h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | -  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### SRC\_GPR3 field descriptions

| Field | Description                                                       |
|-------|-------------------------------------------------------------------|
| -     | Read/write general purpose bits used to store an arbitrary value. |

## 21.8.8 SRC General Purpose Register 4 (SRC\_GPR4)

### NOTE

This register is used by the ROM code and should not be used by application software.

Address: 400F\_8000h base + 2Ch offset = 400F\_802Ch

### SRC\_GPR4 field descriptions

| Field | Description                                                       |
|-------|-------------------------------------------------------------------|
| -     | Read/write general purpose bits used to store an arbitrary value. |

## 21.8.9 SRC General Purpose Register 5 (SRC\_GPR5)

### NOTE

SW needs to write a value to SRC\_GPR5 before writing the SYSRESETREQ bit and use the SRC\_GPR5 value to distinguish if the reset is caused by SYSRESETREQ or CPU lockup

Address: 400F\_8000h base + 30h offset = 400F\_8030h

# Chapter 22

## Fusemap

### 22.1 Boot Fusemap

This section describes the various modes and the selection of the required boot devices.

A separate map is given for each and every boot device. The device select is specified by the BOOT\_CFG1[7:4] fuses.

**Table 22-1. Boot device select**

| Boot Device            | BOOT_CFG1[7] | BOOT_CFG1[6] | BOOT_CFG1[5] | BOOT_CFG1[4] |
|------------------------|--------------|--------------|--------------|--------------|
| FlexSPI1 (Serial NOR)  | 0            | 0            | 0            | 0            |
| SD                     | 0            | 1            | x            | x            |
| MMC/eMMC               | 1            | 0            | x            | x            |
| SEMC (NAND)            | 0            | 0            | 1            | x            |
| SEMC (NOR)             | 0            | 0            | 0            | 1            |
| FlexSPI1 (Serial NAND) | 1            | 1            | x            | x            |

#### NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers **must not** attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'.

Security-related fuses are described in the Security Reference Manual (SRM) for this device.

**Table 22-2. FlexSPI (Serial NOR) boot fusemap**

| Address                   | 7 | 6 | 5 | 4 | 3                       | 2 | 1                            | 0        |
|---------------------------|---|---|---|---|-------------------------|---|------------------------------|----------|
| 0x450[7:0]<br>(BOOT_CFG1) | 0 | 0 | 0 | 0 | HOLD TIME<br>00 - 500us |   | EncryptedXIP<br>0 - Disabled | Reserved |

#### NOTE

Security-related fuses are shown as reserved here. For details, refer to the Security Reference Manual.

### 23.2 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

## 23.2.1 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 1.5 kbit of eFuse OTP.
- Loading and housing of fuse content into shadow registers
- Memory-mapped (restricted) access to shadow registers
- Provides program-protect and read-protect eFuse
- Provides override and read protection of shadow register

## 23.3 Clocks

The table found here describes the clock sources for OCOTP. Please see the chip-specific clocking section for clock setting, configuration and gating information.

**Table 23-2. OCOTP Clocks**

| Clock name | Clock Root   | Description             |
|------------|--------------|-------------------------|
| ipg_clk    | ipg_clk_root | Peripheral clock        |
| ipg_clk_s  | ipg_clk_root | Peripheral access clock |

## 23.4 Top-Level Symbol and Functional Overview

The figure below shows the OCOTP system level diagram.

Figure 23-1. OCOTP System Level Diagram

### 23.4.1 Operation

The IP bus interface of the OCOTP has the following functions.

- Configure control registers for programming and reading all the fuse words
- Override and read shadow registers

OCOTP configuration for programs and reads are performed on 32-bit words for software (SW) convenience. For writes, the 32-bit word reflects the "write-mask." Bit fields with 0 will not be programmed and bit fields with 1 will be programmed. OCOTP will program bit field with 1 in the fuse word one bit by one bit. For reads, OCOTP will read 4 times to get 4 bytes in the fuse word in order.

### 23.4.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers without having to reset the device. To force a reload, complete the following steps:

1. Set the HW\_OCOTP\_TIMING[STROBE\_READ] field value appropriately.
2. Set the HW\_OCOTP\_TIMING[RELAX] field value appropriately.
3. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a new access can be requested.
4. Set the HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] bit. OCOTP will read all the fuses one by one and put it into corresponding shadow register.
5. Wait for HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] bit after the successful completion of the operation.

### 23.4.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the IPS bus. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write, read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from the fusebox, complete the following steps:

1. Program HW\_OCOTP\_TIMING[STROBE\_READ] and HW\_OCOTP\_TIMING[RELAX] fields with timing values to match the current frequency of the ipg\_clk. OTP read will work at maximum bus frequencies as long as the HW\_OCOTP\_TIMING parameters are set correctly.
2. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested fuse address to HW\_OCOTP\_CTRL[ADDR].

4. Set HW\_OCOTP\_READ\_CTRL[READ\_FUSE] to 1. OCOTP will auto read the fuse word according to HW\_OCOTP\_CTRL[ADDR] in fusebox. Then put read value into HW\_OCOTP\_READ\_FUSE\_DATA
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW\_OCOTP\_CTRL[BUSY]. In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW\_OCOTP\_READ\_FUSE\_DATA to get fuse word value. HW\_OCOTP\_READ\_FUSE\_DATA will be 0xBADABADA when HW\_OCOTP\_CTRL[ERROR] is set.

### 23.4.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The HW\_OCOTP\_LOCKn register also has no overwrite or fuse lock bits, but it is always read-only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank complete the following steps:

1. Program the following fields with timing values to match the frequency of ipg\_clk:
  - HW\_OCOTP\_TIMING[STROBE\_PROG]
  - HW\_OCOTP\_TIMING[RELAX]
 OTP writes will work at maximum bus frequencies as long as the HW\_OCOTP\_TIMING parameters are set correctly.
2. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested address to HW\_OCOTP\_CTRL[ADDR] and program the unlock code into HW\_OCOTP\_CTRL[WR\_UNLOCK]. The unlock code must be programmed for each write access. The unlock code is documented in the register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the HW\_OCOTP\_DATA register. This will automatically set HW\_OCOTP\_CTRL[BUSY] and clear HW\_OCOTP\_CTRL[WR\_UNLOCK]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW\_OCOTP\_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to

HW\_OCOTP\_CTRL[ADDR] will not affect an active write operation. During the write operation, HW\_OCOTP\_DATA cannot be modified.

5. Once complete, the controller will clear HW\_OCOTP\_CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of HW\_OCOTP\_CTRL[BUSY]. In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. The write latency is based on the number of "1" bits being written. For example : to program half the fuse bits in one 32-bt word needs 10 us x 16.

HW\_OCOTP\_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] is set). In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to a fuse word which has been read locked.

### 23.4.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations (direct reads, shadow reloads, or other writes) following a write must wait at least 2  $\mu$ s after the clearing of HW\_OCOTP\_CTRL[BUSY] following the write. The delay guarantees programming voltages on-chip reach a steady state when exiting a write sequence.

A recommended software sequence to meet the postamble requirements is as follows:

1. Issue the write and poll for HW\_OCOTP\_CTRL[BUSY].
2. Once HW\_OCOTP\_CTRL[BUSY] is clear, wait 2  $\mu$ s.
3. Perform the next OTP operation.

### 23.4.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the following figure. The registers are grouped by lock region. Their names correspond to the fusemap names.

Figure 23-2. OTP Memory Footprint

### 23.4.3 OTP Read/Write Timing Parameters

The timing fields contained in the HW\_OCOTP\_TIMING register that specify counter limit values, which are used to time how long the state machine remains in the various states, as well as specify the STROBE signal timing.

The timing parameters are specified in ipg\_clk cycles. Since the ipg\_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

| Register Field        | Description                                                                            |
|-----------------------|----------------------------------------------------------------------------------------|
| HW_OCOTP_TIMING[WAIT] | "WAIT" specifies time interval between auto read and write access in one time program. |

Table continues on the next page...

|                              |                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | $t_{SP\_RD} = (WAIT+1)/ipg\_clk\_freq$ , should be $\geq 150$ ns.                                                                                                                                                                                                                                                                          |

### 23.4.4 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time HW\_OCOTP\_CTRL[BUSY] is set.

## 23.5 Fuse Map

See the Fusemap chapter of this reference manual for more information.

## 23.6 OCOTP Memory Map/Register Definition

The OCOTP Memory Map/Register Definition can be found here.

**NOTE**

Writing or reading unimplemented register address in OCOTP Controller will not send error and read data will be 0.

## 23.6.1.2 OTP Controller Control and Status Register (HW\_OCOTP\_CTRL)

### 23.6.1.2.1 Offset

| Register          | Offset | Description                                                                          |
|-------------------|--------|--------------------------------------------------------------------------------------|
| HW_OCOTP_CTRL     | 0h     | OTP Controller Control and Status Register                                           |
| HW_OCOTP_CTRL_SET | 4h     | Writing a 1 to a bit in this register sets the corresponding bit in HW_OCOTP_CTRL    |
| HW_OCOTP_CTRL_CLR | 8h     | Writing a 1 to a bit in this register clears the corresponding bit in HW_OCOTP_CTRL  |
| HW_OCOTP_CTRL_TOG | Ch     | Writing a 1 to a bit in this register toggles the corresponding bit in HW_OCOTP_CTRL |

### 23.6.1.2.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable

ROM). The control fields such as WR\_UNLOCK, ADDR, BUSY and ERROR may be used in conjunction with the HW\_OCOTP\_DATA register to perform write operations. Read operations to the On-Chip OTP involve ADDR, BUSY and ERROR bit fields and the HW\_OCOTP\_READ\_CTRL register. The read value is saved in HW\_OCOTP\_READ\_FUSE\_DATA register.

### 23.6.1.3 OTP Controller Timing Register (HW\_OCOTP\_TIMING)

#### 23.6.1.3.1 Offset

| Register        | Offset |
|-----------------|--------|
| HW_OCOTP_TIMING | 10h    |

#### 23.6.1.3.2 Function

This register specifies timing parameters for programming and reading the OTP fuse array.

See [OTP Read/Write Timing Parameters](#) for more details.

### 23.6.1.3.3 Diagram

### 23.6.1.3.4 Fields

| Field                | Function                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-28<br>—           | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 27-22<br>WAIT        | Wait Interval<br>This count value specifies the time interval between auto read and write access in one time program to the OTP. It is given in number of ipg_clk periods.<br><br>The OTP controller performs a read action before each program action. This is the "auto" read. The purpose of the auto read is to avoid multiple programming to the same bits. |
| 21-16<br>STROBE_READ | Read Strobe Period<br>This count value controls the strobe period in read OTP (Trd). $Trd = ((STROBE\_READ + 1) - 2 * (RELAX\_READ + 1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.                                                                                                                                                           |
| 15-12<br>RELAX       | Relax Count Value<br>This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.                                                                                                                                                                                          |
| 11-0<br>STROBE_PROG  | Write Strobe Period<br>This count value controls the strobe period in one time to write OTP (Tpgm). $Tpgm = ((STROBE\_PROG + 1) - 2 * (RELAX\_PROG + 1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.                                                                                                                                           |

### 23.6.1.4 OTP Controller Write Data Register (HW\_OCOTP\_DATA)

#### 23.6.1.4.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_DATA | 20h    |

### 23.6.1.4.2 Function

This register is used in conjunction with the HW\_OCOTP\_CTRL register to perform one-time writes to the OTP. See the [Fuse and Shadow Register Writes](#) section for operating details.

### 23.6.1.4.3 Diagram

### 23.6.1.4.4 Fields

| Field | Function                                                                                                                |
|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31-0  | Data                                                                                                                    |
| DATA  | Used to initiate a write to OTP. See the <a href="#">Fuse and Shadow Register Writes</a> section for operating details. |

## 23.6.1.5 OTP Controller Write Data Register (HW\_OCOTP\_READ\_CTRL)

### 23.6.1.5.1 Offset

| Register           | Offset |
|--------------------|--------|
| HW_OCOTP_READ_CTRL | 30h    |

### 23.6.1.5.2 Function

This register is used in conjunction with the HW\_OCOTP\_CTRL register to perform reads of the OTP. See the [Fuse and Shadow Register Read](#) section for operating details.

### 23.6.1.5.3 Diagram

### 23.6.1.5.4 Fields

| Field     | Function                                                                                                               |
|-----------|------------------------------------------------------------------------------------------------------------------------|
| 31-1      | Reserved                                                                                                               |
| 0         | Read Fuse                                                                                                              |
| READ_FUSE | Used to initiate a read from OTP. See the <a href="#">Fuse and Shadow Register Read</a> section for operating details. |

### 23.6.1.6 OTP Controller Read Data Register (HW\_OCOTP\_READ\_FUSE\_DATA)

#### 23.6.1.6.1 Offset

| Register                | Offset |
|-------------------------|--------|
| HW_OCOTP_READ_FUSE_DATA | 40h    |

#### 23.6.1.6.2 Function

The data read from OTP

### 23.6.1.6.3 Diagram

### 23.6.1.6.4 Fields

| Field | Function                                                                                                     |
|-------|--------------------------------------------------------------------------------------------------------------|
| 31-0  | Data                                                                                                         |
| DATA  | The data read from OTP. See the <a href="#">Fuse and Shadow Register Read</a> section for operating details. |

## 23.6.1.7 Software Controllable Signals Register (HW\_OCOTP\_SCS)

### 23.6.1.7.1 Offset

| Register         | Offset | Description                                                                         |
|------------------|--------|-------------------------------------------------------------------------------------|
| HW_OCOTP_SCS     | 60h    | Software Controllable Signals Register                                              |
| HW_OCOTP_SCS_SET | 64h    | Writing a 1 to a bit in this register sets the corresponding bit in HW_OCOTP_SCS    |
| HW_OCOTP_SCS_CLR | 68h    | Writing a 1 to a bit in this register clears the corresponding bit in HW_OCOTP_SCS  |
| HW_OCOTP_SCS_TOG | 6Ch    | Writing a 1 to a bit in this register toggles the corresponding bit in HW_OCOTP_SCS |

### 23.6.1.7.2 Function

This register holds volatile configuration values that can be set and locked by software.

### 23.6.1.7.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>LOCK    | Lock<br>This bitfield locks the bits in this register.<br>0b - Bits in this register are unlocked.<br>1b - Bits in this register are locked. When set, all of the bits in this register are locked and can not be changed through SW programming. After this bit is set, it can only be cleared by a POR.                                                                                                                                                                                                                                                                                                                    |
| 30-1<br>SPARE | Spare<br>Unallocated read/write bits for implementation specific software use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0<br>HAB_JDE  | HAB JTAG Debug Enable<br>This bit can be used by the High Assurance Boot (HAB) portion of the Boot ROM to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB will lock the register before passing control to the application whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it cannot be disabled unless the system is reset by POR.<br>0b - JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms).<br>1b - JTAG debugging is enabled by the HAB (though this signal may be gated off). |

### 23.6.1.8 OTP Controller Version Register (HW\_OCOTP\_VERSION)

#### 23.6.1.8.1 Offset

| Register         | Offset |
|------------------|--------|
| HW_OCOTP_VERSION | 90h    |

### 23.6.1.8.2 Function

This register indicates the RTL version in use.

### 23.6.1.8.4 Fields

| Field          | Function                                                                            |
|----------------|-------------------------------------------------------------------------------------|
| 31-24<br>MAJOR | Major RTL Version<br>Read-only value reflecting the MAJOR field of the RTL version. |
| 23-16<br>MINOR | Minor RTL Version<br>Read-only value reflecting the MINOR field of the RTL version. |
| 15-0<br>STEP   | RTL Version Steping<br>Read-only value reflecting the stepping of the RTL version.  |

## 23.6.1.9 OTP Controller Timing Register 2 (HW\_OCOTP\_TIMING2)

### 23.6.1.9.1 Offset

| Register         | Offset |
|------------------|--------|
| HW_OCOTP_TIMING2 | 100h   |

### 23.6.1.9.2 Function

This register specifies timing parameters for programming and reading the OCOTP fuse array.

See [OTP Read/Write Timing Parameters](#) for more details.

### 23.6.1.9.3 Diagram

### 23.6.1.9.4 Fields

| Field               | Function                                                                                                                                                                                                  |

| 21-16<br>RELAX_READ | Relax Read count value<br>This count value specifies the strobe period in one time read OTP. $Trd = ((STROBE\_READ+1)-2*(RELAX\_READ+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.    |
| 15-12<br>—          | Reserved                                                                                                                                                                                                  |
| 11-0<br>RELAX_PROG  | Relax Prog. count value<br>This count value specifies the strobe period in one time write OTP. $Tpgm = ((STROBE\_PROG+1)-2*(RELAX\_PROG+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods. |

### 23.6.1.10 Value of OTP Bank0 Word0 (Lock controls) (HW\_OCOTP\_LOCK)

#### 23.6.1.10.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_LOCK | 400h   |

23.6.1.10.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 0 (ADDR = 0x00).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

23.6.1.10.3 Diagram

23.6.1.10.4 Fields

| Field | Function                                                                                                                                                                                                           |

Table continues on the next page...

| Field    | Function |
|----------|----------|
| 1-0<br>— | Reserved |

### 23.6.1.11 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG0)

#### 23.6.1.11.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG0 | 410h   |

#### 23.6.1.11.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 1 (ADDR = 0x01).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

#### 23.6.1.11.3 Diagram

#### 23.6.1.11.4 Fields

| Field        | Function                                                                                                                                                       |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>BITS | BITS<br>This register reflects the value of OTP Bank 0, Word 1 (ADDR = 0x01). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

### 23.6.1.12 Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG1)

#### 23.6.1.12.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG1 | 420h   |

#### 23.6.1.12.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 2 (ADDR = 0x02).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

#### 23.6.1.12.3 Diagram

#### 23.6.1.12.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 2 (ADDR = 0x02). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

### 23.6.1.13 Value of OTP Bank0 Word3 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG2)

#### 23.6.1.13.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG2 | 430h   |

#### 23.6.1.13.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 3 (ADDR = 0x03).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

#### 23.6.1.13.3 Diagram

#### 23.6.1.13.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 3 (ADDR = 0x03). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

### 23.6.1.14 Value of OTP Bank0 Word4 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG3)

### 23.6.1.14.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG3 | 440h   |

### 23.6.1.14.2 Function

Non-shadowed memory mapped access to OTP Bank 0, Word 4 (ADDR = 0x04).

### 23.6.1.14.3 Diagram

### 23.6.1.14.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 4 (ADDR = 0x04). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.15 Value of OTP Bank0 Word5 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG4)

### 23.6.1.15.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG4 | 450h   |

### 23.6.1.15.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 5 (ADDR = 0x05).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.15.3 Diagram

### 23.6.1.15.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 5 (ADDR = 0x05). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.16 Value of OTP Bank0 Word6 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG5)

### 23.6.1.16.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG5 | 460h   |

### 23.6.1.16.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 6 (ADDR = 0x06).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.16.3 Diagram

### 23.6.1.16.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 6 (ADDR = 0x06). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.17 Value of OTP Bank0 Word7 (Configuration and Manufacturing Info.) (HW\_OCOTP\_CFG6)

### 23.6.1.17.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_CFG6 | 470h   |

### 23.6.1.17.2 Function

Shadowed memory mapped access to OTP Bank 0, Word 7 (ADDR = 0x07).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.17.3 Diagram

### 23.6.1.17.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 0, Word 7 (ADDR = 0x07). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

### 23.6.1.18 Value of OTP Bank 1 Word 7 (Analog Info.) (HW\_OCOTP\_ANA2)

#### 23.6.1.18.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_ANA2 | 4F0h   |

#### 23.6.1.18.2 Function

Shadowed memory mapped access to OTP Bank 1, Word 7 (ADDR = 0x0F).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.18.3 Diagram

### 23.6.1.18.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 1, Word 7 (ADDR = 0x0F). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.19 Value of OTP Bank4 Word0 (Secure JTAG Response Field) (HW\_OCOTP\_SJC\_RESP0)

### 23.6.1.19.1 Offset

| Register           | Offset |
|--------------------|--------|
| HW_OCOTP_SJC_RESP0 | 600h   |

### 23.6.1.19.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 0 (ADDR = 0x20).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.19.3 Diagram

### 23.6.1.19.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 0 (ADDR = 0x20). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.20 Value of OTP Bank4 Word1 (Secure JTAG Response Field) (HW\_OCOTP\_SJC\_RESP1)

### 23.6.1.20.1 Offset

| Register           | Offset |
|--------------------|--------|
| HW_OCOTP_SJC_RESP1 | 610h   |

### 23.6.1.20.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 1 (ADDR = 0x21).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.20.3 Diagram

### 23.6.1.20.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 1 (ADDR = 0x21). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.21 Value of OTP Bank4 Word2 (MAC Address) (HW\_OCOTP\_MAC0)

### 23.6.1.21.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_MAC0 | 620h   |

### 23.6.1.21.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 2 (ADDR = 0x22).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.21.3 Diagram

### 23.6.1.21.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 2 (ADDR = 0x22). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

### 23.6.1.22 Value of OTP Bank4 Word3 (MAC Address) (HW\_OCOTP\_MAC1)

#### 23.6.1.22.1 Offset

| Register      | Offset |
|---------------|--------|
| HW_OCOTP_MAC1 | 630h   |

#### 23.6.1.22.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 3 (ADDR = 0x23).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.22.3 Diagram

### 23.6.1.22.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 3 (ADDR = 0x23). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.23 Value of OTP Bank4 Word4 (MAC Address) (HW\_OCOTP\_GP3)

### 23.6.1.23.1 Offset

| Register     | Offset |
|--------------|--------|
| HW_OCOTP_GP3 | 640h   |

### 23.6.1.23.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 4 (ADDR = 0x24).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

23.6.1.23.3 Diagram

23.6.1.23.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 4 (ADDR = 0x24). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

23.6.1.24 Value of OTP Bank4 Word6 (General Purpose Customer Defined Info) (HW\_OCOTP\_GP1)

23.6.1.24.1 Offset

| Register     | Offset |
|--------------|--------|
| HW_OCOTP_GP1 | 660h   |

23.6.1.24.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 6 (ADDR = 0x26).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.24.3 Diagram

### 23.6.1.24.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 6 (ADDR = 0x26). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

## 23.6.1.25 Value of OTP Bank4 Word7 (General Purpose Customer Defined Info) (HW\_OCOTP\_GP2)

### 23.6.1.25.1 Offset

| Register     | Offset |
|--------------|--------|
| HW_OCOTP_GP2 | 670h   |

### 23.6.1.25.2 Function

Shadowed memory mapped access to OTP Bank 4, Word 7 (ADDR = 0x27).

Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

23.6.1.25.3 Diagram

23.6.1.25.4 Fields

| Field | Function                                                                                                                                               |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 4, Word 7 (ADDR = 0x27). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

23.6.1.26 Value of OTP Bank5 Word0 (SW GP1) (HW\_OCOTP\_SW\_GP1)

23.6.1.26.1 Offset

| Register        | Offset |
|-----------------|--------|
| HW_OCOTP_SW_GP1 | 680h   |

23.6.1.26.2 Function

Shadowed memory mapped access to OTP Bank 5, Word 0 (ADDR = 0x28).  
Copied from the OTP automatically after reset. Can be re-loaded by setting HW\_OCOTP\_CTRL[RELOAD\_SHADOWS].

### 23.6.1.26.3 Diagram

|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | BITS                                                                                                                                                   |
| BITS  | This register reflects the value of OTP Bank 5, Word 6 (ADDR = 0x2E). See the Fusemap Descriptions Table in the Fusemap chapter for more fuse details. |

# Chapter 24

## External Memory Controllers

### 24.1 Overview

This chip has these external memory interfaces and controllers:

- Smart External Memory Controller (SEMC)
- eSD/eMMC/SDIO Interface
- Quad Serial Peripheral Interface (QSPI)

### 24.2 Smart External Memory Controller (SEMC) Overview

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interface supported includes SDRAM, NOR Flash, SRAM and NAND Flash, as well as 8080 display interface.

The key features of the SEMC include:

- Support up to 8 memory regions up to 512Mbit per region which can be configured to be memory space of SDRAM, NOR Flash, NAND Flash, SRAM or 8080 display frame buffer
- Chip Select (CS) signals
- Ability to disable SDRAM and NAND controller by separate fuse bit
- Support Address Latch Enable (ALE)
- SDRAM interface
  - Supports both 8-bit and 16-bit modes
  - Up to 512Mb per each Chip Select (CS) and up to 4x CS
- NOR Flash and SRAM interface
  - Supports 16-bit mode
  - Async mode
  - Address and Data Multiplexing (ADM)
  - Support NOR Flash program via IPBus configuration

- 8080 display interface
  - Supports both 8/16/24-bit modes
  - Up to 100MHz
  - Without tearing effect support
- NAND Flash
  - 8/16-bit NAND FLASH,
  - Async mode only
  - Only supports device which is capable of cache read/write operations
  - Only supports page based operation
- Dynamic I/O sharing which enables multiple external memory device in parallel
- Multi-device access pattern scheduler
  - 8 entries scheduler
  - QoS priority, latency and efficiency adjustable arbitration scheme
- SDRAM access pattern optimization
  - 8 entries command reordering queue
  - QoS priority, latency and efficiency adjustable arbitration scheme

## 24.3 eMMC/eSD/SDIO

This chip has two Ultra Secured Digital Host Controller (uSDHC) modules for SD/eMMC interface. It provides the interface between the host system and the SD/SDIO/MMC cards.

The key features include:

- Support SD/SDIO standard, up to version 3.0
- Support MMC standard, up to version 4.5
- Support 3.3V and 1.8V operation, but do not support 1.2V operation.
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 800 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR mode
  - Up to 800 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR mode
  - Up to 800 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR mode

## 24.4 Quad Serial Peripheral Interface

This chip has one Quad Serial Peripheral Interface block (named FlexSPI) acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines.

The key features includes:

- Each channel can be configured as 1/2/4-bit operation
- Support both dual-channel or single-channel operation
- Support both SDR mode and DDR mode
- Support up to 166MHz SDR Mode and 166MHz DDR Mode (with external Flash device DQS input)
- Support up to 133MHz SDR Mode and 66MHz DDR Mode (with internal DQS loopback mode)

# Chapter 25

## Smart External Memory Controller

#### NOTE

Non-ADMUX ASYNC mode for the SRAM operation is depended on pin availability.

### 25.2 About this module

#### 25.2.1 Introduction

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interface supported includes SDRAM, NOR Flash, SRAM and NAND Flash, as well as 8080 display interface.

