Reference manual

STM32C5 Arm®-based 32-bit MCUs

Introduction

This document is addressed to application developers. It provides complete information on how to use the STM32C5 microcontrollers memory and peripherals.

For ordering information, mechanical, and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-M33 core, refer to the corresponding Arm® Technical Reference Manual available on http://infocenter.arm.com.

The STM32C5 microcontrollers include ST state-of-the-art patented technology.

Contents

1 Documentation conventions 85

1.1 General information 85

1.2 List of abbreviations for registers 85

1.3 Register reset value 86

1.4 Glossary 86

2 Memory and bus architecture 87

2.1 System architecture 87

2.1.1 Fast C-bus 88

2.1.2 Slow C-bus 89

2.1.3 S-bus 89

2.1.4 LPDMA1 and LPDMA2 buses 89

2.1.5 Bus matrix 89

2.1.6 AHB/APB bridges 89

2.2 Memory organization 90

2.2.1 Introduction 90

2.2.2 Memory map and register boundary addresses 91

2.2.3 Embedded SRAM 98

2.2.4 Flash memory overview 98

3 System security 99

3.1 Key security features 99

3.2 Resource isolation 100

3.2.1 Temporal isolation using secure hide protection (HDP) 100

3.2.2 Resource isolation using Cortex privileged mode 100

3.3 Secure execution 101

3.3.1 Memory protection unit (MPU) 101

3.3.2 Embedded flash memory write protection 101

3.3.3 Tamper detection and response 101

3.4 Secure storage 103

3.4.1 Hardware secret key management 104

3.5 Unique ID 105

3.6 Crypto engines 105

3.6.1 Cryptographic engines features . . . 105
3.6.2 Secure AES co-processor (SAES) . . . 106
3.7 Product life cycle . . . 107
3.7.1 Life cycle management with readout protection (RDP) . . . 108
3.8 Summary of protection mechanism . . . 110

4 Boot modes . . . 112
4.1 STM32C5 boot modes . . . 112

5 RAMs configuration controller (RAMCFG) . . . 114
5.1 RAMCFG introduction . . . 114
5.2 RAMCFG main features . . . 114
5.3 RAMCFG functional description . . . 114
5.3.1 Internal SRAMs features . . . 114
5.3.2 Error code correction (SRAM2) . . . 115
5.3.3 Write protection (SRAM2) . . . 116
5.3.4 Software erase . . . 116
5.4 RAMCFG low-power modes . . . 117
5.5 RAMCFG interrupts . . . 117
5.6 RAMCFG registers . . . 118

7 Instruction cache (ICACHE) 207

7.1 ICACHE introduction 207
7.2 ICACHE main features 207
7.3 ICACHE implementation 208
7.4 ICACHE functional description 208
7.4.1 ICACHE block diagram 209
7.4.2 ICACHE reset and clocks 209
7.4.3 ICACHE TAG memory 210
7.4.4 Direct-mapped ICACHE (1-way cache) 211
7.4.5 ICACHE enable 212
7.4.6 Cacheable and noncacheable traffic 212
7.4.7 Address remapping 213
7.4.8 Cacheable accesses 215
7.4.9 Dual-master cache 216

7.4.10 ICACHE maintenance . . . 216
7.4.11 ICACHE performance monitoring . . . 217
7.4.12 ICACHE boot . . . 217
7.5 ICACHE low-power modes . . . 217
7.6 ICACHE error management and interrupts . . . 218
7.7 ICACHE registers . . . 218
7.7.1 ICACHE control register (ICACHE_CR) . . . 218
7.7.2 ICACHE status register (ICACHE_SR) . . . 219
7.7.3 ICACHE interrupt enable register (ICACHE_IER) . . . 220
7.7.4 ICACHE flag clear register (ICACHE_FCR) . . . 220
7.7.5 ICACHE hit monitor register (ICACHE_HMONR) . . . 221
7.7.6 ICACHE miss monitor register (ICACHE_MMONR) . . . 221
7.7.7 ICACHE region x configuration register (ICACHE_CRRx) . . . 221
7.7.8 ICACHE register map . . . 222

8 Power control (PWR) . . . 224
8.1 PWR introduction . . . 224
8.2 PWR main features . . . 224
8.3 PWR pins and internal signals . . . 224
8.4 PWR power supplies and supply domains . . . 225
8.4.1 External power supplies . . . 225
8.4.2 Internal regulator . . . 226
8.4.3 Independent analog peripherals supply . . . 226
8.4.4 RTC domain . . . 226
8.5 PWR system supply voltage regulation . . . 227
8.5.1 Embedded voltage regulator operating modes . . . 227
8.6 PWR power supply and temperature supervision . . . 227
8.6.1 Power-on reset (POR)/power-down reset (PDR) . . . 227
8.6.2 Programmable voltage detector (PVD) . . . 228
8.7 Power modes . . . 229
8.7.1 Slowing down system clocks . . . 233
8.7.2 Peripheral clock gating . . . 233
8.7.3 Low-power modes . . . 233
8.7.4 Sleep mode . . . 234
8.7.5 Stop 0 mode . . . 235
8.7.6 Stop 1 mode . . . 237

8.7.7 Standby mode . . . 239
8.7.8 Power mode output pins . . . 242
8.8 PWR privileged protection . . . 242
8.9 PWR interrupts . . . 243
8.10 PWR registers . . . 243
8.10.1 PWR power mode control register (PWR_PMCR) . . . 243
8.10.2 PWR status register (PWR_PMSR) . . . 244
8.10.3 PWR RTC domain control register (PWR_RTCCR) . . . 245
8.10.4 PWR voltage monitor control register (PWR_VMCR) . . . 245
8.10.5 PWR voltage monitor status register (PWR_VMSR) . . . 246
8.10.6 PWR wake-up status clear register (PWR_WUSCR) . . . 246
8.10.7 PWR wake-up status register (PWR_WUSR) . . . 247
8.10.8 PWR wake-up configuration register (PWR_WUCR) . . . 247
8.10.9 PWR I/O retention register (PWR_IORETR) . . . 248
8.10.10 PWR privilege configuration register (PWR_PRIVCFGR) . . . 249
8.10.11 PWR register map . . . 249

9 Reset and clock control (RCC) . . . 251
9.1 RCC introduction . . . 251
9.2 RCC pins and internal signals . . . 251
9.3 RCC reset functional description . . . 251
9.3.1 Power reset . . . 251
9.3.2 System reset . . . 252
9.3.3 RTC domain reset . . . 253
9.3.4 Reset source identification . . . 253
9.4 RCC clocks functional description . . . 254
9.4.1 HSE clock . . . 256
9.4.2 HSI oscillator and HSIS clock . . . 257
9.4.3 PSI oscillator and PSIS clock . . . 258
9.4.4 HSIDIV3 and PSIDIV3 clock . . . 260
9.4.5 HSIK and PSIK clock . . . 260
9.4.6 LSE clock . . . 261
9.4.7 LSI clock . . . 262
9.4.8 System clock (SYSCLK) selection . . . 262
9.4.9 Handling clock generators in Stop and Standby modes . . . 262
9.4.10 Clock security system (CSS) . . . 263

9.4.11 Clock output generation (MCO1/MCO2/LSCO) 264
9.4.12 Kernel clock selection 265
9.4.13 RTC and TAMP clock 271
9.4.14 Timer clock 271
9.4.15 Peripherals clock gating 271
9.5 RCC privilege functional description 272
9.6 RCC low-power modes 272
9.7 RCC interrupts 273
9.8 RCC registers 274
9.8.1 RCC clock control register (RCC_CR1) 274
9.8.2 RCC clock control register (RCC_CR2) 277
9.8.3 RCC clock configuration register1 (RCC_CFGR1) 279
9.8.4 RCC CPU domain clock configuration register 2 (RCC_CFGR2) 281
9.8.5 RCC clock source interrupt enable register (RCC_CIER) 283
9.8.6 RCC clock source interrupt flag register (RCC_CIFR) 285
9.8.7 RCC clock source interrupt clear register (RCC_CICR) 286
9.8.8 RCC AHB1 reset register (RCC_AHB1RSTR) 288
9.8.9 RCC AHB2 peripheral reset register (RCC_AHB2RSTR) 289
9.8.10 RCC AHB4 peripheral reset register (RCC_AHB4RSTR) 291
9.8.11 RCC APB1 peripheral low reset register (RCC_APB1LRSTR) 291
9.8.12 RCC APB1 peripheral high reset register (RCC_APB1HRSTR) 293
9.8.13 RCC APB2 peripheral reset register (RCC_APB2RSTR) 294
9.8.14 RCC APB3 peripheral reset register (RCC_APB3RSTR) 295
9.8.15 RCC AHB1 peripheral clock register (RCC_AHB1ENR) 296
9.8.16 RCC AHB2 peripheral clock register (RCC_AHB2ENR) 297
9.8.17 RCC AHB4 peripheral clock register (RCC_AHB4ENR) 299
9.8.18 RCC APB1 peripheral clock register (RCC_APB1LENR) 300
9.8.19 RCC APB1 peripheral clock register (RCC_APB1HENR) 302
9.8.20 RCC APB2 peripheral clock register (RCC_APB2ENR) 303
9.8.21 RCC APB3 peripheral clock register (RCC_APB3ENR) 304
9.8.22 RCC AHB1 sleep clock register (RCC_AHB1LPENR) 305
9.8.23 RCC AHB2 sleep clock register (RCC_AHB2LPENR) 306
9.8.24 RCC AHB4 peripheral sleep clock register (RCC_AHB4LPENR) 308
9.8.25 RCC APB1 sleep clock register (RCC_APB1LLPENR) 309
9.8.26 RCC APB1 sleep clock register (RCC_APB1HLPENR) 311
9.8.27 RCC APB2 sleep clock register (RCC_APB2LPENR) 312
9.8.28 RCC APB3 sleep clock register (RCC_APB3LPENR) 313

9.8.29 RCC kernel clock configuration register (RCC_CCIPR1) 314
9.8.30 RCC kernel clock configuration register (RCC_CCIPR2) 315
9.8.31 RCC kernel clock configuration register (RCC_CCIPR3) 317
9.8.32 RCC RTC domain control register (RCC_RTCCR) 318
9.8.33 RCC reset status register (RCC_RSR) 320
9.8.34 RCC privilege configuration register (RCC_PRIVCFGR) 322
9.8.35 RCC register map 322

10 Clock recovery system (CRS) 327
10.1 CRS introduction 327
10.2 CRS main features 327
10.3 CRS implementation 327
10.4 CRS functional description 328
10.4.1 CRS block diagram 328
10.4.2 CRS internal signals 328
10.4.3 Synchronization input 329
10.4.4 Frequency error measurement 329
10.4.5 Frequency error evaluation and automatic trimming 330
10.4.6 CRS initialization and configuration 331
10.5 CRS in low-power modes 332
10.6 CRS interrupts 332
10.7 CRS registers 332
10.7.1 CRS control register (CRS_CR) 332
10.7.2 CRS configuration register (CRS_CFGR) 334
10.7.3 CRS interrupt and status register (CRS_ISR) 335
10.7.4 CRS interrupt flag clear register (CRS_ICR) 337
10.7.5 CRS register map 337

11 General-purpose I/Os (GPIO) 339
11.1 GPIO introduction 339
11.2 GPIO main features 339
11.3 GPIO functional description 339
11.3.1 General-purpose I/O (GPIO) 341
11.3.2 I/O pin alternate function multiplexer and mapping 342
11.3.3 I/O port control registers 342
11.3.4 I/O port data registers 343

11.3.5 I/O data bitwise handling . . . 343
11.3.6 GPIO locking mechanism . . . 343
11.3.7 I/O alternate function input/output . . . 343
11.3.8 External interrupt/wake-up lines . . . 344
11.3.9 Input configuration . . . 344
11.3.10 Output configuration . . . 345
11.3.11 Alternate function configuration . . . 345
11.3.12 Analog configuration . . . 346
11.3.13 Using the HSE or LSE oscillator pins as GPIOs . . . 346
11.3.14 Using the GPIO pins in the RTC supply domain . . . 347
11.3.15 I/Os state retention during standby mode . . . 347
11.3.16 Privileged and unprivileged modes . . . 347
11.3.17 I/O compensation cell . . . 347
11.4 GPIO registers . . . 347
11.4.1 GPIO port mode register (GPIOx_MODER) (x = A to H) . . . 348
11.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to H) . . . 348
11.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to H) . . . 349
11.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to H) . . 349
11.4.5 GPIO port input data register (GPIOx_IDR) (x = A to H) . . . 350
11.4.6 GPIO port output data register (GPIOx_ODR) (x = A to H) . . . 350
11.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to H) . . . 351
11.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to H) . . . 351
11.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to H) . . . 352
11.4.10 GPIO alternate function high register (GPIOx_AFRH) (x = A to H) . . . 353
11.4.11 GPIO port bit reset register (GPIOx_BRR) (x = A to H) . . . 354
11.4.12 GPIO register map . . . 355

12 System configuration, boot, and security (SBS) . . . 357
12.1 SBS introduction . . . 357
12.2 SBS main features . . . 357
12.3 SBS functional description . . . 357
12.3.1 SBS block diagram . . . 357
12.3.2 SBS signals . . . 358
12.3.3 SBS reset and clocks . . . 358
12.3.4 SBS I/O compensation cell management . . . 358
12.3.5 SBS boot control . . . 359
12.3.6 SBS hardware secure storage control . . . 360

12.4 SBS interrupts . . . 361
12.5 SBS registers . . . 361
12.5.1 SBS temporal isolation control register (SBS_HDPLCR) . . . 361
12.5.2 SBS temporal isolation status register (SBS_HDPLSR) . . . 362
12.5.3 SBS next HDPL control register (SBS_NEXTHDPLCR) . . . 362
12.5.4 SBS product mode and configuration register (SBS_PMCR) . . . 363
12.5.5 SBS FPU interrupt mask register (SBS_FPUIMR) . . . 364
12.5.6 SBS memory erase status register (SBS_MESR) . . . 365
12.5.7 SBS compensation cell for I/Os control and status register (SBS_CCCSR) . . . 365
12.5.8 SBS compensation cell for I/Os value register (SBS_CCVALR) . . . 366
12.5.9 SBS compensation cell for I/Os software code register (SBS_CCSWCR) . . . 367
12.5.10 SBS Class B register (SBS_CFGR2) . . . 367
12.5.11 SBS CPU lock register (SBS_CLCKR) . . . 368
12.5.12 SBS ECC NMI mask register (SBS_ECCNMIR) . . . 369
12.5.13 SBS register map . . . 369

13 Peripherals interconnect matrix . . . 371
13.1 Interconnect matrix introduction . . . 371
13.2 Connection summary . . . 371
13.3 Interconnection details . . . 374

14 Low-power direct memory access controller (LPDMA) . . . 382
14.1 LPDMA introduction . . . 382
14.2 LPDMA main features . . . 382
14.3 LPDMA implementation . . . 383
14.3.1 LPDMA instances . . . 383
14.3.2 LPDMA channels . . . 383
14.3.3 LPDMA in low-power modes . . . 384
14.3.4 LPDMA requests . . . 384
14.3.5 LPDMA block requests . . . 387
14.3.6 LPDMA channels with peripheral early termination . . . 387
14.3.7 LPDMA triggers . . . 388
14.4 LPDMA functional description . . . 390
14.4.1 LPDMA block diagram . . . 390

14.4.2 LPDMA channel state and direct programming without any linked-list . . . 390
14.4.3 LPDMA channel suspend and resume . . . 391
14.4.4 LPDMA channel abort and restart . . . 392
14.4.5 LPDMA linked-list data structure . . . 393
14.4.6 Linked-list item transfer execution . . . 395
14.4.7 LPDMA channel state and linked-list programming in run-to-completion mode . . . 395
14.4.8 LPDMA channel state and linked-list programming in link step mode . 400
14.4.9 LPDMA channel state and linked-list programming . . . 406
14.4.10 LPDMA direct transfers . . . 408
14.4.11 LPDMA transfer request and arbitration . . . 410
14.4.12 LPDMA triggered transfer . . . 414
14.4.13 LPDMA circular buffering with linked-list programming . . . 415
14.4.14 LPDMA transfer in peripheral flow-control mode . . . 417
14.4.15 LPDMA privileged/unprivileged channel . . . 418
14.4.16 LPDMA error management . . . 418
14.5 LPDMA in debug mode . . . 420
14.6 LPDMA in low-power modes . . . 420
14.7 LPDMA interrupts . . . 420
14.8 LPDMA registers . . . 422
14.8.1 LPDMA privileged configuration register (LPDMA_PRIVCFGR) . . . 422
14.8.2 LPDMA configuration lock register (LPDMA_RCFGLOCKR) . . . 423
14.8.3 LPDMA masked interrupt status register (LPDMA_MISR) . . . 423
14.8.4 LPDMA channel x linked-list base address register (LPDMA_CxLBAR) . . . 424
14.8.5 LPDMA channel x flag clear register (LPDMA_CxFCR) . . . 424
14.8.6 LPDMA channel x status register (LPDMA_CxSR) . . . 425
14.8.7 LPDMA channel x control register (LPDMA_CxCR) . . . 426
14.8.8 LPDMA channel x transfer register 1 (LPDMA_CxTR1) . . . 429
14.8.9 LPDMA channel x transfer register 2 (LPDMA_CxTR2) . . . 431
14.8.10 LPDMA channel x block register 1 (LPDMA_CxBR1) . . . 433
14.8.11 LPDMA channel x source address register (LPDMA_CxSAR) . . . 435
14.8.12 LPDMA channel x destination address register (LPDMA_CxDAR) . . . 436
14.8.13 LPDMA channel x linked-list address register (LPDMA_CxLLR) . . . 437
14.8.14 LPDMA register map . . . 438

15 Nested vectored interrupt controller (NVIC) . . . 440

15.1 NVIC main features 440
15.2 SysTick calibration value register 440
15.3 Interrupt and exception vectors 440

16 Extended interrupts and event controller (EXTI) 445
16.1 EXTI main features 445
16.2 EXTI block diagram 446
16.2.1 EXTI connections between peripherals and CPU 447
16.2.2 EXTI interrupt/event mapping 447
16.3 EXTI functional description 448
16.3.1 EXTI configurable event input wake-up 449
16.3.2 EXTI direct event input wake-up 449
16.3.3 EXTI mux selection 450
16.4 EXTI functional behavior 450
16.5 EXTI event protection 451
16.5.1 EXTI privilege protection 452
16.6 EXTI registers 452
16.6.1 EXTI rising trigger selection register (EXTI_RTSR1) 452
16.6.2 EXTI falling trigger selection register (EXTI_FTSR1) 453
16.6.3 EXTI software interrupt event register (EXTI_SWIER1) 454
16.6.4 EXTI rising edge pending register (EXTI_RPR1) 454
16.6.5 EXTI falling edge pending register (EXTI_FPR1) 455
16.6.6 EXTI privilege configuration register (EXTI_PRIVCFGR1) 455
16.6.7 EXTI rising trigger selection register 2 (EXTI_RTSR2) 456
16.6.8 EXTI falling trigger selection register 2 (EXTI_FTSR2) 457
16.6.9 EXTI software interrupt event register 2 (EXTI_SWIER2) 458
16.6.10 EXTI rising edge pending register 2 (EXTI_RPR2) 459
16.6.11 EXTI falling edge pending register 2 (EXTI_FPR2) 460
16.6.12 EXTI privilege configuration register 2 (EXTI_PRIVCFGR2) 461
16.6.13 EXTI external interrupt selection register (EXTI_EXTICR1) 461
16.6.14 EXTI external interrupt selection register (EXTI_EXTICR2) 463
16.6.15 EXTI external interrupt selection register (EXTI_EXTICR3) 464
16.6.16 EXTI external interrupt selection register (EXTI_EXTICR4) 466
16.6.17 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1) 468
16.6.18 EXTI CPU wake-up with event mask register (EXTI_EMR1) 468
16.6.19 EXTI CPU wake-up with interrupt mask register 2 (EXTI_IMR2) 469

16.6.20 EXTI CPU wake-up with event mask register 2 (EXTI_EMR2) 469
16.6.21 EXTI register map 470

17 Cyclic redundancy check calculation unit (CRC) 472
17.1 CRC introduction 472
17.2 CRC main features 472
17.3 CRC functional description 473
17.3.1 CRC block diagram 473
17.3.2 CRC internal signals 473
17.3.3 CRC operation 473
17.4 CRC registers 475
17.4.1 CRC data register (CRC_DR) 475
17.4.2 CRC independent data register (CRC_IDR) 475
17.4.3 CRC control register (CRC_CR) 476
17.4.4 CRC initial value (CRC_INIT) 477
17.4.5 CRC polynomial (CRC_POL) 477
17.4.6 CRC register map 478

18 CORDIC coprocessor (CORDIC) 479
18.1 CORDIC introduction 479
18.2 CORDIC main features 479
18.3 CORDIC functional description 479
18.3.1 General description 479
18.3.2 CORDIC functions 479
18.3.3 Fixed point representation 486
18.3.4 Scaling factor 486
18.3.5 Precision 487
18.3.6 Zero-overhead mode 490
18.3.7 Polling mode 491
18.3.8 Interrupt mode 492
18.3.9 DMA mode 492
18.4 CORDIC registers 493
18.4.1 CORDIC control/status register (CORDIC_CSR) 493
18.4.2 CORDIC argument register (CORDIC_WDATA) 495
18.4.3 CORDIC result register (CORDIC_RDATA) 496
18.4.4 CORDIC register map 496