## 25.2.2 Features

The SEMC includes the following features:

- Memory space:
  - Support up to 9 memory regions:
    - Region #0 for SDRAM CS0 device
    - Region #1 for SDRAM CS1 device
    - Region #2 for SDRAM CS2 device
    - Region #3 for SDRAM CS3 device
    - Region #4 and #8 for NAND device (IP command and AXI command use different region to avoid large region address range on AXI interface)
    - Region #5 for NOR device
    - Region #6 for SRAM device
    - Region #7 for 8080 display frame buffer
  - Each region is configurable for base address, memory size and valid bit
- AXI slave interface
  - Support 16 outstanding transfer totally for write and read
  - Support 8 outstanding transfer for write
  - Support 16 outstanding transfer for read
  - Multi-device access pattern optimization with Queue A
    - 8 entries command reordering in Queue A
    - QoS priority, latency and efficiency adjustable arbitration scheme
  - SDRAM access pattern optimization with Queue B
    - 8 entries command reordering in Queue B
    - QoS priority, latency and efficiency adjustable arbitration scheme
  - Trigger device read or write access (AXI command)
  - 32/16/8 bit access supported
  - All burst length supported
  - Only INCR and WRAP burst supported

### NOTE

WRAP read/write with 16 bit or 8 bit data size is not supported

- No prefetch/cachable support
- IP Bus interface
  - Internal configuration register access
  - Trigger device access such as device initialization/configuration/read/write (IP command)
- SDRAM interface

- Support 8/16 bit modes
- Up to 4 Chip Select (CS) and each CS range is 64Mb - 512Mb

**NOTE**

SDRAM device type with 2 banks or 8 columns is not supported

- NAND Flash interface
  - Support 8/16 bit modes
  - No HW ECC
  - Only supports device which is capable of cache read/write operations
  - Only supports page based read/write operation
  - Only supports 32 bit transfer size for AXI write operation
- NOR Flash interface
  - Support 16 bit mode
  - Support Async mode
  - Support ADMUX and AADM modes
  - NOR flash write access is supported only by IP command
  - Up to 512Mb memory size

**NOTE**

- Up to 512Mb memory size if SEMC\_ADDR08 is used as address
- Up to 256Mb memory size if SEMC\_ADDR08 is used as chip select

- SRAM interface
  - Support 16 bit mode
  - Support Async mode
  - Support ADMUX and AADM modes
  - Up to 512Mb memory size

**NOTE**

- Up to 512Mb memory size if SEMC\_ADDR08 is used as address
- Up to 256Mb memory size if SEMC\_ADDR08 is used as chip select

- 8080 display interface
  - Support 8/16 bit modes
  - Without tearing effect support
- Misc
  - Dynamic I/O sharing which enables multiple external memory device in parallel
  - Up to 7 Chip Select (CS) signals

- Ability to disable SDRAM and NAND controller by separate fuse bit
- Support Address Latch Enable (ALE) for SRAM/NOR device

### 25.2.3 Operation Modes

SEMC supports following operation modes:

- Module Disable mode

In module disable mode, internal clock is gated for low power, but access to configuration and status registers is available.

This mode is entered by setting MCR[MDIS], and exited by clearing MCR[MDIS]. Software should polling STS0[IDLE] to make sure there is no pending transaction before entering module disable mode.

- Stop mode

When the system requires SEMC to enter stop mode (ipg\_stop=0x1), SEMC waits for all transactions to complete (STS0[IDLE]=0x1) and return acknowledge handshake to system (ipg\_stop\_ack=0x1). The system can gate off SEMC clock after acknowledge handshake returned. There is no clock gating action internally.

SEMC exit this mode immediately when system stop mode request deasserted with the acknowledge handshake deasserted.

- Normal mode

Access to external devices and internal registers are available in normal mode. SEMC clock is not gated internally.

## 25.2.4 Block diagram

Figure 25-1. SEMC block diagram

## 25.3 Signals

This table describes the SEMC module signals.

| Signal      | Direction | Description           |
|-------------|-----------|-----------------------|
| SEMC_DATA00 | IO        | Data/Address Bit 0    |
| SEMC_DATA01 | IO        | Data/Address Bit 1    |
| SEMC_DATA02 | IO        | Data/Address Bit 2    |
| SEMC_DATA03 | IO        | Data/Address Bit 3    |
| SEMC_DATA04 | IO        | Data/Address Bit 4    |
| SEMC_DATA05 | IO        | Data/Address Bit 5    |
| SEMC_DATA06 | IO        | Data/Address Bit 6    |
| SEMC_DATA07 | IO        | Data/Address Bit 7    |
| SEMC_DATA08 | IO        | Data/Address Bit 8    |
| SEMC_DATA09 | IO        | Data/Address Bit 9    |
| SEMC_DATA10 | IO        | Data/Address Bit 10   |
| SEMC_DATA11 | IO        | Data/Address Bit 11   |
| SEMC_DATA12 | IO        | Data/Address Bit 12   |
| SEMC_DATA13 | IO        | Data/Address Bit 13   |
| SEMC_DATA14 | IO        | Data/Address Bit 14   |
| SEMC_DATA15 | IO        | Data/Address Bit 15   |
| SEMC_DM1    | O         | Write Data Mask Bit 1 |

| SEMC_CAS    | O         | Column Address Strobe                                     |
| SEMC_RAS    | O         | Row Address Strobe                                        |
| SEMC_WE     | O         | Write Enable (For SDRAM only)                             |
| SEMC_CKE    | O         | CKE (For SDRAM only)                                      |
| SEMC_CLK    | O         | CLK (For SDRAM only)                                      |
| SEMC_CS0    | O         | Chip Select (For SDRAM CS0 only)                          |
| SEMC_CSX0   | O         | Configurable Chip Select 0                                |
| SEMC_CSX1   | O         | Configurable Chip Select 1                                |
| SEMC_CSX2   | O         | Configurable Chip Select 2                                |
| SEMC_CSX3   | O         | Configurable Chip Select 3                                |
| SEMC_RDY    | IO        | Ready input pin for NAND                                  |
| SEMC_DQS    | IO        | DQS<br>Dummy read strobe loopback pad for SDRAM/NOR/SRAM. |

### NOTE

For detail pin mux inside SEMC, please refer to [Pin Mux in SEMC](#)

## 25.4 Functional description

The following sections describe functional details of the SEMC module.

## 25.4.1 Clocks

This section describes clocks and special clocking requirements of the SEMC module.

There is only one clock domain which is used for AXI bus interface, IP bus interface, internal logic and external interface.

## 25.4.2 Reset

This section describes how to reset the SEMC module and explains special requirements related to reset.

## 25.4.3 Pin Mux in SEMC

Following table describes the pin mux in SEMC module.

| Signal      | SDRAM | NAND | NOR<br>(ADMUX<br>16bit) | SRAM<br>(ADMUX<br>16bit) | DBI | Comment                                                                          |

| SEMC_DQS    | DQS   | -    | DQS                     | DQS                      | -   | Hardware MUX                                                     |

### NOTE

- Configure register field should be static.
- NOR and SRAM pins are configured as 16 bit ADMUX mode in above table. It is the recommended configuration.

## 25.4.4 Device access by AXI Command

Devices could be read/written by AXI bus access directly. AXI command is the device access sequence triggered by AXI bus access. The device access sequene for AXI command is described in the following sections.

**NOTE**

- The AXI bus memory map for each device is defined by SEMC\_BRx registers.
- There is no software configuration or polling needed for AXI command except SEMC initialization. AXI master access external flash device transparently similar as normal AXI slave.
- AXI command is normally used to read/write access device memory space. IP command should be used to any other access, such as device register/OTP space access, device initialization.
- IP command could be used for memory read/write also similar as AXI command. But it is not recommended if only AXI command is available.

**25.4.4.1 BMCR Registers Configuration**

BMCR registers can be used to balance external memory access efficiency, urgency and latency based on requirement of a specific applications.

**25.4.4.1.1 BMCR0 Registers Configuration**

For Queue A controlled by BMCR0, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates a SCORE for each command based on the formula below. The command with the highest SCORE is served first.

$$\text{SCORE} = \text{QOS} * \text{WQOS} + \text{AGE} * \text{WAGE} / 4 + \text{WSH} + \text{WRWS}$$

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WSH stands for weight of slave hit without read/write switch scenario.
4. WRWS stands for weight of slave hit with read/write switch scenario.

**25.4.4.1.2 BMCR1 Registers Configuration**

For Queue B controlled by BMCR1, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates SCORE for each SDRAM command based on the formula below. The command with the highest SCORE is served first.

$$\text{SCORE} = \text{QOS} * \text{WQOS} + \text{AGE} * \text{WAGE} / 4 + \text{WPH} + \text{WBR} + \text{WRWS}$$

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WPH stands for weight of page hit scenario.
4. WBR stands for weight of bank rotation scenario.
5. WRWS stands for weight of slave hit without read/write switch scenario.

### 25.4.5 Device access by IP Command

Device could be accessed (initialized/configured/read/written) by IP bus access also. IP command is the device access sequence triggered by IP bus access. The device access sequene for IP command is described in the following sections.

Device access could be triggered by IP command in following steps:

1. Set register IPCR0/IPCR1/IPCR2/IPTXD for Device address/Data Size/Write Data/Write Mask.
2. Set register IPCMD with valid command code (IPCMD.CMD) and command key (IPCMD.KEY).
3. Wait for IP Command Done (Wait for interrupt IPCMDDONE generated).
4. Read the device data from IPRXD. This is needed for read access only.

#### NOTE

- If device address or command code setting is not valid, IP command error interrupt is generated (INTR.IPCMDERR) and no device access at all.
- If another IP command triggered when the previous IP command not finished yet, IP command error interrupt is generated.
- IPCR0/IPCR1/IPCR2/IPTXD is protected when IP command triggered by not finished yet. Any write access to these register is ignored.
- IPCR0 device address field should be configured even the device don't need any address bit information such as WRITE ENABLE command. SEMC need the device address to determine which device should be accessed.
- SEMC can access NAND only if the KEY is 0x5AA5.

## 25.4.6 SDRAM Controller Operations

This section describes the SDRAM controller module's operations.

### 25.4.6.1 SDRAM address map

SDRAM device address map on SoC is indicated in following diagram:

SDRAM device address map when SDRAMCR0.PS=0x1 (16 bit mode)

SDRAM device address map when SDRAMCR0.PS=0x0 (8 bit mode)

**Figure 25-2. SDRAM device address map**

### 25.4.6.2 SDRAM device access by IP Command

Following SDRAM device access could be triggered by IP command:

1. SELF REFRESH
2. AUTO REFRESH
3. MODE REGISTER SET
4. PRECHARGE
5. PRECHARGE ALL
6. ACTIVE
7. READ
8. WRITE

#### 25.4.6.2.1 IP command - SDRAM Self Refresh

When IP command triggered with command code - SELF REFRESH to any SDRAM device, SEMC would send SELF REFRESH command to all SDRAM devices. After SELF REFRESH command finished, all SDRAM device should be in self refresh state and SEMC keeps this state on SDRAM interface (SEMC\_CKE=0x0 and SEMC\_CLK=0x0).

SEMC brings all SDRAM device out from self refresh state when there is any new IP command or AXI command triggered to SDRAM device.

Following timing diagram illustrates the sequence for self-refresh entering and exiting by AXI command.

Figure 25-3. IP command - SDRAM Self Refresh

**25.4.6.2.2 IP command - SDRAM Auto Refresh**

When IP command triggered with command code - AUTO REFRESH, SEMC would send AUTO REFRESH command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - AUTO REFRESH.

Figure 25-4. IP command - SDRAM Auto Refresh

**25.4.6.2.3 IP command - SDRAM Mode Register Set**

When IP command triggered with command code - Mode Register Set, SEMC would send MODE REGISTER SET command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - MODE REGISTER SET.

Figure 25-5. IP command - SDRAM MODE REGISTER SET

#### 25.4.6.2.4 IP command - SDRAM Precharge

When IP command triggered with command code - Precharge, SEMC would send PRECHARGE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE.

Figure 25-6. IP command - SDRAM PRECHARGE

#### 25.4.6.2.5 IP command - SDRAM Precharge ALL

When IP command triggered with command code - Precharge ALL, SEMC would send PRECHARGE ALL command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE ALL.

Figure 25-7. IP command - SDRAM PRECHARGE ALL

25.4.6.2.6 IP command - SDRAM Active

When IP command triggered with command code - Active, SEMC would send ACTIVE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - ACTIVE.

Figure 25-8. IP command - SDRAM ACTIVE

25.4.6.2.7 IP command - SDRAM READ

When IP command triggered with command code - READ, SEMC would send READ command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - READ.

Figure 25-9. IP command - SDRAM READ

### 25.4.6.2.8 IP command - SDRAM WRITE

When IP command triggered with command code - WRITE, SEMC would send WRITE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - WRITE.

Figure 25-10. IP command - SDRAM WRITE

### 25.4.6.3 SDRAM device access by AXI Command

SDRAM device read/write access could be triggered by AXI Command. For AXI read access, SEMC would send READ commands to SDRAM device automatically and return data on AXI bus. For AXI write access, SEMC would save AXI bus write data and send WRITE commands to SDRAM device automatically.

### 25.4.6.3.1 SDRAM device read access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Read).

Figure 25-11. AXI command - SDRAM Read

### 25.4.6.3.2 SDRAM device write access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Write).

Figure 25-12. AXI command - SDRAM Write

### 25.4.6.3.3 SDRAM device pipelined access by AXI Command

Following timing diagram illustrates the SDRAM device pipelined read access triggered by AXI command (Read).

Figure 25-13. AXI command - Pipelined SDRAM Read

Following timing diagram illustrates the SDRAM device pipelined write access triggered by AXI command (Write).

Figure 25-14. AXI command - Pipelined SDRAM Write

#### 25.4.6.3.4 SDRAM back-to-back access

This section describes the SDRAM back-to-back access.

##### 25.4.6.3.4.1 SDRAM read-to-read access

SDRAM read-to-read access timing when CL=1 is as following:

Functional description

Figure 25-15. SDRAM Read-to-Read access (CL=1)

SDRAM read-to-read access timing when CL=2 is as following:

Figure 25-16. SDRAM Read-to-Read access (CL=2)

SDRAM read-to-read access timing when CL=3 is as following:

Figure 25-17. SDRAM Read-to-Read access (CL=3)

### 25.4.6.3.4.2 SDRAM read-to-write access

SDRAM read-to-write access timing when CL=1 is as following:

**Figure 25-18. SDRAM Read-to-Write access (CL=1)**

SDRAM read-to-write access timing when CL=2 is as following:

**Figure 25-19. SDRAM Read-to-Write access (CL=2)**

SDRAM read-to-write access timing when CL=3 is as following:

**Figure 25-20. SDRAM Read-to-Write access (CL=3)**

### 25.4.6.3.4.3 SDRAM write-to-write access

SDRAM write-to-write access timing is as following:

Figure 25-21. SDRAM Write-to-Write access

### 25.4.6.3.4.4 SDRAM write-to-read access

SDRAM write-to-read access timing when CL=1 is as following:

Figure 25-22. SDRAM Write-to-Read access (CL=1)

SDRAM write-to-read access timing when CL=2 is as following:

Figure 25-23. SDRAM Write-to-Read access (CL=2)

SDRAM write-to-read access timing when CL=3 is as following:

Figure 25-24. SDRAM Write-to-Read access (CL=3)

#### 25.4.6.4 Refresh command - SDRAM AUTO Refresh

SEMC would send AUTO REFRESH command to all SDRAM devices when the refresh timer expired and SDRAM Refresh enabled (SDRAMCR3.REN=0x1). Multiple AUTO REFRESH command could be sent if refresh burst is not set to one (SDRAMCR3.REBL!=0x0).

Refresh command is triggered by interval refresh timer period.

Following timing diagram illustrates the sequence for Refresh Command.

## Functional description

Figure 25-25. Refresh command - SDRAM Auto Refresh

## 25.4.6.5 SDRAM low power feature

This section describes the low power feature implemented for SDRAM.

### 25.4.6.5.1 Stop mode - SDRAM

When system enter STOP mode, SEMC puts all SDRAM device into self refresh state automatically. When system exit STOP mode, SEMC brings SDRAM device out from self refresh state.

Following timing diagram illustrates the sequence for stop mode entering and exiting.

Figure 25-26. Stop mode Enter and Exit- SDRAM

### 25.4.6.5.2 BUS Idle - SDRAM

When there is no IP/AXI/Refresh command, SDRAM interface would be in IDLE state (NOP command and chip select invalid). When SDRAM interface bus idle timer expired, SEMC closes all pages opened on all SDRAM devices. Please see SDRAMCR2.ITO for more detail about bus idle timer.

### 25.4.6.6 SDRAM Page Management

This section describes the SDRAM page management.

There are 8 pages row address saved internally: 4 pages for CS0/CS2 (4 bank), 4 pages for CS1/CS3 (4 bank). Device CS0 and CS2 page is never opened at the same time. Before SEMC open pages on CS2, it closes all opened pages on CS0. This is similar for CS1/CS3.

SEMC close all pages on all CS in following cases:

1. SELF REFRESH triggered by IP command
2. SELF REFRESH triggered by stop mode enter
3. The idle time on AXI bus and SDRAM interface is longer than SDRAM idle timeout time (SDRAMCR2.ITO).

#### NOTE

SEMC does not sent out PRECHARGE-ALL command if there is no page opened on any bank/CS.

SEMC close all pages on one CS in following cases:

1. PRECHARGE ALL command triggered by IP command
2. AUTO REFRESH command triggered by IP command
3. ACTIVE/WRITE/READ command triggered by IP command and CS miss
4. WRITE/READ command triggered by current AXI command and CS miss
5. WRITE/READ command triggered by next AXI command (not accepted yet), CS miss and not same CS as current AXI command

#### NOTE

One example for CS miss: Current IP command access CS2 but there is page opened on CS0 already.

SEMC close one page on one CS in following cases:

1. PRECHARGE command triggered by IP command and this bank is opened
2. ACTIVE/READ/WRITE command triggered by IP command, this bank is opened and page missed.
3. WRITE/READ command triggered by current AXI command this bank is opened and page missed.
4. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is opened, page missed and different bank accessed with current AXI command.

**NOTE**

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

SEMC open one page on one CS in following cases:

1. ACTIVE/READ/WRITE command triggered by IP command, this bank is not opened.
2. WRITE/READ command triggered by current AXI command this bank is not opened.
3. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is not opened and different bank accessed with current AXI command.

**NOTE**

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

### **25.4.6.7 SDRAM Timers**

This section describes the timers used for SDRAM operation

#### **25.4.6.7.1 Prescaler**

The prescaler timer in SDRAM controller count freely with the period defined by SDRAM3.PRESCALE. When the prescaler timer expired, urgent refresh timer and SDRAM BUS IDLE timer count by 1.

#### **25.4.6.7.2 Refresh interval timer**

The refresh interval timer also count when prescaler timer expires. The timer period is determined by SDRAMCR3.RT and SDRAMCR3.PRESCALE. When refresh interval timer expired, an internal refresh command is triggered and SEMC sends one or multiple AUTO REFRESH command on SDRAM interface.

### 25.4.6.7.3 Urgent Refresh timer

Urgent refresh timer is used to determine whether current refresh request is urgent or normal. Before urgent refresh timer timeout, refresh request is handled in lower priority than AXI/IP command. When urgent refresh timer timed out, refresh request becomes urgent. SDRAM handles Auto-Refresh command in higher priority than AXI/IP command.

### 25.4.6.7.4 Beat timer

The beat timer is used to control SDRAM read/write/Auto Refresh command burst length.

### 25.4.6.7.5 ACTIVE to READ/WRITE timer

The ACTIVE to READ/WRITE timer is used to promise the minimum cycle number between ACITVE command and READ/WRITE command on SDRAM interface.

### 25.4.6.7.6 PRECHARGE to ACTIVE timer

The PRECHARGE to ACTIVE timer is used to promise the minimum cycle number between PRECHARGE/PRECHARGE ALL command and ACTIVE/AUTO REFRESH/SELF REFRESH command on SDRAM interface.

### 25.4.6.7.7 CKE OFF timer

The CKEOFF timer is used to promise the minimum cycle of SDRAM CLK off state.

### 25.4.6.7.8 SELF REFRESH recover timer

The SRRC timer is used to promise the wait time between SDRAM device exit Self Refresh state and sending new Commands to device. SDRAM device may have limitation on Self Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.

### 25.4.6.7.9 AUTO REFRESH recover timer

The RFRC timer is used to promise the minimum cycle number between Auto Refresh command and ACTIVE command on SDRAM interface. SDRAM device may have limitation on Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.

#### **25.4.6.7.10 Refresh to Refresh timer**

The refresh to refresh timer is used to promise the minimum cycle number between Auto Refresh command and Auto Refresh command on SDRAM interface.

#### **25.4.6.7.11 ACTIVE to ACTIVE timer**

There are two ACT2ACT timer in SDRAM controller. ACT2ACT0 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS0/2 device. ACT2ACT1 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS1/3 device.

#### **25.4.6.7.12 ACTIVE to PRECHARGE timer**

There are two ACT2PRE timer in SDRAM controller. ACT2PRE0 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS0/2 device. ACT2PRE1 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS1/3 device.

#### **25.4.6.7.13 Write recovery timer**

The WRC timer is used to promise the minimum cycle number between WRITE command and PRECHARGE/PRECHARGE ALL command on SDRAM interface. SDRAM device may have limitation on WRITE recovery time. Before this recovery time expire, PRECHARGE/PRECHARGE ALL command to device may cause the write process failed.

### **25.4.7 NAND Flash Controller Operations**

This section describes the NAND Flash controller module's operations.

#### **25.4.7.1 NAND Flash address map**

NAND Flash device address map on SoC is indicated in the following diagram:

NAND device address map when NANDCR0.PS=0x1 (16 bit mode)

NAND device address map when NANDCR0.PS=0x0 (8 bit mode)

**Figure 25-27. NAND Flash Address Map**

## 25.4.7.2 NAND Flash access address type

There are 6 type address type access provided:

- One Byte Column address
- Two Byte Column address
- One Byte Row address
- Two Byte Row address
- Three Byte Row address
- Five Byte Row/Column address

For IP command, address type is determined by IPCMD register; For AXI command, address type is fixed to "Two Byte Column Address" because all NAND Flash access is in NAND page boundary.

### 25.4.7.2.1 One Byte Column Address

One Byte column address type access is indicated as following:

Figure 25-28. NAND Flash access Address type - One Byte Column Address

25.4.7.2.2 Two Byte Column Address

Two Byte column address type access is indicated as following:

Figure 25-29. NAND Flash access Address type - Two Byte Column Address

25.4.7.2.3 One Byte Row Address

One Byte row address type access is indicated as following:

**Figure 25-30. NAND Flash access Address type - One Byte Row Address**

#### 25.4.7.2.4 Two Byte Row Address

Two Byte row address type access is indicated as following:

**Figure 25-31. NAND Flash access Address type - Two Byte Row Address**

#### 25.4.7.2.5 Three Byte Row Address

Three Byte row address type access is indicated as following:

Figure 25-32. NAND Flash access Address type - Three Byte Row Address

25.4.7.2.6 Five Byte Row/Column Address

Five Byte row/column address type access is indicated as following:

Figure 25-33. NAND Flash access Address type - Five Byte Row/Column Address

There are some option bits provide to support more NAND address type access. Five byte row/column address type could be overried as following:

Table 25-2. Address byte order for Row/Column Address five Byte mode

| NDOPT3 | NDOPT2 | NDOPT1 | Address byte order  |
|--------|--------|--------|---------------------|
| 0      | 0      | 0      | CA0/CA1/RA0/RA1/RA2 |

Table continues on the next page...

**Table 25-2. Address byte order for Row/Column Address five Byte mode (continued)**

| NDOPT3 | NDOPT2 | NDOPT1 | Address byte order |
|--------|--------|--------|--------------------|
| 0      | 0      | 1      | CA0/RA0/RA1/RA2    |
| 0      | 1      | 0      | CA0/CA1/RA0/RA1    |
| 0      | 1      | 1      | CA0/RA0/RA1        |
| 1      | -      | 0      | CA0/CA1/RA0        |
| 1      | -      | 1      | CA0/RA0            |

### 25.4.7.3 NAND Flash access command type

NAND Flash access support following command types:

1. Command Phase Only
2. Command + Wait Phase
3. Command + Address Phase
4. Command + Address + Wait Phase
5. Command + Address + Read Phase
6. Command + Address + Write Phase (For IP command)
7. Command + Write Phase
8. Command + Read Phase
9. Write Phase Only
10. Read Phase Only
11. Command + Address + Command + Read Phase (For AXI command - Read)
12. Command + Address + Write Phase (For AXI command - Write)

.

#### 25.4.7.3.1 Command Phase Only

NAND Flash Command Phase Only access is indicated as following:

Figure 25-34. NAND Flash access command type - Command Phase Only

### 25.4.7.3.2 Command + Wait Phase

NAND Flash Command + Wait Phase access is indicated as following:

Figure 25-35. NAND Flash access command type - Command + Wait Phase

### 25.4.7.3.3 Command + Address Phase

NAND Flash Command + Address Phase access is indicated as following:

**Figure 25-36. NAND Flash access command type - Command + Address Phase**

#### 25.4.7.3.4 Command + Address + Wait Phase

NAND Flash Command + Address + Wait Phase access is indicated as following:

**Figure 25-37. NAND Flash access command type - Command + Address + Wait Phase**

#### 25.4.7.3.5 Command + Address + Read Phase

NAND Flash Command + Address + Read Phase access is indicated as following:

Figure 25-38. NAND Flash access command type - Command + Address + Read Phase

### 25.4.7.3.6 Command + Address + Write Phase (For IP command)

NAND Flash Command + Address + Write Phase access is indicated as following:

Figure 25-39. NAND Flash access command type - Command + Address + Write Phase

### 25.4.7.3.7 Command + Read Phase

NAND Flash Command + Read Phase access is indicated as following:

Figure 25-40. NAND Flash access command type - Command + Read Phase

### 25.4.7.3.8 Command + Write Phase

NAND Flash Command + Write Phase access is indicated as following:

Figure 25-41. NAND Flash access command type - Command + Write Phase

### 25.4.7.3.9 Read Phase Only

NAND Flash Read Phase Only access is indicated as following:

Figure 25-42. NAND Flash access command type - Read Phase Only

25.4.7.3.10 Write Phase Only

NAND Flash Write Phase Only access is indicated as following:

Figure 25-43. NAND Flash access command type - Write Phase Only

25.4.7.3.11 Command + Address + Command + Read Phase

NAND Flash Command + Address + Command + Read Phase access is indicated as following:

**Figure 25-44. NAND Flash access command type - Command + Address + Command + Read Phase**

### 25.4.7.3.12 Command + Address + Write Phase (For AXI command)

NAND Flash Command + Address + Write Phase access is indicated as following:

**Figure 25-45. NAND Flash access command type - Command + Address + Write Phase**

### 25.4.7.4 NAND Flash read access EDO and non-EDO mode

NAND Flash read access could be done in EDO or non-EDO mode. The timing indicated as following:

**Figure 25-46. NAND Flash Read Access in EDO or non-EDO mode**

## 25.4.8 NOR Flash Controller Operations

This section describes the NOR Flash controller module’s operations.

### 25.4.8.1 NOR Flash address map

NOR Flash device address map on SoC is indicated in the following diagram:

Figure 25-47. NOR Flash Address Map

### 25.4.8.2 NOR Flash Read Operation in ASYNC Mode

Flash read operation in ASYNC mode is indicated in following diagrams:

Figure 25-48. Flash Read in ASYNC mode (ADMUX)

Figure 25-49. Flash Read in ASYNC mode (AADM)

### 25.4.8.3 NOR Flash Write Operation in ASYNC mode

Flash write operation in ASYNC mode is indicated in following diagrams:

Figure 25-50. Flash Write in ASYNC mode (ADMUX)

Figure 25-51. Flash Write in ASYNC mode (AADM)

## 25.4.9 SRAM Controller Operations

This section describes the SRAM controller module's operations.

### 25.4.9.1 SRAM Flash address map

SRAM Flash device address map on SoC is indicated in the following diagram:

SRAM device address map when SRAMCR0.PS=0x1 (16 bit mode)

SRAM device address map when SRAMCR0.PS=0x0 (8 bit mode)

Figure 25-52. SRAM Flash Address Map

25.4.9.2 SRAM Read Operation in ASYNC Mode

SRAM read operation in ASYNC mode is indicated in following diagrams:

Figure 25-53. SRAM Read in ASYNC mode (ADMUX)

Figure 25-54. SRAM Read in ASYNC mode (AADM)

25.4.9.3 SRAM Write Operation in ASYNC mode

SRAM write operation in ASYNC mode is indicated in following diagrams:

Figure 25-55. SRAM Write in ASYNC mode (ADMUX)

Figure 25-56. SRAM Write in ASYNC mode (AADM)

## 25.4.10 Display Bus Interface Controller Operations

DBI read/write operation indicated as following.

Figure 25-57. DBI Write Operation

Figure 25-58. DBI Read Operation

### NOTE

- Read access to DBI is always handled as DBI DATA READ transaction
- Write access to DBI is handled as DBI COMMAND WRITE transaction if address is higher than 0x10000 (with DBI Base address removed). Otherwise, it is handled as DBI DATA WRITE transaction.
- DBI address is not sent to device at all. Only used to determine DBI COMMAND or DATA WRITE.
- DBI bus never sent out address information for COMMAND WRITE, DATA WRITE and DATA READ command.
- AXI WRAP write access to DBI is supported.
- AXI WRAP read access to DBI is not supported except when the first beat address offset is zero in the burst.
- DBI bus interface doesn't support WRITE MASK feature.
- All write strobe in AXI write access to DBI should be valid (one). If AXI write strobe is invalid (zero), SEMC sends write data 8'h00 instead of original write data.
- When DBI bus is 16 bit (DBICR0.PS=0x1), AXI command or IP command access (both read and write) start address to DBI bus should be 16 bit aligned. Otherwise the read data is unknown or the write data to DBI may be wrong. There is no bus error response or internal error status generated for this case.

## 25.5 Memory Map and register definition

This section includes the SEMC module memory map and detailed descriptions of all registers.

### 25.5.1 SEMC register descriptions

#### 25.5.1.1 SEMC memory map

SEMC base address: 402F\_0000h

| Offset | Register                                                                     | Width<br>(In bits) | Access | Reset value |
|--------|------------------------------------------------------------------------------|--------------------|--------|-------------|
| 0h     | Module Control Register (MCR)                                                | 32                 | RW     | 1000_0002h  |
| 4h     | IO Mux Control Register (IOCR)                                               | 32                 | RW     | 0000_0000h  |
| 8h     | Bus (AXI) Master Control Register 0 (BMCR0)                                  | 32                 | RW     | 0000_0000h  |
| Ch     | Bus (AXI) Master Control Register 1 (BMCR1)                                  | 32                 | RW     | 0000_0000h  |
| 10h    | Base Register 0 (For SDRAM CS0 device) (BR0)                                 | 32                 | RW     | 8000_001Dh  |
| 14h    | Base Register 1 (For SDRAM CS1 device) (BR1)                                 | 32                 | RW     | 8400_001Ch  |
| 18h    | Base Register 2 (For SDRAM CS2 device) (BR2)                                 | 32                 | RW     | 8800_001Ch  |
| 1Ch    | Base Register 3 (For SDRAM CS3 device) (BR3)                                 | 32                 | RW     | 8C00_001Ch  |
| 20h    | Base Register 4 (For NAND device) (BR4)                                      | 32                 | RW     | 9E00_001Ah  |
| 24h    | Base Register 5 (For NOR device) (BR5)                                       | 32                 | RW     | 9000_0018h  |
| 28h    | Base Register 6 (For PSRAM device 0) (BR6)                                   | 32                 | RW     | 9800_0018h  |
| 2Ch    | Base Register 7 (For DBI-B (MIPI Display Bus Interface Type B) device) (BR7) | 32                 | RW     | 9C00_001Ah  |
| 30h    | Base Register 8 (For NAND device) (BR8)                                      | 32                 | RW     | 0000_0026h  |
| 38h    | Interrupt Enable Register (INTEN)                                            | 32                 | RW     | 0000_0000h  |
| 3Ch    | Interrupt Enable Register (INTR)                                             | 32                 | RW     | 0000_0000h  |
| 40h    | SDRAM control register 0 (SDRAMCR0)                                          | 32                 | RW     | 0000_0C26h  |
| 44h    | SDRAM control register 1 (SDRAMCR1)                                          | 32                 | RW     | 0099_4934h  |
| 48h    | SDRAM control register 2 (SDRAMCR2)                                          | 32                 | RW     | 8000_0EEh   |
| 4Ch    | SDRAM control register 3 (SDRAMCR3)                                          | 32                 | RW     | 4080_8000h  |
| 50h    | NAND control register 0 (NANDCR0)                                            | 32                 | RW     | 0000_0000h  |
| 54h    | NAND control register 1 (NANDCR1)                                            | 32                 | RW     | 0000_0000h  |

### 25.5.1.7 Base Register 1 (For SDRAM CS1 device) (BR1)

#### 25.5.1.7.1 Offset

| Register | Offset |
|----------|--------|
| BR1      | 14h    |

#### 25.5.1.7.2 Function

This configuration register applied to both AXI command and IP command.

On this device, for data transfer modes, uSDHC1 only supports 1-bit and 4-bit modes, while uSDHC2 can support 1-bit, 4-bit and 8-bit modes.

#### NOTE

HS400 mode is not supported on this device.

### 26.2 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in [Figure 26-1](#).

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

**Figure 26-1. System Connection of the uSDHC**

Figure 26-2. ultra Secure Digital Host Controller Block Diagram

## 26.2.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

Note: IP can support the above listed speed mode and max data throughput. For SOC, speed mode and data throughput should be specific to chip. See the corresponding chip description for details.

## 26.2.2 Modes and Operations

### 26.2.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS200 mode (up to 200 MHz)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

Note: IP can support the above-listed speed mode and max clock frequency. For SOC, speed mode and max clock frequency should be specific to chip. See the corresponding chip description for details.

## 26.3 External Signals

The following table describes the external signals of uSDHC:

**Table 26-2. uSDHC External Signals**

| Signal | Description                                        | Direction |
|--------|----------------------------------------------------|-----------|
| CLK    | Clock for MMC/SD/SDIO card                         | O         |
| CMD    | CMD line connect to card                           | I/O       |
| DATA7  | DAT7 line in 8-bit mode<br>Not used in other modes | I/O       |

*Table continues on the next page...*

**Table 26-2. uSDHC External Signals (continued)**

| Signal  | Description                                                                                                            | Direction |
|---------|------------------------------------------------------------------------------------------------------------------------|-----------|
| DATA6   | DAT6 line in 8-bit mode<br>Not used in other modes                                                                     | I/O       |
| DATA5   | DAT5 line in 8-bit mode<br>Not used in other modes                                                                     | I/O       |
| DATA4   | DAT4 line in 8-bit mode<br>Not used in other modes                                                                     | I/O       |
| DATA3   | DAT3 line in 4/8-bit mode or configured as card detection pin<br>May be configured as card detection pin in 1-bit mode | I/O       |
| DATA2   | DAT2 line or Read Wait in 4-bit mode<br>Read Wait in 1-bit mode                                                        | I/O       |
| DATA1   | DAT1 line in 4/8-bit mode<br>Also used to detect interrupt in 1/4-bit mode                                             | I/O       |
| DATA0   | DAT0 line in all modes<br>Also used to detect busy state                                                               | I/O       |
| CD_B    | Card detection pin<br>If not used(for the embedded memory),tie low to indicate there is a card attached.               | I         |
| WP      | Card write protect detect<br>If not used(for the embedded memory), tie low to indicate it's not write protected.       | I         |
| LCTL    | LED control used to drive an external LED Active high<br>Fully controlled by the driver<br>Optional output             | O         |
| RESET_B | Card hardware reset signal, active LOW                                                                                 | O         |
| VSELECT | IO power voltage selection signal                                                                                      | O         |

## 26.3.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD\_B means that a card is inserted, and a high on WP means that the write protect switch is active.

- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support HS400 mode, STROBE can also be optional and tied to low.

## 26.4 Clocks

The table found here describes the clock sources for uSDHC.

**Table 26-3. uSDHC Clocks**

| Clock name     | Clock Root     | Description                                   |
|----------------|----------------|-----------------------------------------------|
| hclk           | ahb_clk_root   | AHB bus clock                                 |
| ipg_clk        | ipg_clk_root   | Peripheral clock                              |
| ipg_clk_perclk | usdhc_clk_root | Base clock                                    |
| ipg_clk_s      | ipg_clk_root   | Peripheral access clock for register accesses |

## 26.5 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

### 26.5.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

**Figure 26-3. uSDHC Buffer Scheme**

There are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD\_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD\_WML register from the buffer. The write operation is similar.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.

For a read operation, when there are more words in the buffer than the amount set in the RD\_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary

- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

**Figure 26-4. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode**

**Figure 26-5. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode**

### 26.5.1.1 Write Operation Sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR\_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR\_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

### **26.5.1.2 Read Operation Sequence**

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD\_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the

AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD\_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

### 26.5.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

### 26.5.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then

transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

**Figure 26-6. Example for Dividing Large Data Transfers**

## 26.5.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC\_dreq\_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

**Figure 26-7. DMA AHB Interface Block**

### 26.5.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space(for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

### 26.5.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in [Internal DMA Request](#). After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

### 26.5.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS\_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

### 26.5.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### **26.5.2.4.1 ADMA Concept and Descriptor Format**

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

## Functional Description

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

See the figure below for the format of the descriptor table for ADMA1.

| Address/ Page Field    |    | Address/ Page Field |   | Attribute Field |       |   |     |     |       |
|------------------------|----|---------------------|---|-----------------|-------|---|-----|-----|-------|
| 31                     | 12 | 11                  | 6 | 5               | 4     | 3 | 2   | 1   | 0     |
| Address or Data Length |    | 000000              |   | Act 2           | Act 1 | 0 | Int | End | Valid |

| Act 2 | Act1 | Symbol | Comment         | 31- 28             | 27- 12      |
|-------|------|--------|-----------------|--------------------|-------------|
| 0     | 0    | Nop    | No Operation    | Don't Care         |             |
| 0     | 1    | Set    | Set Data Length | 0000               | Data Length |
| 1     | 0    | Tran   | Transfer Data   | Data Address       |             |
| 1     | 1    | Link   | Link Descriptor | Descriptor Address |             |

|       |                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------|
| Valid | Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA. |
| End   | End = 1 indicates current descriptor is the ending one.                                                             |
| Int   | Int = 1 generates DMA Interrupt when this descriptor is processed.                                                  |

**Figure 26-8. Format of the ADMA1 Descriptor Table**

**Figure 26-9. Concept and Access Method of ADMA1 Descriptor Table**

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

## Functional Description

| Address Field  |    | Length        |    | Reserved   |    | Attribute Field |       |    |     |     |       |
|----------------|----|---------------|----|------------|----|-----------------|-------|----|-----|-----|-------|
| 63             | 32 | 31            | 16 | 15         | 06 | 05              | 04    | 03 | 02  | 01  | 00    |
| 32-bit Address |    | 16-bit length |    | 0000000000 |    | Act 2           | Act 1 | 0  | Int | End | Valid |

| Act 2 | Act1 | Symbol | Comment         | Operation                                                         |
|-------|------|--------|-----------------|-------------------------------------------------------------------|
| 0     | 0    | Nop    | No Operation    | Don't Care                                                        |
| 0     | 1    | Rsv    | Reserved        | Same as Nop. Read this line and go to next one                    |
| 1     | 0    | Tran   | Transfer Data   | Transfer data with address and length set in this descriptor line |
| 1     | 1    | Link   | Link Descriptor | Link to another descriptor                                        |

|       |                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------|
| Valid | Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA. |
| End   | End = 1 indicates current descriptor is the ending one.                                                             |
| Int   | Int = 1 generates DMA Interrupt when this descriptor is processed.                                                  |

**Figure 26-10. Format of the ADMA2 Descriptor Table**

**Figure 26-11. Concept and Access Method of ADMA2 Descriptor Table**

#### 26.5.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

### 26.5.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

## 26.5.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See the figure below for the block diagram.

**Figure 26-12. Register Bank Diagram**

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

### 26.5.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.

2. Command control.
3. Data control.
4. Clock control

### **26.5.3.2 SD control misc**

In the SD control misc unit, the card detect(include the CD\_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

### **26.5.3.3 SD Clock control**

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

### **26.5.3.4 Command control**

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

**Figure 26-13. Command CRC Shift Register**

The CRC polynomials for the CMD are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

### 26.5.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

## 26.5.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

## 26.5.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

**Figure 26-14. Two Stages of the Clock Divider**

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (card\_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see [Figure 26-3](#)) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the card\_clk is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of Base clock is 50%, the duty cycle of card\_clk is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(card\_clk).
- In DDR mode, CLK is equal to the card\_clk/2.

## 26.5.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

### 26.5.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

### 26.5.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 26.5.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the

## Functional Description

SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 26-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure**

## 26.5.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD\_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD\_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD\_B pin is always a reference for card detection. Whether the DATA3 pin or the CD\_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

## 26.5.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg\_clk and ipg\_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

### NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be

set. Refer to [Protocol Control \(PROT\\_CTRL\)](#) for more information on the uSDHC Protocol Control register.

### 26.5.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

## 26.5.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

### NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

### 26.5.9.1 Boot operation

### NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 26-16. MultiMediaCard state diagram (normal boot mode)**

### 26.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFF

**Figure 26-17. MultiMediaCard state diagram (alternative boot mode)**

## 26.6 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

## 26.6.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
    recommended to implement in a bit-field manner
    wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
    set CMDTYP, DPSEL, CICCEN, CCCEN, RSTTYP, DTDSEL accorind to the command_index;
    if (internal DMA is used) wCmd |= 0x1;
    if (multi-block transfer) {
        set MSBSEL bit;
        if (finite block number) {
            set BCEN bit;
            if (auto12 command is to use) set AC12EN bit;
        }
    }
    write_reg(CMDARG, <cmd_arg>); // configure the command argument
    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
    read IRQ Status register and check if any error bits about Command are set
    if (any error bits are set) report error;
    write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait\_for\_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

## 26.6.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

### 26.6.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

**Figure 26-18. Flow Diagram for Card Detection**

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

### 26.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go\_Idle\_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

**Figure 26-19. Flow Chart for Reset of the uSDHC and SD I/O Card**

```

software_reset()
{
    set_bit(SYSCTRL, RSTA); // software reset the Host
    set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
    configure IO pad to set the power voltage of external card to around 3.0V
    poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
    or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

### 26.6.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for V<sub>dd</sub> are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_arguement)
{
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
    operation voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO
                function
                    send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                    wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
        for memory part or SD card
            wait_for_response(SD_APP_OP_COND); // voltage range is set
            if (card type is UNKNOWN) label the card as SD;
            return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCombo)
    { //
change label

```

```

        re-label the card as SDIO;
        ignore the error or report it;
        return; // card is identified as SDIO card
    } // of if (card is ...
    send_command(SEND_OP_COND, <voltage range>, <...>);
    if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
        label the card as UNKNOWN;
        return;
    } // of if (RESP_TIMEOUT ...
} // of else
}

```

### 26.6.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards

(the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCCombo ...
else if (card is labelled as SD) { // for SD card
    send_command(ALL_SEND_CID, <...>);
    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
    send_command(SET_RELATIVE_ADDR, <...>);
    retrieve RCA from response;
} // else if (card is labelled as SD ...
else if (card is labelled as MMC) {
    send_command(ALL_SEND_CID, <...>);
    rca = 0x1; // arbitrarily set RCA, 1 here for example
    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
        } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

## 26.6.3 Card Access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

### 26.6.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

### 26.6.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
  4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
  5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
  6. Wait for the Transfer Complete interrupt.
  7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 26.6.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 26.6.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in [Normal Write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

### 26.6.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

#### 26.6.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

### 26.6.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 26.6.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in [Normal Read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

#### 26.6.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card\_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL\_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card\_clk is 100Mhz, then the reference clock period is 10ns, setting target value of 16 means  $5\text{ns} = (16/32) * 10\text{ns}$ . Software can disable automatic update by setting dll\_gate\_update bit.

Since the user may change the frequency of the card\_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card\_clk) is changed. The following is the correct flow, which should be ignored if DLL\_CTRL\_ENABLE is not set.

Step 1: Set DLL\_CTRL\_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL\_CTRL\_RESET bit

Step 5: Wait until both DLL\_STS\_SLV\_LOCK and DLL\_STS\_REF\_LOCK are asserted

Step 6: set DLL\_CTRL\_SLV\_FORCE\_UPD

Step 7: clear DLL\_CTRL\_SLV\_FORCE\_UPD

### NOTE

Software should make sure the DLL\_CTRL\_SLV\_FORCE\_UPD is lasted for at least one card\_clk. So software may need to add some delay between Step6 and Step7.

Figure 26-20. DLL(Delay Line) in Read Path

### 26.6.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

#### 26.6.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only

when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

#### 26.6.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

#### 26.6.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.

4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

### 26.6.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

#### 26.6.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

#### 26.6.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the

next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

### 26.6.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

### 26.6.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

### 26.6.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to [Card Interrupt Handling](#) for the card interrupt handling flow.

### 26.6.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH\_FUNC). For MMC cards, the high speed mode/HS200 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

#### 26.6.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
    send CMD52 to query bit SHS at address 0x13;
    if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
    send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the
    card_clk of around 50MHz;
    (data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
    send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
    cleared;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the
    card_clk of the desired value below 25MHz;
    (data transactions like normal peers)
}
```

#### 26.6.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDR104/DDR50

```
enable_sd_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
    (high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
    wait data transfer done bit is set;
    check if the bit x of received 512 bits is set;
    if (bit 401 is '0') report the SD card does not support high speed mode and return;
    if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
    if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
    if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
    send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
    (high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
    check if the bit field 379~376 is 0xF;
    if (the bit field is 0xF) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the
    card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
    DDR50;
    (data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
    check if the bit field 379~376 is 0xF;
```

```

if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}

```

### 26.6.4.3 Query, Enable and Disable MMC High Speed Mode

```

enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}

```

### 26.6.4.4 Set MMC Bus Width

```

change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5; 8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}

```

### 26.6.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

### 26.6.5.1 ADMA1 Operation

```

Set_adma1_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 4KB align.
        Set 'Set' type descriptor;
        {
            Set Act bits to 01;
            Set [31:12] bits data length (byte unit);
        }
        Set 'Tran' type descriptor;
        {
            Set Act bits to 10;
            Set [31:12] bits address (4KB align);
        }
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to 11;
        Set [31:12] bits the next descriptor address (4KB aligned);
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set End bit to 1;
    }
    if (to generate interrupt for this descriptor) {
        Set Int bit to 1;
    }
    Set Valid bit to 1;
}

```

### 26.6.5.2 ADMA2 Operation