19 Extended-SPI interface (XSPI) 497
19.1 XSPI introduction 497
19.2 XSPI main features 497
19.3 XSPI implementation 498
19.4 XSPI functional description 499
19.4.1 XSPI block diagram 499
19.4.2 XSPI pins and internal signals 500
19.4.3 XSPI interface to memory modes 501
19.4.4 XSPI regular-command protocol 501
19.4.5 XSPI regular-command protocol signal interface 504
19.4.6 HyperBus protocol 508
19.4.7 Specific features 511
19.4.8 XSPI operating mode introduction 512
19.4.9 XSPI indirect mode 512
19.4.10 XSPI automatic status-polling mode 514
19.4.11 XSPI memory-mapped mode 515
19.4.12 XSPI configuration introduction 516
19.4.13 XSPI system configuration 516
19.4.14 XSPI device configuration 517
19.4.15 XSPI regular-command mode configuration 519
19.4.16 XSPI HyperBus protocol configuration 522
19.4.17 XSPI error management 523
19.4.18 XSPI BUSY and ABORT 523
19.4.19 XSPI reconfiguration or deactivation 524
19.4.20 NCS behavior 524
19.4.21 Software control of two external memories 524
19.4.22 Hardware-controlled extended memory support 525
19.5 Address alignment and data number 526
19.6 XSPI interrupts 527
19.7 XSPI registers 528
19.7.1 XSPI control register (XSPI_CR) 528
19.7.2 XSPI device configuration register 1 (XSPI_DCR1) 531
19.7.3 XSPI device configuration register 2 (XSPI_DCR2) 533
19.7.4 XSPI device configuration register 3 (XSPI_DCR3) 534
19.7.5 XSPI device configuration register 4 (XSPI_DCR4) 534
19.7.6 XSPI status register (XSPI_SR) 535

19.7.7 XSPI flag clear register (XSPI_FCR) . . . 536
19.7.8 XSPI data length register (XSPI_DLR) . . . 537
19.7.9 XSPI address register (XSPI_AR) . . . 537
19.7.10 XSPI data register (XSPI_DR) . . . 538
19.7.11 XSPI polling status mask register (XSPI_PSMKR) . . . 538
19.7.12 XSPI polling status match register (XSPI_PSMAR) . . . 539
19.7.13 XSPI polling interval register (XSPI_PIR) . . . 539
19.7.14 XSPI communication configuration register (XSPI_CCR) . . . 540
19.7.15 XSPI timing configuration register (XSPI_TCR) . . . 542
19.7.16 XSPI instruction register (XSPI_IR) . . . 542
19.7.17 XSPI alternate bytes register (XSPI_ABR) . . . 543
19.7.18 XSPI low-power timeout register (XSPI_LPTR) . . . 543
19.7.19 XSPI wrap communication configuration register (XSPI_WPCCR) . . . 544
19.7.20 XSPI wrap timing configuration register (XSPI_WPTCR) . . . 546
19.7.21 XSPI wrap instruction register (XSPI_WPIR) . . . 546
19.7.22 XSPI wrap alternate bytes register (XSPI_WPABR) . . . 547
19.7.23 XSPI write communication configuration register (XSPI_WCCR) . . . 547
19.7.24 XSPI write timing configuration register (XSPI_WTCR) . . . 549
19.7.25 XSPI write instruction register (XSPI_WIR) . . . 550
19.7.26 XSPI write alternate bytes register (XSPI_WABR) . . . 550
19.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR) . . . 551
19.7.28 XSPI register map . . . 551

20 Delay block (DLYB) . . . 555

20.1 DLYB introduction . . . 555
20.2 DLYB main features . . . 555
20.3 DLYB functional description . . . 555
20.3.1 DLYB diagram . . . 555
20.3.2 DLYB pins and internal signals . . . 556
20.3.3 General description . . . 556
20.3.4 Delay line length configuration procedure . . . 557
20.3.5 Output clock phase configuration procedure . . . 558
20.4 DLYB registers . . . 558
20.4.1 DLYB control register (DLYB_CR) . . . 558
20.4.2 DLYB configuration register (DLYB_CFGR) . . . 559

20.4.3 DLYB register map 560

21 Analog-to-digital converters (ADC) 561

21.1 ADC introduction 561

21.2 ADC main features 561

21.3 ADC implementation 563

21.4 ADC functional description 564

21.4.1 ADC block diagram 564

21.4.2 ADC pins and internal signals 565

21.4.3 ADC clocks 567

21.4.4 ADC connectivity 569

21.4.5 Slave AHB interface 571

21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) 572

21.4.7 Calibration (ADCAL, ADC_CALFACT) 572

21.4.8 ADC on-off control (ADEN, ADDIS, ADRDY) 574

21.4.9 Constraints when writing the ADC control bits 575

21.4.10 Channel selection (ADC_SQRy, ADC_JSQR) 576

21.4.11 Channel preselection register (ADC_PCSEL) 576

21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2) 577

21.4.13 Single conversion mode 578

21.4.14 Continuous conversion mode (CONT = 1) 579

21.4.15 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 580

21.4.16 Starting conversions (ADSTART, JADSTART) 581

21.4.17 Timing 582

21.4.18 Stopping an ongoing conversion (ADSTP, JADSTP) 583

21.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) 585

21.4.20 Injected channel management 586

21.4.21 Programmable resolution (RES) - fast conversion mode 587

21.4.22 End of conversion and end of sampling phase (EOC, JEOC, EOSMP) 588

21.4.23 End of conversion sequence (EOS, JEOS) 588

21.4.24 Timing diagram examples (single/continuous modes, hardware/software triggers) 589

21.4.25 Data management 591

21.4.26 Dynamic low-power features 599

21.4.27 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT) . . . 603
21.4.28 Oversampler . . . 608
21.4.29 Dual ADC modes . . . 614
21.4.30 Temperature sensor . . . 629
21.4.31 Monitoring the internal voltage reference . . . 631
21.5 ADC interrupts . . . 633
21.6 ADC registers (for each ADC) . . . 634
21.6.1 ADC interrupt and status register (ADC_ISR) . . . 634
21.6.2 ADC interrupt enable register (ADC_IER) . . . 636
21.6.3 ADC control register (ADC_CR) . . . 638
21.6.4 ADC configuration register (ADC_CFGR1) . . . 641
21.6.5 ADC configuration register 2 (ADC_CFGR2) . . . 644
21.6.6 ADC sample time register 1 (ADC_SMPR1) . . . 647
21.6.7 ADC sample time register 2 (ADC_SMPR2) . . . 648
21.6.8 ADC channel preselection register (ADC_PCSEL) . . . 649
21.6.9 ADC regular sequence register 1 (ADC_SQR1) . . . 649
21.6.10 ADC regular sequence register 2 (ADC_SQR2) . . . 650
21.6.11 ADC regular sequence register 3 (ADC_SQR3) . . . 651
21.6.12 ADC regular sequence register 4 (ADC_SQR4) . . . 652
21.6.13 ADC regular data register (ADC_DR) . . . 653
21.6.14 ADC injected sequence register (ADC_JSQR) . . . 653
21.6.15 ADC offset y configuration register (ADC_OFCFGRy) . . . 655
21.6.16 ADC offset y register (ADC_OFRy) . . . 656
21.6.17 ADC gain compensation register (ADC_GCOMP) . . . 657
21.6.18 ADC injected channel y data register (ADC_JDRy) . . . 658
21.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) . . . 658
21.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) . . . 659
21.6.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR) . 659
21.6.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR) . . . 660
21.6.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR) . 660
21.6.24 ADC analog watchdog 2 higher threshold register (ADC_AWD2HTR) . . . 661
21.6.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR) . 661
21.6.26 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR) . . . 661

21.6.27 ADC calibration factors (ADC_CALFACT) 662
21.6.28 ADC option register (ADC_OR) 663
21.7 ADC common registers 663
21.7.1 ADC common status register (ADCC_CSR) 663
21.7.2 ADC common control register (ADCC_CCR) 665
21.7.3 ADC common regular data register for dual mode (ADCC_CDR) 666
21.7.4 ADC common regular data register for dual mode (ADCC_CDR2) 667
21.8 ADC register map 667

22 Digital-to-analog converter (DAC) 672
22.1 DAC introduction 672
22.2 DAC main features 672
22.3 DAC implementation 673
22.4 DAC functional description 674
22.4.1 DAC block diagram 674
22.4.2 DAC pins and internal signals 675
22.4.3 DAC clocks 676
22.4.4 DAC channel enable 676
22.4.5 DAC data format 677
22.4.6 DAC conversion 678
22.4.7 DAC output voltage 679
22.4.8 DAC trigger selection 680
22.4.9 DMA requests 680
22.4.10 Noise generation 681
22.4.11 Triangle-wave generation 682
22.4.12 DAC channel modes 683
22.4.13 DAC channel buffer calibration 686
22.4.14 DAC channel conversion modes 687
22.4.15 Dual DAC channel conversion modes (if dual channels are available) 688
22.5 DAC in low-power modes 692
22.6 DAC interrupts 692
22.7 DAC registers 693
22.7.1 DAC control register (DAC_CR) 693
22.7.2 DAC software trigger register (DAC_SWTRGR) 696

22.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) . . . 697
22.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1) . . . 698
22.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1) . . . 698
22.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2) . . . 699
22.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2) . . . 699
22.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2) . . . 700
22.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD) . . . 700
22.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD) . . . 701
22.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD) . . . 701
22.7.12 DAC channel1 data output register (DAC_DOR1) . . . 702
22.7.13 DAC channel2 data output register (DAC_DOR2) . . . 702
22.7.14 DAC status register (DAC_SR) . . . 703
22.7.15 DAC calibration control register (DAC_CCR) . . . 704
22.7.16 DAC mode control register (DAC_MCR) . . . 705
22.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1) . . . 706
22.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2) . . . 707
22.7.19 DAC sample and hold time register (DAC_SHHR) . . . 707
22.7.20 DAC sample and hold refresh time register (DAC_SHRR) . . . 708
22.7.21 DAC register map . . . 709

23 Comparator (COMP) . . . 711

23.1 Introduction . . . 711
23.2 COMP main features . . . 711
23.3 COMP implementation . . . 712
23.3.1 COMP implementation for STM32C55x/562 and STM32C59x/5A3 devices . . . 712
23.3.2 COMP implementation for STM32C53x/542 device . . . 712
23.4 COMP functional description . . . 713
23.4.1 COMP block diagram . . . 713

23.4.2 COMP pins and internal signals . . . 713
23.4.3 COMP reset and clocks . . . 715
23.4.4 Comparator LOCK mechanism . . . 715
23.4.5 Window comparator (optional feature) . . . 715
23.4.6 Hysteresis . . . 716
23.4.7 Comparator output blanking function . . . 716
23.4.8 COMP startup stabilization time . . . 717
23.4.9 COMP power and speed modes . . . 717
23.5 COMP low-power modes . . . 717
23.6 COMP interrupts . . . 718
23.6.1 COMP wake-up interrupt through EXTI . . . 718
23.6.2 COMP NVIC interrupt through EXTI . . . 718
23.6.3 COMP interrupt through NVIC of the CPU . . . 719
23.7 SCALER function . . . 719
23.8 COMP registers . . . 720
23.8.1 Comparator status register (COMP_SR) . . . 720
23.8.2 Comparator interrupt clear flag register (COMP_ICFR) . . . 721
23.8.3 Comparator configuration register 1 (COMP_CFGR1) . . . 721
23.8.4 Comparator configuration register 2 (COMP_CFGR2) . . . 723
23.8.5 COMP register map . . . 725

24 Operational amplifier (OPAMP) . . . 726
24.1 Introduction . . . 726
24.2 OPAMP main features . . . 726
24.3 OPAMP implementation . . . 726
24.4 OPAMP functional description . . . 727
24.4.1 OPAMP block diagram . . . 727
24.4.2 OPAMP pins and internal signals . . . 728
24.4.3 OPAMP reset and clocks . . . 729
24.4.4 OPAMP output redirection to an internal COMP channel . . . 729
24.4.5 OPAMP initial configuration . . . 730
24.4.6 OPAMP operational amplifier speed . . . 730
24.4.7 OPAMP enable . . . 730
24.4.8 OPAMP operating modes . . . 730
24.4.9 OPAMP programmable gain . . . 736
24.4.10 OPAMP operational amplifier offset compensation . . . 737

24.4.11 OPAMP calibration . . . 737
24.4.12 Timer-controlled operation . . . 739
24.5 OPAMP in low-power modes . . . 740
24.6 OPAMP registers . . . 741
24.6.1 OPAMP control/status register (OPAMP_CSR) . . . 741
24.6.2 OPAMP timer-controlled mode register (OPAMP_TCMR) . . . 743
24.6.3 OPAMP register map . . . 746

25 Coupling and chaining bridge (CCB) . . . 747
25.1 CCB introduction . . . 747
25.2 CCB main features . . . 747
25.3 CCB implementation . . . 748
25.4 CCB functional description . . . 748
25.4.1 CCB block diagram . . . 748
25.4.2 CCB internal signals . . . 749
25.4.3 CCB reset and clocks . . . 749
25.4.4 CCB coupling and chaining . . . 749
25.4.5 CCB error management . . . 752
25.5 CCB coupling and chaining operations . . . 752
25.5.1 Preliminary steps before any protected operation . . . 754
25.5.2 ECDSA signature . . . 755
25.5.3 ECC scalar multiplication . . . 762
25.5.4 RSA modular exponentiation . . . 765
25.6 CCB interrupts . . . 767
25.7 CCB registers . . . 768
25.7.1 CCB control register (CCB_CR) . . . 768
25.7.2 CCB status register (CCB_SR) . . . 769
25.7.3 CCB reference tag register (CCB_REFTAGRx) . . . 771
25.7.4 CCB register map . . . 772

26 True random number generator (RNG) . . . 773
26.1 RNG introduction . . . 773
26.2 RNG main features . . . 773
26.3 RNG functional description . . . 774
26.3.1 RNG block diagram . . . 774
26.3.2 RNG internal signals . . . 774

26.3.3 Random number generation . . . 775
26.3.4 RNG initialization . . . 777
26.3.5 RNG operation . . . 778
26.3.6 RNG clocking . . . 780
26.3.7 Error management . . . 780
26.3.8 RNG low-power use . . . 782
26.4 RNG interrupts . . . 782
26.5 RNG processing time . . . 783
26.6 RNG entropy source validation . . . 783
26.6.1 Introduction . . . 783
26.6.2 Validation conditions . . . 783
26.7 RNG registers . . . 785
26.7.1 RNG control register (RNG_CR) . . . 785
26.7.2 RNG status register (RNG_SR) . . . 787
26.7.3 RNG data register (RNG_DR) . . . 788
26.7.4 RNG noise source control register (RNG_NSCR) . . . 789
26.7.5 RNG health test control register x (RNG_HTCRx) . . . 789
26.7.6 RNG health test status register 0 (RNG_HTSR0) . . . 790
26.7.7 RNG health test status register 1 (RNG_HTSR1) . . . 790
26.7.8 RNG noise source mask register (RNG_NSMR) . . . 791
26.7.9 RNG register map . . . 792

27 AES hardware accelerator (AES) . . . 793
27.1 AES introduction . . . 793
27.2 AES main features . . . 793
27.3 AES implementation . . . 794
27.4 AES functional description . . . 794
27.4.1 AES block diagram . . . 794
27.4.2 AES internal signals . . . 795
27.4.3 AES reset and clocks . . . 795
27.4.4 AES symmetric cipher implementation . . . 795
27.4.5 AES encryption or decryption typical usage . . . 796
27.4.6 AES authenticated encryption, decryption, and cipher-based message authentication . . . 799
27.4.7 AES ciphertext stealing and data padding . . . 799
27.4.8 AES suspend and resume operations . . . 800

27.4.9 AES basic chaining modes (ECB, CBC) 800
27.4.10 AES counter (CTR) mode 804
27.4.11 AES Galois/counter mode (GCM) 806
27.4.12 AES Galois message authentication code (GMAC) 811
27.4.13 AES counter with CBC-MAC (CCM) 812
27.4.14 AES key sharing with secure AES co-processor 817
27.4.15 AES data registers and data swapping 818
27.4.16 AES key registers 820
27.4.17 AES initialization vector registers 820
27.4.18 AES error management 821
27.5 AES interrupts 822
27.6 AES DMA requests 822
27.7 AES processing latency 823
27.8 AES registers 825
27.8.1 AES control register (AES_CR) 825
27.8.2 AES status register (AES_SR) 827
27.8.3 AES data input register (AES_DINR) 828
27.8.4 AES data output register (AES_DOUTR) 829
27.8.5 AES key register 0 (AES_KEYR0) 829
27.8.6 AES key register 1 (AES_KEYR1) 830
27.8.7 AES key register 2 (AES_KEYR2) 830
27.8.8 AES key register 3 (AES_KEYR3) 830
27.8.9 AES initialization vector register 0 (AES_IVR0) 831
27.8.10 AES initialization vector register 1 (AES_IVR1) 831
27.8.11 AES initialization vector register 2 (AES_IVR2) 831
27.8.12 AES initialization vector register 3 (AES_IVR3) 832
27.8.13 AES key register 4 (AES_KEYR4) 832
27.8.14 AES key register 5 (AES_KEYR5) 832
27.8.15 AES key register 6 (AES_KEYR6) 833
27.8.16 AES key register 7 (AES_KEYR7) 833
27.8.17 AES suspend registers (AES_SUSPRx) 833
27.8.18 AES interrupt enable register (AES_IER) 834
27.8.19 AES interrupt status register (AES_ISR) 835
27.8.20 AES interrupt clear register (AES_ICR) 836
27.8.21 AES register map 836

28 Secure AES coprocessor (SAES) 839

28.1 SAES introduction . . . 839
28.2 SAES main features . . . 839
28.3 SAES implementation . . . 840
28.4 SAES functional description . . . 840
28.4.1 SAES block diagram . . . 840
28.4.2 SAES internal signals . . . 841
28.4.3 SAES reset and clocks . . . 842
28.4.4 SAES symmetric cipher implementation . . . 842
28.4.5 SAES encryption or decryption typical usage . . . 843
28.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication . . . 845
28.4.7 SAES ciphertext stealing and data padding . . . 846
28.4.8 SAES suspend and resume operations . . . 846
28.4.9 SAES basic chaining modes (ECB, CBC) . . . 847
28.4.10 SAES counter (CTR) mode . . . 851
28.4.11 SAES Galois/counter mode (GCM) . . . 853
28.4.12 SAES Galois message authentication code (GMAC) . . . 857
28.4.13 SAES counter with CBC-MAC (CCM) . . . 859
28.4.14 SAES operation with wrapped keys . . . 864
28.4.15 SAES operation with shared keys . . . 868
28.4.16 SAES data registers and data swapping . . . 869
28.4.17 SAES key registers . . . 872
28.4.18 SAES initialization vector registers . . . 873
28.4.19 SAES error management . . . 873
28.5 SAES interrupts . . . 875
28.6 SAES DMA requests . . . 876
28.7 SAES processing latency . . . 876
28.8 SAES registers . . . 878
28.8.1 SAES control register (SAES_CR) . . . 878
28.8.2 SAES status register (SAES_SR) . . . 881
28.8.3 SAES data input register (SAES_DINR) . . . 882
28.8.4 SAES data output register (SAES_DOUTR) . . . 882
28.8.5 SAES key register 0 (SAES_KEYR0) . . . 883
28.8.6 SAES key register 1 (SAES_KEYR1) . . . 883
28.8.7 SAES key register 2 (SAES_KEYR2) . . . 884
28.8.8 SAES key register 3 (SAES_KEYR3) . . . 884

28.8.9 SAES initialization vector register 0 (SAES_IVR0) 884
28.8.10 SAES initialization vector register 1 (SAES_IVR1) 885
28.8.11 SAES initialization vector register 2 (SAES_IVR2) 885
28.8.12 SAES initialization vector register 3 (SAES_IVR3) 885
28.8.13 SAES key register 4 (SAES_KEYR4) 886
28.8.14 SAES key register 5 (SAES_KEYR5) 886
28.8.15 SAES key register 6 (SAES_KEYR6) 886
28.8.16 SAES key register 7 (SAES_KEYR7) 887
28.8.17 SAES suspend registers (SAES_SUSPRx) 887
28.8.18 SAES interrupt enable register (SAES_IER) 887
28.8.19 SAES interrupt status register (SAES_ISR) 888
28.8.20 SAES interrupt clear register (SAES_ICR) 890
28.8.21 SAES register map 890

29 Hash processor (HASH) 893

29.1 HASH introduction 893
29.2 HASH main features 893
29.3 HASH implementation 894
29.4 HASH functional description 894
29.4.1 HASH block diagram 894
29.4.2 HASH internal signals 895
29.4.3 About secure hash algorithms 895
29.4.4 Message data feeding 895
29.4.5 Message digest computing 897
29.4.6 Message padding 899
29.4.7 HMAC operation 901
29.4.8 HASH suspend/resume operations 902
29.4.9 HASH DMA interface 904
29.4.10 HASH error management 905
29.4.11 HASH processing time 905
29.5 HASH interrupts 906
29.6 HASH registers 906
29.6.1 HASH control register (HASH_CR) 906
29.6.2 HASH data input register (HASH_DIN) 908
29.6.3 HASH start register (HASH_STR) 909
29.6.4 HASH digest registers 910

29.6.5 HASH interrupt enable register (HASH_IMR) 912
29.6.6 HASH status register (HASH_SR) 912
29.6.7 HASH context swap registers 913
29.6.8 HASH register map 914

30 Public key accelerator (PKA) 916
30.1 PKA introduction 916
30.2 PKA main features 916
30.3 PKA functional description 917
30.3.1 PKA block diagram 917
30.3.2 PKA internal signals 917
30.3.3 PKA reset and clocks 918
30.3.4 PKA public key acceleration 918
30.3.5 Typical applications for PKA 920
30.3.6 PKA procedure to perform an operation 922
30.3.7 Private keys protection using CCB 923
30.3.8 PKA error management 927
30.4 PKA operating modes 927
30.4.1 Introduction 927
30.4.2 Montgomery parameter computation 929
30.4.3 Modular addition 929
30.4.4 Modular subtraction 930
30.4.5 Modular and Montgomery multiplication 930
30.4.6 Modular exponentiation 931
30.4.7 Modular inversion 933
30.4.8 Modular reduction 933
30.4.9 Arithmetic addition 934
30.4.10 Arithmetic subtraction 934
30.4.11 Arithmetic multiplication 935
30.4.12 Arithmetic comparison 935
30.4.13 RSA CRT exponentiation 935
30.4.14 Point on elliptic curve Fp check 936
30.4.15 ECC Fp scalar multiplication 937
30.4.16 ECDSA sign 938
30.4.17 ECDSA verification 940
30.4.18 ECC complete addition 941
30.4.19 ECC double base ladder 941