```

Set_adma2_descriptor
{
    if (to start data transfer) {
        // Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
        Set higher 32-bit of descriptor for this data transfer initial address;
        Set [31:16] bits data length (byte unit);
        Set Act bits to '10';
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to '11';
        // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
        Set higher 32-bit of descriptor for the next descriptor address;
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set 'End' bit '1';
    }
    if (to generate interrupt for this descriptor) {
        Set 'Int' bit '1';
    }
    Set the 'Valid' bit to '1';
}

```

## 26.6.6 Fast Boot Operation

### 26.6.6.1 Normal fast boot flow

1. Software must configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, `CMDINX`, `CMDTYP`, `RSPTYP`, `CICEN`, `CCEN`, `AC12EN`, `BCEN` and `DMAEN` are kept at the default value. `DPSEL` bit is set to 1, `DTDSEL` is set to 1, `MSBSEL` is set to 1.
7. `DMAEN` should be configured as 0 in polling mode. And if `BCEN` is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, `DDR_EN` needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes `CMD` high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make `CMD` line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

### 26.6.6.2 Alternative fast boot flow

1. Software needs to configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR\_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

### 26.6.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT\_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK\_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that that the host will stop at the block gap when the uSDHC controller gets VALUE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK\_CNT) to the max value (16'hffff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512byte\*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VALUE2). Note: the second couple desc also transfer useful data even at least 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process . CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Block Attributes Register to the max value. And if in ddr fast boot mode, DDR\_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.

10. When TC, BGE bit is 1, . SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code(VALUE3 the remain boot code block). Remeber set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the  $(BLK\_CNT - (VALUE1+1+VALUE3))$ , that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence. Please note, Software doesn't need to configure the *BLK\_CNT* again, because it's counted down automatically by the uSDHC controller.
12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

## 26.7 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

**Table 26-4. Commands for MMC/SD/SDIO Cards**

| CMD INDEX         | Type | Argument                                                                                                                                                                                                 | Response type   | Abbreviation               | Description                                                                                                                                                                                                                                  |
|-------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD0              | bc   | [31:0] stuff bits                                                                                                                                                                                        | -               | GO_IDLE_STATE              | Resets all MMC and SD memory cards to idle state.                                                                                                                                                                                            |
| CMD1              | bcr  | [31:0] OCR without busy                                                                                                                                                                                  | R3              | SEND_OP_COND               | Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.                                                                                                         |
| CMD2              | bcr  | [31:0] stuff bits                                                                                                                                                                                        | R2              | ALL_SEND_CID               | Asks all cards to send their CID numbers on the CMD line.                                                                                                                                                                                    |
| CMD3 <sup>1</sup> | ac   | [31:6] RCA<br>[15:0] stuff bits                                                                                                                                                                          | R1<br>R6 (SDIO) | SET/<br>SEND_RELATIVE_ADDR | Assigns relative address to the card.                                                                                                                                                                                                        |
| CMD4              | bc   | [31:0] DSR<br>[15:0] stuff bits                                                                                                                                                                          | -               | SET_DSR                    | Programs the DSR of all cards.                                                                                                                                                                                                               |
| CMD5              | bc   | [31:0] OCR without busy                                                                                                                                                                                  | R4              | IO_SEND_OP_COND            | Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.                                                                                                                      |

**Table 26-4. Commands for MMC/SD/SDIO Cards (continued)**

| CMD INDEX | Type     | Argument                        | Response type | Abbreviation         | Description                                                                                                                        |
|-----------|----------|---------------------------------|---------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| CMD8      | adtc     | [31:0] stuff bits               | R1            | SEND_EXT_CSD         | The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.                                            |
| CMD9      | ac       | [31:6] RCA<br>[15:0] stuff bits | R2            | SEND_CSD             | Addressed card sends its card-specific data (CSD) on the CMD line.                                                                 |
| CMD10     | ac       | [31:6] RCA<br>[15:0] stuff bits | R2            | SEND_CID             | Addressed card sends its card-identification (CID) on the CMD line.                                                                |
| CMD11     | adtc     | [31:0] data address             | R1            | READ_DAT_UNTIL_STOP  | Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.                                 |
| CMD12     | ac       | [31:0] stuff bits               | R1b           | STOP_TRANSMISSION    | Forces the card to stop transmission.                                                                                              |
| CMD13     | ac       | [31:6] RCA<br>[15:0] stuff bits | R1            | SEND_STATUS          | Addressed card sends its status register.                                                                                          |
| CMD14     | Reserved |                                 |               |                      |                                                                                                                                    |
| CMD15     | ac       | [31:6] RCA<br>[15:0] stuff bits | -             | GO_INACTIVE_STATE    | Sets the card to inactive state in order to protect the card stack against communication breakdowns.                               |
| CMD16     | ac       | [31:0] block length             | R1            | SET_BLOCKLEN         | Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.  |
| CMD17     | adtc     | [31:0] data address             | R1            | READ_SINGLE_BLOCK    | Reads a block of the size selected by the SET_BLOCKLEN command.                                                                    |
| CMD18     | adtc     | [31:0] data address             | R1            | READ_MULTIPLE_BLOCK  | Continuously transfers data blocks from card to host until interrupted by a stop command.                                          |
| CMD19     | adtc     | [31:0] reserved bits(all 0)     | R1            | SEND_TUNING_BLOCK    | 64 bytes tuning pattern is sent for SDR50 and SDR104.                                                                              |
| CMD20     | adtc     | [31:0] data address             | R1            | WRITE_DAT_UNTIL_STOP | Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.                                |
| CMD21     | adtc     | [31:0] stuff bits               | R1            | SEND_TUNING_BLOCK    | 128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection. |
| CMD22-23  | Reserved |                                 |               |                      |                                                                                                                                    |
| CMD24     | adtc     | [31:0] data address             | R1            | WRITE_BLOCK          | Writes a block of the size selected by the SET_BLOCKLEN command.                                                                   |
| CMD25     | adtc     | [31:0] data address             | R1            | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows.                                                              |

**Table 26-4. Commands for MMC/SD/SDIO Cards (continued)**

| CMD INDEX | Type     | Argument                               | Response type | Abbreviation          | Description                                                                                                                                                                                                                                 |
|-----------|----------|----------------------------------------|---------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD26     | adtc     | [31:0] stuff bits                      | R1            | PROGRAM_CID           | Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer. |
| CMD27     | adtc     | [31:0] stuff bits                      | R1            | PROGRAM_CSD           | Programming of the programmable bits of the CSD.                                                                                                                                                                                            |
| CMD28     | ac       | [31:0] data address                    | R1b           | SET_WRITE_PROT        | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).                                         |
| CMD29     | ac       | [31:0] data address                    | R1b           | CLR_WRITE_PROT        | If the card provides write protection features, this command clears the write protection bit of the addressed group.                                                                                                                        |
| CMD30     | adtc     | [31:0] write protect data address      | R1            | SEND_WRITE_PROT       | If the card provides write protection features, this command asks the card to send the status of the write protection bits.                                                                                                                 |
| CMD31     | Reserved |                                        |               |                       |                                                                                                                                                                                                                                             |
| CMD32     | ac       | [31:0] data address                    | R1            | TAG_SECTOR_START      | Sets the address of the first sector of the erase group.                                                                                                                                                                                    |
| CMD33     | ac       | [31:0] data address                    | R1            | TAG_SECTOR_END        | Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.                                                                                                                 |
| CMD34     | ac       | [31:0] data address                    | R1            | UNTAG_SECTOR          | Removes one previously selected sector from the erase selection.                                                                                                                                                                            |
| CMD35     | ac       | [31:0] data address                    | R1            | TAG_ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase.                                                                                                                                                          |
| CMD36     | ac       | [31:0] data address                    | R1            | TAG_ERASE_GROUP_END   | Sets the address of the last erase group within a continuous range to be selected for erase.                                                                                                                                                |
| CMD37     | ac       | [31:0] data address                    | R1            | UNTAG_ERASE_GROUP     | Removes one previously selected erase group from the erase selection.                                                                                                                                                                       |
| CMD38     | ac       | [31:0] stuff bits                      | R1b           | ERASE                 | Erase all previously selected sectors.                                                                                                                                                                                                      |
| CMD39     | ac       | [31:0] RCA<br>[15] register write flag | R4            | FAST_IO               | Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if                                                                                                     |

**Table 26-4. Commands for MMC/SD/SDIO Cards (continued)**

| CMD INDEX | Type     | Argument                                                                                  | Response type | Abbreviation         | Description                                                                                                                                                                                                                                                                      |
|-----------|----------|-------------------------------------------------------------------------------------------|---------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |          | [14:8] register address<br>[7:0] register data                                            |               |                      | the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.                                                                                            |
| CMD40     | bcr      | [31:0] stuff bits                                                                         | R5            | GO_IRQ_STATE         | Sets the system into interrupt mode.                                                                                                                                                                                                                                             |
| CMD41     | Reserved |                                                                                           |               |                      |                                                                                                                                                                                                                                                                                  |
| CMD42     | adtc     | [31:0] stuff bits                                                                         | R1b           | LOCK_UNLOCK          | Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.                                                                                                                                                          |
| CMD43~51  | Reserved |                                                                                           |               |                      |                                                                                                                                                                                                                                                                                  |
| CMD52     | ac       | [31:0] stuff bits                                                                         | R5            | IO_RW_DIRECT         | Access a single register within the total 128k of register space in any I/O function.                                                                                                                                                                                            |
| CMD53     | ac       | [31:0] stuff bits                                                                         | R5            | IO_RW_EXTENDED       | Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.                                                                                                                                                        |
| CMD54     | Reserved |                                                                                           |               |                      |                                                                                                                                                                                                                                                                                  |
| CMD55     | ac       | [31:16] RCA<br>[15:0] stuff bits                                                          | R1            | APP_CMD              | Indicates to the card that the next command is an application specific command rather than a standard command.                                                                                                                                                                   |
| CMD56     | adtc     | [31:1] stuff bits<br>[0]: RD/WR                                                           | R1b           | GEN_CMD              | Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.                                                                       |
| CMD57-59  | Reserved |                                                                                           |               |                      |                                                                                                                                                                                                                                                                                  |
| CMD60     | adtc     | [31] WR<br>[30:24] stuff bits<br>[23:16] address<br>[15:8] stuff bits<br>[7:0] byte count | R1b           | RW_MULTIPLE_REGISTER | These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers. |
| CMD61     | adtc     | [31] WR<br>[30:16] stuff bits<br>[15:0] data unit count                                   | R1b           | RW_MULTIPLE_BLOCK    | The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.                                                                                                                                                                                                          |
| CMD62-63  | Reserved |                                                                                           |               |                      |                                                                                                                                                                                                                                                                                  |

Table continues on the next page...

**Table 26-4. Commands for MMC/SD/SDIO Cards (continued)**

| CMD INDEX           | Type | Argument                                      | Response type | Abbreviation           | Description                                                                                                                                   |
|---------------------|------|-----------------------------------------------|---------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| ACMD6 <sup>4</sup>  | ac   | [31:2] stuff bits<br>[1:0] bus width          | R1            | SET_BUS_WIDTH          | Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.  |
| ACMD13 <sup>4</sup> | adtc | [31:0] stuff bits                             | R1            | SD_STATUS              | Send the SD Memory Card status.                                                                                                               |
| ACMD22 <sup>4</sup> | adtc | [31:0] stuff bits                             | R1            | SEND_NUM_WR_SECTORS    | Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.                                        |
| ACMD23 <sup>4</sup> | ac   | [31:23] stuff bits<br>[22:0] Number of blocks | R1            | SET_WR_BLK_ERASE_COUNT | Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block). |
| ACMD41 <sup>4</sup> | bcr  | [31:0] OCR                                    | R3            | SD_APP_OP_COND         | Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.                               |
| ACMD42 <sup>4</sup> | ac   | [31:1] stuff bits<br>[0] set_cd               | R1            | SET_CLR_CARD_DETECT    | Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/ DATA3 of the card.                                                              |
| ACMD51 <sup>4</sup> | adtc | [31:0] stuff bits                             | R1            | SEND_SCR               | Reads the SD Configuration Register (SCR).                                                                                                    |

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in [Table 2](#).
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown below.

**Table 26-5. EXT\_CSD Access Modes**

| Bits | Access Name | Operation                                                                             |
|------|-------------|---------------------------------------------------------------------------------------|
| 00   | Command Set | The command set is changed according to the Cmd Set field of the argument             |
| 01   | Set Bits    | The bits in the pointed byte are set, according to the 1 bits in the Value field.     |
| 10   | Clear Bits  | The bits in the pointed byte are cleared, according to the 1 bits in the Value field. |
| 11   | Write Byte  | The Value field is written into the pointed byte.                                     |

## 26.8 Software Restrictions

### 26.8.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

### 26.8.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD\_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 26.8.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

## 26.8.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

## 26.8.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

## 26.8.6 Data Port Access

Data Port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or internal DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

## 26.8.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC\_SDCLK\_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

## 26.8.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

## 26.9 uSDHC Memory Map/Register Definition

### 26.9.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

#### NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

#### 26.9.1.1 uSDHC Memory map

Base address: 402C\_0000h for uSDHC1, 402C\_4000h for uSDHC2.

| Offset | Register                                     | Width<br>(In bits) | Access | Reset value      |
|--------|----------------------------------------------|--------------------|--------|------------------|
| 0h     | DMA System Address (DS_ADDR)                 | 32                 | RW     | 0000_0000h       |
| 4h     | Block Attributes (BLK_ATT)                   | 32                 | RW     | 0000_0000h       |
| 8h     | Command Argument (CMD_ARG)                   | 32                 | RW     | 0000_0000h       |
| Ch     | Command Transfer Type (CMD_XFR_TYP)          | 32                 | RW     | 0000_0000h       |
| 10h    | Command Response0 (CMD_RSP0)                 | 32                 | RO     | 0000_0000h       |
| 14h    | Command Response1 (CMD_RSP1)                 | 32                 | RO     | 0000_0000h       |
| 18h    | Command Response2 (CMD_RSP2)                 | 32                 | RO     | 0000_0000h       |
| 1Ch    | Command Response3 (CMD_RSP3)                 | 32                 | RO     | 0000_0000h       |
| 20h    | Data Buffer Access Port (DATA_BUFF_ACC_PORT) | 32                 | RW     | 0000_0000h       |
| 24h    | Present State (PRES_STATE)                   | 32                 | RO     | See description. |
| 28h    | Protocol Control (PROT_CTRL)                 | 32                 | RW     | 0880_0020h       |
| 2Ch    | System Control (SYS_CTRL)                    | 32                 | RW     | 0080_800Fh       |
| 30h    | Interrupt Status (INT_STATUS)                | 32                 | W1C    | 0000_0000h       |
| 34h    | Interrupt Status Enable (INT_STATUS_EN)      | 32                 | RW     | 0000_0000h       |

*Table continues on the next page...*

| Offset | Register                                             | Width<br>(In bits) | Access | Reset value |
|--------|------------------------------------------------------|--------------------|--------|-------------|
| 38h    | Interrupt Signal Enable (INT_SIGNAL_EN)              | 32                 | RW     | 0000_0000h  |
| 3Ch    | Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)       | 32                 | RW     | 0000_0000h  |
| 40h    | Host Controller Capabilities (HOST_CTRL_CAP)         | 32                 | RW     | 07F3_B407h  |
| 44h    | Watermark Level (WTMK_LVL)                           | 32                 | RW     | 0810_0810h  |
| 48h    | Mixer Control (MIX_CTRL)                             | 32                 | RW     | 8000_0000h  |
| 50h    | Force Event (FORCE_EVENT)                            | 32                 | WORZ   | 0000_0000h  |
| 54h    | ADMA Error Status Register (ADMA_ERR_STATUS)         | 32                 | RO     | 0000_0000h  |
| 58h    | ADMA System Address (ADMA_SYS_ADDR)                  | 32                 | RW     | 0000_0000h  |
| 60h    | DLL (Delay Line) Control (DLL_CTRL)                  | 32                 | RW     | 0000_0000h  |
| 64h    | DLL Status (DLL_STATUS)                              | 32                 | RO     | 0000_0200h  |
| 68h    | CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) | 32                 | RW     | 0000_0000h  |
| C0h    | Vendor Specific Register (VEND_SPEC)                 | 32                 | RW     | 2000_7809h  |
| C4h    | MMC Boot Register (MMC_BOOT)                         | 32                 | RW     | 0000_0000h  |
| C8h    | Vendor Specific 2 Register (VEND_SPEC2)              | 32                 | RW     | 0000_1006h  |
| CCh    | Tuning Control Register (TUNING_CTRL)                | 32                 | RW     | 0021_2800h  |

## 26.9.1.2 DMA System Address (DS\_ADDR)

### 26.9.1.2.1 Offset

| Register | Offset |
|----------|--------|
| DS_ADDR  | 0h     |

### 26.9.1.2.2 Function

This register contains the physical system memory address used for DMA transfers.

### 26.9.1.2.3 Diagram

### 26.9.1.2.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>DS_ADDR | <p><b>DS_ADDR</b></p> <p><b>DMA System Address / Argument 2</b></p> <p>When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.</p> <p><b>1. SDMA System Address</b></p> <p>Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.</p> <p>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.</p> <p>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a>.</p> <p><b>2. Argument 2</b></p> <p>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.</p> <p>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.</p> |

### 26.9.1.3 Block Attributes (BLK\_ATT)

#### 26.9.1.3.1 Offset

| Register | Offset |
|----------|--------|
| BLK_ATT  | 4h     |

#### 26.9.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

#### 26.9.1.3.3 Diagram

#### 26.9.1.3.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>BLKCNT | <p>Block Count</p> <p>Blocks Count For Current Transfer:</p> <p>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend.</p> |

## 26.9.1.4 Command Argument (CMD\_ARG)

### 26.9.1.4.1 Offset

| Register | Offset |
|----------|--------|
| CMD_ARG  | 8h     |

### 26.9.1.4.2 Function

This register contains the SD / MMC Command Argument.

.

### 26.9.1.4.3 Diagram

### 26.9.1.4.4 Fields

| Field          | Function                                                                                                                                                                                                                                               |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>CMDARG | <p>Command Argument</p> <p>The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification. This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.</p> |

## 26.9.1.5 Command Transfer Type (CMD\_XFR\_TYP)

### 26.9.1.5.1 Offset

| Register    | Offset |
|-------------|--------|
| CMD_XFR_TYP | Ch     |

### 26.9.1.5.2 Function

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

**Table 26-6. Transfer Type Register Setting for Various Transfer Types**

| Multi/Single Block Select | Block Count Enable | Block Count     | Function          |
|---------------------------|--------------------|-----------------|-------------------|
| 0                         | Don't Care         | Don't Care      | Single Transfer   |
| 1                         | 0                  | Don't Care      | Infinite Transfer |
| 1                         | 1                  | Positive Number | Multiple Transfer |
| 1                         | 1                  | Zero            | No Data Transfer  |

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

**Table 26-7. Relationship Between Parameters and the Name of the Response Type**

| Response Type | Index Check Enable | CRC Check Enable | Name of Response Type |
|---------------|--------------------|------------------|-----------------------|
| 00            | 0                  | 0                | No Response           |
| 01            | 0                  | 1                | R2                    |
| 10            | 0                  | 0                | R3,R4                 |
| 10            | 1                  | 1                | R1,R5,R6              |
| 11            | 1                  | 1                | R1b,R5b               |

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

| 31-30<br>—      | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 29-24<br>CMDINX | Command Index<br>These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 23-22<br>CMDTYP | Command Type<br>There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> <li>• Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to <a href="#">Suspend Resume</a> for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.</li> </ul> |

### 26.9.1.6.4 Fields

| Field   | Function                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0    | Command Response 0                                                                                                                                  |
| CMDRSP0 | Refer to <a href="#">Command Response3 (CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type. |

## 26.9.1.7 Command Response1 (CMD\_RSP1)

### 26.9.1.7.1 Offset

| Register | Offset |
|----------|--------|
| CMD_RSP1 | 14h    |

### 26.9.1.7.2 Function

This register is used to store part 1 of the response bits from the card.

### 26.9.1.7.3 Diagram

### 26.9.1.7.4 Fields

| Field   | Function                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0    | Command Response 1                                                                                                                                  |
| CMDRSP1 | Refer to <a href="#">Command Response3 (CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type. |

## 26.9.1.8 Command Response2 (CMD\_RSP2)

### 26.9.1.8.1 Offset

| Register | Offset |
|----------|--------|
| CMD_RSP2 | 18h    |

### 26.9.1.8.2 Function

This register is used to store part 2 of the response bits from the card.

### 26.9.1.8.3 Diagram

### 26.9.1.8.4 Fields

| Field           | Function                                                                                                                                                                  |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>CMDRSP2 | Command Response 2<br>Refer to <a href="#">Command Response3 (CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type. |

## 26.9.1.9 Command Response3 (CMD\_RSP3)

### 26.9.1.9.1 Offset

| Register | Offset |
|----------|--------|
| CMD_RSP3 | 1Ch    |

### 26.9.1.9.2 Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

**Table 26-8. Response Bit Definition for Each Response Type**

| Response Type            | Meaning of Response | Response Field | Response Register |
|--------------------------|---------------------|----------------|-------------------|
| R1,R1b (normal response) | Card Status         | R[39:8]        | CMDRSP0           |

*Table continues on the next page...*

**Table 26-8. Response Bit Definition for Each Response Type (continued)**

| Response Type             | Meaning of Response                               | Response Field | Response Register                                   |
|---------------------------|---------------------------------------------------|----------------|-----------------------------------------------------|
| R1b (Auto CMD12 response) | Card Status for Auto CMD12                        | R[39:8]        | CMDRSP3                                             |
| R2 (CID, CSD register)    | CID/CSD register [127:8]                          | R[127:8]       | {CMDRSP3[23:0],<br>CMDRSP2,<br>CMDRSP1,<br>CMDRSP0} |
| R3 (OCR register)         | OCR register for memory                           | R[39:8]        | CMDRSP0                                             |
| R4 (OCR register)         | OCR register for I/O etc.                         | R[39:8]        | CMDRSP0                                             |
| R5, R5b                   | SDIO response                                     | R[39:8]        | CMDRSP0                                             |
| R6 (Publish RCA)          | New Published RCA[31:16]<br>and card status[15:0] | R[39:9]        | CMDRSP0                                             |

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows the uSDHC to avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

## 26.9.1.11 Present State (PRES\_STATE)

### 26.9.1.11.1 Offset

| Register   | Offset |
|------------|--------|
| PRES_STATE | 24h    |

### 26.9.1.11.2 Function

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.
- Note: the reset value of Present State Register depend on board connectivity.

|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <ul style="list-style-type: none"> <li>After the end bit of the write command.</li> <li>When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy".</li> <li>When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request.</li> </ul> <p>In the case of command with busy pending:</p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.</p> <p>0b - DATA Line Inactive<br/>1b - DATA Line Active</p> |
| 1<br>CDIHB | <p>Command Inhibit (DATA)</p> <p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>0b - Can issue command which uses the DATA line<br/>1b - Cannot issue command which uses the DATA line</p>                                                                                                                                                                                                                                                                                                                                  |
| 0<br>CIHB  | <p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.</p> <p>0b - Can issue command using only CMD line<br/>1b - Cannot issue command</p>                                                                                |

## 26.9.1.12 Protocol Control (PROT\_CTRL)

### 26.9.1.12.1 Offset

| Register  | Offset |
|-----------|--------|
| PROT_CTRL | 28h    |

### 26.9.1.12.2 Function

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

|               | <i>In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 19<br>IABG    | <p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>0b - Disabled<br/>1b - Enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 18<br>RWCTL   | <p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</p> <p>0b - Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set<br/>1b - Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 17<br>CREQ    | <p>Continue Request</p> <p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</p> <p>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</p> <p>0b - No effect<br/>1b - Restart</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 16<br>SABGREQ | <p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</p> <p>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.</p> <p>0b - Transfer<br/>1b - Stop</p> |
| 15-10<br>—    | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 28<br>RSTT  | Reset Tuning<br>When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 27<br>INITA | Initialization Active<br>When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared. |

| 24<br>RSTA      | <p>Software Reset For ALL</p> <p>This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver shall set this bit to 1 to reset the uSDHC. The uSDHC shall reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. After this bit is set, SW should wait for self-clear.</p> <p>In tuning process, after every CMD19 is finished, this bit will be set to retest the uSDHC.</p> <p><b>NOTE:</b> When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC INT_STATUS register is set.</p> <p>0b - No Reset<br/>1b - Reset</p>                                                |

|            | <p>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.</p> <p>The frequency of SDCLK is set by the following formula:</p> <p>Clock Frequency = (Base Clock) / (prescaler x divisor)</p> <p>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.</p> <p>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p><i>If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.</i></p> |
| 7-4<br>DVS | <p>Divisor</p> <p>This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>The setting are as following:</p> <p>0000b - Divide-by-1<br/>0001b - Divide-by-2<br/>1110b - Divide-by-15<br/>1111b - Divide-by-16</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 26.9.1.14 Interrupt Status (INT\_STATUS)

### 26.9.1.14.1 Offset

| Register   | Offset |
|------------|--------|
| INT_STATUS | 30h    |

### 26.9.1.14.2 Function

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For

Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

**Table 26-9. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations**

| Command Complete | Command Timeout Error | Meaning of the Status                        |
|------------------|-----------------------|----------------------------------------------|
| 0                | 0                     | X                                            |
| X                | 1                     | Response not received within 64 SDCLK cycles |
| 1                | 0                     | Response received                            |

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 26-10. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations**

| Transfer Complete | Data Timeout Error | Meaning of the Status            |
|-------------------|--------------------|----------------------------------|
| 0                 | 0                  | X                                |
| 0                 | 1                  | Timeout occurred during transfer |
| 1                 | X                  | Data Transfer Complete           |

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

**Table 26-11. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations**

| Command Complete | Command Timeout Error | Meaning of the Status  |
|------------------|-----------------------|------------------------|
| 0                | 0                     | No error               |
| 0                | 1                     | Response Timeout Error |
| 1                | 0                     | Response CRC Error     |
| 1                | 1                     | CMD line conflict      |

| 28<br>DMAE  | DMA Error<br>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.<br><br>0b - No Error<br>1b - Error |
| 27<br>—     | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 26<br>TNE   | Tuning Error: (only for SD3.0 SDR104 mode and EMMC HS200 mode)<br>This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.                                                                                                                                                                                                                                                                                                                                                                                               |

| CTOE      | Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in <a href="#">Interrupt Status (INT_STATUS)</a> ), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.<br><br>This bit will be not asserted in tuning process.<br><br>0b - No Error<br>1b - Time out                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 8<br>CINT | Card Interrupt<br><br>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit.<br><br>When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.<br><br>0b - No Card Interrupt<br>1b - Generate Card Interrupt |
| 7<br>CRM  | Card Removal<br><br>This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.<br><br>0b - Card state unstable or inserted<br>1b - Card removed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 26.9.1.15 Interrupt Status Enable (INT\_STATUS\_EN)

### 26.9.1.15.1 Offset

| Register      | Offset |
|---------------|--------|
| INT_STATUS_EN | 34h    |

### 26.9.1.15.2 Function

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

## 26.9.1.16 Interrupt Signal Enable (INT\_SIGNAL\_EN)

### 26.9.1.16.1 Offset

| Register      | Offset |
|---------------|--------|
| INT_SIGNAL_EN | 38h    |

### 26.9.1.16.2 Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

### 26.9.1.17 Auto CMD12 Error Status (AUTOCMD12\_ERR\_STATUS)

#### 26.9.1.17.1 Offset

| Register                 | Offset |
|--------------------------|--------|
| AUTOCMD12_ERR_ST<br>ATUS | 3Ch    |

### 26.9.1.17.2 Function

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMD12 CRC Error and the Auto CMD12 Command Timeout Error.

**Table 26-12. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12**

| Auto CMD12 CRC Error | Auto CMD12 Timeout Error | Type of Error          |
|----------------------|--------------------------|------------------------|
| 0                    | 0                        | No Error               |
| 0                    | 1                        | Response Timeout Error |
| 1                    | 0                        | Response CRC Error     |
| 1                    | 1                        | CMD line conflict      |

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
  - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
  - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
  - Check errors correspond to bits 1-4.
  - Set bits 1-4 corresponding to detected errors.
  - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
  - Set bit 7 to 1 if there is a command that can't be issued
  - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

| 23<br>SMP_CLK_SEL    | Sample Clock Select<br>When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.<br><br>0b - Fixed clock is used to sample data<br>1b - Tuned clock is used to sample data |
| 22<br>EXECUTE_TUNING | Execute Tuning<br>When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when runing procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 21-8<br>—            | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 26.9.1.18 Host Controller Capabilities (HOST\_CTRL\_CAP)

### 26.9.1.18.1 Offset

| Register      | Offset |
|---------------|--------|
| HOST_CTRL_CAP | 40h    |

### 26.9.1.18.2 Function

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

### 26.9.1.19 Watermark Level (WTMK\_LVL)

#### 26.9.1.19.1 Offset

| Register | Offset |
|----------|--------|
| WTMK_LVL | 44h    |

#### 26.9.1.19.2 Function

Both write and read watermark levels (FIFO threshold) are configurable. Their value can range from 1 to 128 words. Both write and read burst lengths are also Configurable. Their value can range from 1 to 31 words.

#### 26.9.1.19.3 Diagram

| 12-8<br>RD_BRST_LEN  | Read Burst Length Due to system restriction, the actual burst length may not exceed 16.<br>The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).     |
| 7-0<br>RD_WML        | Read Watermark Level<br>The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.                                                                                                                                                                                  |

## 26.9.1.20 Mixer Control (MIX\_CTRL)

### 26.9.1.20.1 Offset

| Register | Offset |
|----------|--------|
| MIX_CTRL | 48h    |

### 26.9.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

**Table 26-13. Transfer Type Register Setting for Various Transfer Types**

| Multi/Single Block Select | Block Count Enable | Block Count     | Function          |
|---------------------------|--------------------|-----------------|-------------------|
| 0                         | Don't Care         | Don't Care      | Single Transfer   |
| 1                         | 0                  | Don't Care      | Infinite Transfer |
| 1                         | 1                  | Positive Number | Multiple Transfer |
| 1                         | 1                  | Zero            | No Data Transfer  |

| 2<br>AC12EN        | Auto CMD12 Enable<br>Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not. |

| FORCE_EVENT | 50h    |

### 26.9.1.21.2 Function

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG\_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

## 26.9.1.22 ADMA Error Status Register (ADMA\_ERR\_STATUS)

### 26.9.1.22.1 Offset

| Register        | Offset |
|-----------------|--------|
| ADMA_ERR_STATUS | 54h    |

### 26.9.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST\_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST\_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST\_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST\_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST\_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

**Table 26-14. ADMA Error State Coding**

| D01-D00 | ADMA Error State (when error has occurred) | Contents of ADMA System Address Register                    |
|---------|--------------------------------------------|-------------------------------------------------------------|
| 00      | ST_STOP (Stop DMA)                         | Holds the address of the next executable Descriptor command |
| 01      | ST_FDS (Fetch Descriptor)                  | Holds the valid Descriptor address                          |
| 10      | ST_CADR (Change Address)                   | No ADMA Error is generated                                  |
| 11      | ST_TFR (Transfer Data)                     | Holds the address of the next executable Descriptor command |

### 26.9.1.23 ADMA System Address (ADMA\_SYS\_ADDR)

### 26.9.1.23.1 Offset

| Register      | Offset |
|---------------|--------|
| ADMA_SYS_ADDR | 58h    |

### 26.9.1.23.2 Function

This register contains the physical system memory address used for ADMA transfers.

### 26.9.1.23.3 Diagram

### 26.9.1.23.4 Fields

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2<br>ADS_ADDR | <p>ADMA System Address</p> <p>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a>.</p> |
| 1-0<br>—         | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 26.9.1.24 DLL (Delay Line) Control (DLL\_CTRL)

### 26.9.1.24.1 Offset

| Register | Offset |
|----------|--------|
| DLL_CTRL | 60h    |

### 26.9.1.24.2 Function

This register contains control bits for DLL.

### 26.9.1.24.3 Diagram

### 26.9.1.24.4 Fields

| Field | Function                |
|-------|-------------------------|
| 31-28 | DLL_CTRL_REF_UPDATE_INT |

Table continues on the next page...

| Field                             | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DLL_CTRL_REF_UPDATE_INT           | DLL control loop update interval. The interval cycle is $(2 + \text{REF\_UPDATE\_INT}) * \text{REF\_CLOCK}$ . By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)                                                                                                              |
| 27-20<br>DLL_CTRL_SLV_UPDATE_INT  | DLL_CTRL_SLV_UPDATE_INT<br>Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).                                                                                       |
| 19<br>—                           | -<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 18-16<br>DLL_CTRL_SLV_DLY_TARGET1 | DLL_CTRL_SLV_DLY_TARGET1<br>Refer to DLL_CTRL_SLV_DLY_TARGET0 below.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15-9<br>DLL_CTRL_SLV_OVERRIDE_VAL | DLL_CTRL_SLV_OVERRIDE_VAL<br>When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.                                                                                                                                                                                                                                                                                                                                   |
| 8<br>DLL_CTRL_SLV_OVERRIDE        | DLL_CTRL_SLV_OVERRIDE<br>Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0                                                                                                                                                                            |
| 7<br>DLL_CTRL_GATE_UPDATE         | DLL_CTRL_GATE_UPDATE<br>Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.                                                                                                                                                                                                                                          |
| 6-3<br>DLL_CTRL_SLV_DLY_TARGET0   | DLL_CTRL_SLV_DLY_TARGET0<br>The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is $((\{\text{DLL\_CTRL\_SLV\_DLY\_TARGET1}, \text{DLL\_CTRL\_SLV\_DLY\_TARGET0}\} + 1) * \text{REF\_CLOCK} / 2) / 16$ So the input read-clock can be delayed relative input data from $(\text{REF\_CLOCK} / 2) / 16$ to $\text{REF\_CLOCK} * 4$ .                                                                                                     |
| 2<br>DLL_CTRL_SLV_FORCE_UPD       | DLL_CTRL_SLV_FORCE_UPD<br>Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response. |
| 1<br>DLL_CTRL_RESET               | DLL_CTRL_RESET<br>Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.                                                                                                                                                                                                    |
| 0<br>DLL_CTRL_ENABLE              | DLL_CTRL_ENABLE<br>Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.                                                                                                                                                                                                                                                                     |

## 26.9.1.25 DLL Status (DLL\_STATUS)

### 26.9.1.25.1 Offset

| Register   | Offset |
|------------|--------|
| DLL_STATUS | 64h    |

### 26.9.1.25.2 Function

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

| Field                  | Function                                                                                                                                                                                                                                                                |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8-2<br>DLL_STS_SLV_SEL | DLL_STS_SLV_SEL<br>Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked. |
| 1<br>DLL_STS_REF_LOCK  | DLL_STS_REF_LOCK<br>Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays                                                                    |
| 0<br>DLL_STS_SLV_LOCK  | DLL_STS_SLV_LOCK<br>Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value                                                                 |

## 26.9.1.26 CLK Tuning Control and Status (CLK\_TUNE\_CTRL\_ST ATUS)

### 26.9.1.26.1 Offset

| Register              | Offset |
|-----------------------|--------|
| CLK_TUNE_CTRL_ST ATUS | 68h    |

### 26.9.1.26.2 Function

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

#### NOTE

The soft reset bit (MCR\_SWRESET) should be set, to enable the inverted clock, after setting the SCKBDIFFOPT bit.

#### NOTE

Octal mode is supported by combining SIOA[3:0] and SIOB[3:0], on this device.

#### 27.1.1 Master ID allocation

This table summarizes the master IDs for all system master modules:

Table 27-2. Master IDs

| Module        | Master ID |
|---------------|-----------|
| Core Platform | 000b      |

*Table continues on the next page...*

**Table 27-2. Master IDs (continued)**

| Module     | Master ID |
|------------|-----------|
| eDMA       | 001b      |
| DCP        | 010b      |
| All others | 011b      |

## 27.2 Overview

Flexible Serial Peripheral Interface (FlexSPI) host controller supports two SPI channels and up to 4 external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

### NOTE

FlexSPI configuration is dependent on the chip configuration. Please refer to the system-level sections for boot and pinmux for chip specific information regarding the modes and number of devices supported.

### 27.2.1 Features

FlexSPI block supports following features:

- Flexible sequence engine (LUT table) to support various vendor devices
  - Serial NOR Flash or other device with similar SPI protocol as Serial NOR Flash
  - Serial NAND Flash
  - HyperBus device (HyperFlash/HyperRAM)
  - FPGA device
- Flash access mode
  - Single/Dual/Quad/Octal mode
  - SDR/DDR mode
  - Individual/Parallel mode
- Support sampling clock mode:
  - Internal dummy read strobe loopbacked internally
  - Internal dummy read strobe loopbacked from pad
  - Flash provided read strobe
- Memory mapped read/write access by AHB Bus
  - AHB RX Buffer implemented to reduce read latency. Total AHB RX Buffer size: 128 \* 64 Bits
  - 16 AHB masters supported with priority for read access

- 4 flexible and configurable buffers in AHB RX Buffer
- AHB TX Buffer implemented to buffer all write data from one AHB burst. AHB TX Buffer size: 8 \* 64 Bits
- All AHB masters share this AHB TX Buffer. No AHB master number limitation for Write Access.
- Software triggered Flash read/write access by IP Bus
  - IP RX FIFO implemented to buffer all read data from External device. FIFO size: 16 \* 64 Bits
  - IP TX FIFO implemented to buffer all Write data to External device. FIFO size: 16 \* 64 Bits
  - DMA support to fill IP TX FIFO
  - DMA support to read IP RX FIFO
  - SCLK stopped when reading flash data and IP RX FIFO is full
  - SCLK stopped when writing flash data and IP TX FIFO is empty

## 27.2.2 Block diagram

The block diagram of FlexSPI is indicated in following figure:

Figure 27-1. FlexSPI block diagram

## 27.2.3 Operation Modes

This section provides information about the modes FlexSPI could be used.

- Module Disable mode

This mode is low power mode in FlexSPI module.

In module disable mode, AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by setting MCR0[MDIS], and exited by clearing MCR0[MDIS].

- Doze mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter doze mode and MCR0[DOZEEN] is set, the FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and enter doze mode. In doze mode, the AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by system request, and exited by deasserting this system request.

- Stop mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter stop mode, FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and return ACK handshake to system. After ACK handshake returned, IP will gate off the AHB clock and serial clock domain internally, the system can gate the AHB Bus clock, IPS Bus clock and serial clock in system level.

This mode is entered by system stop mode request. When all command sequences finish, FlexSPI enters stop mode and returns ACK handshake. This mode is exited by deasserting system stop mode request, the ACK handshake is also deasserted immediately.

- Normal mode

In normal mode, all clocks are not gated internally. Normal register access and serial flash memory access is available.

## 27.3 Glossary for FlexSPI module

**Table 27-3. Glossary**

| Term             | Definition                                                                                                                                                                                                                                                                                                                               |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AHB Command      | AHB Command is one or several Serial Flash Memory access command sequences triggered by AHB read/write access to AHB address ranged mapped for Serial Flash Memory.                                                                                                                                                                      |
| ASFM_BASE        | Base address of AHB address space mapped to Serial Flash Memory.                                                                                                                                                                                                                                                                         |
| ARDF_BASE        | Base address of AHB address space mapped to IP RX FIFO.                                                                                                                                                                                                                                                                                  |
| ATDF_BASE        | Base address of AHB address space mapped to IP TX FIFO.                                                                                                                                                                                                                                                                                  |
| Set              | Write 1 to register bit to establish logic level one on the bit.                                                                                                                                                                                                                                                                         |
| Clear            | Write 0 to register bit to establish logic level zero on the bit.                                                                                                                                                                                                                                                                        |
| Command Sequence | A command sequence is 4*32 bits sequence code consisting of up to 8 instructions.<br>Command sequence should be programmed in LUT according to Flash command.<br>When a command sequence executed, the chip selection signal becomes asserted.<br>When a command sequence execution finished, the chip selection signal becomes negated. |
| DDR              | Dual data transfer rate for flash access mode<br>Flash receive data on both SCLK rise and fall edge and transmit data on both SCLK rise and fall edge.                                                                                                                                                                                   |
| Endianness       | Byte Ordering scheme.                                                                                                                                                                                                                                                                                                                    |
| Field            | Two or more register bits grouped together.                                                                                                                                                                                                                                                                                              |
| Fill             | To add entries to a FIFO by software or hardware.                                                                                                                                                                                                                                                                                        |
| Instruction Code | 16 bits code defining the type of command to be executed on FlexSPI interface.                                                                                                                                                                                                                                                           |
| IP Command       | IP Command is one or several Serial Flash Memory access command sequences triggered by set register bit IPCMD.TRG.                                                                                                                                                                                                                       |
| Negated          | A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.                                                                                                                                 |
| SDR              | Single data transfer rate for flash access mode<br>Flash receive data on SCLK rise edge and transmit data on SCLK fall edge.                                                                                                                                                                                                             |
| Set              | To set a bit or bits means to establish logic level one on the bit or bits.                                                                                                                                                                                                                                                              |
| SFM              | Serial Flash Memory                                                                                                                                                                                                                                                                                                                      |
| Individual Mode  | Access to a single, individual serial flash device at a time.                                                                                                                                                                                                                                                                            |
| Parallel Mode    | Read/Program Access to two serial flash devices in parallel (Port A and Port B).<br>FlexSPI will split flash program data before transmitting to Flash or merge flash read data before putting into IP RX FIFO or AHB RX Buffer automatically.                                                                                           |
| Memory Command   | Serial access Command for reading/programming/configuring.<br>A memory command may consist one or several command sequences, for each command sequence the Chip selection signal will be asserted and deasserted once.                                                                                                                   |
| LUT              | Look-up table to preserve command sequence.<br>LUT is programmed by software with command sequences which is used to issue memory commands.                                                                                                                                                                                              |

## 27.4 External Signal Description

This section provides the external signal information of the FlexSPI module.

**Table 27-4. External Signal List**

| Signal Name | Function                        | Direction | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 27.5 Functional description

The following sections describe functional details of the FlexSPI module.

### 27.5.1 Clocks

This section describes clocks and special clocking requirements of the FlexSPI module.

**Table 27-5. Clock Usage**

| Clock Name                       | Description                  | Comment |
|----------------------------------|------------------------------|---------|
| serial clock root (ipg_clk_sfck) | Root clock for Serial domain | -       |
| ahb clock (hclk)                 | AHB Bus clock                | -       |
| ipg clock (ipg_clk)              | IPS Bus clock                | -       |

*Table continues on the next page...*

**Table 27-5. Clock Usage (continued)**

| Clock Name | Description              | Comment                                                                                                                      |
|------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------|
| DQS_OUT    | Dummy Read Strobe output | Same frequency as SCLK. Clock output toggles during READ/LEARN instructions.                                                 |
| DQS_IN     | Sample clock for RX Data | Same frequency as SCLK. Sample clock comes from loopbacked dummy read strobe, loopbacked SCLK or Flash provided read strobe. |

## 27.5.2 Interrupts

This section describes all the interrupts that the FlexSPI module generates.

- **IP command done interrupt**

When IP command is finished, there will be interrupt generated if INTEN[IPCMDDONEEN] is set to 0x1.

- **IP command grant error interrupt**

When IP command grant timeout (not grant after MCR0[IPGRANTWAIT] \* 1024 ahb clock cycles), there will be interrupt generated if INTEN[IPCMDGEEN] is set to 0x1.

- **AHB command grant error interrupt**

When AHB command grant timeout (not grant after MCR0[AHBGRANTWAIT] \* 1024 ahb clock cycles), there will be interrupt generated if INTEN[AHBCMDGEEN] is set to 0x1.

- **IP command error interrupt**

When there is command check error or command execution error for IP command, there will be interrupt generated if INTEN[IPCMDERREN] is set to 0x1. Refer [Overview of Error Flags](#) for more details.

- **AHB command error interrupt**

When there is command check error or command execution error for AHB command, there will be interrupt generated if INTEN[AHBCMDERREN] is set to 0x1. Refer [Overview of Error Flags](#) for more details.

- **IP RX FIFO watermark available interrupt**

When the fill level of IP RX FIFO is no less than watermark level (IPRXFCR[RXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **IP TX FIFO watermark exceed interrupt**

When the empty level of IP TX FIFO is no less than watermark level (IPTXFCR[TXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **Sequence execution timeout interrupt**

When a sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]), an interrupt will be generated if INTEN[SEQTIMEOUTEN] is set to 0x1. For example, the following flash read command sequence will last about 8000000 cycle (ipg\_clk\_sfck). If SEQWAIT is set 0xFFFF, there will be sequence timeout interrupt generated.

- Triggered by IP command
- Flash read data size is 0x1000000 bytes
- Flash accessed in Single mode and SDR mode,

- **AHB Bus timeout interrupt**

When AHB bus response timeout, there will be interrupt generated if INTEN[AHBBUSTIMEOUTEN] is set to 0x1. A typical case is AHB read sequence is not configured properly in LUT (such as without READ instruction). There will never be data read from external device, then FlexSPI will never hit the read data in AHB RX Buffers for AHB Read command.

- **SCLK stopped by write command interrupt**

When IP TX FIFO is empty during write command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for write data filling. At this time, this interrupt is generated if enabled by INTEN register.

- **SCLK stopped by read command interrupt**

When IP RX FIFO is full during read command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for read data read out from IP RX FIFO. At this time, this interrupt is generated if enabled by INTEN register.

## 27.5.3 Flash Connection

There are two FlexSPI interface ports (A port and B port). Each port supports 2 flash devices by providing 2 chip select outputs.

**NOTE**

FlexSPI configuration is dependent on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

The connection diagram with 4 devices is as following:

**Figure 27-2. Flash connection diagram with four devices**

**NOTE**

- Flash A1 and A2 could be two flash chip package or two flash die on the same package. There is no difference to FlexSPI. Same for Flash B1 and B2.
- Flash A1 and B1 could be accessed in parallel, using parallel mode. FlexSPI will merge/split the flash read/program data automatically. Same for A2 and B2.
- In parallel mode, A1 and A2 could not be accessed at the same time. Same for B1 and B2.
- In individual mode, A1, A2, B1 and B2 could not be accessed at the same time. But these four device could be accessed separately.

There is a combination mode to provide octal flash support by combining A port (A\_DATA[3:0]) and B port (B\_DATA[3:0]) together. The connection diagram for this combination mode is as following:

Figure 27-3. Flash connection diagram with combination mode

## 27.5.4 Flash Access mode

This section describes flash access mode.

### 27.5.4.1 SPI clock mode

FlexSPI supports only SPI clock mode 0: Clock polarity (CPOL)=0 and Clock Phase (CPHA)=0. SCLK will stay at logic low state when SPI bus is idle.

### 27.5.4.2 Flash Individual mode and Parallel mode

In individual mode, Flash read/write data is received/transmit on port A or port B.

In parallel mode, Flash read/write data is received/transmit on port A and B port parallelly. FlexSPI will merge/split the flash read/program data automatically. Please note that only read/program data is merged/split (READ/WRITE instruction). For other instructions (such as Command/Address/Mode/Data size), same command code/address/mode bits/data size information will be transmit to port A and port B device. For more detail, please refer to [Instruction execution on SPI interface](#).

Individual mode and parallel mode is determined statically by register field IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command).

### **27.5.4.3 SDR mode and DDR mode**

In SDR (Single Data transfer Rate) mode, Flash receives data on SCLK rise edge and transmit data on SCLK fall edge.

In DDR (Dual Data transfer Rate) mode, Flash receives data on both SCLK rise and fall edges and transmit data on both SCLK rise and fall edges.

SDR and DDR mode is determined by instruction (opcode) in LUT sequence dynamically. There is no static configuration register field setting for SDR and DDR mode. For more details about input and output timing, please refer to [FlexSPI Input Timing](#) and [FlexSPI Output Timing](#).

### **27.5.4.4 Single, Dual, Quad, and Octal mode**

In Single mode, flash transmit/receive data on 1 Data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, flash transmit/receive data on 2 Data pin (DATA0~DATA1 for both transmitting and receiving).

In Quad mode, flash transmit/receive data on 4 Data pin (DATA0~DATA3 for both transmitting and receiving).

In Octal mode, flash transmit/receive data on 8 Data pin (DATA0~DATA7 for both transmitting and receiving).

Single, Dual, Quad and Octal mode is determined by instruction (num\_pads) in LUT sequence dynamically. There is no static configuration register field setting for Single, Dual, Quad and Octal mode.

## 27.5.5 Flash memory map

Flash memory map in individual and parallel mode is as following:

**Figure 27-4. Flash memory map in individual and parallel mode**

Flash memory map in individual mode:

- Flash A1 address range:  $0x00000000 \sim FA1\_SIZE$
- Flash A2 address range:  $FA1\_SIZE \sim (FA1\_SIZE + FA2\_SIZE)$
- Flash B1 address range:  $(FA1\_SIZE + FA2\_SIZE) \sim (FA1\_SIZE + FA2\_SIZE + FB1\_SIZE)$
- Flash B2 address range:  $(FA1\_SIZE + FA2\_SIZE + FB1\_SIZE) \sim (FA1\_SIZE + FA2\_SIZE + FB1\_SIZE + FB2\_SIZE)$

Flash memory map in parallel mode:

- Flash A1+B1 address range:  $0x00000000 \sim FA1\_SIZE*2$
- Flash A2+B2 address range:  $FA1\_SIZE*2 \sim (FA1\_SIZE*2 + FA2\_SIZE*2)$

### NOTE

- When  $MCR2[SAMEDEVICEEN]$  is set to 0x1,  $FA1\_SIZE/FA2\_SIZE/FB1\_SIZE/FB2\_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte$
- When  $MCR2[SAMEDEVICEEN]$  is set to 0x0,  $FA1\_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte$ ;  $FA2\_SIZE = FLSHA2CR0[FLSHSZ] * 1KByte$ ;  $FB1\_SIZE = FLSHB1CR0[FLSHSZ] * 1KByte$ ;  $FB2\_SIZE = FLSHB2CR0[FLSHSZ] * 1KByte$
- Flash B1/B2 size setting are ignored in parallel mode ( $FLSHB1CR0[FLSHSZ]$ ,  $FLSHB2CR0[FLSHSZ]$ ). To

support parallel mode application, Flash B1 should be same device as A1 and Flash B2 should be same device as A2.

## 27.5.6 Flash address sent to Device

Flash access start address is determined by AHB address (AHB command) or IPCR0[SFAR] register (IP command). Refer [Flash access by AHB Command](#) and [Flash access by IP Command](#) for more details.

For AHB command, FlexSPI controller will remove flash base address automatically when sending flash address to devices. For IP command, the address in IPCR0[SFAR] should be the flash device's address without base address. Flash address is sent to devices in two part: Row Address and Column Address. For flash devices not supporting Column address, please set register field FLSHxCR1[CAS] to 0. Then all flash address bits will be sent to Flash device as Row address. For flash device supporting word-addressable feature, the last bit of flash address is not needed because flash is read/programmed in terms of 2 bytes. For parallel mode, Flash A1/B1 (or A2/B2) is accessed parallelly, so the flash address sent to flash device should be divided by 2. Following table indicates the relationship of Row/Column Address and flash address (FA)

**Table 27-6. Flash Row/Column Address**

| Parallel mode | Word-addressable | Row Address  | Column Address | Comment                                               |
|---------------|------------------|--------------|----------------|-------------------------------------------------------|
| 0             | 0                | FA[31:CAS]   | FA[CAS-1:0]    | There is no limitation on FA and data size alignment. |
| 0             | 1                | FA[31:CAS+1] | FA[CAS:1]      | FA and data size should be 2 byte aligned.            |
| 1             | 0                | FA[31:CAS+1] | FA[CAS:1]      | FA and data size should be 2 byte aligned.            |