30.4.20 ECC projective to affine 942
30.5 Example of configurations and processing times 943
30.5.1 Supported elliptic curves 943
30.5.2 Computation times 945
30.6 PKA interrupts 947
30.7 PKA registers 948
30.7.1 PKA control register (PKA_CR) 948
30.7.2 PKA status register (PKA_SR) 950
30.7.3 PKA clear flag register (PKA_CLRFR) 952
30.7.4 PKA RAM 953
30.7.5 PKA register map 954

31 Advanced-control timers (TIM1/TIM8) 955
31.1 TIM1/TIM8 introduction 955
31.2 TIM1/TIM8 main features 955
31.3 TIM1/TIM8 functional description 956
31.3.1 Block diagram 956
31.3.2 TIM1/TIM8 pins and internal signals 957
31.3.3 Time-base unit 961
31.3.4 Counter modes 964
31.3.5 Repetition counter 976
31.3.6 External trigger input 977
31.3.7 Clock selection 978
31.3.8 Capture/compare channels 982
31.3.9 Input capture mode 985
31.3.10 PWM input mode 986
31.3.11 Forced output mode 987
31.3.12 Output compare mode 987
31.3.13 PWM mode 988
31.3.14 Asymmetric PWM mode 997
31.3.15 Combined PWM mode 1000
31.3.16 Combined 3-phase PWM mode 1003
31.3.17 Complementary outputs and dead-time insertion 1004
31.3.18 Clock dividers for dead-time generators and digital filters 1007
31.3.19 Using the break function 1007
31.3.20 Delayed break 1013

31.3.21 Bidirectional break inputs . . . 1015
31.3.22 Output idle state override . . . 1017
31.3.23 Clearing the tim_ocxref signal on an external event . . . 1018
31.3.24 6-step PWM generation . . . 1021
31.3.25 One-pulse mode . . . 1022
31.3.26 Retriggerable One-pulse mode . . . 1024
31.3.27 Pulse on compare mode . . . 1025
31.3.28 Encoder interface mode . . . 1027
31.3.29 Encoder with built-in debouncer . . . 1044
31.3.30 Direction bit output . . . 1046
31.3.31 Clock drift measurement . . . 1046
31.3.32 UIF bit remapping . . . 1047
31.3.33 Timer input XOR function . . . 1047
31.3.34 Interfacing with Hall sensors . . . 1049
31.3.35 Timer synchronization . . . 1050
31.3.36 ADC triggers . . . 1055
31.3.37 ADC synchronization . . . 1055
31.3.38 DMA burst mode . . . 1056
31.3.39 TIM1/TIM8 DMA requests . . . 1057
31.3.40 Debug mode . . . 1058
31.4 TIM1/TIM8 low-power modes . . . 1058
31.5 TIM1/TIM8 interrupts . . . 1058
31.6 TIM1/TIM8 registers . . . 1060
31.6.1 TIM control register 1 (TIM_CR1) . . . 1060
31.6.2 TIM control register 2 (TIM_CR2) . . . 1062
31.6.3 TIM slave mode control register (TIM_SMCR) . . . 1067
31.6.4 TIM DMA/interrupt enable register (TIM_DIER) . . . 1071
31.6.5 TIM status register (TIM_SR) . . . 1072
31.6.6 TIM event generation register (TIM_EGR) . . . 1076
31.6.7 TIM capture/compare mode register 1 (TIM_CCMR1) . . . 1077
31.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1079
31.6.9 TIM capture/compare mode register 2 (TIM_CCMR2) . . . 1083
31.6.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2) . . . 1085
31.6.11 TIM capture/compare enable register (TIM_CCER) . . . 1088
31.6.12 TIM counter (TIM_CNT) . . . 1092
31.6.13 TIM prescaler (TIM_PSC) . . . 1092
31.6.14 TIM autoreload register (TIM_ARR) . . . 1093

31.6.15 TIM repetition counter register (TIM_RCR) 1093
31.6.16 TIM capture/compare register 1 (TIM_CCR1) 1094
31.6.17 TIM capture/compare register 2 (TIM_CCR2) 1094
31.6.18 TIM capture/compare register 3 (TIM_CCR3) 1095
31.6.19 TIM capture/compare register 4 (TIM_CCR4) 1096
31.6.20 TIM break and dead-time register (TIM_BDTR) 1097
31.6.21 TIM capture/compare register 5 (TIM_CCR5) 1101
31.6.22 TIM capture/compare register 6 (TIM_CCR6) 1103
31.6.23 TIM capture/compare mode register 3 (TIM_CCMR3) 1104
31.6.24 TIM timer deadtime register 2 (TIM_DTR2) 1107
31.6.25 TIM timer encoder control register (TIM_ECR) 1108
31.6.26 TIM timer input selection register (TIM_TISEL) 1109
31.6.27 TIM alternate function option register 1 (TIM_AF1) 1110
31.6.28 TIM alternate function register 2 (TIM_AF2) 1115
31.6.29 TIM capture/compare register 7 (TIM_CCR7) 1119
31.6.30 TIM capture/compare mode register 4 (TIM_CCMR4) 1120
31.6.31 TIM multilevel protection register 1 (TIM_MPR1) 1122
31.6.32 TIM multilevel protection register 2 (TIM_MPR2) 1124
31.6.33 TIM output override register (TIM_OOR) 1125
31.6.34 TIM DMA control register (TIM_DCR) 1127
31.6.35 TIM DMA address for full transfer (TIM_DMAR) 1128
31.6.36 TIM1/TIM8 register map 1129

32 General-purpose timers(TIM2/TIM3/TIM4/TIM5) 1133

32.1 TIM2/TIM3/TIM4/TIM5 introduction 1133
32.2 TIM2/TIM3/TIM4/TIM5 main features 1133
32.3 TIM2/TIM3/TIM4/TIM5 implementation 1134
32.4 TIM2/TIM3/TIM4/TIM5 functional description 1135
32.4.1 Block diagram 1135
32.4.2 TIM2/TIM3/TIM4/TIM5 pins and internal signals 1136
32.4.3 Time-base unit 1140
32.4.4 Counter modes 1142
32.4.5 External trigger input 1153
32.4.6 Clock selection 1154
32.4.7 Capture/compare channels 1158
32.4.8 Input capture mode 1160
32.4.9 PWM input mode 1161

32.4.10 Forced output mode 1162
32.4.11 Output compare mode 1162
32.4.12 PWM mode 1164
32.4.13 Asymmetric PWM mode 1172
32.4.14 Combined PWM mode 1174
32.4.15 Clock dividers for dead-time generators and digital filters 1175
32.4.16 Clearing the tim_ocxref signal on an external event 1176
32.4.17 One-pulse mode 1179
32.4.18 Retriggerable one-pulse mode 1181
32.4.19 Pulse on compare mode 1182
32.4.20 Encoder interface mode 1184
32.4.21 Encoder with built-in debouncer 1202
32.4.22 Direction bit output 1204
32.4.23 Clock drift measurement 1204
32.4.24 UIF bit remapping 1205
32.4.25 Timer input XOR function 1205
32.4.26 Timers and external trigger synchronization 1207
32.4.27 Timer synchronization 1210
32.4.28 ADC triggers 1215
32.4.29 ADC synchronization 1217
32.4.30 DMA burst mode 1217
32.4.31 TIM2/TIM3/TIM4/TIM5 DMA requests 1218
32.4.32 Debug mode 1219
32.4.33 TIM2/TIM3/TIM4/TIM5 low-power modes 1219
32.4.34 TIM2/TIM3/TIM4/TIM5 interrupts 1220
32.5 TIM2/TIM3/TIM4/TIM5 registers 1221
32.5.1 TIM control register 1 (TIM_CR1) 1221
32.5.2 TIM control register 2 (TIM_CR2) 1223
32.5.3 TIM slave mode control register (TIM_SMCR) 1226
32.5.4 TIM DMA/interrupt enable register (TIM_DIER) 1230
32.5.5 TIM status register (TIM_SR) 1231
32.5.6 TIM event generation register (TIM_EGR) 1234
32.5.7 TIM capture/compare mode register 1 (TIM_CCMR1) 1235
32.5.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1237
32.5.9 TIM capture/compare mode register 2 (TIM_CCMR2) 1239
32.5.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2) . . . 1240
32.5.11 TIM capture/compare enable register (TIM_CCER) 1243

32.5.12 TIM counter (TIM_CNT) 1245
32.5.13 TIM prescaler (TIM_PSC) 1245
32.5.14 TIM autoreload register (TIM_ARR) 1246
32.5.15 TIM capture/compare register 1 (TIM_CCR1) 1246
32.5.16 TIM capture/compare register 2 (TIM_CCR2) 1247
32.5.17 TIM capture/compare register 3 (TIM_CCR3) 1248
32.5.18 TIM capture/compare register 4 (TIM_CCR4) 1249
32.5.19 TIM timer encoder control register (TIM_ECR) 1250
32.5.20 TIM timer input selection register (TIM_TISEL) 1251
32.5.21 TIM alternate function register 1 (TIM_AF1) 1252
32.5.22 TIM alternate function register 2 (TIM_AF2) 1253
32.5.23 TIM DMA control register (TIM_DCR) 1254
32.5.24 TIM DMA address for full transfer (TIM_DMAR) 1255
32.5.25 TIM2/TIM3/TIM4/TIM5 register map 1256

33 Basic timers (TIM6/TIM7) 1259

33.1 TIM6/TIM7 introduction 1259
33.2 TIM6/TIM7 main features 1259
33.3 TIM6/TIM7 functional description 1260
33.3.1 TIM6/TIM7 block diagram 1260
33.3.2 TIM6/TIM7 internal signals 1260
33.3.3 TIM6/TIM7 clocks 1261
33.3.4 Time-base unit 1261
33.3.5 Counting mode 1263
33.3.6 UIF bit remapping 1270
33.3.7 ADC triggers 1271
33.3.8 ADC synchronization 1271
33.3.9 TIM6/TIM7 DMA requests 1272
33.3.10 Debug mode 1272
33.3.11 TIM6/TIM7 low-power modes 1272
33.3.12 TIM6/TIM7 interrupts 1272
33.4 TIM6/TIM7 registers 1273
33.4.1 TIM control register 1 (TIM_CR1) 1273
33.4.2 TIM control register 2 (TIM_CR2) 1275
33.4.3 TIM DMA/interrupt enable register (TIM_DIER) 1275
33.4.4 TIM status register (TIM_SR) 1277
33.4.5 TIM event generation register (TIM_EGR) 1277

33.4.6 TIM counter (TIM_CNT) 1278
33.4.7 TIM prescaler (TIM_PSC) 1278
33.4.8 TIM autoreload register (TIM_ARR) 1279
33.4.9 TIM6/TIM7 register map 1280

34 General-purpose timers (TIM12) 1281

34.1 TIM12 introduction 1281
34.2 TIM12 main features 1281
34.3 TIM12 functional description 1282
34.3.1 Block diagram 1282
34.3.2 TIM12 pins and internal signals 1282
34.3.3 Time-base unit 1284
34.3.4 Counter modes 1286
34.3.5 Clock selection 1290
34.3.6 Capture/compare channels 1292
34.3.7 Input capture mode 1294
34.3.8 PWM input mode 1295
34.3.9 Forced output mode 1296
34.3.10 Output compare mode 1297
34.3.11 PWM mode 1298
34.3.12 Combined PWM mode 1303
34.3.13 Clock dividers for digital filters 1304
34.3.14 One-pulse mode 1305
34.3.15 Retriggerable one pulse mode 1306
34.3.16 UIF bit remapping 1307
34.3.17 Timer input XOR function 1307
34.3.18 TIM12 external trigger synchronization 1309
34.3.19 Slave mode – combined reset + trigger mode 1312
34.3.20 Slave mode – combined reset + gated mode 1312
34.3.21 Timer synchronization 1312
34.3.22 ADC triggers 1312
34.3.23 ADC synchronization 1313
34.3.24 Debug mode 1314
34.4 TIM12 low-power modes 1314
34.5 TIM12 interrupts 1314
34.6 TIM12 registers 1314

34.6.1 TIM control register 1 (TIM_CR1) 1315
34.6.2 TIM control register 2 (TIM_CR2) 1316
34.6.3 TIM slave mode control register (TIM_SMCR) 1318
34.6.4 TIM interrupt enable register (TIM_DIER) 1320
34.6.5 TIM status register (TIM_SR) 1321
34.6.6 TIM event generation register (TIM_EGR) 1322
34.6.7 TIM capture/compare mode register 1 (TIM_CCMR1) 1323
34.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1324
34.6.9 TIM capture/compare enable register (TIM_CCER) 1327
34.6.10 TIM counter (TIM_CNT) 1328
34.6.11 TIM prescaler (TIM_PSC) 1329
34.6.12 TIM autoreload register (TIM_ARR) 1329
34.6.13 TIM capture/compare register 1 (TIM_CCR1) 1330
34.6.14 TIM capture/compare register 2 (TIM_CCR2) 1330
34.6.15 TIM timer input selection register (TIM_TISEL) 1331
34.6.16 TIM12 register map 1332

35 General purpose timers (TIM15/TIM16/TIM17) 1334

35.1 TIM15/TIM16/TIM17 introduction 1334
35.2 TIM15 main features 1334
35.3 TIM16/TIM17 main features 1335
35.4 TIM15/TIM16/TIM17 implementation 1335
35.5 TIM15/TIM16/TIM17 functional description 1336
35.5.1 Block diagram 1336
35.5.2 TIM15/TIM16/TIM17 pins and internalsignals 1337
35.5.3 Time-base unit 1341
35.5.4 Counter modes 1343
35.5.5 Repetition counter 1355
35.5.6 Clock selection 1357
35.5.7 Capture/compare channels 1359
35.5.8 Input capture mode 1361
35.5.9 PWM input mode (only for TIM15) 1362
35.5.10 Forced output mode 1363
35.5.11 Output compare mode 1364
35.5.12 PWM mode 1365
35.5.13 Asymmetric PWM mode (TIM15 only) 1372
35.5.14 Combined PWM mode (TIM15 only) 1373

35.5.15 Complementary outputs and dead-time insertion 1374
35.5.16 Clock dividers for dead-time generators and digital filters 1377
35.5.17 Using the break function 1377
35.5.18 Delayed break 1382
35.5.19 Bidirectional break input 1384
35.5.20 Output idle state override 1386
35.5.21 Clearing the tim_ocxref signal on an external event 1386
35.5.22 6-step PWM generation 1388
35.5.23 One-pulse mode 1390
35.5.24 Retriggerable one pulse mode (TIM15 only) 1391
35.5.25 Encoder interface mode 1392
35.5.26 Encoder with built-in debouncer (TIM15 only) 1399
35.5.27 Clock drift measurement 1400
35.5.28 UIF bit remapping 1401
35.5.29 Timer input XOR function (TIM15 only) 1401
35.5.30 External trigger synchronization (TIM15 only) 1403
35.5.31 Slave mode – combined reset + trigger mode (TIM15 only) 1406
35.5.32 Slave mode – combined reset + gated mode (TIM15 only) 1406
35.5.33 Timer synchronization (TIM15 only) 1407
35.5.34 Using timer output as trigger for other timers (TIM16/TIM17 only) . . 1407
35.5.35 ADC triggers (TIM15 only) 1407
35.5.36 ADC synchronization (TIM15 only) 1408
35.5.37 DMA burst mode 1408
35.5.38 TIM15/TIM16/TIM17 DMA requests 1409
35.5.39 Debug mode 1410
35.6 TIM15/TIM16/TIM17 low-power modes 1410
35.7 TIM15/TIM16/TIM17 interrupts 1410
35.8 TIM15 registers 1412
35.8.1 TIM control register 1 (TIM_CR1) 1412
35.8.2 TIM control register 2 (TIM_CR2) 1414
35.8.3 TIM slave mode control register (TIM_SMCR) 1417
35.8.4 TIM DMA/interrupt enable register (TIM_DIER) 1420
35.8.5 TIM status register (TIM_SR) 1421
35.8.6 TIM event generation register (TIM_EGR) 1423
35.8.7 TIM capture/compare mode register 1 (TIM_CCMR1) 1424
35.8.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1426
35.8.9 TIM capture/compare enable register (TIM_CCER) 1429

35.8.10 TIM counter (TIM_CNT) 1432
35.8.11 TIM prescaler (TIM_PSC) 1432
35.8.12 TIM autoreload register (TIM_ARR) 1432
35.8.13 TIM repetition counter register (TIM_RCR) 1433
35.8.14 TIM capture/compare register 1 (TIM_CCR1) 1433
35.8.15 TIM capture/compare register 2 (TIM_CCR2) 1435
35.8.16 TIM break and dead-time register (TIM_BDTR) 1435
35.8.17 TIM timer deadtime register 2 (TIM_DTR2) 1438
35.8.18 TIM input selection register (TIM_TISEL) 1439
35.8.19 TIM alternate function register 1 (TIM_AF1) 1440
35.8.20 TIM alternate function register 2 (TIM_AF2) 1444
35.8.21 TIM multilevel protection register 1 (TIM_MPR1) 1445
35.8.22 TIM multilevel protection register 2 (TIM_MPR2) 1445
35.8.23 TIM output override register (TIM_OOR) 1446
35.8.24 TIM DMA control register (TIM_DCR) 1447
35.8.25 TIM DMA address for full transfer (TIM_DMAR) 1448
35.8.26 TIM15 register map 1449
35.9 TIM16/TIM17 registers 1452
35.9.1 TIM control register 1 (TIM_CR1) 1452
35.9.2 TIM control register 2 (TIM_CR2) 1454
35.9.3 TIM DMA/interrupt enable register (TIM_DIER) 1455
35.9.4 TIM status register (TIM_SR) 1456
35.9.5 TIM event generation register (TIM_EGR) 1457
35.9.6 TIM capture/compare mode register 1 (TIM_CCMR1) 1458
35.9.7 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1459
35.9.8 TIM capture/compare enable register (TIM_CCER) 1461
35.9.9 TIM counter (TIM_CNT) 1464
35.9.10 TIM prescaler (TIM_PSC) 1464
35.9.11 TIM auto-reautoreload register (TIM_ARR) 1465
35.9.12 TIM repetition counter register (TIM_RCR) 1465
35.9.13 TIM capture/compare register 1 (TIM_CCR1) 1466
35.9.14 TIM break and dead-time register (TIM_BDTR) 1467
35.9.15 TIM timer deadtime register 2 (TIM_DTR2) 1470
35.9.16 TIM input selection register (TIM_TISEL) 1471
35.9.17 TIM alternate function register 1 (TIM_AF1) 1471
35.9.18 TIM alternate function register 2 (TIM_AF2) 1475
35.9.19 TIM multilevel protection register 1 (TIM_MPR1) 1476

35.9.20 TIM multilevel protection register 2 (TIM_MPR2) 1477
35.9.21 TIM output override register (TIM_OOR) 1477
35.9.22 TIM DMA control register (TIM_DCR) 1478
35.9.23 TIM DMA address for full transfer (TIM_DMAR) 1479
35.9.24 TIM16/TIM17 register map 1480

36 Low-power timer (LPTIM) 1483
36.1 LPTIM introduction 1483
36.2 LPTIM main features 1483
36.3 LPTIM implementation 1483
36.4 LPTIM functional description 1485
36.4.1 LPTIM block diagram 1485
36.4.2 LPTIM pins and internal signals 1485
36.4.3 LPTIM input and trigger mapping 1487
36.4.4 LPTIM reset and clocks 1488
36.4.5 Glitch filter 1488
36.4.6 Prescaler 1489
36.4.7 Trigger multiplexer 1489
36.4.8 Operating mode 1490
36.4.9 Timeout function 1492
36.4.10 Waveform generation 1492
36.4.11 Register update 1493
36.4.12 Counter mode 1494
36.4.13 Timer enable 1495
36.4.14 Timer counter reset 1495
36.4.15 Encoder mode 1496
36.4.16 Repetition counter 1497
36.4.17 Capture/compare channels 1498
36.4.18 Input capture mode 1499
36.4.19 PWM mode 1501
36.4.20 DMA requests 1503
36.4.21 Debug mode 1504
36.5 LPTIM low-power modes 1504
36.6 LPTIM interrupts 1504
36.7 LPTIM registers 1505
36.7.1 LPTIM1 interrupt and status register [alternate] (LPTIM1_ISR) 1506

36.7.2 LPTIM1 interrupt and status register [alternate] (LPTIM1_ISR) 1508
36.7.3 LPTIM1 interrupt clear register [alternate] (LPTIM1_ICR) 1510
36.7.4 LPTIM1 interrupt clear register [alternate] (LPTIM1_ICR) 1511
36.7.5 LPTIM1 interrupt enable register [alternate] (LPTIM1_DIER) 1513
36.7.6 LPTIM1 interrupt enable register [alternate] (LPTIM1_DIER) 1514
36.7.7 LPTIM configuration register (LPTIM_CFGR) 1516
36.7.8 LPTIM control register (LPTIM_CR) 1518
36.7.9 LPTIM compare register 1 (LPTIM_CCR1) 1519
36.7.10 LPTIM autoreload register (LPTIM_ARR) 1520
36.7.11 LPTIM counter register (LPTIM_CNT) 1520
36.7.12 LPTIM configuration register 2 (LPTIM_CFGR2) 1521
36.7.13 LPTIM repetition register (LPTIM_RCR) 1522
36.7.14 LPTIM capture/compare mode register 1 (LPTIM_CCMR1) 1523
36.7.15 LPTIM compare register 2 (LPTIM_CCR2) 1525
36.7.16 LPTIM register map 1526