| 1             | 1                | FA[31:CAS+2] | FA[CAS+1:2]    | FA and data size should be 4 byte aligned.            |

### NOTE

- FA is the flash address with flash base address removed.
- If the Row/Column Flash Address bit number to be sent to Flash device defined in Instructions is more than valid Row/Column Flash Address bit number, high position bits will be supplemented with zero. Refer [Programmable Sequence Engine](#) for more details about Row/Column Address instruction.

When parallel mode enabled or word-addressable flash used, there is limitation on flash start address and data size. This requirement could be met by aligning AHB bus access address (For AHB command) or IP command address IPCR0[SFAR] (For IP command) in software. There are two ways to avoid these limitation in specified case.

1. For **AHB Read Command** only:

When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both set to 1, FlexSPI will guarantee flash access start address and data size are 64 bit aligned by hardware.

When AHBCR[READADDROPT] is set to 1, FlexSPI will fetch redundant data to guarantee flash start address aligned with 8 bytes. When prefetch enabled (AHBCR[PREFETCHEN] is set to 1), flash read data size is determined by AHB RX Buffer size which is 64 bit aligned.

2. For **AHB Write Command and Individual mode** only:

By default, FlexSPI will guarantee flash write access start address and data size are 16 bit aligned by using DQS as write mask.

This feature is not applied in parallel mode and should be used only if external device supports write mask feature.

## 27.5.7 Look Up Table

The LUT (Look Up Table) is an internal memory to preserve a number of pre-programmed sequences. Each sequence consists of up to 8 instructions which are executed sequentially. When a flash access is triggered by an IP command or an AHB command, FlexSPI controller will fetch the sequence from LUT according to sequence index/number and execute it to generate a valid flash transaction on SPI interface.

Following figure indicates the structure of LUT, sequence and instruction.

Figure 27-5. LUT and sequence structure

**NOTE**

If the instruction number needed is less than 8 for a flash transaction, STOP instruction should be programmed for the unneeded instructions (instruction code 8'h00).

For IP command and AHB write command, FlexSPI controller always executes from instruction pointer 0. For AHB read command, FlexSPI controller executes from a saved instruction start pointer. FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointer are zero before JMP\_ON\_CS instruction is executed,. When JMP\_ON\_CS instruction is executed, the operand in JMP\_ON\_CS instruction will be saved as instruction start pointer. Refer [XIP Enhanced Mode](#) for more details.

The reset value of LUT is unknown because it is implemented as internal memory. LUT should be programmed according to the device connected on board. In order to protect its contents during a code runover, the LUT could be locked/unlocked to avoid change by mistake after programmed. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and unlocking the LUT is as follows:

**Locking the LUT**

1. Write the key (**0x5AF05AF0**) in to the LUT Key Register [LUT Key Register \(LUTKEY\)](#).

- Write 1b1 to LUTCR[LOCK] and 1b0 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not successfully locked if there is any other register write access to FlexSPI between these two write accesses.

### Unlocking the LUT

- Write the key (**0x5AF05AF0**) in to the LUT Key Register [LUT Key Register \(LUTKEY\)](#).
- Write 1b0 to LUTCR[LOCK] and 1b1 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not successfully unlocked if there is any other register write access to FlexSPI between these two write accesses.

The lock status of the LUT can be read from register field LUTCR[LOCK] and LUTCR[UNLOCK].

## 27.5.8 Programmable Sequence Engine

FlexSPI controller implements a programmable sequence engine that executes the sequence from LUT. FlexSPI controller executes the instructions sequentially and generates flash transaction on the SPI interface accordingly. The following table is a complete list of the supported instructions.

**Table 27-7. Instruction set**

| Name                    | Opcode          | Num_pads                         | Action on SPI interface          | Transmit Data                 | Bits/Bytes/Cycle Number  |
|-------------------------|-----------------|----------------------------------|----------------------------------|-------------------------------|--------------------------|
| CMD_SDR/<br>CMD_DDR     | 6'h01/<br>6'h21 | 2'h0 - one pad<br>(Single mode)  | Transmit Command code to Flash   | Command code:<br>Operand[7:0] | Bit number: 8            |
| RADDR_SDR/<br>RADDR_DDR | 6'h02/<br>6'h22 | 2'h1 - two pad<br>(Dual mode)    | Transmit Row Address to Flash    | Row_Address[31:0]             | Bit number: operand[7:0] |
| CADDR_SDR/<br>CADDR_DDR | 6'h03/<br>6'h23 | 2'h2 - four pad<br>(Quad mode)   | Transmit Column Address to Flash | Column_Address[31:0]          | Bit number: operand[7:0] |
| MODE1_SDR/<br>MODE1_DDR | 6'h04/<br>6'h24 | 2'h3 - eight pad<br>(Octal mode) | Transmit Mode bits to Flash      | Mode bits:<br>Operand[0]      | Bit number: 1            |
| MODE2_SDR/<br>MODE2_DDR | 6'h05/<br>6'h25 |                                  |                                  | Mode bits:<br>Operand[1:0]    | Bit number: 2            |
| MODE4_SDR/<br>MODE4_DDR | 6'h06/<br>6'h26 |                                  |                                  | Mode bits:<br>Operand[3:0]    | Bit number: 4            |
| MODE8_SDR/<br>MODE8_DDR | 6'h07/<br>6'h27 |                                  |                                  | Mode bits:<br>Operand[7:0]    | Bit number: 8            |

*Table continues on the next page...*

Table 27-7. Instruction set (continued)

| Name                    | Opcode          | Num_pads | Action on SPI interface                                                                                                                                                       | Transmit Data                                                              | Bits/Bytes/Cycle Number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Next command sequence (to the same flash device)                                                                                                                                                                                                                                                                                                                                                                                       | -             |                                                                                                                                                                                                                                                                                                                                                            |

**Table 27-7. Instruction set**

| Name | Opcode | Num_pads | Action on SPI interface                  | Transmit Data | Bits/Bytes/Cycle Number |
|------|--------|----------|------------------------------------------|---------------|-------------------------|
|      |        |          | will started from instruction pointer 0. |               |                         |

The programmable sequence engine allows the software to configure the FlexSPI LUT according to external serial device connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

DDR sequence is a flash access sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. SDR sequence is a flash access sequence that don't contain any DDR instruction. FlexSPI controller determines instruction SDR or DDR mode by decoding bit 5 of instruction opcode. The output/input timing on FlexSPI is different for SDR and DDR sequences. Especially note that SDR instruction in SDR sequence and DDR sequence is executed differently. Refer [FlexSPI Input Timing](#) and [FlexSPI Output Timing](#) for more details.

### 27.5.8.1 Instruction execution on SPI interface

This section describes the detail of instruction execution on SPI interface. For all instructions transmitting/receiving data bits to/from flash, the bit order in one byte is higher on DATA3 than DATA0, and higher on B port than A port.

#### 1. Command Instruction

Command Instruction (CMD\_SDR/CMD\_DDR) is normally used to transmit command code to external flash device. Command code is the 8 bits operand in instruction. Command code will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 2. Address Instruction

Address Instructions (RADDR\_SDR/RADDR\_DDR/CADDR\_SDR/CADDR\_DDR) are normally used to send Flash access start address (Row/Column Address) to external flash device. Row/Column Address bits are determined by FlexSPI according to AHB access address or IP command address. Refer [Flash address sent to Device](#) for more details. The bit number is the operand value in instruction code. Row/Column address bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 3. Mode Instruction

Mode Instructions (MODE<sub>x</sub>\_SDR/MODE<sub>x</sub>\_DDR) are normally used to send mode bits to external flash device. Mode bits are the (lower) bits value of the instruction operand. The transition bit number is 1 for MODE1\_SDR/MODE1\_DDR, 2 for MODE2\_SDR/MODE2\_DDR, 4 for MODE4\_SDR/MODE4\_DDR and 8 for MODE8\_SDR/MODE8\_DDR. Note that pad number should be no more than mode bit number. For example, it is not allowed to set num\_pads to 2'b11 (Octal mode) for MODE4\_\* instructions. Mode bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 4. Data Size Instruction

Data Size Instructions (DATSZ\_SDR/DATSZ\_DDR) are used to send program/read data size (byte number) to external device. This instruction is normally used in FPGA application when the memory space in external device acts similar as a FIFO. The device needs data size information to determine how much data will be popped from or pushed into internal FIFO. The bit number is the operation value in the instruction. Data size bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 5. Write Instruction

Write Instructions (WRITE\_SDR/WRITE\_DDR) are normally used to send program data to external device. Programming data are fetched from IP TX FIFO (IP Command) or AHB TX Buffer (AHB command). For more details about flash program data size, refer [Flash access by AHB Command](#) and [Flash access by IP Command](#). The byte order for programming date is always from low to high. Odd bytes are send on A port and Even bytes are send on B port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 6. Read Instruction

Read Instructions (READ\_SDR/READ\_DDR) are normally used to receive flash data from external device. Received data will be put into IP RX FIFO (IP Command) or AHB RX Buffer f(AHB command). For more detail about flash read data size, refer [Flash access by AHB Command](#) and [Flash access by IP Command](#). The byte order for reading date is always from low to high. Odd bytes are received from A port and Even bytes are received from B port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 7. Dummy Instruction

Dummy Instructions (DUMMY\_SDR/DUMMY\_DDR/DUMMY\_RWDS\_SDR/DUMMY\_RWDS\_DDR) are used to provide turnaround cycles on SPI interface. During dummy instruction, neither FlexSPI controller nor external device drives SPI interface. Refer [Programmable Sequence Engine](#) for more details about dummy cycle number.

DUMMY\_RWDS\_DDR could be used for HyperBus device which use "RWDS" pin to indicate whether extra latency count needed. DUMMY\_RWDS\_SDR is reserved for future. FlexSPI controller checks DQS pin input level at the 4th cycle after SCLK output toggling is enabled. DQS pins is called "RWDS" in HyperBus specification. Refer [Flash access sequence example](#) for examples.

### NOTE

The FlexSPI releases the bus after at least one cycle. Therefore, to avoid data contention, number of dummy lines should be programmed more than 1 if data is transferred on more than 1 line.

## 27.5.8.2 Flash access sequence example

Following is an example for SDR single I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

Figure 27-6. Flash access sequence example (SDR Single I/O Read sequence)

**NOTE**

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S datasheet).

Following is an example for SDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

**Figure 27-7. Flash access sequence example (SDR Quad I/O Read sequence)**

**NOTE**

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S datasheet).

Following is an example for DDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.

Figure 27-8. Flash access sequence example (DDR Quad I/O Read sequence)

Following is an example for HyperBus device read transaction (Single latency count) in individual mode.

**Figure 27-9. HyperBus device read transaction with single latency count**

Following is an example for HyperBus device read transaction (Additional latency count) in individual mode.

**Figure 27-10. HyperBus device read transaction with additional latency count**

Functional description

Following is an example for HyperBus device write transaction (Single latency count) in individual mode.

Figure 27-11. HyperBus device write transaction with single latency count

Following is an example for HyperBus device write transaction (Additional latency count) in individual mode.

Figure 27-12. HyperBus device write transaction with additional latency count

## 27.5.9 Flash access by IP Command

Flash access could be triggered by IP command in following steps.

- Fill IP TX FIFO with programming data if this is a programming command (programming flash data, flash status registers etc.)
- Set flash access start address (IPCR0[SFAR]), read/program data size, sequence index in LUT and sequence number (IPCR1[ISEQNUM]).
- Trigger flash access command by writing 1 to register bit IPCMD[TRG]
- Polling register bit INTR[IPCMDDONE] to wait for this IP command to finish on FlexSPI interface.

### NOTE

- IP TX FIFO could be filled before or after writing IPCR0/ IPCR1/IPCMD register. If SFM command is started with IP TX FIFO empty, FlexSPI will stop SCLK toggling to wait for TX data ready automatically.
- IPCMD register must be written after writing IPCR0/ IPCR1 register.

- Multiple Command sequences (8 at most) could be issued by one IP command.
- It is not allowed to issue another IP command before the previous IP command is finished. The behaviour is unknown in this case.

If this is a Reading command to Serial Flash Memory, all reading data from Flash will be put into IP RX FIFO. Software will need to read out data from IP RX FIFO by AHB bus or IP Bus. When IP RX FIFO is full and there is more data to be read from Flash device, FlexSPI will stop SCLK output clock toggling until IP RX FIFO is not full. Please refer to [SCLK stop feature](#) for more detail.

The detail of triggered Serial Flash Command is as following:

- Flash access start address:

Determined by register field IPCR0[SFAR]

- Flash Chip Select:

Determined by flash access address and Flash size setting (FLSHxCR0[FLSHSZ]).

- Flash command Sequence Index and Sequence Number:

The sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT will be executed by FlexSPI sequentially.

- Flash Individual/Parallel access mode

Determined by IPCR1[IPAREN].

- Flash Read/Program Data Size:

- If IPCR1[IDATSZ] value is non-zero, flash read/program data size (in byte) is IPCR1[IDATSZ].
- If IPCR1[IDATSZ] value is zero, flash read/program data size (in byte) will be the operand value in the READ/WRITE instruction.

### NOTE

- Software should make sure the last sequence index never exceeds the LUT sequence number (IPCR1[ISEQID] + IPCR1[ISEQNUM] < 16).
- Data size is applied to every command sequence if sequence number is more than one.
- Data size is ignored if there is no WRITE/READ instruction in the command sequence .

IP command request is sent to arbitrator after triggered by software. It is not executed on FlexSPI Interface until granted by arbitrator. Please refer to [Command Arbitration](#) for more details.

### 27.5.9.1 Reading Data from IP RX FIFO

FlexSPI put the read data from external device into IP RX FIFO for IP command. These data could be read out by following two memory space access.

- 0x100 - 0x180 (by IPS Bus)
- 0x7FC00000 - 0x7FC00080 (by AHB Bus)

If MCR0[ARDFEN] is set to 0x1, read data in IP RX FIFO could only be read out by AHB Bus, IP Bus read access to IP RX FIFO will always return with data zero and no bus error occur.

If MCR0[ARDFEN] is set to 0x0, read data in IP RX FIFO could only be read out by IPS Bus, AHB Bus read access to IP RX FIFO will trigger bus error.

FlexSPI push read data into IP RX FIFO in terms of 64 bits every time it receives 64 bits data from external device. When read data bits number is not 64 bits aligned, FlexSPI will push additional zero bits into IP RX FIFO for the last push.

IP RX FIFO could be read by processor or DMA. Following is the detail flow for processor and DMA reading:

#### 1. Reading by processor

To read by processor, following register settings are needed:

- Set register field IPRXFCR[RXDMAEN] to 0.
- Set watermark level by IPRXFCR[RXWMRK], watermark level is  $(IPRXFCR[RXWMRK]+1)*8$  bytes.
- Set register field INTEN[IPRXWAEN] to enable IP RX FIFO watermark available interrupt (optional).

Processor needs to poll register INTR[IPRXWA] or wait for IP RX FIFO Watermark Available interrupt before reading IP RX FIFO. This is to make sure there is a watermark level Data filled in IP RX FIFO before reading.

After reading a watermark level data from IP RX FIFO, software need to set register bit INTR[IPRXWA]. This set action will pop out a watermark level data from IP RX FIFO.

Following digram indicates the reading flow from IP RX FIFO by processor.

**Figure 27-13. Reading IP RX FIFO by processor**

### NOTE

- Processor need to read out a watermark level data from IP RX FIFO each time before set register bit INTR[IPRXWA].
- It's supported that the total flash read/program data size is not multiple of watermark level. In this case, the reading data size from IP RX FIFO will be less than a watermark level for the last time, software should poll IPRXSTS[FILL] field instead of polling INTR[IPRXWA]. After copying all the data from IP RX FIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), software should clear IP RX FIFO by setting IPRXFCR[CLRIPRXF]. Otherwise, the reading data will be wrong for the next reading command to Flash.
- IP RX FIFO data is not popped out by each reading access to IP RX FIFO, but popped by writing 0x1 to register INTR[IPRXWA] bit.

## 2. Reading by DMA

To read IP RX FIFO by DMA, following setting is needed:

- Set register field IPRXFCR[RXDMAEN] to 1.
- Set watermark level by IPRXFCR[RXWMRK], watermark level is  $(IPRXFCR[RXWMRK]+1)*8$  bytes.
- Set DMA transfer Minor loop size to same watermark level.

**Figure 27-14. Reading from IP RX FIFO by DMA**

### NOTE

- DMA request is generated when the fill level of IP RX FIFO is higher than (or equal) watermark level. This request is not pulse valid but level valid.
- DMA should read out watermark level data from IP RX FIFO each time (set minor loop size with the same value as watermark level).
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished reading a watermark level data.
- IP RX FIFO data is not popped out by each reading access, but popped by DMA done handshake.
- It is not supported that the total read/write data size (Major loop size) is not multiple of watermark level. Because the DMA does not know when the data is ready for the last reading. It makes the DMA driver too complex to poll IPRXFSTS[FILL] field.

### 27.5.9.2 Filling Data to IP TX FIFO

The programming should be put into IP TX FIFO and then transmit to Flash by FlexSPI. It could be filled by two memory space.

- 0x180 - 0x200 (by IP Bus)
- 0x7F800000 - 0x7F800080 (by AHB Bus)

## Functional description

To fill by AHB Bus, need to set MCR0[ATDFEN] to 1, IP Bus write access to IP TX FIFO will be ignored, but no bus error.

To fill by IP Bus, need to set MCR0[ATDFEN] to 0, AHB Bus write access to IP TX FIFO will return Bus Error.

IP TX FIFO is popped with 64 bits data every time FlexSPI fetch data for transmitting. If the programming data size is not multiple of 64 bits, last popped valid bits will be less than 64 bits. But there is no problem because these invalid bits are not transmitted to Flash at all.

IP TX FIFO could be filled by processor or DMA.

To fill by processor, need following setting:

- Set register field IPTXFCR[TXDMAEN] to 0.
- Set watermark level by IPTXFCR[TXWMRK], watermark level is  $(\text{IPTXFCR}[\text{TXWMRK}] + 1) * 8$  bytes.
- Set register field INTEN[IPTXWEEN] to enable IP TX FIFO watermark empty interrupt (optional).

Processor needs to poll register INTR[IPTXWE] or wait for IP TX FIFO Watermark empty interrupt before filling IP TX FIFO. This is to make sure there is enough space for a watermark level Data filling before filling.

After filling a watermark level data to IP TX FIFO, need to set register bit INTR[IPTXWE]. This will push a watermark level data into IP TX FIFO (write pointer is incremented).

### NOTE

IP TX FIFO data is not pushed by each write access, only pushed by set INTR[IPTXWE] bit.

Following digram indicates the filling flow to IP TX FIFO by processor.

**Figure 27-15. Filling IP TX FIFO by processor**

### NOTE

- Processor will need to fill a watermark level data to IP TX FIFO each time.
- It's allowed that total write data size is not multiple of watermark level. In this case, the writing size will be less than a watermark level for the last time. After filling all data into IP TX FIFO and all Command Sequences to Flash are finished ( $\text{INTR}[\text{IPCMDDONE}] = 1$ ), processor should clear IP TX FIFO by setting  $\text{IPTXFCR}[\text{CLRIPTXF}]$ . Otherwise, the programming data will be wrong for the next programming Command to Flash.

To fill IP TX FIFO by DMA, need following setting:

- Set register field  $\text{IPTXFCR}[\text{TXDMAEN}]$  to 1.
- Set watermark level by  $\text{IPTXFCR}[\text{TXWMRK}]$ , watermark level is  $(\text{IPTXFCR}[\text{TXWMRK}] + 1) * 8$  bytes.
- Set DMA transfer Minor loop size to same watermark level.

**Figure 27-16. Filling from IP TX FIFO by DMA**

### NOTE

- DMA request is generated when there is empty space more than watermark level in IP TX FIFO. This request is not pulse valid but level valid.
- DMA should fill watermark level data into IP TX FIFO each time (set minor loop size with the same value as watermark level).
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished filling a watermark level data.
- IP TX FIFO data is not pushed in by each reading access, but pushed by DMA done handshake.
- It's allowed that total program data size (Major loop size) is not multiple of watermark level. After filling all data into IP TXFIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), need to clear IP TX FIFO by setting IPTXFCR[CLRIPTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

## 27.5.10 Flash access by AHB Command

Flash could be accessed by AHB bus directly on AHB address space: 60000000~0x80000000. This address space is mapped to Serial Flash Memory in FlexSPI. AHB bus access to this address space may trigger Flash access command sequence as needed.

For AHB read access to Serial Flash Memory, FlexSPI will fetch data from flash into AHB RX Buffers and then return the data on AHB Bus. For AHB write access to Serial Flash Memory, FlexSPI will buffer AHB Bus write data into AHB TX Buffer and then transmit to Serial Flash memory.

There is no software configuration or polling need for AHB command except FlexSPI initialization. AHB master access external flash device transparently similar as normal AHB slave.

AHB command is normally used to access serial Flash memory space. IP command should be used to access the control and status registers or other spaces such as OTP in external flash device.

Following section described AHB command for read and write in more detail.

### **NOTE**

When FlexSPI controller return AHB bus error for SFM access, AHB master should stop following access beats in current burst.

#### **27.5.10.1 AHB write access to Flash**

For AHB write access to Flash, FlexSPI will buffer the write data from AHB bus into internal AHB TX Buffer and then transmit them to Flash. FlexSPI only buffers write data for one AHB burst. Following diagram indicates the hardware operation in response to AHB write access to Flash.

**Figure 27-17. Hardware operation in response to AHB write access to Flash**

FlexSPI triggers new AHB write command in following cases:

- This beat is the last one in current AHB burst (any burst type except INCR).
- AHB TX Buffer is full after buffering current beat data.
- AHB bus becomes IDLE or a new burst comes with AHB TX Buffer not empty.

The detail information about the triggered AHB write command:

- Flash Access Start Address:

Determined by AHB burst address. FlexSPI will record the start address for the data in AHB TX Buffer and this address will be used as flash access start address

- Flash Chip Select:

FlexSPI determined the chip selection by flash access start address and flash size setting.

- Flash Command Sequence Index:

Determined by FLSHxCR2[AWRSEQID].

- Flash Command Sequence Number:

Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT will be executed sequentially.

- Flash access mode (Individual/Parallel)

Determined by AHBCR[APAREN].

- Flash Data Size:

Determined by byte number of buffered data in AHB TX Buffer.

Following examples indicates internal logic for AHB write access to Flash. In these examples, AHB\_TX\_BUF is 64 Bytes (8\*64bits) .

- AHB INCR/64bit/Bufferable burst with address sequence 0x8, 0x10, 0x18, 0x20, ..., 0x50 (10 beat totally):

Two AHB write command will be triggered: the first command with flash start address 0x8 and data size 0x40; the second command with flash start address 0x48 and data size 0x10. See [Figure 27-18](#).

**Figure 27-18. AHB write access (INCR/64bit/Bufferable)**

- AHB WRAP8/64bit/Bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

One AHB write command will be triggered with flash start address 0x0 and data size 0x40. See [Figure 27-19](#).

**Figure 27-19. AHB write access (WRAP8/64bit/Bufferable)**

- AHB WRAP8/64bit/Non-bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

One AHB write command will be triggered with flash start address 0x0 and data size 0x40;

**Figure 27-20. AHB write access (WRAP8/64bit/Non-Bufferable)**

### NOTE

The wrapper burst is not supported if burst data size (in byte) is larger than AHB TX Buffer size (in byte). For example, if AHB\_TX\_BUF is 64 Bytes (8\*64bits), AHB WRAP16 \* 64bit writet burst access is not supported.

## 27.5.10.2 AHB read access to Flash

For AHB read access to Flash, FlexSPI will check whether hit AHB TX Buffer/AHB RX Buffer/pending AHB read command according to the burst access type and register setting. If all these miss, FlexSPI trigger a new AHB read command to fetch data from Flash. Following diagram indicates the hardware operation in response to AHB read access to Flash.

**Figure 27-21. Hardware operation in response to AHB read access to Flash**

### NOTE

1. AHB prefetch is enabled when both AHBCR[PREFETCHEN]=0x1 and AHB\_RX\_BUFxCR0[PREFETCHEN]=0x1 (x is the ahb rx buffer ID for current AHB master).
2. AHB RX Buffer holds the data read from Flash. This data may become incoherent if the AHB writes to the same flash address.

The detail information about the triggered AHB read command:

- Flash Access Start Address and Data Size:

Determined by AHB address, burst type and burst size. FlexSPI will fetch read data from the start address for current burst or beat.

**Table 27-8. AHB read command flash start address and data size**

| Prefetch Enable | Cross flash boundary                                                       | Burst Type                     | Flash start address [28:0] | Data Size                                                                                                          |
|-----------------|----------------------------------------------------------------------------|--------------------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| 0               | Never cross flash boundary because AHB burst never cross 1K Byte boundary. | SINGLE/INCR4/INCR8/INCR16      | hbeat_start_address        | (hburst_end_address-hbeat_start_address)                                                                           |
|                 |                                                                            | INCR                           | hbeat_start_address        | byte size of current beat<br><br>For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst. |
|                 |                                                                            | WRAP4/WRAP8/WRAP16             | hburst_start_address       | (hburst_end_address-hburst_start_address)                                                                          |
| 1               | No                                                                         | INCR/SINGLE/INCR4/INCR8/INCR16 | hbeat_start_address        | ahb_rx_buf_sz                                                                                                      |
|                 | No                                                                         | WRAP4/WRAP8/WRAP16             | hburst_start_address       | ahb_rx_buf_sz                                                                                                      |
|                 | Yes                                                                        | INCR/SINGLE/INCR4/INCR8/INCR16 | hbeat_start_address        | (flash_top_address-hbeat_start_address)                                                                            |
|                 | Yes                                                                        | WRAP4/WRAP8/WRAP16             | hburst_start_address       | (flash_top_address-hburst_start_address)                                                                           |

### NOTE

- hbeat\_start\_address is HADDR input from AHB master for current beat.
- hburst\_start\_address (for e.g.0x00) is the lowest address for current burst; hburst\_end\_address (for e.g. 0x10) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 0x8,0xC, 0x0, 0x4.

- `ahb_rx_buf_sz` is the buffer size in byte of AHB RX Buffer which is used by current master.
  - `flash_top_address` is the top address of currently accessed flash.
- **Flash Chip Select:**  
FlexSPI determined the chip selection by flash access start address and flash size setting.
  - **Flash Command Sequence Index:**  
Determined by `FLSHxCR2[ARDSEQID]`.
  - **Flash Command Sequence Number:**  
Determined by `FLSHxCR2[ARDSEQNUM]`. If `ARDSEQNUM` is not zero, multiple flash access command sequences will be triggered every time for AHB read command. The sequences indexed from `ARDSEQID` to `(ARDSEQID + ARDSEQNUM)` in LUT will be executed sequentially.
  - **Flash access mode (Individual/Parallel):**  
Determined by `AHBCR[APAREN]`.

### NOTE

- FlexSPI determines which `ARDSEQNUM/ARDSEQID` fields will be used as sequence ID by flash device chip selection automatically. Refer [MCR2\[SAMEDEVICEEN\]](#) for more detail.
- FlexSPI determines which AHB RX Buffer used for current AHB read access by master ID. For more details about the AHB RX buffer ID and AHB master ID mapping, refer [AHB RX Buffer Management](#).
- It is not allowed to allocate AHB RX Buffer less than AHB Burst size. The behaviour is unknown for this case.

### 27.5.10.3 AHB RX Buffer Management

There are 4 buffers (Buffer 0 - Buffer 3) in AHB RX Buffer, which are transparent to AHB masters. FlexSPI fetch flash data and return on AHB Bus automatically. There is no status register polling needed for AHB read access to Serial Flash Memory.

AHB Rx Buffers total size is 1 KBytes . The buffer size is flexibly configurable for each buffer in AHB RX Buffers by register fields

AHBRXBUF0CR0[BUFSZ]~AHBRXBUF6CR0[BUFSZ]. The buffer size for Buffer 0 to Buffer 3 could be set 0. If the buffer size is set to 0x0, the related MSTRID field setting (in same AHBRXBUFxCR0 register) is ignored by FlexSPI. Buffer 3 is used for all AHB masters which is not assigned to Buffer 0 - Buffer 2. Buffer 3 size setting field (AHBRXBUF3CR0[BUFSZ]) is ignored by FlexSPI, its buffer size is: AHB RX Buffer total size - sum of (Buffer 0 - Buffer 2 size).

When there is AHB read access to Serial Flash Memory, FlexSPI determines which AHB RX Buffer to use as following:

1. If master ID equal AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 will be used.
2. If master ID equal AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 will be used.
3. If master ID equal AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 will be used.
4. If all above case not meet, Buffer 3 will be used

### NOTE

- Software should make sure the buffer size of each buffer is no less than the max burst size of AHB Read access from the master using this buffer. Otherwise the behaviour is undefined.
- It is not supported to assign multiple buffers for single AHB master.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] is set), the prefetch data size will be determined by buffer size. FlexSPI will fetch data from external Flash with buffer size if no flash boundary across.
- AHB master priority setting (register field AHBRXBUFxCR0[PRIORITY] is used only for the suspending control of AHB prefetching. Refer [Command Abort and Suspend](#).

## 27.5.11 Command Arbitration

There are four Flash access command sources:

1. AHB Command (triggered by AHB Write access to SFM space)

2. AHB Command (triggered by AHB Read access to SFM space)
3. IP command (triggered by writing IPCMD[TRG])
4. Suspended command (AHB Read prefetch sequence which is suspended)

### NOTE

- An AHB bus access never triggers a write command and a read command at the same time.
- AHB prefetch sequence is an AHB Command sequence triggered by AHB Read access when AHB prefetch is enabled. After all read data fetched for current AHB read burst, FlexSPI will prefetch more data to reduce the read latency for next AHB read access. AHB command for read is never aborted while fetching read data for current AHB read burst. But AHB read command could be aborted by any new IP command or AHB command request when it's prefetching data (not for current read burst).

The granted priority of these 4 command source is as following when Arbitrator is idle (STS0[ARBIDLE]=1):

1. AHB command (Read/Write)
2. IP Command
3. Suspended Command

### NOTE

Suspended command is not granted immediately when arbitrator is idle and no AHB/IP command request. Arbitrator will wait for n AHB clock cycle idle state before resuming the suspended command (n is the register field value in MCR2[RESUMEWAIT]). This intend to avoid AHB prefetch sequence being resumed and suspended frequently.

All command request are not granted if Arbitrator is busy in executing AHB/IP command (not suspended command), and there will AHB/IP Command granted error if the grant is timeout.

If new AHB/IP command request comes while Arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence will be aborted (but not immediately). Arbitrator will grant AHB/IP command request after AHB read prefetch sequence is aborted on FlexSPI interface and saved all internal data pointers.

## 27.5.11.1 Command Abort and Suspend

This section describes command abort and suspend mechanism.

### 1. Command Abort

As mentioned above, AHB read prefetch sequence could be aborted if new AHB/IP command request comes.

### 2. Command Suspend

When AHB read prefetch sequence is aborted on FlexSPI interface, FlexSPI will save this suspended sequence in following cases and resume this sequence if arbitrator is idle for enough time:

- There is no valid suspended command (Register field AHBSPNDSTS[ACTIVE] is 0x0). This is possible if there is no suspended command yet or suspended command is resumed.
- Aborted AHB read prefetch sequence is higher priority than current active suspend sequence.

### NOTE

Original suspended sequence will be ignored and never resumed by FlexSPI.

### 3. Suspended Command

The suspended command (internal status) turns active when there is any AHB prefetch command aborted and suspended. It turns inactive in following cases:

- Suspended command is resumed by Arbitrator.
- There is a new AHB read command request and it's triggered by AHB master using the same AHB RX Buffer (Buffer ID).

Following is an example indicating command abort/suspend/resume flow:

**Figure 27-22. Command Instructions Execution on FlexSPI interface**

## 27.5.12 SCLK stop feature

FlexSPI will stop SCLK output toggling when programming data is not ready for programming command sequence or there is no space (in internal FIFO) to receive data for reading command sequence.

There may be certain devices that do not support SCLK stopped during command sequence (chip select is valid). SCLK stopping could be avoid as following:

- For flash reading triggered by IP command
  - Never trigger a read command with data size larger than IP RX FIFO size.
  - Internal async FIFO for flash reading should never be full.

FlexSPI pop data from this async FIFO in 64 bits per AHB clock cycle, and receiving data from FlexSPI interface in serial root clock. The receiving speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. This async FIFO is never full if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash programming triggered by IP command
  - Never trigger a program command with data size larger than IP TX FIFO size.
  - Fill all programming data into IP TX FIFO before trigger the IP command.
  - Internal async FIFO for flash programming should never be empty

FlexSPI fetch programming data into this async FIFO in 64 bits per AHB clock cycle, and transmitting data to FlexSPI interface in serial root clock. The transmitting speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. This async FIFO is never empty if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash reading/programming triggered by AHB command
  - Internal async FIFO for flash reading/programming should never be full/empty. The frequency ratio limitation is same as flash reading/programming triggered by IP command.

### NOTE

- FlexSPI never trigger a AHB read command with data size larger than internal AHB RX buffer size.
- FlexSPI never trigger a AHB program command with data size larger than internal AHB TX buffer size.
- All programming data is buffered into AHB TX Buffer before triggering AHB program command in FlexSPI.

## 27.5.13 FlexSPI Output Timing

This section describes the output timing in FlexSPI.

### 27.5.13.1 Output timing between Data and SCLK

This section describes the output timing relationship of data (on A\_DATA/B\_DATA) and SCLK. There are three cases for the data output timing:

- **SDR instruction in SDR sequence**

SDR sequence is the sequence which contains only SDR instructions. In this case, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

**Figure 27-23. SDR instruction in SDR sequence**

- **SDR instruction in DDR sequence**

DDR sequence is a flash access command sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. In the case of SDR instruction in DDR sequence, all data bits last two serial root clock cycles on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

**Figure 27-24. SDR instruction in DDR sequence**

- **DDR instruction in DDR sequence**

In the case of DDR instruction in DDR sequence, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

Figure 27-25. DDR instruction in DDR sequence

### 27.5.13.2 Output timing between Chip selection and SCLK

This section describes the output timing relationship of Chip select (on A\_SS0\_B/A\_SS1\_B/B\_SS0\_B/B\_SS1\_B) and SCLK. The timing relationship is a little different for SDR sequence and DDR sequence.

- **Chip Select timing in SDR sequence**

For SDR sequence, the delay from chip select assertion and the SCLK rising edge is **(FLSHxCR1[TCSS]+0.5)** cycles of serial root clock; The delay from SCLK falling edge and chip select deassertion is **FLSHxCR1[TCSH]** cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCLK:

Figure 27-26. Chip selection output timing for SDR sequence

- **Chip Selection timing in DDR sequence**

For DDR sequence, the delay from chip selection assertion and SCLK rise edge is **(TCSS+0.5)** cycles of serial root clock; The delay from SCLK fall edge and chip selection deassertion is **(TCSH+0.5)** cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCLK:

**Figure 27-27. Chip selection output timing for DDR sequence**

For certain device (such as FPGA device), there is limitation on the interval between Chip Selection valid. FlexSPI will ensure a delay time between chip selection valid if register field `FLSHxCR1[CSINTERVAL]` is set to non-zero value. The delay time is:  $CSINTERVAL * 1024$  cycle of serial root clock no matter SDR or DDR sequence. Please set this register field value to zero if there is no this limitation for external device. Following diagram indicates the timing of chip selection interval.

**Figure 27-28. Chip Selection Valid interval**

## 27.5.14 FlexSPI Input Timing

This section describes the input timing of FlexSPI.

### 27.5.14.1 RX Clock Source Features

This section describes the features of each RX clock source.

- **Internal dummy read strobe and loopbacked internally**(`MCR0[RXCLKSRC]==0`)

Supporting legacy device with zero device output hold time.

Saving one pad(DQS pad).

Supporting low frequency clock for boot up usage.

- **Internal dummy read strobe and loopbacked from DQS pad**(`MCR0[RXCLKSRC]==1`)

Supporting higher frequency than mode "MCR0[RXCLKSRC]==0".

Supporting device doesn't provide read strobe.

- **Flash provided read strobe(MCR0[RXCLKSRC]==3)**

Supporting the highest frequency.

Supporting device provides read strobe.

### 27.5.14.2 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with internal dummy read strobe (MCR0[RXCLKSRC] is set to 0x0 or 0x1). The timing is very similar for sampling with dummy read strobe loopback internally and loopback from pad. But it could achieve higher read frequency by sampling with dummy read strobe loopback from DQS pad because it will compensate the delay of SCLK output path and Data pin input path. The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

For SDR Read/Learn instruction, FlexSPI samples input data pins with the falling edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in SDR mode

**Figure 27-29. Input Timing for sampling with dummy read strobe in SDR mode**

- **Input timing for sampling with dummy read strobe in DDR mode**

For DDR Read/Learn instruction, FlexSPI sample input data pins with both rise and fall edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in DDR mode

Figure 27-30. Input Timing for sampling with dummy read strobe in DDR mode

### 27.5.14.3 Input timing for sampling with flash provided read strobe

This section describes the input timing when sampling with flash provided read strobe (MCR0[RXCLKSRC] is set to 0x3). The input timing is different for SDR mode and DDR mode.

#### NOTE

There are no known devices that provide read strobe and support SDR mode operation.

There are two kinds of Flash provided read strobe:

- **Flash provide read strobe with SCLK**

For certain flash devices, it provides both read data and read strobes with SCLK. Then the read strobe edge is aligned with read data change. FlexSPI controller should delay read strobe by half cycle in serial root clock (with DLL) and then sample read data with delayed strobe. Refer [DLL configuration for sampling](#) for more details. Following diagrams indicates the input timing for sampling with flash read strobe in SDR mode and DDR mode:

Figure 27-31. Input Timing 2 for Flash provided read strobe in SDR mode

**Figure 27-32. Input Timing 2 for Flash provided read strobe in DDR mode**

#### 27.5.14.4 DLL configuration for sampling

The input timing is different for those four sampling clock source. This is handled by setting register DLLxCR differently according to the sampling clock source mode. DLL is a delay line chain, which could be set to a fixed number of delay cells or auto-adjusted to lock on a certain phase delay to the reference clock.

- In following cases, DLLxCR should be set 0x00000100 (1 fixed delay cells in DLL delay chain) :
  - Sampling data with Dummy read strobe loopbacked internally (MCR0[RXCLKSRC]=0x0)
  - Sampling data with Dummy read strobe loopbacked from DQS pad (MCR0[RXCLKSRC]=0x1)
- When data is sampled with Flash provided read strobe (MCR0[RXCLKSRC]=0x3) and flash provides read strobe with SCLK, DLL should be set as following to lock on half cycle of the reference clock (serial root clock)
  - SLVDLYTARGET=0xF

- DLEN=0x1
- OVRDEN=0x0
- Other fields in DLLxCR should be kept as reset value (all zero)

### NOTE

If serial root clock is lower than 100 MHz, DLL is unable to lock on half cycle of serial root clock because the delay cell number is limited in delay chain. Then DLL should be configured as following instead:

- OVRDEN=0x1
- OVRDVAL=N; Each delay cell in DLL is about 75 ps~225 ps. The delay of DLL delay chain is (N \* Delay\_cell\_delay), N should be set based on max. DDR frequency that current project supported, N = 17, please notice this is a recommended value. May need to adjust in real application if facing failure.
- Other fields in DLLxCR should be kept as reset value (all zero).

## 27.5.15 XIP Enhanced Mode

FlexSPI always supports Execute-In-Place (XIP), no matter external device provided XIP enhanced mode or not. Execute-In-Place is supported by putting program code on External device, then read/execute on external device directly by AHB read access to SFM space. There is no configuration or status polling needed during AHB read access to External device memory and AHB RX buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, there is no need to provide Command code for Read Sequence. It saves many cycles for Command Instructions and greatly improves code execution. This XIP enhanced mode is entered/exit by a special sequence which is device specified. Please refer to external device datasheet for more detail.

Normally, the XIP enhanced mode is entered by following sequence:

1. Enable XIP enhanced mode in External Flash by IP command
2. Send the first Read Sequence to External Flash device with correct Mode bits.  
Command code is needed in this Read sequence.
3. Send following Read sequences to External Flash device with correct Mode bits.  
Command code is not needed in these Read Sequences. But Mode bits should be sent according to Flash specified. Otherwise Flash will exit Execute-In-Place Enhanced mode.

The instruction `JMP_ON_CS` in FlexSPI should be used to support external device XIP enhanced mode. This instruction is only allowed in AHB Read command, otherwise there will be `IPCMDERR` or `AHBCDMERR` error interrupt generated if this interrupt is enabled. `JMP_ON_CS` should never be used if device doesn't support XIP enhanced mode. To support XIP enhanced mode, the first instruction in the Read Sequence should be Command instruction and the last valid instruction should be `JMP_ON_CS` (with operand `0x1`).

For the first AHB read Command triggered, FlexSPI will execute the instructions from the instruction pointer 0 in the sequence (which is Command instruction). After this sequence executed FlexSPI will save operand in `JMP_ON_CS` instruction as start pointer for next Command to current device internally. For the following AHB read Command triggered, FlexSPI will execute from instruction pointer `0x1` and Command instruction is bypassed.

Following diagram indicates XIP operation with Flash XIP Enhanced mode:

**Figure 27-33. XIP Enhanced Mode operation**

## 27.6 Application information

This section describes applications supported by the FlexSPI module.

### 27.6.1 FlexSPI Initialization

FlexSPI controller initialization sequence is as following:

- Enable controller clocks (AHB clock/IP Bus clock/Serial root clock) in System level.
- Set `MCR0[MDIS]` to `0x1` (Make sure controller is configured in module stop mode)
- Configure module control registers: `MCR0`, `MCR1`, `MCR2`. (Don't change `MCR0[MDIS]`)
- Configure AHB bus control register (`AHBCR`) and AHB RX Buffer control register (`AHBRXBUFxCR0`) optionally, if AHB command will be used
- Configure Flash control registers (`FLSHxCR0`, `FLSHxCR1`, `FLSHxCR2`) according to external device type
- Configure DLL control register (`DLLxCR`) according to sample clock source selection

- set MCR0[MDIS] to 0x0 (Exit module stop mode)
- Configure LUT as needed (For AHB command or IP command)
- Reset controller optionally (by set MCR0[SWRESET] to 0x1)

External device needs configuration by IP command normally after controller initialization. For example, the device configuration is done by WRITE STATUS command for most serial NOR Flash.

## 27.6.2 Overview of Error Flags

The following table gives an overview of error category, flags and triggered source.

**Table 27-9. Error category and flags in FlexSPI**

| Error Category      | Triggered Source  | Description                                                                                                                                                                                                                                                                                                                         | Error Flags                                                                                 |
|---------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|

**NOTE**

- flash\_top\_address is the top address of currently accessed flash

## 27.6.3 Application on Serial NOR Flash device

This section provides the example sequences for serial NOR flash device (Cypress Flash S25FS128S).

### 27.6.3.1 Write Enable command

The following table shows WRITE ENABLE command sequence.

**Table 27-10. WRITE ENABLE command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment           |
|-----------------|-------------------------|---------------------------|--------------------------|-------------------|
| 0               | CMD_SDR                 | 0x0                       | 0x06                     | command name:WREN |
| 1~7             | STOP (0x00)             | 0x0                       | 0x00                     |                   |

### 27.6.3.2 Write Registers command

The following table shows Write Registers command sequence.

**Table 27-11. Write Registers command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                                                                    |
|-----------------|-------------------------|---------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0x01                     | command name:WRR                                                                                                                                                           |
| 1               | WRITE_SDR               | 0x0 (Single)              | 0x1 or 0x2               | Data size is 1 or 2byte.<br>Byte 0 write data for Status Register 1;<br>Byte 1 write data for Configuration Register 1<br>This value could be overridden by IPCR1[IDATSZ]. |
| 2~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                                                            |

### 27.6.3.3 Page Program command

The following table shows Page Program command sequence.

**Table 27-12. PAGE PROGRAM command (Cypress serial NOR flash)**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                            |
|-----------------|-------------------------|---------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0x02 or 0x12             | command name: PP or 4PP<br>PP is 3-Byte address mode.<br>4PP is 4-Byte address mode                                                |
| 1               | ADDR_SDR                | 0x0 (Single)              | 0x18 or 0x20             | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.                              |
| 2               | WRITE_SDR               | 0x0 (Single)              | Any non-zero value       | This operand value could be used as default programming data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command. |
| 3~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                    |

The following table shows Page Program command sequence (QPI mode).

**Table 27-13. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                            |
|-----------------|-------------------------|---------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x2 (Quad)                | 0x02 or 0x12             | command name: PP or 4PP<br>PP is 3-Byte address mode.<br>4PP is 4-Byte address mode                                                |
| 1               | ADDR_SDR                | 0x2 (Quad)                | 0x18 or 0x20             | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.                              |
| 2               | WRITE_SDR               | 0x2 (Quad)                | Any non-zero value       | This operand value could be used as default programming data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command. |
| 3~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                    |

### 27.6.3.4 Read Status 1 command

The following table shows READ STATUS 1 command sequence.

**Table 27-14. READ STATUS 1 command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                      |
|-----------------|-------------------------|---------------------------|--------------------------|------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0x05                     | command name:RDSR1           |
| 1               | READ_SDR                | 0x0 (Single)              | 0x1                      | 1 Byte for Status register 1 |
| 2~7             | STOP (0x00)             | 0x0                       | 0x00                     |                              |

### 27.6.3.5 Read command

The following table shows READ command sequence.

**Table 27-15. READ command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                        |
|-----------------|-------------------------|---------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0x03 or 0x13             | command name:READ or 4READ<br>READ is 3-Byte address mode.<br>4READ is 4-Byte address mode                                     |
| 1               | ADDR_SDR                | 0x0 (Single)              | 0x18 or 0x20             | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.                          |
| 2               | READ_SDR                | 0x0 (Single)              | Any non-zero value       | This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command. |
| 3~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                |

### 27.6.3.6 Fast Read command

The following table shows Fast Read command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8).

**Table 27-16. FAST\_READ command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                        |
|-----------------|-------------------------|---------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0x0B or 0x0C             | command name:FAST_READ or 4FAST_READ<br>FAST_READ is 3-Byte address mode.<br>4FAST_READ is 4-Byte address mode                 |
| 1               | ADDR_SDR                | 0x0 (Single)              | 0x18 or 0x20             | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.                          |
| 2               | DUMMY_SDR               | 0x0 (Single)              | 0x08                     | Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.                                                                      |
| 3               | READ_SDR                | 0x0 (Single)              | Any non-zero value       | This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command. |
| 4~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                |

### 27.6.3.7 Dual IO Fast Read command

The following table shows Dual IO FAST\_READ command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8, Continuous Read mode).

**Table 27-17. Dual IO FAST\_READ command (Continuous Read mode)**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                        |
|-----------------|-------------------------|---------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0xBB or 0xBC             | command name:DIOR or 4DIOR<br>DIOR is 3-Byte address mode.<br>4DIOR is 4-Byte address mode                                     |
| 1               | ADDR_SDR                | 0x1 (Dual)                | 0x18 or 0x20             | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.                          |
| 2               | MODE8_SDR               | 0x1 (Dual)                | 0xAx                     | Enter continuous read mode or keep in continuous read mode.                                                                    |
| 3               | DUMMY_SDR               | 0x1 (Dual)                | 0x08                     | Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.                                                                      |
| 4               | READ_SDR                | 0x1 (Dual)                | Any non-zero value       | This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command. |
| 5               | JMP_ON_CS               | 0x0 (or Dont care)        | 0x01                     | The CMD instruction will be bypassed after the first read access.                                                              |
| 6~7             | STOP (0x00)             | 0x0                       | 0x00                     |                                                                                                                                |

The following table shows Dual IO FAST\_READ command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8, Non-continuous Read mode).

**Table 27-18. Dual IO FAST\_READ command (Non-continuous Read mode)**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0]  | Comment                                                                                               |
|-----------------|-------------------------|---------------------------|---------------------------|-------------------------------------------------------------------------------------------------------|
| 0               | CMD_SDR                 | 0x0 (Single)              | 0xBB or 0xBC              | command name:DIOR or 4DIOR<br>DIOR is 3-Byte address mode.<br>4DIOR is 4-Byte address mode            |
| 1               | ADDR_SDR                | 0x1 (Dual)                | 0x18 or 0x20              | Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode. |
| 2               | MODE8_SDR               | 0x1 (Dual)                | Any value other than 0xAx | Exit continuous read mode or keep in non-continuous read mode.                                        |

*Table continues on the next page...*

**Table 27-18. Dual IO FAST\_READ command (Non-continuous Read mode) (continued)**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment                                                                                                                        |

### 27.6.5 Application on Serial NAND Flash device

This section provides the example sequences for serial NAND flash device (Micron Flash MT29 series). The operation to serial NAND flash is quite similar to serial NOR flash.

READ operation sequence is as following:

- Page Read (Transfer the data from the NAND Flash array to the cache register)
- Get Feature to read the status
- Random Data Read

The following table shows Page Read command sequence.

**Table 27-30. Page Read command**

| Instruction No. | Instruction opcode[5:0] | Instruction num_pads[1:0] | Instruction operand[7:0] | Comment             |
|-----------------|-------------------------|---------------------------|--------------------------|---------------------|
| 0               | CMD_SDR                 | 0x1 (Single)              | 0x13                     | Command code: 0x13  |
| 1               | RADDR_SDR               | 0x1 (Single)              | 0x18                     | Row Address: 24 bit |

| 2-7             | STOP (0x0)              | 0x0                       | 0x00                     |                     |

## 27.6.6 Application on FPGA device

FPGA device should be accessed by AHB command. All AHB accesses to FPGA will be transparent to SW driver (no SW intervention). There may be some special requirements from FPGA device.

### 1. Device type may be different on A1/A2/B1/B2

For this case, clear the MCR2[SAMEDEVICEEN] bit and configure FLSHxCR0 and FLSHxCR1 register separately for up to four external devices.

### 2. Device needs different wait cycle for Programming.

The AHB write wait cycle number could be set separately for these four external devices (by register field FLSHxCR2[AWRWAIT]). Software could configure the sequences in LUT with different DUMMY instructions (operand will determine dummy cycle). Note that FlexSPI will hold AHB bus ready for this wait time, so AHB Bus performance may become very low when this wait time is very long.

### 3. Device needs different wait cycle for Reading.

The AHB Read Sequence index and Sequence Number could be set separately for these four external devices (by register field FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software could configure the sequences in LUT with different DUMMY instruction (operand will determine dummy cycle).

### 4. Device may be sensitive to read instruction clock cycle number

Device will be sensitive to read instruction clock cycle number if its internal memory is implemented similar as FIFO. For this case, software could send the data size information to external device by DATSZ instruction. FPGA device should decode the data size information and determine how much data bytes should be popped.

### 5. Device may needs interval time between Chip selection valid

This could be handled by register field FLSHxCR1[CSINTERVAL] setting.

6. **Device may use SCLK as reference clock for its internal PLL**

In this case, SCLK should be free-running and clock frequency should be stable. This could be achieved by setting MCR0[SCKFREERUNEN] and use SDR sequence only.

**27.7 Memory Map and register definition**

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

**27.7.1 Register Access**

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the setting value of reserved fields in control registers. Changing the value of reserved fields may impact the normal functioning of the controller.

**NOTE**

For usage that FlexSPI is capable of accessing sensitive memory contents, protection should be done to FlexSPI controller using resource isolation (e.g. XRDC2, XRDC, RDC) or any kind of equivalent partition control via SCFW, to make sure only trusted software be allowed to access the FlexSPI controller register interface.

**27.7.2 FlexSPI register descriptions**

**27.7.2.1 FlexSPI memory map**

FLEXSPI base address: 402A\_8000h

| Offset | Register                         | Width<br>(In bits) | Access | Reset value |
|--------|----------------------------------|--------------------|--------|-------------|
| 0h     | Module Control Register 0 (MCR0) | 32                 | RW     | FFFF_80C2h  |

Table continues on the next page...

| 11<br>CLRAHBBUOPT   | This bit determines whether AHB RX Buffer and AHB TX Buffer will be cleaned automatically when FlexSPI returns STOP mode ACK. Software should set this bit if AHB RX Buffer or AHB TX Buffer will be powered off in STOP mode. Otherwise AHB read access after exiting STOP mode may hit AHB RX Buffer or AHB TX Buffer but their data entries are invalid.<br>0b - AHB RX/TX Buffer will not be cleaned automatically when FlexSPI return Stop mode ACK.<br>1b - AHB RX/TX Buffer will be cleaned automatically when FlexSPI return Stop mode ACK.                       |

| 6<br>READADDROP<br>T  | <p>AHB Read Address option bit. This option bit is intend to remove AHB burst start address alignment limitation.</p> <p>When FlexSPI controller is used for FPGA application, there may be requirement that FlexSPI fetch exactly the byte number as AHB burst. In this case, FPGA device should be designed as non-wordaddressable and this option bit should be set 0.</p> <p>0b - There is AHB read burst start address alignment limitation when flash is accessed in parallel mode or flash is wordaddressable.</p> <p>1b - There is no AHB read burst start address alignment limitation. FlexSPI will fetch more data than AHB burst required to meet the alignment requirement.</p> |
| 5<br>PREFETCHEN       | <p>AHB Read Prefetch Enable.</p> <p>When AHB read prefetch is enabled, FlexSPI will fetch more flash read data than current AHB burst needed so that the read latency for next AHB read access will be reduced.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4<br>BUFFERABLEE<br>N | <p>Enable AHB bus bufferable write access support. This field affects the last beat of AHB write access, refer for more details about AHB bufferable write.</p> <p>0b - Disabled. For all AHB write access (no matter bufferable or non-bufferable ), FlexSPI will return AHB Bus ready after all data is transmitted to External device and AHB command finished.</p> <p>1b - Enabled. For AHB bufferable write access, FlexSPI will return AHB Bus ready when the AHB command is granted by arbitrator and will not wait for AHB command finished.</p>                                                                                                                                     |
| 3<br>CACHABLEEN       | <p>Enable AHB bus cachable read access support.</p> <p>0b - Disabled. When there is AHB bus cachable read access, FlexSPI will not check whether it hit AHB TX Buffer.</p> <p>1b - Enabled. When there is AHB bus cachable read access, FlexSPI will check whether it hit AHB TX Buffer first.</p>                                                                                                                                                                                                                                                                                                                                                                                           |

| Reset | 0   | 1  | 0  | 1  | 1  | 0  | 1  | 0  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  |

### 27.7.2.8.4 Fields

| Field | Function                                                |
|-------|---------------------------------------------------------|
| 31-0  | The Key to lock or unlock LUT.                          |
| KEY   | The key is 0x5AF05AF0. Read value is always 0x5AF05AF0. |

### 27.7.2.9 LUT Control Register (LUTCR)

#### 27.7.2.9.1 Offset

| Register | Offset |
|----------|--------|
| LUTCR    | 1Ch    |

#### 27.7.2.9.2 Function

The LUT control register is used along with LUTKEY register to lock or unlock LUT. This register has to be written immediately after writing 0x5AF05AF0 to LUTKEY register for the lock or unlock operation to be successful. Refer [Look Up Table](#) for details on locking/unlocking LUT. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

## 27.7.2.14 Flash Control Register 0 (FLSHA1CR0 - FLSHB2CR0)

### 27.7.2.14.1 Offset

| Register  | Offset |
|-----------|--------|
| FLSHA1CR0 | 60h    |
| FLSHA2CR0 | 64h    |
| FLSHB1CR0 | 68h    |
| FLSHB2CR0 | 6Ch    |

### 27.7.2.14.2 Function

The Flash control register 0 contains Flash size setting. FlexSPI determines which device is accessed with this register setting (Chip Selection).

### 27.7.2.14.3 Diagram

| Field          | Function                                                                                                                                                                                                                                                                                                                                 |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>—        | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 30-23<br>—     | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 22-0<br>FLSHSZ | Flash Size in KByte.<br>The max flash size supported for each device is 0 GB. When FLSHSZ setting value is greater than 0x400000, the device flash size would be taken as 0 GB. The max total flash size supported (for all 4 devices) is also 0 GB. If the total flash size is larger than 0 GB, only 0 GB address space is accessible. |

## 27.7.2.15 Flash Control Register 1 (FLSHA1CR1 - FLSHB2CR1)

### 27.7.2.15.1 Offset

| Register  | Offset |
|-----------|--------|
| FLSHA1CR1 | 70h    |
| FLSHA2CR1 | 74h    |
| FLSHB1CR1 | 78h    |
| FLSHB2CR1 | 7Ch    |

### 27.7.2.15.2 Function

The Flash control register 1 contains the setting for FlexSPI to meet Flash device specific timings and Flash internal address space.

### 27.7.2.15.3 Diagram

|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>CSINTERVALUNIT | CS interval unit<br>0b - The CS interval unit is 1 serial clock cycle<br>1b - The CS interval unit is 256 serial clock cycle                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 14-11<br>CAS         | Column Address Size.<br>When external flash has separate address field for row address and column address, this field should be set to flash column address bit width. FlexSPI will automatically split flash mapped address to Row address and Column address according to CAS field and WA field setting. This bit should be set to 0x0 when external Flash don't support column address. FlexSPI will transmit all flash address bits as Row address. For flash address mapping, please refer to <a href="#">Flash memory map</a> for more detail. |
| 10<br>WA             | Word Addressable.<br>This bit should be set when external Flash is word addressable. If Flash is word addressable, it should be access in terms of 16 bits. At this time, FlexSPI will not transmit Flash address bit 0 to external Flash. For flash address mapping, please refer to <a href="#">Flash memory map</a> for more detail.                                                                                                                                                                                                               |
| 9-5<br>TCSH          | Serial Flash CS Hold time.<br>This field is used to meet flash TCSH timing requirement. Serial flash CS Hold time promised by FlexSPI is: TCSH in serial root clock cycles (for both SDR and DDR mode). Please refer to <a href="#">FlexSPI Input Timing</a> for more detail.                                                                                                                                                                                                                                                                         |
| 4-0<br>TCSS          | Serial Flash CS setup time.<br>This field is used to meet flash TCSS timing requirement. Serial flash CS Setup time promised by FlexSPI is: (TCSS + 1/2) serial root clock cycles (for both SDR and DDR mode). Please refer to <a href="#">FlexSPI Input Timing</a> for more detail.                                                                                                                                                                                                                                                                  |

## 27.7.2.16 Flash Control Register 2 (FLSHA1CR2 - FLSHB2CR2)

### 27.7.2.16.1 Offset

| Register  | Offset |
|-----------|--------|
| FLSHA1CR2 | 80h    |
| FLSHA2CR2 | 84h    |
| FLSHB1CR2 | 88h    |
| FLSHB2CR2 | 8Ch    |

### 27.7.2.16.2 Function

Flash Control Register 2 contains setting field for AHB Bus access configuration. If the 4 external device are in different types, AHB read/write command may use different command sequences and AHB bus ready wait time may be also different.

There is limitation on AHB write burst start address alignment when flash is accessed in individual mode. |

## 27.7.2.18 IP Control Register 0 (IPCR0)

### 27.7.2.18.1 Offset

| Register | Offset |
|----------|--------|
| IPCR0    | A0h    |

### 27.7.2.18.2 Function

The IP control registers provide all the configuration required for IP commands. This register provides the flash device's start address, instead of SoC address, to be accessed for IP command. FlexSPI will determine the chip select automatically according to this start address.

#### NOTE

- It's not allowed to issue IP command crossing Flash device boundaries. Otherwise there will be IPCMDERR interrupt generated.
- This register should be set before IP command triggered.
- This register setting should not be changed while an IP command is in progress.

| 31-0<br>SFAR | Serial Flash Address for IP command. |

## 27.7.2.19 IP Control Register 1 (IPCR1)

### 27.7.2.19.1 Offset

| Register | Offset |
|----------|--------|
| IPCR1    | A4h    |

### 27.7.2.19.2 Function

The IP control registers provide all the configuration required for IP command. This register provides the flash read/program data size, sequence index in LUT, sequence number and individual/parallel mode setting for IP command.

#### NOTE

- This register should be before IP command triggered.
- This register setting should not be changed before IP command finished.

## 27.7.2.22 IP TX FIFO Control Register (IPTXFCR)

### 27.7.2.22.1 Offset

| Register | Offset |
|----------|--------|
| IPTXFCR  | BCh    |

### 27.7.2.22.2 Function

This register provides the configuration fields for IP TX FIFO management.

### 27.7.2.22.3 Diagram

## 27.7.2.22.4 Fields

## 27.7.2.23 DLL Control Register 0 (DLLACR - DLLBCR)

### 27.7.2.23.1 Offset

| Register | Offset |
|----------|--------|
| DLLACR   | C0h    |
| DLLBCR   | C4h    |

### 27.7.2.23.2 Function

This register provides the configuration fields for Flash A/B sample clock DLL.

### 27.7.2.23.3 Diagram

| 1<br>DLLRESET       | Software could force a reset on DLL by setting this field to 0x1. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. The reset action is edge triggered, so software need to clear this bit after set this bit (no delay limitation). |
| 0<br>DMLLEN         | DLL calibration enable.<br>When this bit is cleared, DLL calibration is disabled and the delay cell number in slave delay line is always 1. Please note that SLV delay line is overridden when OVRDEN bit is set and this bit field setting is ignored.                                  |

| 7-4<br>—         | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3-2<br>ARBCMDSRC | This status field indicates the trigger source of current command sequence granted by arbitrator. This field value is meaningless when ARB_CTL is not busy (STS0[ARBIDLE]=0x1).<br>00b - Triggered by AHB read command (triggered by AHB read).<br>01b - Triggered by AHB write command (triggered by AHB Write).<br>10b - Triggered by IP command (triggered by setting register bit IPCMD.TRG).<br>11b - Triggered by suspended command (resumed). |
| 1<br>ARBIDLE     | This status bit indicates the state machine in ARB_CTL is busy and there is command sequence granted by arbitrator and not finished yet on FlexSPI interface. When ARB_CTL state (ARBIDLE=0x1) is idle, there will be no transaction on FlexSPI interface also (SEQIDLE=0x1). So this bit should be polled to wait for FlexSPI controller become idle instead of SEQIDLE.                                                                            |

## 27.7.2.26 Status Register 2 (STS2)

### 27.7.2.26.1 Offset

| Register | Offset |
|----------|--------|
| STS2     | E8h    |

### 27.7.2.26.2 Function

This register indicates the status of Flash A and B sample clock DLLs.

### 27.7.2.26.3 Diagram

### 27.7.2.26.4 Fields

| Field            | Function                                                               |
|------------------|------------------------------------------------------------------------|
| 31-30<br>—       | Reserved                                                               |
| 29-24<br>BREFSEL | Flash B sample clock reference delay line delay cell number selection. |
| 23-18<br>BSLVSEL | Flash B sample clock slave delay line delay cell number selection.     |
| 17<br>BREFLOCK   | Flash B sample clock reference delay line locked.                      |
| 16<br>BSLVLOCK   | Flash B sample clock slave delay line locked.                          |
| 15-14<br>—       | Reserved                                                               |
| 13-8<br>AREFSEL  | Flash A sample clock reference delay line delay cell number selection. |
| 7-2<br>ASLVSEL   | Flash A sample clock slave delay line delay cell number selection .    |
| 1<br>AREFLOCK    | Flash A sample clock reference delay line locked.                      |
| 0<br>ASLVLOCK    | Flash A sample clock slave delay line locked.                          |

27.7.2.27 AHB Suspend Status Register (AHBSPNDSTS)

27.7.2.27.1 Offset

| Register   | Offset |
|------------|--------|
| AHBSPNDSTS | ECh    |

27.7.2.27.2 Function