37 Independent watchdog (IWDG) 1528

37.1 IWDG introduction 1528
37.2 IWDG main features 1528
37.3 IWDG implementation 1528
37.4 IWDG functional description 1529
37.4.1 IWDG block diagram 1529
37.4.2 IWDG internal signals 1530
37.4.3 Software and hardware watchdog modes 1530
37.4.4 Window option 1531
37.4.5 Debug 1534
37.4.6 Register access protection 1534
37.5 IWDG low power modes 1535
37.6 IWDG interrupts 1535
37.7 IWDG registers 1537
37.7.1 IWDG key register (IWDG_KR) 1538
37.7.2 IWDG prescaler register (IWDG_PR) 1538
37.7.3 IWDG reload register (IWDG_RLR) 1539
37.7.4 IWDG status register (IWDG_SR) 1539
37.7.5 IWDG window register (IWDG_WINR) 1541
37.7.6 IWDG early wake-up interrupt register (IWDG_EWCR) 1541

37.7.7 IWDG interrupt clear register (IWDG_ICR) 1542
37.7.8 IWDG register map 1543

38 System window watchdog (WWDG) 1544
38.1 WWDG introduction 1544
38.2 WWDG main features 1544
38.3 WWDG implementation 1544
38.4 WWDG functional description 1545
38.4.1 WWDG block diagram 1545
38.4.2 WWDG internal signals 1545
38.4.3 Enabling the watchdog 1546
38.4.4 Controlling the down-counter 1546
38.4.5 How to program the watchdog timeout 1546
38.4.6 Debug mode 1547
38.5 WWDG interrupts 1548
38.6 WWDG registers 1548
38.6.1 WWDG control register (WWDG_CR) 1548
38.6.2 WWDG configuration register (WWDG_CFR) 1549
38.6.3 WWDG status register (WWDG_SR) 1550
38.6.4 WWDG register map 1550

39 Real-time clock (RTC) 1551
39.1 RTC introduction 1551
39.2 RTC main features 1551
39.3 RTC functional description 1551
39.3.1 RTC block diagram 1551
39.3.2 RTC pins and internal signals 1553
39.3.3 GPIOs controlled by the RTC and TAMP 1554
39.3.4 RTC privilege protection modes 1556
39.3.5 Clock and prescalers 1557
39.3.6 Real-time clock and calendar 1558
39.3.7 Calendar ultra-low power mode 1559
39.3.8 Programmable alarms 1559
39.3.9 Periodic auto-wake-up 1559
39.3.10 RTC initialization and configuration 1560
39.3.11 Reading the calendar 1563

39.3.12 Resetting the RTC 1564
39.3.13 RTC synchronization 1565
39.3.14 RTC reference clock detection 1565
39.3.15 RTC smooth digital calibration 1566
39.3.16 Timestamp function 1568
39.3.17 Calibration clock output 1569
39.3.18 Tamper and alarm output 1569
39.4 RTC low-power modes 1570
39.5 RTC interrupts 1570
39.6 RTC registers 1571
39.6.1 RTC time register (RTC_TR) 1571
39.6.2 RTC date register (RTC_DR) 1572
39.6.3 RTC subsecond register (RTC_SSR) 1573
39.6.4 RTC initialization control and status register (RTC_ICSR) 1573
39.6.5 RTC prescaler register (RTC_PRER) 1575
39.6.6 RTC wake-up timer register (RTC_WUTR) 1576
39.6.7 RTC control register (RTC_CR) 1576
39.6.8 RTC privilege mode control register (RTC_PRIVCFGR) 1580
39.6.9 RTC write protection register (RTC_WPR) 1582
39.6.10 RTC calibration register (RTC_CALR) 1582
39.6.11 RTC shift control register (RTC_SHIFTR) 1584
39.6.12 RTC timestamp time register (RTC_TSTR) 1585
39.6.13 RTC timestamp date register (RTC_TSDR) 1586
39.6.14 RTC timestamp subsecond register (RTC_TSSSR) 1586
39.6.15 RTC alarm A register (RTC_ALRMAR) 1587
39.6.16 RTC alarm A subsecond register (RTC_ALRMASSR) 1588
39.6.17 RTC alarm B register (RTC_ALRMBR) 1589
39.6.18 RTC alarm B subsecond register (RTC_ALRMBSSR) 1590
39.6.19 RTC status register (RTC_SR) 1591
39.6.20 RTC masked interrupt status register (RTC_MISR) 1592
39.6.21 RTC status clear register (RTC_SCR) 1593
39.6.22 RTC alarm A binary mode register (RTC_ALRABINR) 1594
39.6.23 RTC alarm B binary mode register (RTC_ALRBBINR) 1594
39.6.24 RTC register map 1595

40 Tamper and backup registers (TAMP) 1597

40.1 TAMP introduction 1597

40.2 TAMP main features . . . 1597
40.3 TAMP functional description . . . 1598
40.3.1 TAMP block diagram . . . 1598
40.3.2 TAMP pins and internal signals . . . 1599
40.3.3 GPIOs controlled by the RTC and TAMP . . . 1600
40.3.4 TAMP register write protection . . . 1600
40.3.5 Backup registers protection zones . . . 1601
40.3.6 TAMP privilege protection modes . . . 1601
40.3.7 Tamper detection . . . 1602
40.3.8 TAMP backup registers and other device secrets erase . . . 1602
40.3.9 Tamper detection configuration and initialization . . . 1603
40.4 TAMP low-power modes . . . 1606
40.5 TAMP interrupts . . . 1606
40.6 TAMP registers . . . 1606
40.6.1 TAMP control register 1 (TAMP_CR1) . . . 1606
40.6.2 TAMP control register 2 (TAMP_CR2) . . . 1608
40.6.3 TAMP control register 3 (TAMP_CR3) . . . 1610
40.6.4 TAMP filter control register (TAMP_FLTCR) . . . 1611
40.6.5 TAMP configuration register (TAMP_CFGR) . . . 1612
40.6.6 TAMP privilege configuration register (TAMP_PRIVCFGR) . . . 1613
40.6.7 TAMP interrupt enable register (TAMP_IER) . . . 1614
40.6.8 TAMP status register (TAMP_SR) . . . 1616
40.6.9 TAMP masked interrupt status register (TAMP_MISR) . . . 1617
40.6.10 TAMP status clear register (TAMP_SCR) . . . 1619
40.6.11 TAMP option register (TAMP_OR) . . . 1620
40.6.12 TAMP backup x register (TAMP_BKPxR) . . . 1621
40.6.13 TAMP register map . . . 1622

41 Inter-integrated circuit interface (I2C) . . . 1624
41.1 I2C introduction . . . 1624
41.2 I2C main features . . . 1624
41.3 I2C implementation . . . 1625
41.4 I2C functional description . . . 1625
41.4.1 I2C block diagram . . . 1626
41.4.2 I2C pins and internal signals . . . 1626
41.4.3 I2C clock requirements . . . 1627

41.4.4 I2C mode selection . . . 1627
41.4.5 I2C initialization . . . 1628
41.4.6 I2C reset . . . 1632
41.4.7 I2C data transfer . . . 1633
41.4.8 I2C target mode . . . 1635
41.4.9 I2C controller mode . . . 1644
41.4.10 I2C_TIMINGR register configuration examples . . . 1655
41.4.11 SMBus specific features . . . 1657
41.4.12 SMBus initialization . . . 1659
41.4.13 SMBus I2C_TIMEOUTR register configuration examples . . . 1661
41.4.14 SMBus target mode . . . 1662
41.4.15 SMBus controller mode . . . 1665
41.4.16 Wake-up from Stop mode on address match . . . 1668
41.4.17 Error conditions . . . 1669
41.5 I2C in low-power modes . . . 1671
41.6 I2C interrupts . . . 1671
41.7 I2C DMA requests . . . 1672
41.7.1 Transmission using DMA . . . 1672
41.7.2 Reception using DMA . . . 1672
41.8 I2C debug modes . . . 1672
41.9 I2C registers . . . 1673
41.9.1 I2C control register 1 (I2C_CR1) . . . 1673
41.9.2 I2C control register 2 (I2C_CR2) . . . 1676
41.9.3 I2C own address 1 register (I2C_OAR1) . . . 1678
41.9.4 I2C own address 2 register (I2C_OAR2) . . . 1678
41.9.5 I2C timing register (I2C_TIMINGR) . . . 1679
41.9.6 I2C timeout register (I2C_TIMEOUTR) . . . 1680
41.9.7 I2C interrupt and status register (I2C_ISR) . . . 1681
41.9.8 I2C interrupt clear register (I2C_ICR) . . . 1684
41.9.9 I2C PEC register (I2C_PECR) . . . 1685
41.9.10 I2C receive data register (I2C_RXDR) . . . 1685
41.9.11 I2C transmit data register (I2C_TXDR) . . . 1686
41.9.12 I2C register map . . . 1687

42 Improved inter-integrated circuit (I3C) . . . 1688

42.1 I3C introduction . . . 1688

42.2 I3C main features 1688
42.3 I3C implementation 1690
42.3.1 I3C instantiation 1690
42.3.2 I3C wake-up from low-power mode(s) 1690
42.3.3 I3C FIFOs 1690
42.3.4 I3C triggers 1690
42.3.5 I3C interrupt(s) 1690
42.3.6 I3C MIPI® support 1691
42.4 I3C block diagram 1692
42.5 I3C pins and internal signals 1692
42.6 I3C reset and clocks 1693
42.6.1 I3C reset 1693
42.6.2 I3C clocks and requirements 1693
42.7 I3C peripheral state and programming 1695
42.7.1 I3C peripheral state 1695
42.7.2 I3C controller state and programming sequence 1696
42.7.3 I3C target state and programming sequence 1701
42.8 I3C registers and programming 1705
42.8.1 I3C register set, as controller/target 1705
42.8.2 I3C registers and fields use versus peripheral state, as controller . . 1706
42.8.3 I3C registers and fields usage versus peripheral state, as target . . . 1709
42.9 I3C bus transfers and programming 1711
42.9.1 I3C command set (CCCs), as controller/target 1711
42.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller 1715
42.9.3 I3C broadcast ENTDAA CCC transfer, as controller 1717
42.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller 1717
42.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target 1719
42.9.6 I3C broadcast ENTDAA CCC transfer, as target 1721
42.9.7 I3C broadcast DEFTGTS CCC transfer, as target 1722
42.9.8 I3C broadcast DEFGRPA CCC transfer, as target 1723
42.9.9 I3C direct GETSTATUS CCC response, as target 1724
42.9.10 I3C private read/write transfer, as controller 1725
42.9.11 I3C private read/write transfer, as target 1726
42.9.12 Legacy I2C read/write transfer, as controller 1727
42.9.13 I3C IBI transfer, as controller/target 1728

42.9.14 I3C hot-join request transfer, as controller/target 1729
42.9.15 I3C controller-role request transfer, as controller/target 1730
42.10 I3C FIFOs management, as controller 1731
42.10.1 C-FIFO management, as controller 1731
42.10.2 TX-FIFO management, as controller 1732
42.10.3 RX-FIFO management, as controller 1735
42.10.4 S-FIFO management, as controller 1737
42.11 I3C FIFOs management, as target 1739
42.11.1 RX-FIFO management, as target 1739
42.11.2 TX-FIFO management, as target 1740
42.12 I3C error management 1743
42.12.1 Controller error management 1743
42.12.2 Target error management 1745
42.13 I3C wake-up from low-power mode(s) 1746
42.13.1 Wake-up from Stop 1746
42.14 I3C in low-power modes 1749
42.15 I3C interrupts 1750
42.16 I3C registers 1750
42.16.1 I3C message control register (I3C_CR) 1750
42.16.2 I3C message control register [alternate] (I3C_CR) 1752
42.16.3 I3C configuration register (I3C_CFGR) 1754
42.16.4 I3C receive data byte register (I3C_RDR) 1759
42.16.5 I3C receive data word register (I3C_RDWR) 1760
42.16.6 I3C transmit data byte register (I3C_TDR) 1761
42.16.7 I3C transmit data word register (I3C_TDWR) 1762
42.16.8 I3C IBI payload data register (I3C_IBIDR) 1763
42.16.9 I3C target transmit configuration register (I3C_TGTTDR) 1764
42.16.10 I3C status register (I3C_SR) 1765
42.16.11 I3C status error register (I3C_SER) 1766
42.16.12 I3C received message register (I3C_RMR) 1768
42.16.13 I3C event register (I3C_EVR) 1769
42.16.14 I3C interrupt enable register (I3C_IER) 1773
42.16.15 I3C clear event register (I3C_CEVR) 1775
42.16.16 I3C masked interrupt status register (I3C_MISR) 1777
42.16.17 I3C own device characteristics register (I3C_DEVR0) 1778
42.16.18 I3C device x characteristics register (I3C_DEVRx) 1780

42.16.19 I3C maximum read length register (I3C_MAXRLR) 1782
42.16.20 I3C maximum write length register (I3C_MAXWLR) 1783
42.16.21 I3C timing register 0 (I3C_TIMINGR0) 1784
42.16.22 I3C timing register 1 (I3C_TIMINGR1) 1785
42.16.23 I3C timing register 2 (I3C_TIMINGR2) 1787
42.16.24 I3C bus characteristics register (I3C_BCR) 1788
42.16.25 I3C device characteristics register (I3C_DCR) 1789
42.16.26 I3C get capability register (I3C_GETCAPR) 1790
42.16.27 I3C controller-role capability register (I3C_CRCAPR) 1791
42.16.28 I3C get max data speed register (I3C_GETMXDSR) 1792
42.16.29 I3C extended provisioned ID register (I3C_EPIDR) 1794
42.16.30 I3C register map 1795

43 Universal synchronous/asynchronous receiver transmitter (USART/UART) 1798

43.1 USART introduction 1798
43.2 USART main features 1798
43.3 USART extended features 1799
43.4 USART implementation 1799
43.5 USART functional description 1801
43.5.1 USART block diagram 1801
43.5.2 USART pins and internal signals 1801
43.5.3 USART clocks 1803
43.5.4 USART character description 1803
43.5.5 USART FIFOs and thresholds 1806
43.5.6 USART transmitter 1806
43.5.7 USART receiver 1809
43.5.8 USART baud rate generation 1816
43.5.9 Tolerance of the USART receiver to clock deviation 1818
43.5.10 USART auto baud rate detection 1819
43.5.11 USART multiprocessor communication 1821
43.5.12 USART Modbus communication 1823
43.5.13 USART parity control 1824
43.5.14 USART LIN (local interconnection network) mode 1825
43.5.15 USART synchronous mode 1827
43.5.16 USART single-wire half-duplex communication 1831
43.5.17 USART receiver timeout 1831

43.5.18 USART smartcard mode 1832
43.5.19 USART IrDA SIR ENDEC block 1836
43.5.20 Continuous communication using USART and DMA 1839
43.5.21 RS232 hardware flow control and RS485 driver enable 1841
43.5.22 USART low-power management 1844
43.6 USART in low-power modes 1847
43.7 USART interrupts 1847
43.8 USART registers 1850
43.8.1 USART control register 1 (USART_CR1) 1850
43.8.2 USART control register 1 [alternate] (USART_CR1) 1854
43.8.3 USART control register 2 (USART_CR2) 1857
43.8.4 USART control register 3 (USART_CR3) 1861
43.8.5 USART control register 3 [alternate] (USART_CR3) 1865
43.8.6 USART baud rate register (USART_BRR) 1868
43.8.7 USART guard time and prescaler register (USART_GTPR) 1869
43.8.8 USART receiver timeout register (USART_RTOR) 1870
43.8.9 USART request register (USART_RQR) 1871
43.8.10 USART interrupt and status register (USART_ISR) 1872
43.8.11 USART interrupt and status register [alternate] (USART_ISR) 1878
43.8.12 USART interrupt flag clear register (USART_ICR) 1883
43.8.13 USART receive data register (USART_RDR) 1884
43.8.14 USART transmit data register (USART_TDR) 1885
43.8.15 USART prescaler register (USART_PRESC) 1885
43.8.16 USART register map 1886

44 Low-power universal asynchronous receiver transmitter (LPUART) 1888

44.1 LPUART introduction 1888
44.2 LPUART main features 1888
44.3 LPUART implementation 1889
44.4 LPUART functional description 1891
44.4.1 LPUART block diagram 1891
44.4.2 LPUART pins and internal signals 1892
44.4.3 LPUART clocks 1893
44.4.4 LPUART character description 1893
44.4.5 LPUART FIFOs and thresholds 1895

44.4.6 LPUART transmitter . . . 1895
44.4.7 LPUART receiver . . . 1899
44.4.8 LPUART baud rate generation . . . 1903
44.4.9 Tolerance of the LPUART receiver to clock deviation . . . 1904
44.4.10 LPUART multiprocessor communication . . . 1905
44.4.11 LPUART parity control . . . 1907
44.4.12 LPUART single-wire half-duplex communication . . . 1908
44.4.13 Continuous communication using DMA and LPUART . . . 1908
44.4.14 RS232 hardware flow control and RS485 driver enable . . . 1911
44.4.15 LPUART low-power management . . . 1913
44.5 LPUART in low-power modes . . . 1916
44.6 LPUART interrupts . . . 1917
44.7 LPUART registers . . . 1918
44.7.1 LPUART control register 1 (LPUART_CR1) . . . 1918
44.7.2 LPUART control register 1 [alternate] (LPUART_CR1) . . . 1921
44.7.3 LPUART control register 2 (LPUART_CR2) . . . 1924
44.7.4 LPUART control register 3 (LPUART_CR3) . . . 1926
44.7.5 LPUART control register 3 [alternate] (LPUART_CR3) . . . 1929
44.7.6 LPUART baud rate register (LPUART_BRR) . . . 1931
44.7.7 LPUART request register (LPUART_RQR) . . . 1931
44.7.8 LPUART interrupt and status register (LPUART_ISR) . . . 1932
44.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 1937
44.7.10 LPUART interrupt flag clear register (LPUART_ICR) . . . 1940
44.7.11 LPUART receive data register (LPUART_RDR) . . . 1941
44.7.12 LPUART transmit data register (LPUART_TDR) . . . 1941
44.7.13 LPUART prescaler register (LPUART_PRESC) . . . 1942
44.7.14 LPUART register map . . . 1943

45 Serial peripheral interface (SPI) . . . 1945
45.1 SPI introduction . . . 1945
45.2 SPI main features . . . 1945
45.3 SPI implementation . . . 1946
45.4 SPI functional description . . . 1947
45.4.1 SPI block diagram . . . 1947
45.4.2 SPI pins and internal signals . . . 1948
45.4.3 SPI communication general aspects . . . 1949

45.4.4 Communications between one master and one slave 1949
45.4.5 Standard multislave communication 1952
45.4.6 Multimaster communication 1955
45.4.7 Slave select (NSS pin) management 1956
45.4.8 Ready pin (RDY) management 1960
45.4.9 Communication formats 1960
45.4.10 Configuring the SPI 1962
45.4.11 Enabling the SPI 1963
45.4.12 SPI data transmission and reception procedures 1964
45.4.13 Disabling the SPI 1968
45.4.14 Communication using DMA (direct memory addressing) 1969
45.5 SPI specific modes and control 1971
45.5.1 TI mode 1971
45.5.2 SPI error flags 1971
45.5.3 CRC computation 1975
45.6 SPI in low-power modes 1976
45.7 SPI interrupts 1976
45.8 I2S main features 1978
45.9 I2S functional description 1978
45.9.1 I2S general description 1978
45.9.2 Pin sharing with SPI function 1979
45.9.3 Bitfields usable in I2S/PCM mode 1979
45.9.4 Slave and master modes 1980
45.9.5 Supported audio protocols 1980
45.9.6 Additional serial interface flexibility 1986
45.9.7 Startup sequence 1988
45.9.8 Stop sequence 1990
45.9.9 Clock generator 1991
45.9.10 Internal FIFOs 1993
45.9.11 FIFO status flags 1994
45.9.12 Handling of underrun situation 1994
45.9.13 Handling of overrun situation 1995
45.9.14 Frame error detection 1996
45.9.15 DMA interface 1998
45.9.16 Programing examples 1998
45.10 I2S interrupts 2000

45.11 SPI/I2S registers 2001
45.11.1 SPI/I2S control register 1 (SPI_CR1) 2001
45.11.2 SPI/I2S control register 2 (SPI_CR2) 2003
45.11.3 SPI/I2S configuration register 1 (SPI_CFG1) 2003
45.11.4 SPI/I2S configuration register 2 (SPI_CFG2) 2007
45.11.5 SPI/I2S interrupt enable register (SPI_IER) 2009
45.11.6 SPI/I2S status register (SPI_SR) 2010
45.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR) 2013
45.11.8 SPI/I2S transmit data register (SPI_TXDR) 2014
45.11.9 SPI/I2S receive data register (SPI_RXDR) 2014
45.11.10 SPI/I2S polynomial register (SPI_CRCPOLY) 2015
45.11.11 SPI/I2S transmitter CRC register (SPI_TXCRC) 2015
45.11.12 SPI/I2S receiver CRC register (SPI_RXCRC) 2016
45.11.13 SPI/I2S underrun data register (SPI_UDRDR) 2017
45.11.14 SPI/I2S configuration register (SPI_I2SCFGR) 2017
45.11.15 SPI/I2S register map 2019

46 FD controller area network (FDCAN) 2021
46.1 FDCAN introduction 2021
46.2 FDCAN main features 2023
46.3 FDCAN implementation 2023
46.4 FDCAN functional description 2024

46.4.2 FDCAN pins and internal signals 2025
46.4.3 Bit timing 2026
46.4.4 Operating modes 2027
46.4.5 Error management 2036
46.4.6 Message RAM 2037
46.4.7 FIFO acknowledge handling 2046
46.4.8 FDCAN Rx FIFO element 2046
46.4.9 FDCAN Tx buffer element 2048
46.4.10 FDCAN Tx event FIFO element 2050
46.4.11 FDCAN standard message ID filter element 2051
46.4.12 FDCAN extended message ID filter element 2052
46.5 FDCAN registers 2054
46.5.1 FDCAN core release register (FDCAN_CREL) 2054

46.5.2 FDCAN endian register (FDCAN_ENDN) 2054
46.5.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP) 2054
46.5.4 FDCAN test register (FDCAN_TEST) 2055
46.5.5 FDCAN RAM watchdog register (FDCAN_RWD) 2056
46.5.6 FDCAN CC control register (FDCAN_CCCR) 2057
46.5.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) . 2058
46.5.8 FDCAN timestamp counter configuration register (FDCAN_TSCC) . 2060
46.5.9 FDCAN timestamp counter value register (FDCAN_TSCV) 2060
46.5.10 FDCAN timeout counter configuration register (FDCAN_TOCC) . . . 2061
46.5.11 FDCAN timeout counter value register (FDCAN_TOCV) 2062
46.5.12 FDCAN error counter register (FDCAN_ECR) 2062
46.5.13 FDCAN protocol status register (FDCAN_PSR) 2063
46.5.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) . . 2065
46.5.15 FDCAN interrupt register (FDCAN_IR) 2065
46.5.16 FDCAN interrupt enable register (FDCAN_IE) 2068
46.5.17 FDCAN interrupt line select register (FDCAN_ILS) 2070
46.5.18 FDCAN interrupt line enable register (FDCAN_ILE) 2071
46.5.19 FDCAN global filter configuration register (FDCAN_RXGFC) 2071
46.5.20 FDCAN extended ID and mask register (FDCAN_XIDAM) 2073
46.5.21 FDCAN high-priority message status register (FDCAN_HPMS) 2073
46.5.22 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) 2074
46.5.23 CAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) 2075
46.5.24 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) 2075
46.5.25 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) 2076
46.5.26 FDCAN Tx buffer configuration register (FDCAN_TXBC) 2076
46.5.27 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) 2077
46.5.28 FDCAN Tx buffer request pending register (FDCAN_TXBRP) 2077
46.5.29 FDCAN Tx buffer add request register (FDCAN_TXBAR) 2078
46.5.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) . . 2079
46.5.31 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) 2079
46.5.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) . . 2080
46.5.33 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) 2080
46.5.34 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) 2081
46.5.35 FDCAN Tx event FIFO status register (FDCAN_TXEFS) 2081
46.5.36 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) . . . 2082
46.5.37 FDCAN CFG clock divider register (FDCAN_CKDIV) 2082

1 Documentation conventions

1.1 General information

The STM32C5 devices have an Arm® Cortex®-M33 core.

Note: Arm and Cortex are registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere.

The Arm word and logo are trademarks of Arm Limited (or its subsidiaries) in the US and/or elsewhere. All rights reserved.

1.2 List of abbreviations for registers

The following abbreviations[a] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

a. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

2 Memory and bus architecture

2.1 System architecture

The STM32C5 architecture relies on an Arm Cortex-M33 core, optimized for execution thanks to an instruction cache (ICACHE) that has a direct access to the embedded flash memory (FLASH).

This architecture also features a 32-bit multilayer AHB bus matrix with the interconnections details in *Table 1* and *Table 2*.

Table 1. Implementation of masters on STM32C5 series

Master	Comment	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
Cortex-M33 Fast C-bus	Connecting Cortex-M33 (with FPU) to the internal SRAMs and flash memory through ICACHE	X	X	X
Cortex-M33 Slow C-bus	Connecting Cortex-M33 (with FPU) to the external memories through ICACHE	-	-	X
Cortex-M33 S-bus	Connecting the Cortex-M33 (with FPU) to internal SRAMs without latency	2 masters		
LPDMA1		1 master		
LPDMA2		1 master		
Ethernet MAC		-	-	X(1)

1. Not available on STM32C591xx devices.

Table 2. Implementation of slaves on STM32C5 series

Slave	Comment	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
Flash memory	-	X	X	X
SRAM1	-	X	X	X
SRAM2	-	X	X	X
AHB1	Peripherals including AHB and APB bridge, and APB peripherals (connected to APB1 and APB2)	X	X	X
AHB2	Peripherals	X	X	X
XSPI1	-	-	-	X

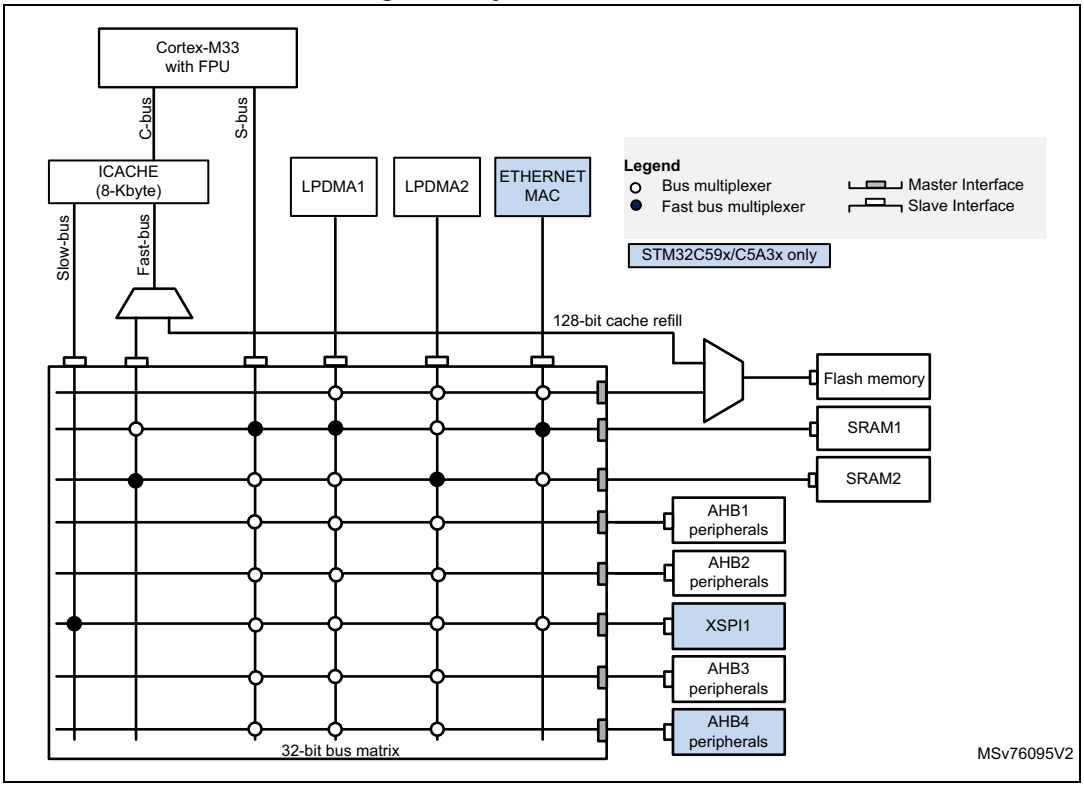
Table 2. Implementation of slaves on STM32C5 series (continued)

Slave	Comment	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
AHB3	Including AHB to APB bridge, and APB peripherals (connected to APB3)	X	X	X
AHB4	Peripherals	-	-	X

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation, even when several high-speed peripherals work simultaneously.

This architecture is shown in *Figure 1*.

Figure 1. System architecture



2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the FLASH and to the bus matrix through the ICACHE. This bus is used for instruction fetch and data access to the internal memories mapped in code region. This bus targets the FLASH and the internal SRAMs (SRAM1/2).

SRAM1 and SRAM2 are accessible on this bus with a continuous mapping.

2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the bus matrix through the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. This bus targets the external memories (XSPI).

2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1/2), the AHB1 peripherals (including APB1/2), AHB2, and AHB3 peripherals.

SRAM1 and SRAM2 are accessible on this bus with a continuous mapping.

2.1.4 LPDMA1 and LPDMA2 buses

These buses connect the two AHB master interfaces of LPDMA1/2 to the bus matrix. These buses target the FLASH, the internal SRAMs (SRAM1/2), the AHB1 peripherals (including APB1/2), AHB2, AHB3, and AHB4 peripherals.

2.1.5 Bus matrix

The bus matrix manages the access arbitration between masters. The arbitration uses a Round-Robin algorithm. This bus matrix features a fast bus multiplexer used to connect each master to a given slave without latency (see *Figure 1*). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.6 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between AHB and APB buses, allowing flexible selection of the peripheral frequency.

Refer to *Section 2.2.2: Memory map and register boundary addresses* for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for internal SRAMs and FLASH). Before using a peripheral, its clock must be enabled in RCC_AHBxENR and RCC_APBxENR registers.

Note: When an 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.2 Memory organization

2.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.2.2 Memory map and register boundary addresses

Figure 2. Memory map for STM32C53x/542

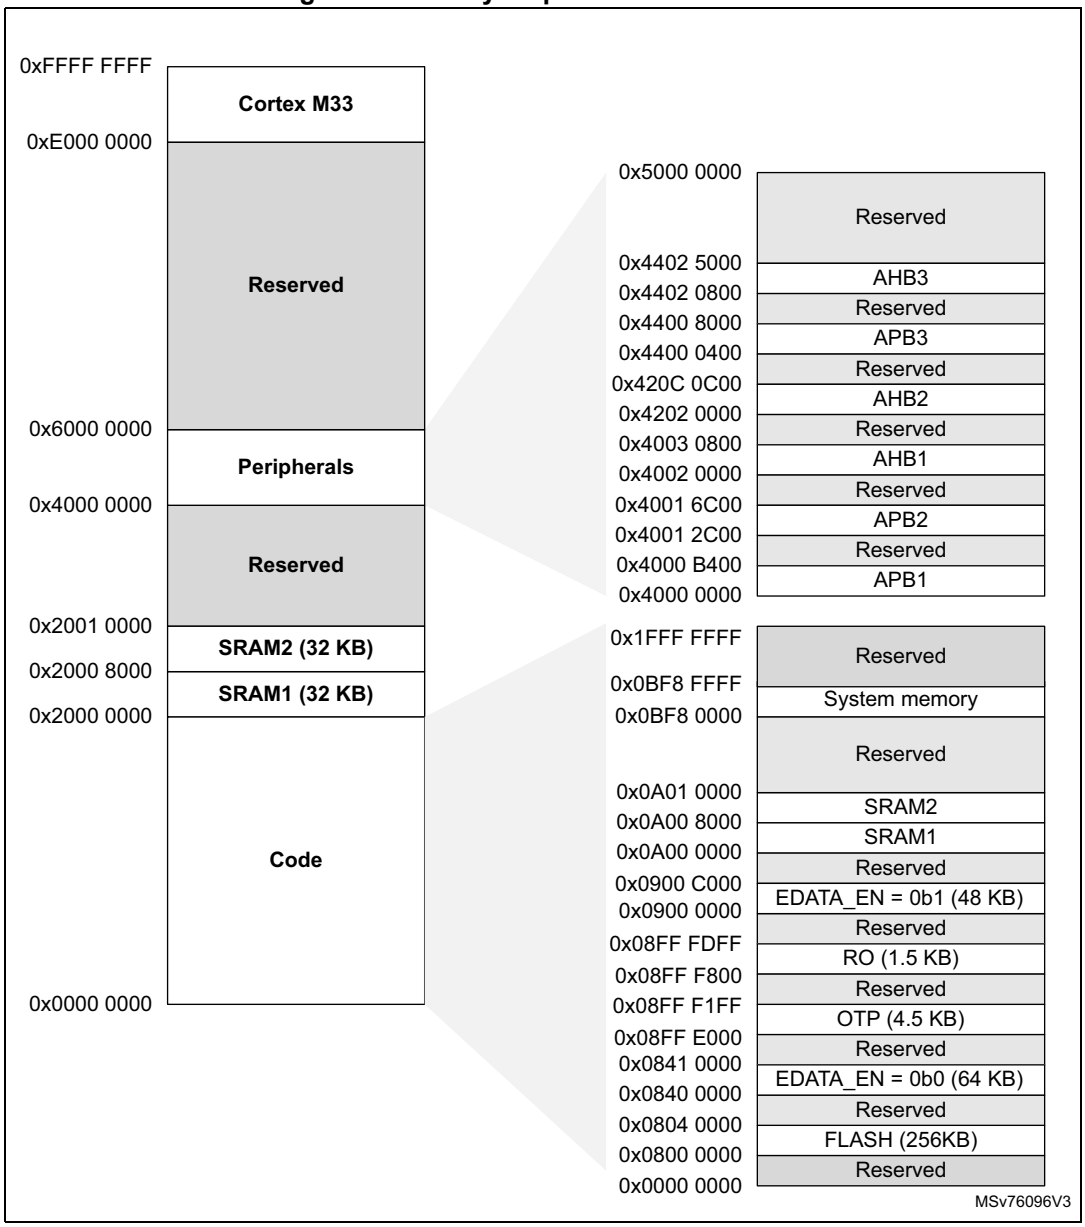


Figure 3. Memory map for STM32C55x/562

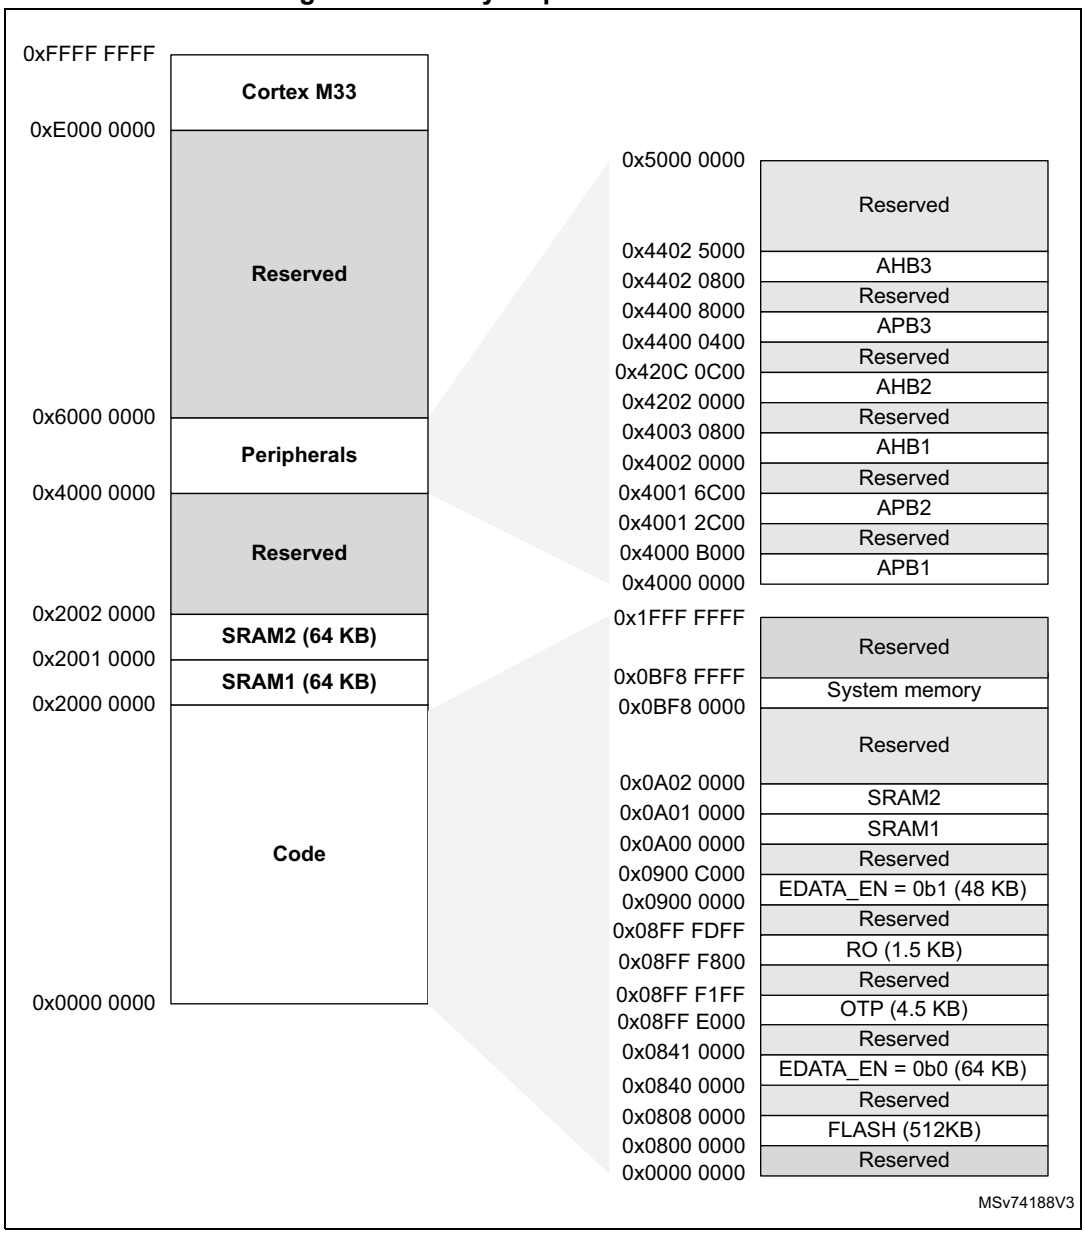

Figure 4. Memory map for STM32C59x/5A3

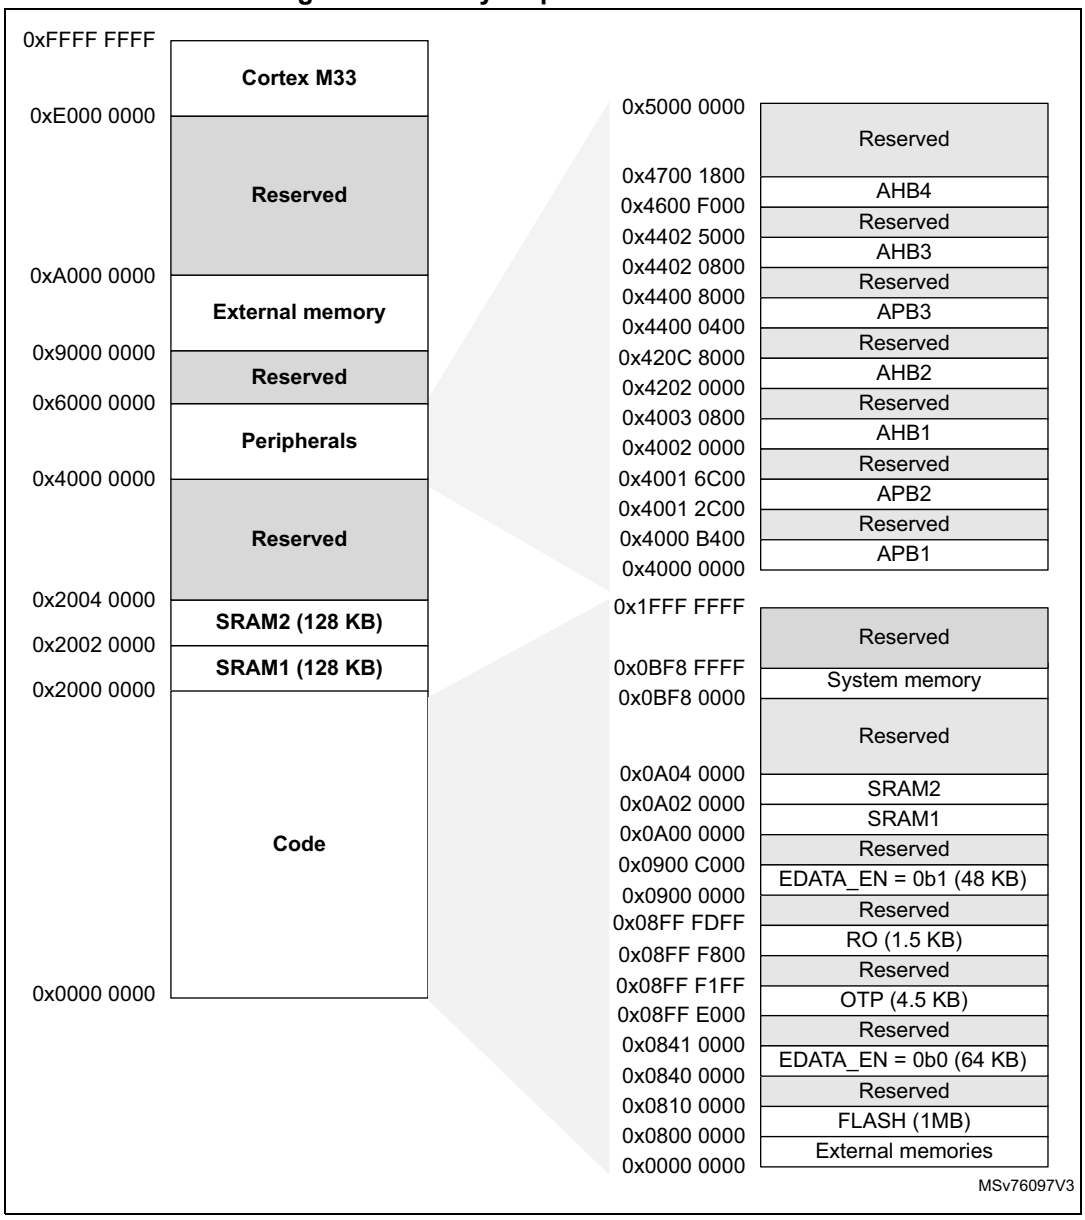

All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. The following table gives the boundary addresses of the peripherals available in the devices.

Table 3. Memory map and peripheral register boundary addresses

Bus	Boundary address	Peripheral	Peripheral register map	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
AHB4	0x4700 1800 - 0x47FF FFFF	Reserved	-	-	-	-
	0x4700 1400 - 0x4700 17FF	XSPI1	XSPI register map	-	-	X
	0x4600 F400 - 0x4700 13FF	Reserved	-	-	-	-

	0x4000 0C00 - 0x4000 0FFF	TIM5	TIM5 register map	-	X	X
	0x4000 0800 - 0x4000 0BFF	TIM4	TIM4 register map	-	-	X
	0x4000 0400 - 0x4000 07FF	TIM3	TIM3 register map	-	-	X
	0x4000 0000 - 0x4000 03FF	TIM2	TIM2 register map	X	X	X

1. For STM32C55x/562 devices, FDCAN RAM boundary end address is 0x4000 AFFF.

2. The COMP2 peripheral is only available in STM32C53x/542.

2.2.3 Embedded SRAM

Table 4. SRAM sizes

SRAM	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
SRAM1	32 Kbytes	64 Kbytes	128 Kbytes
SRAM2	32 Kbytes with ECC	64 Kbytes with ECC	128 Kbytes with ECC

These SRAMs can be accessed as bytes, half-words (16 bits), or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1 and SRAM2 through the system bus or through the C-bus depending on the selected address. SRAM features are detailed in *Section 5.3.1: Internal SRAMs features*.