Indicates the status of Suspended AHB Read Prefetch command sequence. When there is IP/AHB command triggered and arbitrator is processing an AHB Read sequence ( prefetching more data not for current AHB burst), the prefetch sequence will be suspended and may be resumed when there is no transaction on FlexSPI any more. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence suspended already, previous suspended sequence will be removed and never resumed. Refer [Command Abort and Suspend](#) for more details.

27.7.2.27.3 Diagram

27.7.2.27.4 Fields

| Field           | Function                                                 |
|-----------------|----------------------------------------------------------|
| 31-16<br>DATLFT | Left Data size for suspended command sequence (in byte). |
| 15-4            | Reserved                                                 |

Table continues on the next page...

| Field        | Function                                                               |
|--------------|------------------------------------------------------------------------|
| —            |                                                                        |
| 3-1<br>BUFID | AHB RX BUF ID for suspended command sequence.                          |
| 0<br>ACTIVE  | Indicates if an AHB read prefetch command sequence has been suspended. |

## 27.7.2.28 IP RX FIFO Status Register (IPRXFSTS)

### 27.7.2.28.1 Offset

| Register | Offset |
|----------|--------|
| IPRXFSTS | F0h    |

### 27.7.2.28.2 Function

This status register indicates the status of IP RX FIFO.

### 27.7.2.28.3 Diagram

### 27.7.2.28.4 Fields

| Field           | Function                                   |
|-----------------|--------------------------------------------|
| 31-16<br>RDCNTR | Total Read Data Counter: RDCNTR * 64 Bits. |
| 15-8<br>—       | Reserved                                   |

Table continues on the next page...

| Field | Function                                             |
|-------|------------------------------------------------------|
| 7-0   | Fill level of IP RX FIFO.                            |
| FILL  | Valid Data entries in IP RX FIFO is: FILL * 64 Bits. |

## 27.7.2.29 IP TX FIFO Status Register (IPTXFSTS)

### 27.7.2.29.1 Offset

| Register | Offset |
|----------|--------|
| IPTXFSTS | F4h    |

### 27.7.2.29.2 Function

This status register indicates the status of IP TX FIFO.

### 27.7.2.29.3 Diagram

|       |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| W     |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

|       |          |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|-------|----------|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| Bits  | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | Reserved |    |    |    |    |    |   |   | FILL |   |   |   |   |   |   |   |
| W     |          |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 27.7.2.29.4 Fields

| Field           | Function                                                                          |
|-----------------|-----------------------------------------------------------------------------------|
| 31-16<br>WRCNTR | Total Write Data Counter: WRCNTR * 64 Bits.                                       |
| 15-8<br>—       | Reserved                                                                          |
| 7-0<br>FILL     | Fill level of IP TX FIFO.<br>Valid Data entries in IP TX FIFO is: FILL * 64 Bits. |

### 27.7.2.30 IP RX FIFO Data Register a (RFDR0 - RFDR31)

#### 27.7.2.30.1 Offset

For a = 0 to 31:

| Register | Offset          |
|----------|-----------------|
| RFDRa    | 100h + (a × 4h) |

#### 27.7.2.30.2 Function

These registers provide read access to IP RX FIFO by IPS bus. The read value is unknown for read access to invalid entries in IP RX FIFO.

#### 27.7.2.30.3 Diagram

#### 27.7.2.30.4 Fields

| Field          | Function |
|----------------|----------|
| 31-0<br>RXDATA | RX Data  |

### 27.7.2.31 IP TX FIFO Data Register a (TFDR0 - TFDR31)

### 27.7.2.31.1 Offset

For a = 0 to 31:

| Register | Offset          |
|----------|-----------------|
| TFDRa    | 180h + (a × 4h) |

### 27.7.2.31.2 Function

These registers provide write access to IP TX FIFO by IPS bus.

### 27.7.2.31.3 Diagram

### 27.7.2.31.4 Fields

| Field          | Function |
|----------------|----------|
| 31-0<br>TXDATA | TX Data  |

## 27.7.2.32 LUT a (LUT0 - LUT63)

### 27.7.2.32.1 Offset

For a = 0 to 63:

| Register | Offset          |
|----------|-----------------|
| LUTa     | 200h + (a × 4h) |

### 27.7.2.32.2 Function

The LUT is a look-up-table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI will fetch the command sequence from LUT when IP/AHB command triggered. There are 16 command sequences in LUT. Refer [Look Up Table](#) for more details.

#### NOTE

LUT is implemented as memory, so the reset value is unknown.

### 27.7.2.32.3 Diagram

### 27.7.2.32.4 Fields

| Field              | Function  |
|--------------------|-----------|
| 31-26<br>OPCODE1   | OPCODE1   |
| 25-24<br>NUM_PADS1 | NUM_PADS1 |
| 23-16<br>OPERAND1  | OPERAND1  |
| 15-10<br>OPCODE0   | OPCODE    |
| 9-8<br>NUM_PADS0   | NUM_PADS0 |
| 7-0                | OPERAND0  |

| Field    | Function |
|----------|----------|
| OPERAND0 |          |

## 27.8 AHB Memory Map definition

This section describes FlexSPI module AHB memory map in detail.

### 27.8.1 AHB Memory Map for Serial Flash memory access

Following address range is mapped for AHB read/write access to serial flash memory: 0x60000000 - 0x80000000.

AHB Bus feature supported for Serial Flash memory reading:

- Cachable and Non-Cachable access
- Prefetch Enable/Disable
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

AHB Bus feature for Serial Flash memory writing:

- Bufferable and Non-Bufferable access
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Flash access by AHB Command](#) for more details about AHB access to Serial Flash memory.

### 27.8.2 AHB Memory Map for IP RX FIFO read access

Following address range is mapped for AHB read access to IP RX FIFO: 0x7FC00000 - 0x7FC00080.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Reading Data from IP RX FIFO](#) for more details about IP RX FIFO reading.

### 27.8.3 AHB Memory Map for IP TX FIFO write access

Following address range is mapped for AHB write access to IP TX FIFO: 0x7F800000 - 0x7F800080.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Filling Data to IP TX FIFO](#) for more details about IP TX FIFO filling.

## 28.2 Arm Cortex M7 Platform

### 28.2.1 Overview

The Cortex-M7 platform features a single Arm®Cortex®-M7 processor in this chip. The Arm®Cortex®-M7 processor is a highly efficient, high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline by which many instructions can be dual-issued, including load/load and load/store instruction pairs because of multiple memory interfaces.

Memory interfaces that the processor supports include:

- Tightly-Coupled Memory (TCM)
- Harvard instruction and data caches and AXI master (AXIM) interface
- Dedicated low-latency AHB-Lite peripheral (AHBP) interface

The Arm Cortex-M7 Platform supports the following:

- 32 KB L1 Instruction Cache
- 32 KB L1 Data Cache
- Floating Point Unit (FPU) with support for the FPv5 architecture
- Internal Trace (TRC)

The number of IRQs supported for this chip is 160. In addition, it supports various components composing the Arm CoreSight debug/Trace system, such as ETM and CTI.

#### NOTE

This chip supports up to 16 interrupt priority levels, i.e. it implements bits [7:4] of each NVIC Interrupt Priority Register.

### 28.2.2 Block Diagram

A block diagram for the Cortex-M7 is given below:

### 29.2 Overview

This section provides an overview of the

- NIC-301 (Network Inter-Connect) AXI arbiter IP

The NIC-301 (by Arm Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the Arm specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual, version r2p3*.

## NOTE

The NIC-301 default settings are configured by NXP's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

### 29.2.1 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via internal "GPV" ports.
- Support for cross-clock domain synchronization.

### 29.2.2 Modes and Operations

The NIC-301 supports a normal functional mode only.

## 29.3 External Signals

There are no external I/O interfaces for NIC-301.

## 29.4 Memory Map and Register Definition

The bus system is composed of five instances: SIM\_M7, SIM\_PER, SIM\_M, SIM\_MAIN and SIM\_EMS. Three of them have GPV registers which are helpful for bus arbitration and performance. For detailed descriptions of these registers, see the Arm document: *DDI0397I\_corelink\_network\_interconnect\_nic301\_r2p3\_trm.pdf*.

### 1. SIM\_MAIN registers

The SIM\_MAIN GPV base address is GPV0\_BASE = 0x41000000. The following registers are implemented in this NIC.

| Register Name | Port Name | Module Name | Absolute Address            | Reset Value | Descriptions                                                                                                                                                                                                                                                                                        |
|---------------|-----------|-------------|-----------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| read_qos      | m_a_2     | LCD         | GPV0_BASE + 0x44000 + 0x100 | 1           | Set the priority of master's read. The priority level would be used when the master's read transaction is being arbitrated by the NIC.<br><br>Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; ...; 15: the highest priority).   |
| read_qos      | m_a_3     | CSI         | GPV0_BASE + 0x45000 + 0x100 | 4           | Same as above                                                                                                                                                                                                                                                                                       |
| read_qos      | m_a_4     | PXP         | GPV0_BASE + 0x46000 + 0x100 | 2           | Same as above                                                                                                                                                                                                                                                                                       |
| write_qos     | m_a_2     | LCD         | GPV0_BASE + 0x44000 + 0x104 | 1           | Set the priority of master's write. The priority level would be used when the master's write transaction is being arbitrated by the NIC.<br><br>Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; ...; 15: the highest priority). |
| write_qos     | m_a_3     | CSI         | GPV0_BASE + 0x45000 + 0x104 | 4           | Same as above                                                                                                                                                                                                                                                                                       |
| write_qos     | m_a_4     | PXP         | GPV0_BASE + 0x46000 + 0x104 | 2           | Same as above                                                                                                                                                                                                                                                                                       |
| fn_mod        | m_a_2     | LCD         | GPV0_BASE + 0x44000 + 0x108 | 0           | Issuing functionality modification register. This register sets the block issuing capability to one outstanding transaction.<br><br>Legal programmable values are 0, 1, 2 and 3.                                                                                                                    |

Table continues on the next page...

| Register Name | Port Name | Module Name | Absolute Address            | Reset Value | Descriptions                                                                                                                                                                                                                                                                                                                                                                                             |

### 3. SIM\_M7 registers

The SIM\_M7 GPV base address is GPV4\_BASE = 0x41400000. The following registers are implemented in this NIC.

| Register Name | Port Name | Module Name | Absolute Address            | Reset Value | Descriptions                      |
|---------------|-----------|-------------|-----------------------------|-------------|-----------------------------------|
| fn_mod_ahb    | m_b_1     | DMA         | GPV4_BASE + 0x43000 + 0x028 | 0           | This register has 3 control bits. |

#### 4. IB registers

There are no IB registers implemented in this chip.

#### 5. Address region control registers

There are not such type of registers implemented in this chip.

#### 6. Peripheral ID registers

The peripheral ID registers are implemented in SIM\_MAIN, SIM\_M, and SIM\_M7. For more details, please see the Arm document: *DDI0397I\_corelink\_network\_interconnect\_nic301\_r2p3\_trm.pdf*.

### 30.2 Overview

There is 1 OCRAM controller implemented in the chip. One controller is for up to 512 KB on-chip RAM. The size of OCRAM is configured in the FlexRAM module via IOMUXC. For more details, refer to the FlexRAM chapter.

The on-chip RAM block is implemented as an slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

The memory banks are organized with the lower 2 bits of the address which is the AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding a pipeline or wait-states in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

**Figure 30-1. On-chip RAM Block Diagram**

## 30.3 Basic Functions

### 30.3.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

## 30.4 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Register (IOMUXC.GPR3) bits [3:0] in the IOMUX chapter.

### 30.4.1 Read Data Wait State

When the wait state is enabled, it will take 2 cycles for each read access (each beat of a read burst).

This can avoid the potential timing problem caused by the longer memory access time at higher frequency.

When this feature is disabled, it only takes 1 clock cycle to finish a read transaction. That is, read data is available in the next cycle of read request becomes valid on the bus.

For the normal OCRAM, the read data wait state is configurable via IOMUXC.GPR3[0].

### 30.4.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

For the normal OCRAM, the read address pipeline is configurable via IOMUXC.GPR3[1].

### **30.4.3 Write Data Pipeline**

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

For the normal OCRAM, the write data pipeline is configurable via IOMUXC.GPR3[2].

### **30.4.4 Write Address Pipeline**

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would take at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

For the normal OCRAM, the write address pipeline is configurable via IOMUXC.GPR3[3]

## 30.5 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC\_GPR10

For additional information see application note [AN12077: Using the i.MX RT FlexRAM](#). This document describes the flexible memory array available on the i.MX RT MCUs. It includes the following information:

- Configuration of the bank array
- Memory type size definition
- Available memory controllers
- Power domains and clocks
- Interrupt request generation
- Example of FlexRAM configuration usage on a specific application use case

## 31.2 Overview

### 31.2.1 Introduction

This SoC has 512 KB of on-chip RAM which is shared by I-TCM, D-TCM and general purpose On Chip RAM (OCRAM). The FlexRAM is the manager of the big on-chip RAM array.

### 31.2.2 Features

The FLEXRAM includes the following features:

- Integrated I-TCM and D-TCM RAM controller
  - 64-bit I-TCM interface and 2x 32-bit D-TCM interface.
  - The controller supports up to 512 KB TCM (for both ITCM and DTCM) space.
  - The controller supports two access modes:
    - Fast mode: RAM accesses is expected to be finished in 1-cycle for both read and write.
    - Wait mode: RAM accesses is expected to be finished in 2-cycle. Wait mode for read and write path can be enabled separately.
  - Synchronous interface to the M7 Core, run at the same frequency as the core
  - Automatically clock gating control to reduce power consumption
- Integrated OCRAM controller
  - single SRAM bank controller.
  - support up to 512 KB SRAM size
  - Synchronous to the system bus, runs at the same frequency as bus fabric
- Parameterized RAM Array
  - Support up to 512 KB total memory space
  - Support up to 32 block of 32-bit RAM
- RAM Array portioning
  - RAM size of ITCM, DTCM and OCRAM can be configured from 0 to full RAM Array size separately
  - Step of the RAM size partitioning for ITCM, DTCM and OCRAM is (Total RAM SIZE)/16
  - Flexible RAM bank organization.
- Flexible power mode:
  - Run mode: All RAM banks are powered on

- Retention mode: Only 1 (Bank0) out of the 16 RAM banks is on while the rest banks are powered off
- Partial mode: 8 out of the 16 RAM banks (bank8 to bank15) can be powered off dynamically
- Bank8~15 can be disabled with hardware fuse setting. When the fuse is set, total RAM size will be limit to 256 KB
- Generates interrupt upon TCM, OCRM access out of configured RAM range

### 31.2.3 Block diagram

Figure 31-1. FLEXRAM block diagram

## 31.3 Functional description

FLEXRAM converts AXI and TCM interface signals to RAM interface signals and implements mux control for OCRM, DTCM and ITCM access to on-chip RAM.

### 31.3.1 Interface Conversion

FLEXRAM integrate OCRM controller which converts AXI master interface signals to RAM interface signals(Please see OCRM section). OCRM controller can support to add pipeline or wait-state in read/write access by IOMUX GPR.

FLEXRAM also implement TCM controller module to convert DTCM/ITCM interface to RAM interface. TCM read/write access can be extended to 2 cycles by setting TCM\_CTRL register. When DTCM and ITCM access unallocated RAM address, TCM controller can send tcm\_err to DTCM/ITCM interface.

### 31.3.2 RAM Bank Allocation

OCRAM, DTCM and ITCM share 512 KB of on-chip RAM. SW can configure from 0 to 512 KB full RAM array size for OCRM, DTCM and ITCM by IOMUX GPR16 and GPR17. The RAM size step is 32KB. The allocated RAM bank can be not overlapped for OCRM, DTCM and ITCM. Table below show an example of a 128KB ITCM, 128KB DTCM and 256KB OCRM configuration.

**Table 31-2. FLEXRAM Partitioning Example**

|        | ITCM | DTCM | OCRAM |
|--------|------|------|-------|
| Bank0  | 0    | 0    | 1     |
| Bank1  | 0    | 0    | 1     |
| Bank2  | 0    | 0    | 1     |
| Bank3  | 0    | 0    | 1     |
| Bank4  | 1    | 0    | 0     |
| Bank5  | 1    | 0    | 0     |
| Bank6  | 0    | 1    | 0     |
| Bank7  | 0    | 1    | 0     |
| Bank8  | 0    | 0    | 1     |
| Bank9  | 0    | 0    | 1     |
| Bank10 | 0    | 0    | 1     |
| Bank11 | 0    | 0    | 1     |
| Bank12 | 1    | 0    | 0     |
| Bank13 | 1    | 0    | 0     |
| Bank14 | 0    | 1    | 0     |
| Bank15 | 0    | 1    | 0     |

Each RAM bank has 2 bits bank configuration from IOMUX GPR17.

**Table 31-3. RAM Bank configuration**

|    | RAM Bank Configuration |
|----|------------------------|
| 00 | Not used               |
| 01 | OCRAM                  |
| 10 | DTCM                   |
| 11 | ITCM                   |

### 31.3.3 Low power modes

FLEXRAM has input fuse control signal to control ocram bank8~bank15 interface access. When the fuse bit is programmed, bank8~bank15 can't be accessed again and can be power down.

### 31.3.4 Clocks

The following table describes the clock sources of the FlexRAM module.

**Table 31-4. FlexRAM Clocks**

| Clock name | Clock Root   | Description                                   |
|------------|--------------|-----------------------------------------------|
| ipg_clk    | ipg_clk_root | Peripheral clock                              |
| ipg_clk_s  | ipg_clk_root | Peripheral access clock for register accesses |

### 31.3.5 Reset

FLAMRAM has 2 reset siganls. One is used for OCRAM interface and in always on power domain. The other is used for TCM interface and in core power domain.

### 31.3.6 Interrupts

FLEXRAM can generate interrput in the following cases:

- OCRAM, DTCM or ITCM access the RAM address which is not allocated.

## 31.4 Memory Map and register definition

This section includes the FLEXRAM module memory map and detailed descriptions of all registers.

### 31.4.1 FLEXRAM register descriptions

| Power management  | PMU               | <a href="#">Power Management</a><br><a href="#">Power Management Unit</a>      |

### 32.2 Overview

This section provides an overview of the AHB to IP Bridge (AIPSTZ). This particular peripheral is designed as the bridge between AHB bus and peripherals with the lower bandwidth IP Slave (IPS) buses.

#### 32.2.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals. This interface is only meant for slave peripherals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 16-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 1 MBytes of total address space.

- The bridge provides configurable per-block and per-master access protections. Access permissions are based on bus master (e.g. DMA or core) privilege levels and resource domain. More details on the protection features and configuration can be found in the Security Reference Manual
- Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.
- The bridge uses one single asynchronous reset and one global clock.

## 32.3 Clocks

The following table describes the clock sources for AIPSTZ. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 32-2. AIPSTZ Clocks**

| Clock name | Clock Root   | Description  |
|------------|--------------|--------------|
| hclk       | ahb_clk_root | Module clock |

## 32.4 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus.

Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

Each bridge that connects to the IPS (or peripherals) are referred as AIPS. The chip has several separate AIPS modules, and peripherals are grouped and assigned under each AIPS block. The list of peripherals are indicated as n-1, ... and n-x for AIPS-1, ... and AIPS-x respectively.

AIPS occupies a 1-Mbyte portion of the address space. The register maps of the IPS peripherals are located on 16-Kbyte boundaries. Each IPS peripheral is allocated one 16-Kbyte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 16-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 16-Kbytes. Two global external IPS block enables are available for the remaining address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

The bridge supports the notion of "trusted" masters for security purposes. Masters may be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user-mode privilege level. Refer to [AIPSTZ Memory Map/Register Definition](#) for more information.

The AIPSTZ prevents access to a peripheral if the transaction originated from a source from a resource domain that has been explicitly omitted. Resource domains are assigned in the RDC submodule. Please refer to the RDC chapter for programming details.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

## 32.5 Access Protections

The AIPSTZ bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege, and allows masters to be designated as trusted or untrusted.

Peripherals may require supervisor privilege level for access, may restrict access to a trusted master only, and may be write-protected. IP bus peripherals are subject to access control policies set in both CSU registers and AIPSTZ registers. An access is blocked if it is denied by either policy.

Masters and peripherals are assigned to one or more resource domains in the RDC submodule (see the RDC chapter for details). Depending on RDC programming, masters transactions through the AIPSTZ may or may not be allowed access to peripherals in different resource domains.

## 32.6 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS.

Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge. The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

## 32.7 Initialization Information

The AIPS bridge should be programmed before use.

The following registers should be initialized: The Master Privilege Registers (AIPSTZ\_MPRs), the Peripheral Access Control registers (AIPSTZ\_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ\_OPACRs) described in [AIPSTZ Memory Map/Register Definition](#).

### 32.7.1 Security Block

The AIPSTZ contains a security block that is connected to each off-platform peripheral. This block filters accesses based on write/read, non-secure, and supervisor signals.

Each peripheral can be individually configured to allow or deny each of the following transactions as described in the table below:

**Table 32-3. Peripheral Access Configuration options**

| Config Bit | Write | Non-Secure | Supervisor | Meaning          |
|------------|-------|------------|------------|------------------|
| 0          | 0     | 0          | 0          | Secure User Read |

*Table continues on the next page...*

**Table 32-3. Peripheral Access Configuration options (continued)**

| Config Bit | Write | Non-Secure | Supervisor | Meaning                     |
|------------|-------|------------|------------|-----------------------------|
| 1          | 0     | 0          | 1          | Secure Supervisor Read      |
| 2          | 0     | 1          | 0          | Non-Secure User Read        |
| 3          | 0     | 1          | 1          | Non-Secure Supervisor Read  |
| 4          | 1     | 0          | 0          | Secure User Write           |
| 5          | 1     | 0          | 1          | Secure Supervisor Write     |
| 6          | 1     | 1          | 0          | Non-Secure User Write       |
| 7          | 1     | 1          | 1          | Non-Secure Supervisor Write |

Each peripheral has a security configuration (sec\_config\_X) input for determining whether to allow or deny a given access type. These are 8-bit vectors, with each bit corresponding to one of the transactions above as listed in the Config Bit column of [Table 32-3](#). If the bit is asserted (1'b1), the transaction is allowed. If the bit is negated (1'b0), the transaction is not allowed.

For example, if peripheral 0 is configured as follows:

sec\_config\_0 [7:0] = 8'b0011\_0011

This peripheral can only be accessed by secure transactions. Bits 0, 1, 4, and 5 are asserted and these bits refer to the four types of secure transactions. If an insecure transaction is attempted to this peripheral, it will result in an error.

Eight bits per peripheral across an entire system can result in a large number of configuration bits that must be assigned and controlled, most likely in a series of registers in another block. To reduce the number of register bits required predefined sets of security profiles can be defined and encapsulated in an external security translation block. The table below describes one set of security profiles that has been proposed for use with the AIPSTZ.

**Table 32-4. Security Levels**

| CSU_SEC_LEVEL | Non-Secure User | Non-Secure Supervisor | Secure User | Secure Supervisor |
|---------------|-----------------|-----------------------|-------------|-------------------|
| 0             | RD+WR           | RD+WR                 | RD+WR       | RD+WR             |
| 1             | NOT ALLOWED     | RD+WR                 | RD+WR       | RD+WR             |
| 2             | Read Only       | Read Only             | RD+WR       | RD+WR             |
| 3             | NOT ALLOWED     | Read Only             | RD+WR       | RD+WR             |
| 4             | NOT ALLOWED     | NOT ALLOWED           | RD+WR       | RD+WR             |
| 5             | NOT ALLOWED     | NOT ALLOWED           | NOT ALLOWED | RD+WR             |
| 6             | NOT ALLOWED     | NOT ALLOWED           | Read Only   | Read Only         |
| 7             | NOT ALLOWED     | NOT ALLOWED           | NOT ALLOWED | NOT ALLOWED       |

Information regarding CSU is provided in the Security Reference Manual. Contact your NXP representative for information about obtaining this document.

A 3-bit input, 8-bit output translation block can be used such that only three register bits are required to set the security profile and the translation block will drive the correct 8-bit configuration vector. Each peripheral connected to the AIPSTZ would require this translation block. The top level AIPSTZ has this three bit input line `csu\_sec\_level[2:0]' corresponding to each peripheral X.

## 32.8 AIPSTZ Memory Map/Register Definition

The memory map for the AIPS SW-visible registers is shown in the table below.

The MPROT and OPACR fields are 4 bits in width. Some bits may be reserved depending on device.

**AIPSTZ memory map**

| Absolute address (hex) | Register name                                                     | Width (in bits) | Access | Reset value | Section/ page               |
|------------------------|-------------------------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 4007_C000              | Master Priviledge Registers (AIPSTZ1_MPR)                         | 32              | R/W    | 7700_0000h  | <a href="#">32.8.1/1803</a> |
| 4007_C040              | Off-Platform Peripheral Access Control Registers (AIPSTZ1_OPACR)  | 32              | R/W    | 4444_4444h  | <a href="#">32.8.2/1806</a> |
| 4007_C044              | Off-Platform Peripheral Access Control Registers (AIPSTZ1_OPACR1) | 32              | R/W    | 4444_4444h  | <a href="#">32.8.3/1809</a> |

| 4037_C050              | Off-Platform Peripheral Access Control Registers (AIPSTZ4_OPACR4) | 32              | R/W    | 4444_4444h  | <a href="#">32.8.6/1818</a> |

### 32.8.1 Master Priviledge Registers (AIPSTZx\_MPR)

Each AIPSTZ\_MPR specifies 16 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable shown in [Table 32-5](#)

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in the table below.

**Table 32-5. MPROT Field**

| Bit | Field | Description                                                                                                        |
|-----|-------|--------------------------------------------------------------------------------------------------------------------|
| 3   | MBW   | <b>Master Buffer Writes</b> - This bit determines whether the AIPSTZ is enabled to buffer writes from this master. |
| 2   | MTR   | <b>Master Trusted for Reads</b> - This bit determines whether the master is trusted for read accesses.             |
| 1   | MTW   | <b>Master Trusted for Writes</b> - This bit determines whether the master is trusted for write accesses.           |
| 0   | MPL   | <b>Master Privilege Level</b> - This bit determines how the privilege level of the master is determined.           |

**NOTE**

The reset value is set to 0000\_0000\_7700\_0000, which makes master 0 and master 1 (Arm CORE) the trusted masters. Trusted software can change the settings after reset.

**Table 32-6. Master Index Allocation**

| Master Index | Master Name | Comments                          |
|--------------|-------------|-----------------------------------|
| Master 0     | Arm core    |                                   |
| Master 1     | eDMA        |                                   |
| Master 2     | DCP         |                                   |
| Master 3     | Others      | Share the same number allocation. |
| Master 4-15  | Reserved    |                                   |

Address: Base address + 0h offset

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |        |    |   |   |          |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|--------|----|---|---|----------|---|---|---|---|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11     | 10 | 9 | 8 | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    | MPROT5 |    |   |   | Reserved |   |   |   |   |   |   |   |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |        |    |   |   |          |   |   |   |   |   |   |   |

## 32.8.2 Off-Platform Peripheral Access Control Registers (AIPSTZx\_OPACR)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ\_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ\_OPACR has the following format shown in [Table 32-7](#)

**Table 32-7. OPAC Field**

| Bit | Field | Description                                                                                                                   |
|-----|-------|-------------------------------------------------------------------------------------------------------------------------------|
| 3   | BW    | <b>Buffer Writes</b> - This bit determines whether write accesses to this peripheral are allowed to be buffered. <sup>1</sup> |
| 2   | SP    | <b>Supervisor Protect</b> - This bit determines whether the peripheral requires supervisor privilege level for access.        |
| 1   | WP    | <b>Write Protect</b> - This bit determines whether the peripheral allows write accesses.                                      |
| 0   | TP    | <b>Trusted Protect</b> - This bit determines whether the peripheral allows accesses from an untrusted master.                 |

1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'.

Address: Base address + 40h offset

## AIPSTZx\_OPACR field descriptions (continued)

| Field | Description                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xxx1  | <b>TP1</b> — Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.                                                                                                                         |
| xx0x  | <b>WP0</b> — This peripheral allows write accesses.                                                                                                                                                                                                                                                                                             |
| xx1x  | <b>WP1</b> — This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.                                                                                                                                                          |
| x0xx  | <b>SP0</b> — This peripheral does not require supervisor privilege level for accesses.                                                                                                                                                                                                                                                          |
| x1xx  | <b>SP1</b> — This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. |
| 0xxx  | <b>BW0</b> — Write accesses to this peripheral are not bufferable by the AIPSTZ.                                                                                                                                                                                                                                                                |
| 1xxx  | <b>BW1</b> — Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.                                                                                                                                                                                                                                                        |

### 32.8.3 Off-Platform Peripheral Access Control Registers (AIPSTZx\_OPACR1)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ\_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ\_OPACR has the following format shown in [Table 32-7](#)

Address: Base address + 44h offset

|       |       |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |        |   |   |   |   |   |   |   |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |

**AIPSTZx\_OPACR1 field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xxx0  | <b>TP0</b> — Accesses from an untrusted master are allowed.                                                                                                                                                                                                                                                                                     |
| xxx1  | <b>TP1</b> — Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.                                                                                                                         |
| xx0x  | <b>WP0</b> — This peripheral allows write accesses.                                                                                                                                                                                                                                                                                             |
| xx1x  | <b>WP1</b> — This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.                                                                                                                                                          |
| x0xx  | <b>SP0</b> — This peripheral does not require supervisor privilege level for accesses.                                                                                                                                                                                                                                                          |
| x1xx  | <b>SP1</b> — This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. |
| 0xxx  | <b>BW0</b> — Write accesses to this peripheral are not bufferable by the AIPSTZ.                                                                                                                                                                                                                                                                |
| 1xxx  | <b>BW1</b> — Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.                                                                                                                                                                                                                                                        |

**32.8.4 Off-Platform Peripheral Access Control Registers (AIPSTZx\_OPACR2)**

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ\_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ\_OPACR has the following format shown in [Table 32-7](#)

Address: Base address + 48h offset

|       |        |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |        |   |   |   |   |   |   |   |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |        |  |  |  |  |  |  |  |

The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. |