2.2.4 Flash memory overview

The flash memory is composed of two distinct physical areas:

- The main flash memory block that contains the application program and user data.
- The information block that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area

The flash memory interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the flash memory operations (program/erase) controlled through the flash memory registers plus security access control features. Refer to *Section 6: Embedded flash memory (FLASH)* for more details.

3 System security

The STM32C5 is designed with a comprehensive set of security features.

These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the reuse, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on the STM32C5 devices.

3.1 Key security features

- Resource isolation using privilege mode of Cortex-M33
- Temporal isolation: boot levels are isolated thanks to the HDPL (hide protect level) monotonic counter
- General purpose cryptographic acceleration
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes
  - Secure AES 256-bit security coprocessor, supporting ECB, CBC, CTR, GCM, and CCM chaining modes with side-channel counter-measures and mitigations on STM32C59x and STM32C5Ax.
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash (SHA2-224, SHA2-256) for STM32C53x/C54x/C55x/C56x, and SHA2-384, SHA2-512 in addition for STM32C59x/C5Ax.
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets on STM32C59x/C5Ax.
  - True random number generator (RNG), NIST SP800-90B pre-certified
  - Coupling and chaining bridge (CCB) for special coupling and chaining operations (involving PKA, SAES, and RNG peripherals) to protect private keys used in PKA-protected operations on STM32C59x/C5Ax.
- Secure storage, featuring:
  - Nonvolatile on-chip secure storage, protected with HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - On-chip enhance storage technology, using hardware secret nonvolatile derived hardware unique keys (DHUK), and application-defined volatile boot hardware key (BHK), both loadable by hardware to the DPA-resistant SAES engine
- Device 96-bit unique ID
- Readout protection-based life cycle scheme
  - Debug protection, depending on the RDP level
  - Password-based RDP level regressions
- Tamper and protection against frequency attacks

3.2 Resource isolation

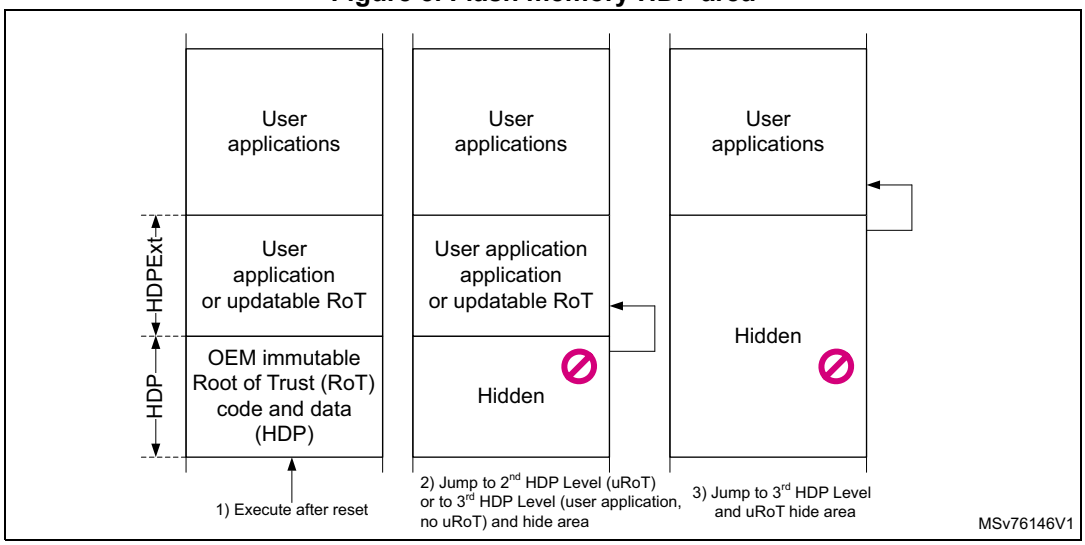
3.2.1 Temporal isolation using secure hide protection (HDP)

The embedded flash memory allows an HDP (high-density protection) area to be defined for each watermarked-secure area of each bank, with a granularity of 8-Kbyte sectors.

The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset.

The following figure shows the hidden protection principle.

Figure 5. Flash memory HDP area



The activation of the HDP area in the user flash memory is related to HDPL1. It means that as soon as HDPL becomes equal or greater than 2, data read, write, and instruction fetch on the area defined by HDPx_PSTRT and HDPx_PEND in FLASH_HDPxR_PRG option bytes are denied until the next device reset.

The END of the HDPx areas can be extended dynamically by the application using the FLASH_HDPEXTR register. This extension prevents access to protected sectors under HDPL3.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.2.2 Resource isolation using Cortex privileged mode

The hardware and software resources of STM32C5 devices can be partitioned to restrict access to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, a critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions, each aligned to a multiple of 32 bytes. Each memory region can be programmed to generate faults when accessed inappropriately by unprivileged software.

3.3 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

3.3.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M33 operating mode (privileged, unprivileged)
- Data/instruction fetch

The memory map and the programming of the MPU split memory into up to eight regions.

3.3.2 Embedded flash memory write protection

The write protection (WRP) prevents illegal or unwanted write/erase to selected sectors of the embedded flash memory user area (system area is permanently write protected).

Write-protected sectors can be modified through option byte changes only when RDP_LEVEL = L0.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area). For more information, see Section 6.5.5: Write protection.

3.3.3 Tamper detection and response

Principle

The devices include protection of critical security assets against attacks, with the following features:

- Erase of device secrets upon tamper detection
- Improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - Out-of-range clocking (LSE) detection
  - Security watchdog IWDG clocked by the internal oscillator LSI
  - Possible selection of internal oscillator HSI as system clock

See *Section 40: Tamper and backup registers (TAMP)*, for more details.

Tamper detection sources

The devices support three input tampers that can be mapped on five different pins.

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparisons in four consecutive comparison samples).

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in the table below.

Table 5. Internal tampers in TAMP

Tamper input	Tamper source
itamp3	LSE monitoring(1)
itamp4	HSE monitoring
itamp5	RTC calendar overflow (rtc_calovf)
itamp6	JTAG/SWD access
itamp9	Fault generation for cryptographic peripherals (SAES, PKA, AES, RNG)(2)
itamp11	IWDG timeout and potential tamper (IWDG reset when at least one enabled tamper flag is set)

1. LSE missing or over frequency detection (> 2 MHz), glitch filter (> 2 MHz).
2. Only RNG fault on STM32C53x/C54x/C55x/C56x.

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxPOM bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - Symmetric keys stored in backup registers (x32), and in HASH
  - Other secrets stored in SRAM2 and CPU instruction cache memory

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2, or by performing a RDP_LEVEL regression as defined in Section 3.7.1.

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxPOM bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such a situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:

- Backup registers, SRAM2: read-as-zero, write-ignored
- AES, SAES, CCB, HASH, PKA peripherals : automatically reset by RCC
- The CPU instruction cache (ICACHE) is erased

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application clears the flags to release the blocking of secrets (false tamper).

Note: If the tamper software fails to react to such a tamper flag, the tamper input associated to IWDG reset must trigger automatically the erase of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection is summarized in the following table.

Table 6. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.

3.4 Secure storage

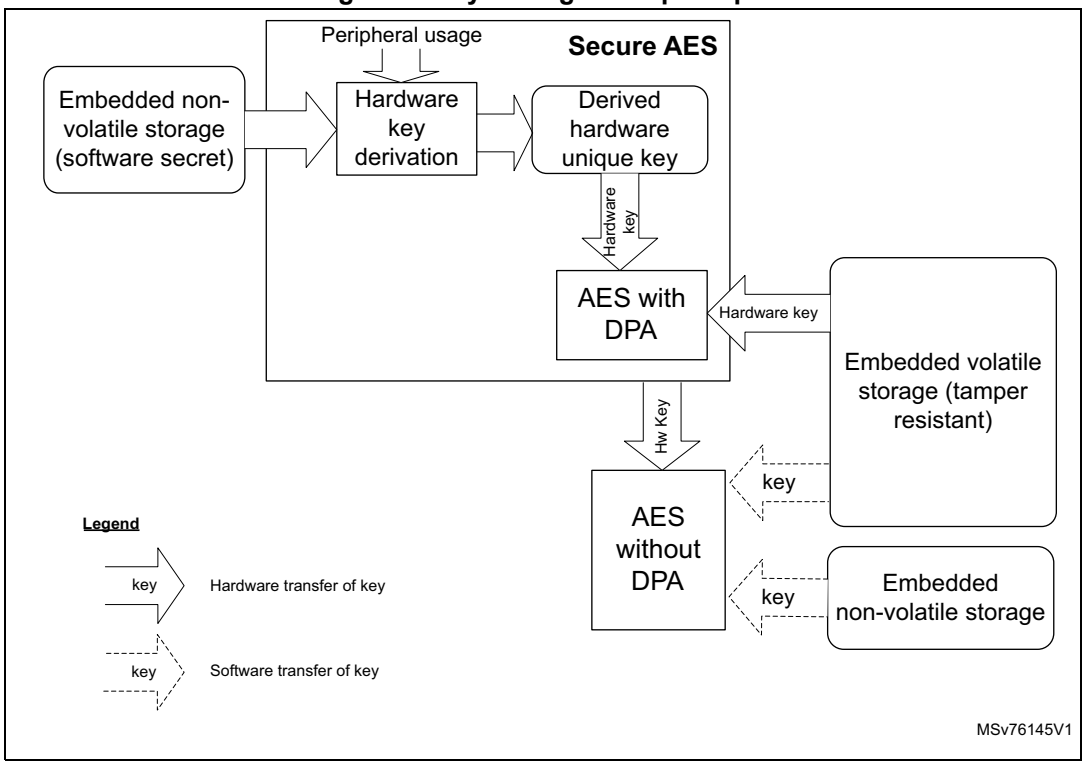
This section applies only to STM32C59xx and STM32C5Axx devices.

A critical feature of security systems is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image or handling critical user data.

Figure 6 shows how the key management service application can use the AES engine, for example, to compute external image decryption keys. Nonvolatile keys are stored in the flash memory in a dedicated area with access control (*Section 3.2.1: Temporal isolation using secure hide protection (HDP)*), while volatile key storage consists of tamper-protected SRAM.

Figure 6 also shows keys that are manipulated by software, or keys that are managed only by hardware (such as DHUK). More information about those hardware keys can be found in *Section 3.4.1: Hardware secret key management*.

Figure 6. Key management principle



3.4.1 Hardware secret key management

As shown in the previous figure, the devices provide better protection for application keys by using hardware secret keys. This AES key can be made usable by the application, without exposing it in clear text (unencrypted). Such keys also become immediately unusable in case of tampering.

STM32C59xx/C5Axx devices embed a unique source of hardware secret key:

- **DHUK**: derived keys based on a 256-bit nonvolatile device-unique secret in flash memory. The flash memory provides a value provisioned during product manufacturing (called RHUK). The generation of DHUK key considers the NEXT-HDPL (temporal isolation counter) and key use state (KMOD).
- BHK: 256-bit application key stored in tamper-resistant volatile storage in TAMP. This key is written at boot time, then read/write locked to application until next reset.
- XORK: result of an XOR of BHK and DHUK

These keys can be used in the following modes:

- As a normal key, loaded into write-only key registers (software key mode).
- As an encryption/decryption key for another key, used in the DPA-resistant SAES (wrapped key mode).
- As an encryption or decryption key for another key, used in a faster AES engine (shared key mode)

3.5 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 50.1: Unique device ID register (96 bits)*).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (*Section 3.4.1: Hardware secret key management*).

3.6 Crypto engines

Refer to the product datasheet to identify the cryptographic engines embedded in the selected devices.

The devices implement advanced cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the United States, BSI for Germany, and ANSSI for France. These algorithms support privacy, authentication, integrity, entropy, and identity attestation.

The cryptographic engines embedded in STM32 reduce the weaknesses in the implementation of critical cryptographic functions. They prevent the use of weak cryptographic algorithms and key sizes. They enable lower processing times, and lower power consumption during cryptographic operations. These engines offload computations from Cortex-M33, particularly true for asymmetric cryptography.

For product certification purposes, ST can provide certified device information detailing how these security functions are implemented and validated.

For more information about cryptographic engine processing times, refer to their respective sections in the reference manual.

3.6.1 Cryptographic engines features

Figure 7 lists the accelerated cryptographic operations available in the devices. Two AES accelerators are supported.

Note: Additional operations can be added by using the firmware.

The PKA can accelerate asymmetric cryptographic operations (such as key pair generation, ECC scalar multiplication, point on curve check). See *Section 30: Public key accelerator (PKA)* for more details.

Table 7. Accelerated cryptographic operations

Operations	Algorithm	Specification	Key lengths (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware(2) modes running in parallel

Table 7. Accelerated cryptographic operations (continued)

Operations	Algorithm	Specification	Key lengths (in bit)	Modes
Encryption, decryption	AES(3)	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D	128, 256	GCM, CCM
Cipher-based message authentication code		NIST SP800-38D	128, 256	GMAC
Checksum	SHA-1	FIPS PUB 180-4	N/A	Digest 160-bit
Cryptographic hash	SHA-2			SHA-224, SHA-256, SHA-384, SHA-51
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (> 64 bytes)	-
Encryption/decryption key-pair generation	RSA(4)	IETF RFC 8017	Up to 4160	RSAES-OAEP
		NIST SP800-56B		
Signature with hashing	RSA(4)	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
Signature verification	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to *Table 269: Family of supported curves for ECC operations*t for details.
Key agreement	ECDH	ANSI X9.42		

1. Certifiable by using STMicroelectronics-reviewed documents.
2. Random number distribution to SAES and PKA through a dedicated hardware bus.
3. ECB and CBC chaining modes are protected against side-channel and timing attacks in SAES (see *Section 3.6.2: Secure AES co-processor (SAES)*.
4. Private key cryptography is protected against side-channel and timing attacks.

3.6.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements countermeasures and mitigations against power and electromagnetic side-channel attacks.

Clocked by the system clock, the SAES delivers excellent performance for a DPA-resistant hardware accelerator. The SAES engine supports 128-bit or 256-bit keys in electronic code book (ECB), cipher block chaining (CBC), (CTR), (GCM), (CCM), (GMAC) modes.

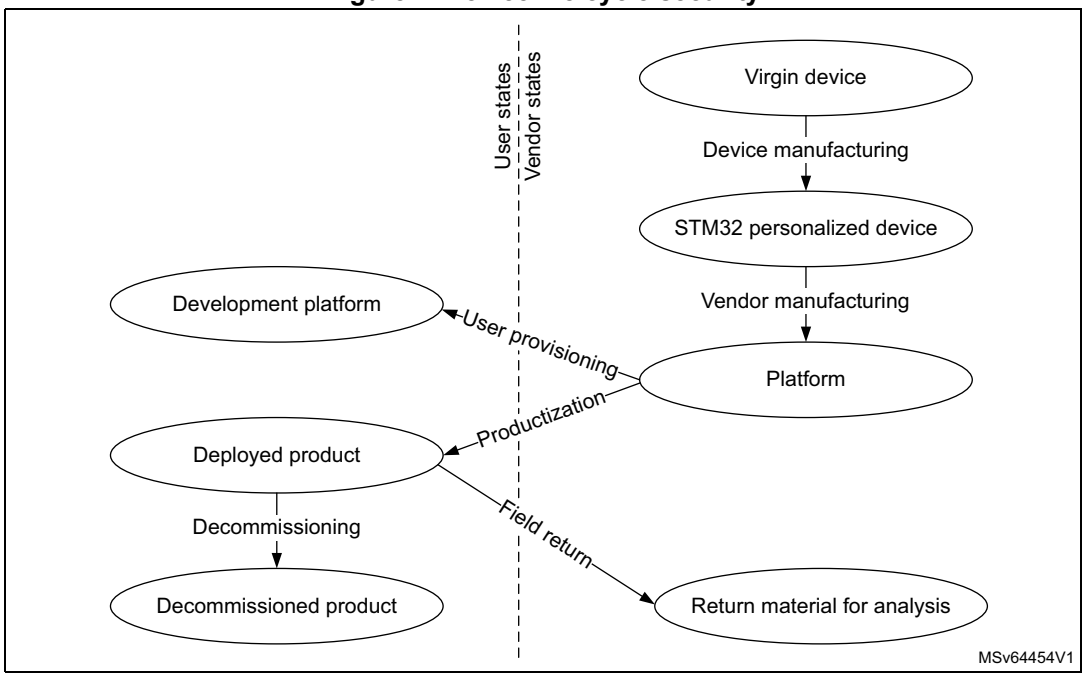
As shown in *Section 3.4: Secure storage*, the SAES can be used for highly secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to *Section 27: AES hardware accelerator (AES)*.

3.7 Product life cycle

A typical IoT device life cycle is summarized in the figure below. For each step, the devices propose secure life cycle management mechanisms embedded in the hardware.

Figure 7. Device life cycle security



More details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in the table below.

Table 8. Main product life cycle transitions

Transitions	Description
Device manufacturing	STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware.
Vendor manufacturing	One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“production” transition) or he/she can use the platform for software development (“user provisioning” transition).
Production	The end-user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.
User provisioning	Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.
Field return or decommissioning	These are one-way transitions, with devices kept in user premises or returned to the manufacturer. In both cases, all data including user data is destroyed, therefore the devices lose the ability to operate securely (like connecting to a managed IoT network).

The features described hereafter contribute to secure the device life cycle.

3.7.1 Life cycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the devices debug, test and provisioned secrets, as summarized in the table below.

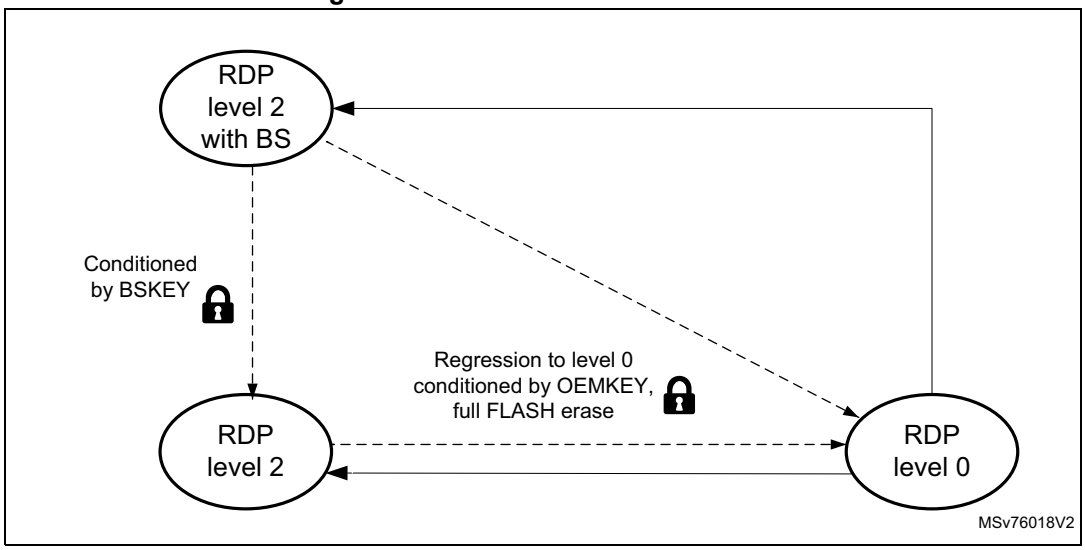
Table 9. Typical product life cycle phases

RDP protection level		Debug	Comments
Level 0	Device open	Available	OEM and BS unlocking/locking keys can be provisioned in the flash memory user options. The keys programming, while not readable, can be verified under reset through debugger.
Level 2 with boundary scan	Device closed	None (boundary scan available under reset)	Boot address must target the user flash memory. Option-byte modification limited, RDP_LEVEL not modifiable hence RDP level 2 with boundary scan cannot be changed, unless the OEM unlocking key is activated or the BS locking key to progress to level 2 (see *Table 10*).
Level 2	Device closed	None (JTAG fuse)	Boot address must target the user flash memory. Option-byte modification limited, RDP_LEVEL not modifiable hence RDP level 2 cannot be changed, unless the OEM unlocking key is activated (see *Table 10*).

Note: OEMKEY option byte can be modified when RDP = 0 only.

The supported transitions, summarized in the following figure can be requested (when available) through the debug interface, or via the system bootloader to go to RDP L2_wBS or L2. Additionally, through JTAG/SWD under reset, once in L2_wBS or L2, it is possible to either progress to L2 or regress to L0.

Figure 8. RDP level transition scheme



As shown in the previous figure, the user flash memory is automatically erased, during an RDP regression. These regressions can be conditioned on dedicated 128-bit password keys, if provisioned by the OEM (see the next subsection). During the regression from RDP L2 or L2_wBS to RDP L0, the FLASH is erased. The OTP area in the flash memory is kept, all SRAMS and targeted device secrets are erased. Hence, no secrets must be stored in the OTP as they are revealed after a regression to RDP L0. These secrets, also erased as response to tamper, are defined in *Section 3.3.3: Tamper detection and response*.

For more details on RDP, refer to *Section 6: Embedded flash memory (FLASH)*.

RDP unlocking sequences

The use of the OEM and BS password keys described in *Figure 8* is described hereafter.

Note: The devices support password-based RDP L2 (or L2_wBS) regression to L0. This L2 regression erases the application code.

Details on the password-based regression can be found in the tables below.

Table 10. OEM RDP unlocking methods

OEM password options		
OEM LOCK	**RDP level**	**RDP regression**
1	L2_wBS	Automatic regression to L0 triggered upon successful OEM unlock sequence
	L2	
0	L2_wBS	Regression to L0 impossible. Possibility to transition to RDP L2.
	L2	Regression to L0 impossible. RDP L2 remains a permanent state.

Table 11. BS RDP locking methods

BS password options	
Initial RDP level	**RDP regression**
L2_wBS, with BSKEY not provisioned	Automatic progression to L2 triggered upon successful BS lock sequence using default key
L2_wBS, with BSKEY provisioned	Automatic progression to L2 triggered upon successful BS lock sequence using custom key provisioned under RDP L0

- OEM unlock sequence, starting at RDP L2 or L2_wBS:
  - Shift the password key through JTAG/SWD under reset.
  - If this key matches the OEMKEY provisioned in the device, the device automatically triggers a regression sequence to level 0. After the regression is completed, a power-on reset has to be performed by the user.
  - In case of mismatch value, the RDP regression is blocked, and RDP L2 protections are enforced until the next power-on reset.
- BS lock sequence, starting at RDP L2_wBS:
  - Shift the password key through JTAG/SWD under reset (see the note below). A default key is provisioned in ST factory 0xAAAAAAAA. The user can provision a custom one under RDP L0.

– If this key matches the BSKEY provisioned in the device, the device automatically triggers a progression sequence to L2. After the progression is completed, a power-on reset has to be performed by the user.
– In case of a mismatch value, the RDP progression is blocked until the next power-on reset.

Note: Unlocking the device with a password is possible only once per power cycle.

Shifting the OEM password key through JTAG/SWD corresponds to writing four 32-bit key words: AUTH_KEY[31:0], then AUTH_KEY[63:32], AUTH_KEY[95:64], then AUTH_KEY[127:96] in the DBGMCU_DBG_AUTH_HOST register.

Shifting the BS password key through JTAG/SWD corresponds to writing a 32-bit key word: BS_KEY[31:0] in the DBG_BSKEY_PWD register.

JTAG 32-bit device specific ID

Unless the JTAG port is deactivated (OEMLOCK = 0 and RDP L2), a 32-bit device specific quantity can always be read through the JTAG port. This information is stored in DBGMCU_DBG_AUTH_DEVICE.

The OEM can use this 32-bit information to derive the expected OEM password keys to unlock this specific device.

3.8 Summary of protection mechanism

The different security mechanism may reset, block or erase device secrets or sensitive peripherals. To be more explicit on those effects, please refer to the below table:

Table 12. Summary of protected assets and protection mechanism(1)

Assets	Regression to RDP L0	Potential tamper	Confirmed tamper	POR	System reset	RTC domain reset
SRAM1	E	-	-	-	Erase if SRAM1_RST bit is ‘0’ (erase done at OPT activation)	-
SRAM2	E	B	E	E	Erase if SRAM2_RST bit is ‘0’ (erase done at OPT activation)	-
FLASH	E	-	-	-	-	-
FLASH EDATA page	E	-	-	-	-	-
Flash OTP	-	-	-	-	-	-
BKUP registers	R	B(2)	R/B(2)	R(3)	-	R
ICACHE	E	E	E	E	E	-
PKA RAM	E	E/B(4)	E/B(4)	E	E	-
FDCAN RAM	-	-	-	-	-	-
USB RAM	-	-	-	-	-	-
ETH RAM	-	-	-	-	-	-
AES/HASH/SAES/ CCB registers	R	R	R	R	R	-

Table 12. Summary of protected assets and protection mechanism(1)

Assets	Regression to RDP L0	Potential tamper	Confirmed tamper	POR	System reset	RTC domain reset
PKA registers	R	R	R	R	R	-
RNG registers	R	-	-	R	R	-

1. E = Erase, B = Access blocked, R = Reset, N.A. = Not applicable, “-” = No effect
2. Bocked up to clearing of TAMP status register flag.
3. Erase after POR
4. Blocked during erasing.

4 Boot modes

At startup, the BOOT0 pin or option bit (based on the value of the BOOT_SEL option bit) and BOOTADD[31:8] option bytes are used to select the boot memory address that includes:

- Boot from any address in user flash memory, excluding EDATA sectors.
- Boot from system memory
  - Bootloader

When boot from user flash is selected, the boot address is defined by BOOTADD. This address can be locked thanks to BOOT_LOCK.

Embedded bootloader

The embedded bootloader is located in the system memory and is programmed by ST during production. It is used to reprogram the flash memory using USART, SPI, FDCAN, or USB in device mode through the DFU (device firmware upgrade).

Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

4.1 STM32C5 boot modes

The following table provides the details of the boot mode for the STM32C5 devices.

Table 13. STM32C5 boot modes

RDP_LEVEL	BOOT_SEL option bit	BOOT0 option bit	BOOT0 pin	EMPTY flag value(1)	Boot area
Level 0	1	x	0	x	Boot address defined by user option byte BOOTADD[31:8]
			1		Bootloader
	0	0	x	0	Boot address defined by user option byte BOOTADD[31:8]
				1	Bootloader
		1		x	Bootloader
Level 2 with boundary scan and level 2	x	x	x	x	Boot address defined by user option byte BOOTADD[31:8]

1. The boot address, defined by BOOTADD option byte, is considered empty only if the FLASH word is equal to 0xFFFF FFFF. In this case, at option byte loading, the EMPTY bit is set in FLASH_ACR.

Empty check

During the option byte loading phase, after loading all options, the flash memory interface checks whether the boot location in the main memory, indicated by BOOTADD[31:8], is programmed. The result of this check, with the boot0 information, is used to determine where the system should boot from. It prevents the system from booting from the main flash memory area when, for instance, no user code has been programmed.

The main flash memory empty check status can be read from the EMPTY bit in the FLASH access control register (FLASH_ACR). Software can modify it by writing an appropriate value to the EMPTY bit.

The BOOT_LOCK, which locks modifications of option bytes involved in BOOT selection, has no impact on this empty check mechanism

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. It is used to reprogram the flash memory by using USART, SPI, FDCAN, or USB in device mode through the DFU (device firmware upgrade).

For further information, refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

5 RAMs configuration controller (RAMCFG)

5.1 RAMCFG introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1 and SRAM2).

5.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Error code correction (ECC):
  - Single-error detection and correction with interrupt generation
  - Double-error detection with interrupt or NMI generation
  - Status with failing address
- Write protection (1-Kbyte granularity)
- SRAM software erase

5.3 RAMCFG functional description

5.3.1 Internal SRAMs features

Two SRAMs are embedded in the device, each with specific features:

- SRAM1 and SRAM2 are the main SRAMs (see *Table 15*), made of several blocks that can be powered down in Stop mode to reduce consumption
- SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the flash memory user option bytes. SRAM1 is erased when a system reset occurs if the SRAM1_RST option bit is selected in the flash memory user option bytes. Refer to *Section 6: Embedded flash memory (FLASH)* for more details.
- SRAM2 is protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a backup domain reset. Refer to *Section 40: Tamper and backup registers (TAMP)* for more details.
- The RAMCFG embeds registers related to the internal SRAMs ECC, write protection, and software erase.

Table 14. SRAM density (Kbytes)

SRAM feature	SRAM1	SRAM2
STM32C53x/542	32	32
STM32C55x/562	64	64
STM32C59x/5A3	128	128

The table below summarizes the features supported by each internal SRAM

Table 15. Internal SRAMs features

SRAM feature	SRAM1	SRAM2
Optional retention in Standby mode	-	-
Optional retention in Stop mode	X	X
Erased with RDP level regression	X	X
Optionally erased with tamper detection	-	X
Optionally erased with system reset	X	X
Software erase	X	X
ECC	-	X
Write protection	-	X

5.3.2 Error code correction (SRAM2)

The ECC is supported by SRAM2 when enabled with the SRAM2_ECC user option bits. Refer to *Section 6: Embedded flash memory (FLASH)* for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing 2-bit error detection and 1-bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these bytes or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is two AHB clock cycles.

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when the SRAM is no more accessed).

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDC/CSEDC bits are set in RAMCFG_MxISR and RAMCFG_MxICR respectively. An interrupt is generated if enabled by the SEIE bit in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxSEAR if the ALE bit is set in RAMCFG_MxCR.

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, the DED and CDED bits are set in RAMCFG_MxISR and RAMCFG_MxICR respectively. An interrupt or NMI is generated if enabled by the DEIE or ECCNMI bit in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxDEAR if the ALE bit is set in RAMCFG_MxCR.

Caution: Double errors cannot be detected when the DED bit is set.

SRAM2 with ECC memory map

When the ECC is enabled for SRAM2, the full SRAM2 has ECC.

The figure below shows the SRAM areas, when ECC is enabled for both SRAM1 and SRAM2.

Table 16. SRAM with ECC memory map

Product	SRAM	Address over C-bus	Address over S-bus	SRAM size	
STM32C53x/542	SRAM1	0x0A00 0000 - 0x0A00 7FFF	0x2000 0000 - 0x2000 7FFF	32 Kbytes	
	SRAM2	0x0A00 8000 - 0x0A00 FFFF	0x2000 8000 - 0x2000 FFFF	32 Kbytes	ECC
STM32C55x/562	SRAM1	0x0A00 0000 - 0x0A00 FFFF	0x2000 0000 - 0x2000 FFFF	64 Kbytes	
	SRAM2	0x0A01 0000 - 0x0A01 FFFF	0x2001 0000 - 0x2001 FFFF	64 Kbytes	ECC
STM32C59x/5A3	SRAM1	0x0A00 0000 - 0x0A01 FFFF	0x2000 0000 - 0x2001 FFFF	128 Kbytes	
	SRAM2	0x0A00 0002 - 0x0A03 FFFF	0x2002 0000 - 0x2003 FFFF	128 Kbytes	ECC

When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in the related RAMCFG_MxCR.

The ECC can be deactivated by executing the following software sequence:

1. Write 0xAE in RAMCFG_MxECCKEYR.
2. Write 0x75 in RAMCFG_MxECCKEYR.
3. Write 0 in RAMCFG_MxCR.

Testing ECC mechanism

To test the ECC mechanism, 1 or 2 bits by word for single- or double-error test respectively.

The procedure to check ECC is the following:

1. On an erased memory, write data with ECC ON.
2. Disable ECC.
3. Write the same data with 1- or 2-bit modification (for single or double error test respectively).
4. Enable ECC.
5. Read the data. Enabled interrupt is generated because of a single or double error.

5.3.3 Write protection (SRAM2)

SRAM2 is made up of 1-Kbyte pages, each of which can be write-protected by setting its corresponding PxWP bit in RAMCFG_M2WPR1, RAMCFG_M2WPR2, RAMCFG_M2WPR3[(a)], and RAMCFG_M2WPR4[(a)].

5.3.4 Software erase

SRAM erase can be requested by executing this software sequence:

1. Write 0xCA in RAMCFG_MxERKEYR.
2. Write 0x53 in RAMCFG_MxERKEYR.
3. Write 1 to the SRAMER bit in RAMCFG_MxCR.

a. This register is available only on STM32C59x/5A3 devices. If not present, consider this register as reserved, and keep its bits at reset value.

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is ongoing.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is ongoing, wait states are inserted on the AHB bus until the end of the erase operation.

5.4 RAMCFG low-power modes

Table 17. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit Sleep mode.
Stop	The content of RAMCFG registers is kept.
Standby	The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby mode.

5.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

Table 18. RAMCFG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
RAMCFG	ECC single-error detection and correction	SEDC	SEIE	Write 1 in CSEDC	Yes	No	No
	ECC double-error detection	DED	DEIE = 1 and ECCNMI = 0	Write 1 in CDED	Yes	No	No
NMI	ECC double-error detection	DED	ECCNMI	Write 1 in CDED	Yes	No	No

5.6 RAMCFG registers

In the registers described below, x refers to:

- SRAM1 when x = 1
- SRAM2 when x = 2

5.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x000 + 0x40 * (x - 1), (x = 1, 2)

Reset value: 0x0000 000X

ECCE reset value depends on the ECC enable user option bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	ALE	Res.	Res.	Res.	ECCE
							rs				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation ongoing

1: Erase operation ongoing

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in the SRAMx ECC single/double error address registers

1: Failing address stored in the SRAMx ECC single/double error address registers

Note: This bit is reserved and must be kept at reset value in SRAM1 control register.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable.

This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.

0: ECC disabled

1: ECC enabled

Note: This bit is reserved and must be kept at reset value in SRAM1 control register.

5.6.2 RAMCFG memory x interrupt status register (RAMCFG_MxISR)

Address offset: 0x008 + 0x40 * (x - 1), (x = 1, 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	DED	SEDC
							r							r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

0: No erase operation ongoing

1: Erase operation ongoing

Note: Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or RDP level regression. Refer to Table 15: Internal SRAMs features.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DED**: ECC double error detected

0: No double error

1: Double error detected

Note: This bit is reserved and must be kept at reset value in SRAM1 interrupt status register.

Bit 0 **SEDC**: ECC single error detected and corrected

0: No single error

1: Single error detected and corrected

Note: This bit is reserved and must be kept at reset value in SRAM1 interrupt status register.

5.6.3 RAMCFG memory x erase key register (RAMCFG_MxERKEYR)

Address offset: 0x028 + 0x40 * (x - 1), (x = 1, 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of SRAMER in RAMCFG_MxCR.

1) Write 0xCA into ERASEKEY[7:0].

2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

5.6.4 RAMCFG memory 2 interrupt enable register (RAMCFG_M2IER)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCNMI	Res.	DEIE	SEIE
												rs		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCNMI**: Double error NMI

This bit is set by software and cleared only by a global RAMCFG reset.

0: NMI not generated in case of ECC double error

1: NMI generated in case of ECC double error

Note: if ECCNMI is set, the RAMCFG maskable interrupt is not generated whatever DEIE bit value.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DEIE**: ECC double error interrupt enable

0: Double error interrupt disabled

1: Double error interrupt enabled

Bit 0 **SEIE**: ECC single error interrupt enable

0: Single error interrupt disabled

1: Single error interrupt enabled

5.6.5 RAMCFG memory 2 ECC single error address register (RAMCFG_M2SEAR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ESEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ESEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ESEA[31:0]**: ECC single error address

When the ALE bit is set in RAMCFG_M2CR, this bitfield is updated with the address corresponding to the ECC single error.

5.6.6 RAMCFG memory 2 ECC double error address register (RAMCFG_M2DEAR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EDEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EDEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **EDEA[31:0]**: ECC double error address

When the ALE bit is set in RAMCFG_M2CR, this bitfield is updated with the address corresponding to the ECC double error.

5.6.7 RAMCFG memory 2 interrupt clear register (RAMCFG_M2ICR)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CDED	CSEDC
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CDED**: Clear ECC double error detected

Writing 1 to this flag clears the DED bit in RAMCFG_M2ISR. Reading this flag returns the DED value.

Bit 0 **CSEDC**: Clear ECC single error detected and corrected

Writing 1 to this flag clears the SEDC bit in RAMCFG_M2ISR. Reading this flag returns the SEDC value.

5.6.8 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 31 to 0)
These bits are set by software and cleared only by a global RAMCFG reset.
0: Write protection of SRAM2 1-Kbyte page y is disabled.
1: Write protection of SRAM2 1-Kbyte page y is enabled.

5.6.9 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2)

Address offset: 0x05C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 63 to 32)
These bits are set by software and cleared only by a global RAMCFG reset.
0: Write protection of SRAM2 1-Kbyte page y is disabled.
1: Write protection of SRAM2 1-Kbyte page y is enabled.

5.6.10 RAMCFG memory 2ECC key register (RAMCFG_M2ECCKEYR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ECCKEY[7:0]**: ECC write protection key

The following steps are required to unlock the write protection of ECCE in RAMCFG_M2CR.

1) Write 0xAE into ECCKEY[7:0].

2) Write 0x75 into ECCKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

5.6.11 RAMCFG memory 2 write protection register 3 (RAMCFG_M2WPR3)

Address offset: 0x070

Reset value: 0x0000 0000

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

6 Embedded flash memory (FLASH)

6.1 FLASH introduction

The embedded flash memory (FLASH) manages the accesses of any master to the up to 1 Mbyte of embedded nonvolatile memory. It implements the read, program and erase operations, error corrections, as well as various integrity and confidentiality protection mechanisms.

The FLASH manages the automatic loading of nonvolatile user option bytes at power-on reset, and implements the dynamic update of these options.

The FLASH also features a one-time-programmable (OTP) area and a read-only area provisioned by STMicroelectronics during the product manufacturing.

6.2 FLASH main features

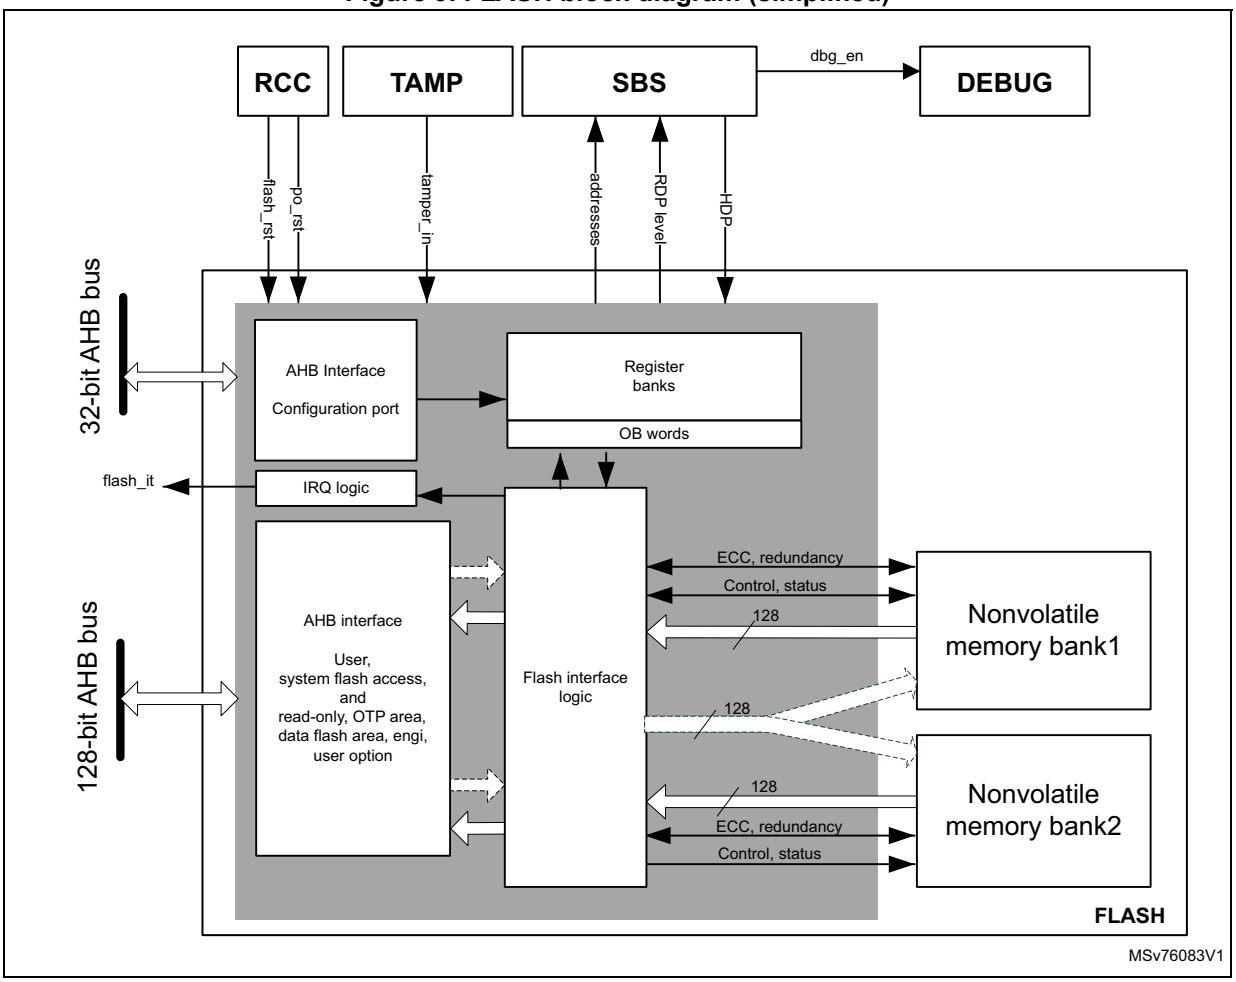
- Up to 1 Mbyte of nonvolatile memory divided into two banks
- Flash memory read operations supporting multiple lengths: 128, 64, 32, 16 bits, or 1 byte
- Flash memory programming by 128 bits in user area and 32 or 16 bits for OTP and flash data area
- 8-Kbyte page erase, bank erase and dual-bank mass erase
- 16 EDATA pages per bank that can be configured
  - to extend user area, 2-Kbyte pages, 128-bit programming
  - to offer user data flash memory, 1.5-Kbyte pages, 16- or 32-bit programming
- Dual-bank organization supporting:
  - Simultaneous operations: read-while-write (program and erase) is supported.
  - The two banks share the same interface. Write and erase can not be performed in parallel (write-while-write is not supported).
  - Bank swapping: the address mapping of the user flash memory of each bank can be swapped, along with the corresponding registers. Security flags remain valid for the physical bank. So the data are not reveled by swapping to a bank with lower security configuration.
- Error code correction (ECC): one error detection/correction or two error detections per 128-bit FLASH word using 9 ECC bits
- User configurable nonvolatile option bytes
- Flash memory enhanced protections, activated by option bytes
  - Read out protection for protecting memory content from debug access
  - Page group write-protection (WRPG)
  - HDP protection providing temporal isolation for startup code
- 4.5-Kbyte one-time programmable (OTP) area
- Read-only area provisioned by STMicroelectronics
- Prefetch is reading the next sequential instruction from flash memory

6.3 FLASH functional description

6.3.1 FLASH block diagram

The following figure shows the simplified FLASH block diagram.

Figure 9. FLASH block diagram (simplified)



6.3.2 FLASH signals

The flash memory has two AHB connections: the flash AHB register interface and the main AHB interface.

FLASH AHB register interface

- Data size is 32 bits.
- Except for some registers (FLASH_KEYR and FLASH_OPTKEYR that are used to insert unlock sequences for control and option registers and can be written in 32 bits), it is possible to read and write all registers in 8, 16, and 32 bits.
- When an unlock sequence for control and option registers is incorrect, a bus error is raised. Otherwise, no read or write errors are generated on the bus.

Main AHB interface

The AHB data bus size is 128 bits. This interface is used to handle two different targets:

- Code placed in user and system memory. 128-bit data are protected by 9 bits of ECC.
- OTP, user data flash, and read only memory. 16-bit data are protected by 6 bits of ECC.

The main AHB interface is implemented as follows:

- User and system memory:
  - Supports multiple length: 128-, 64-, 32-, 16-, and 8-bit data width.
  - There is a read buffer of 128 bits for each bank where the last data read is stored. If the data is available in the read buffer, no read access is done to the flash memory. Buffer is flushed when write access, OTP access, flash data area access user option change request or erase operation occurs
  - There is a prefetch of the same size as the read buffer.
  - A 9-bit ECC is associated to each 128-bit data flash memory word
- OTP, user data flash and read only
  - Two dedicated data buffer of 137 bits are used to manage 16-bit data with 6-bit ECC.
  - Reading two times the same address triggers two FLASH read accesses.
  - During a read access, two wait states are added in addition of the memory wait states. These wait states are necessary to parse the data buffer
  - Each write access triggers a write in the flash memory.
  - 6-bit ECC is associated to each 16-bit data.

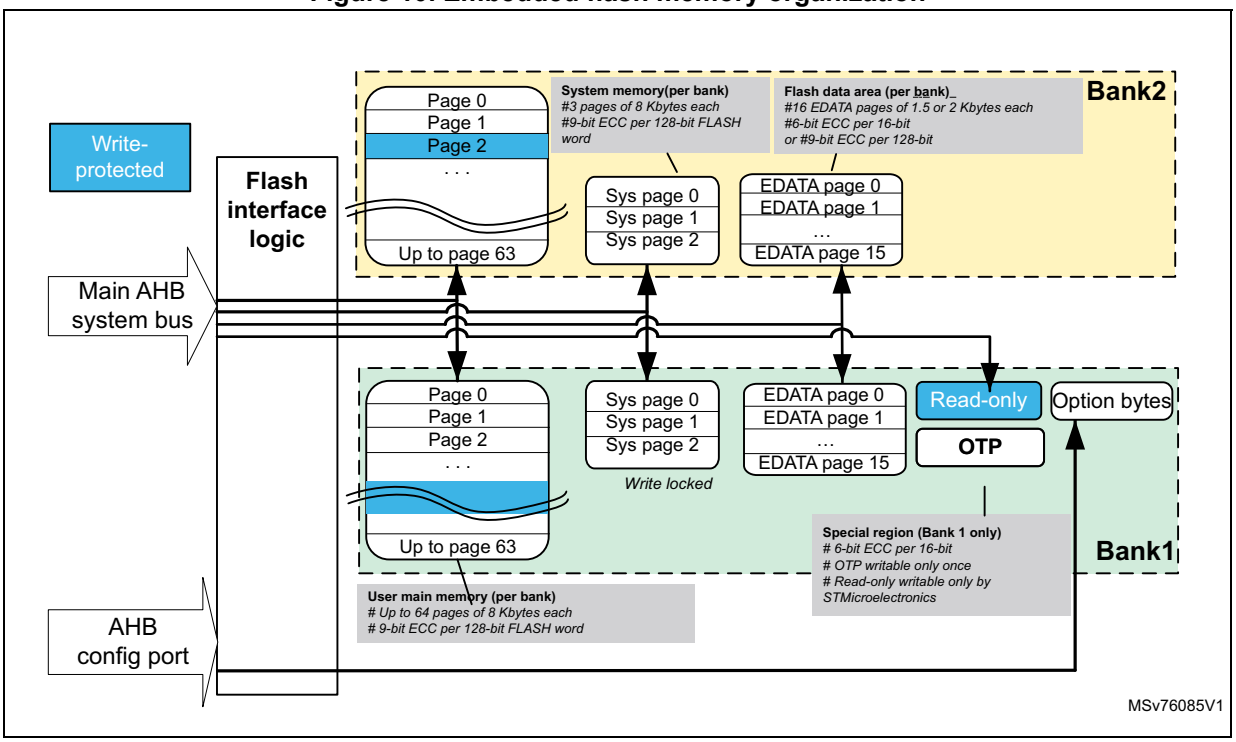
Caution: By default, all the AHB memory range is cacheable. For regions where caching is not permitted (OTP, RO, data area), MPU has to be used to disable local cacheability. An attempt to cache these regions will generate a Hard Fault.

6.3.3 Flash memory architecture and usage

Flash memory architecture

Figure 10 shows the nonvolatile memory organization supported by the FLASH.

Figure 10. Embedded flash memory organization



The embedded flash nonvolatile memory is composed of:

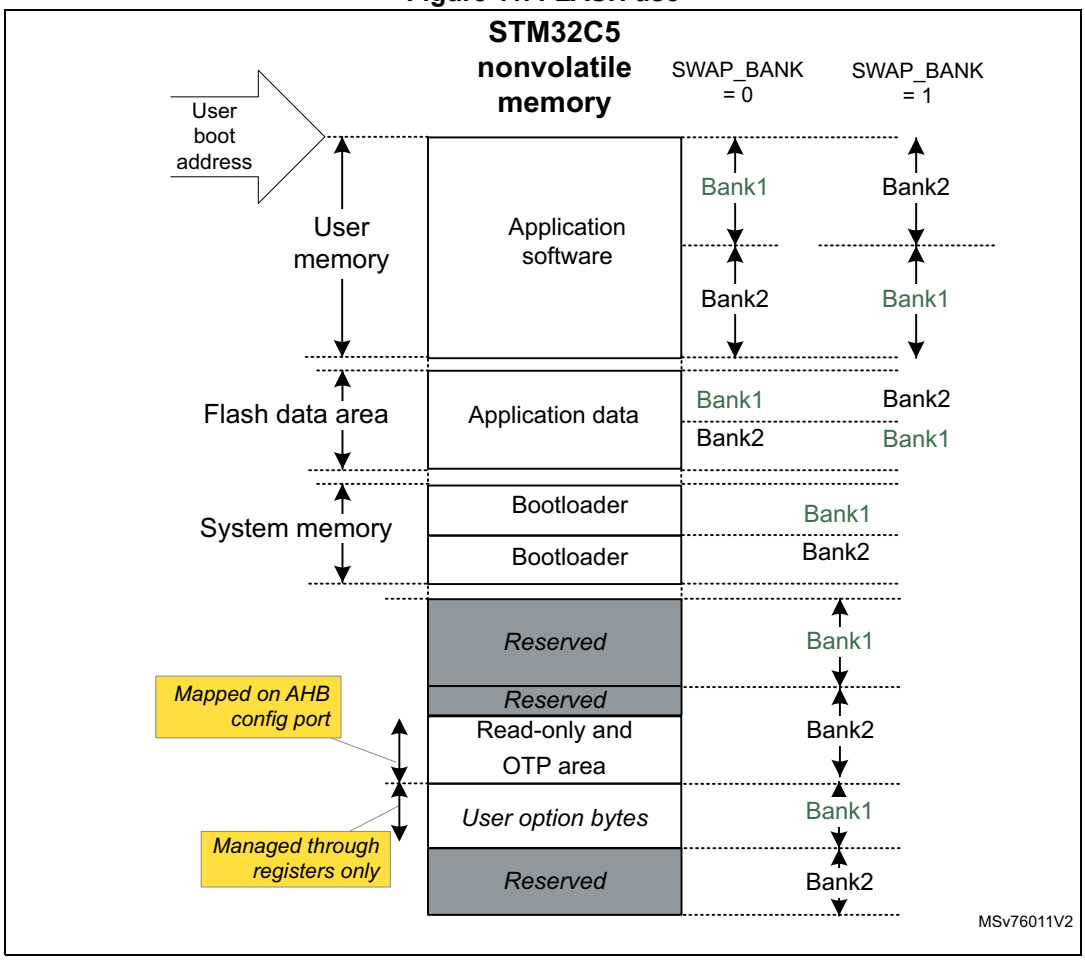
- A main memory block is organized into two banks. Each bank is divided in pages of 8 Kbytes each and features flash-word rows of 128 bits + 9 bits of ECC per word.
- A system memory block of 48 Kbytes is divided into two 24-Kbyte banks. Each bank is divided in three 8-Kbyte pages. The system flash memory is ECC protected (9-bit ECC per 128-bit word).
- A set of nonvolatile option bytes loaded at reset by the FLASH, and accessible by the application software only through the AHB configuration register interface.
- A 4.5-Kbyte OTP area that can be written only once by the application software
- A 1.5-Kbyte read-only area . It contains a unique device ID and product information.
- Up to 32 pages of user flash memory for data, 16 pages of 2 Kbytes per bank if EDATA_EN bit is reset, or 16 pages of 1.5 Kbytes per bank if EDATA_EN bit is set.

The overall flash memory architecture and its corresponding access interface is summarized in *Table 24*.

Partition usage

The figure below shows how the FLASH is used by both STMicroelectronics and the application software.

Figure 11. FLASH use



User and system memories are used differently according to RDP level and other option-byte settings.

The user memory contains the application code and associated constant data. The flash data area contains application nonvolatile data.The system memory contains the STM32 bootloader. When a reset occurs, the core jumps to the boot address configured through the BOOT pin (or BOOT option bit), the BOOTADD option bytes, and the RDP level.

Note: For more information on option-byte setup for boot, refer to Section 6.4.8.

6.3.4 FLASH read operations

Read operation overview

Read access to main flash memory and system flash memory operates as follows:

- There is a 128-bit read data buffer associated to each bank, which stores the last data read. If several consecutive read accesses request data belonging to the same FLASH data word (128 bits), the data are read directly from the current data read buffer, without triggering additional FLASH read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons, the corresponding read error response is issued by the FLASH and no read operation to flash memory is triggered
- The read data buffer is disabled when write access or OTP access, user option change request or other erase operation occurs

Read access to OTP, RO, and user data flash area operates as follows:

1. A FLASH data word of 137 bits is read and stored in a temporary buffer.
2. The interface parses the 137-bit data word, and selects the 16- or 32-bit data requested.
3. While parsing the 137-bit data word, two wait states are added and the AHB bus is stalled.
4. If the application reads an OTP data or user data FLASH not previously written, a double ECC error is reported, and only word full of set bits is returned (see *Section 6.3.9* for details). The read data (in 16 bits) is stored in FLASH_ECCDR, so that the user can identify if the double ECC error is due to a virgin data or a real ECC error.
5. Reading two times the same address triggers two reads in the flash memory.
6. For 8-bit accesses, an AHB bus error is generated.

Note: The FLASH can perform single-error correction and double-error detection while read operations are being executed (see Section 6.3.8).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-Bus and through the instruction cache if it is enabled. The prefetch block aims at increasing the efficiency of C-Bus accesses when the ICACHE is enabled, by reducing the cache refill latency.
Prefetch is efficient in case of sequential code; prefetch in the flash memory allows the next sequential instruction line to be read from the flash memory, while the current instruction line is being filled in the ICACHE and executed by the CPU.
Prefetch is enabled by setting the PRFTEN bit in FLASH_ACR. PRFTEN must be set only if at least one wait state is needed to access the flash memory.

Adjusting read-timing constraints

The FLASH clock must be enabled and running before reading data from a nonvolatile memory.

To correctly read data from the flash memory, the number of wait states (LATENCY) must be correctly programmed in FLASH_ACR, according to the FLASH main AHB interface clock frequency.

The table below shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ) and the FLASH clock frequency.

Table 20. FLASH recommended number of wait states and programming delay

Number of wait states (LATENCY)	Programming delay (WRHIGHFREQ)	Interface clock frequency
0 WS (1 FLASH clock cycle)	00	[0 MHz; 34 MHz]
1 WS (2 FLASH clock cycles)		[34 MHz; 68 MHz]
2 WS (3 FLASH clock cycles)	01	[68 MHz; 102 MHz]
3 WS (4 FLASH clock cycles)		[102 MHz; 136 MHz]
4 WS (5 FLASH clock cycles)	10	[136 MHz; 144 MHz]

Adjusting system frequency

After power-on, the FLASH is clocked by the divided by 3 high speed internal oscillator HSIDIV3 at 48 MHz. As a result, a conservative 7 wait-state latency is specified in FLASH_ACR register (see the previous table).

When changing the bus frequency, the application software must follow the sequence described below, in order to tune the number of wait states required to access the nonvolatile memory.

To increase the CPU frequency:

1. If necessary, program LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 20.*
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the FLASH clock source and/or the clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new FLASH clock source and/or the new AHB clock prescaler value are taken in account by reading back the FLASH clock source status and/or the prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the CPU frequency:

1. Modify the FLASH clock source and/or the clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the FLASH new clock source and/or the new clock prescaler value are taken in account by reading back the FLASH clock source status and/or the AHB interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in *Table 20.*
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Error code correction (ECC)

The embedded flash memory embeds an error correction mechanism. Single-error correction and double-error detection are performed for each read operation. For more details, refer to *Section 6.3.8*.

Read errors

When the ECC mechanism is not able to correct the read operation, the embedded flash memory reports read errors as described in *Section 6.8.5*

Read interrupts

See *Section 6.9* for details.

6.3.5 FLASH program operations

Program operation overview

Program operation consists in issuing write commands. The FLASH supports the execution of only one write-command at a time. Write-while-write are not supported. Nothing prevents overwriting a nonvirgin FLASH word but this is not recommended. The result may lead to invalid data and inconsistent ECC code.

User flash memory

For the user flash memory, 9-bit ECC is associated to each 128-bit data FLASH word. In this case, the FLASH must always perform write operations to nonvolatile memory with a 128-bit word granularity. Once the write buffer is full (128 bits), the busy flag BSY is set and a programming operation is triggered.

There is a write buffer common to bank1 and 2, which support multiple write-access types (128, 64, 32, 16, or 8 bits). The application can decide to write as little as 8- to a 128-bit FLASH word. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW bit in FLASH_CR register).

When the write request is issued to the memory any new write request stalls the main AHB bus.

Moreover, while a write operation is ongoing, any new read request to the same bank stalls the main AHB bus.

OTP, RO and flash data area

When the target memory is OTP, RO, and flash data area pages, 6-bit ECC code is associated to each 16-bit data FLASH word. The FLASH supports 16- or 32-bit write operations (8-bit write operations are not supported). For 8-bit accesses, write accesses are ignored. There is no write data buffer. Each write access triggers a write in the flash memory.

Note: The OTP area is typically write-protected on the final product, as described in Section 6.3.9.

The write protection check is performed at the reception of the write request (during address phase). Write protection is not checked anymore at the output of the write buffer. If a write protection violation is detected, the write operation is canceled and write protection error (WRPERR) is raised in FLASH_SR register.

Note: For write protections of main FLASH, flash data area, and OTP, see Section 6.5.

Monitoring ongoing write operations

The application software can use a status flag located in FLASH_SR to monitor ongoing write operations. Since only one operation is possible at a time, this flag indicates if any operation (write, erase, option change) is ongoing, whatever the banks.

- **BSY**: This bit indicates that an effective write, erase, option-byte change is ongoing in the nonvolatile memory. This flag is not dedicated to a specific bank. It is set when an operation is starting on the memory, whatever the bank. An operation is triggered by:
  - An erase (FLASH_CR.STRT)
  - A write (FLASH_CR.PG + AHB write)
  - An option modification (FLASH_OPTCR.OPTSTRT)

  It is cleared when the current operation is ending or in case of error.

Note: BSY is also set when an OBL launch is triggered (OBL_LAUNCH in FLASH_OPTCR).

- **WBNE**: This bit indicates that the FLASH is waiting for new data to complete the 128-bit write buffer. In this state, the write buffer is not empty. It is reset as soon as the application software fills the write buffer, or forces the writes by using FW bit in FLASH_CR, or an error is detected. When WBNE is high, it is not possible to launch an erase or an option modification on flash memory.
- **DBNE**: This bit indicates that the data buffer for parsing 16-bits data is not empty:
  - 16-bit data write access is received and that the data buffer is being filled. It is set at the receipt of the a valid write access and it is reset as soon as the write request preparation has been processed.

Note: If the flash memory is busy at the receipt of the AHB write request, the CPU execution is stalled.

Enabling write operations

Before programming the user flash memory in bank1 or bank2, the application software must make sure that the PG bit is set to 1 in FLASH_CR. If it is not the case, an unlock sequence must be used (see *Section 6.5.4*), and the PG bit must be set.

When the option bytes must be modified, the application software must make sure that FLASH_OPTCR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 6.5.4*).

Note: The application software must not unlock an already unlocked register, otherwise this register remains locked until the next system reset.

If needed, the application software can update the programming delay, as described in *Adjusting programming timing constraints*.

Writing to FLASH_CR and FLASH_OPTCR

The FLASH_CR and FLASH_OPTCR registers are not accessible in write mode when the BSY bit is set. Any attempt to write these registers while the BSY bit is set causes the AHB bus to stall until BSY bit is cleared.

Single-write sequence

The recommended single-write sequence is the following:

1. Make sure protection mechanism does not prevent to attempt programming.
2. Check that no flash memory operation is ongoing by checking the BSY bit in FLASH_SR and DBNE bit in FLASH_SR. Check that the write buffer is empty by checking the WBNE bit in FLASH_SR.
3. Check and clear all the error flags due to previous programming/erase operation.
4. Unlock the FLASH_CR register, as described in *Section 6.5.4* (only if register is not already unlocked).
5. Enable write operations by setting PG bit in FLASH_CR.
6. Write one FLASH word at aligned address.

Note: WBNE flag indicates if the 128-bit write buffer is waiting for new data.

No erase request or options change request is allowed between the first write to the write buffer and the completion of the FLASH write operation.

7. Wait for the BSY bit to be cleared in the corresponding FLASH_SR register.
8. Clear PG bit in FLASH_CR if there are not any more programming requests.

If step 6 is executed incrementally (for example byte per byte), the write buffer can become partially filled. In this case, the application software can decide to force-write what is stored in the write buffer by using FW bit in FLASH_CR. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Note: Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a unexpected or inconsistent data or ECC.

Adjusting programming timing constraints

Program operation timing constraints depend of the FLASH clock frequency, which directly impacts the performance. If timing constraints are too tight, the nonvolatile memory does not operate correctly. If they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to *Table 20* in *Section 6.3.4* for the recommended programming delay depending on the FLASH clock frequency. FLASH_ACR configuration register is common to both banks.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the flash memory may corrupt the flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in *Section 6.8*.

Programming interrupts

See *Section 6.9* for details.

6.3.6 FLASH erase operations

Erase operation overview

The FLASH can perform erase operations on 8-Kbyte or 2-Kbyte user pages, on one user flash memory bank, or on two user flash memory banks (for example mass erase).

For more details in user flash memory, user data flash, user options, and OTP erase protection, see *Section 6.5*.

Erase commands are issued through the AHB configuration interface. Since the FLASH supports one operation at a time, if it receives simultaneously a write and an erase request, an error flag is raised and both operation are canceled (see *Section 6.8* for details).

After successful completion of erase, all the bytes in the erased flash sectors are set to the flash default 0xFF value.

Erase and WRP

If the application software attempts to erase a user page that is write protected, the page erase operation is aborted, and the WRPERR flag is raised in FLASH_SR, as described in *Section 6.8.1*.

FLASH busy

Busy signals are described in *Monitoring ongoing write operations*.

Writing to FLASH_CR and FLASH_OPTCR

Refer to *Writing to FLASH_CR and FLASH_OPTCR*.

Enabling erase operations

Before erasing a page, the application software must make sure that FLASH_CR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 6.5.4*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset. This can be used to deliberately lock-out a register from further accesses.

Similar constraints apply to bank erase requests.

FLASH page-erase sequence

To erase an 8-Kbyte, a 2-Kbyte user page, or a 1.5K-byte if in data flash without security protections, proceed as follows:

1. Make sure protection mechanism does not prevent to attempt page erase (WRP, HDP).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in FLASH_SR, and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the error flags due to previous programming/erase operation (refer to *Section 6.8* for details).
4. Unlock the FLASH_CR register, as described in *Section 6.5.4* (only if register is not already unlocked).

5. Set BKSEL bit, PER bit, EDATASEL bit, and PNB bitfield in FLASH_CR.
   - BKSEL indicates in which physical bank page has to be erased.
   - PER indicates a page erase operation.
   - EDATASEL indicates if the page targeted is a 2-Kbyte EDATA page or a standard page.
   - PNB contains the target page number.
6. Set the STRT bit in FLASH_CR.
7. Wait for the BSY bit to be cleared in FLASH_SR.
8. STRT bit is automatically cleared at the end of the page erase or in case of error.
9. Clear PER in FLASH_CR if there are not anymore page erase request to be issued.

Note: If another erase flag is requested simultaneously to the page erase, an PGSERR error is generated.

Standard flash memory bank-erase sequence

To erase a bank , proceed as follows:

1. Make sure protection mechanism does not prevent to attempt bank erase.
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in FLASH_SR, and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the error flags due to previous programming/erase operation (refer to *Section 6.8* for details).
4. Unlock the FLASH_CR register, as described in *Section 6.5.4* (only if register is not already unlocked).
5. Set the BKSEL bit and the BER bit in FLASH_CR to the targeted physical bank (swap setting is ignored).
6. Set the STRT bit in FLASH_CR to start the bank erase operation. Then wait until the BSY bit is cleared in FLASH_SR.
7. STRT bit is automatically cleared at the end of erase sequence or in case of error.
8. Clear BER in FLASH_CR if there is not other bank erase request to be issued.

FLASH mass-erase sequence

The application software can set the MER bit to 1 in FLASH_CR, as described below:

1. Make sure protection mechanisms do not prevent to attempt mass erase (*Section 6.5*)
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in FLASH_SR, and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the error flags due to previous programming/erase operation (refer to *Section 6.8* for details).
4. Unlock the FLASH_CR register as described in *Section 6.5.4* (only if the registers are not already unlocked).
5. Set the MER bit to 1 in FLASH_CR.
6. Set the STRT bit in FLASH_CR. Then wait until BSY bit is cleared in FLASH_SR.
7. STRT bit is cleared automatically at the end of the erase sequence or in case of error.
8. Clear MER in FLASH_CR.

Note: Mass and bank erase also erase flash data area pages from the erased bank.

6.3.7 FLASH parallel operations

Since the nonvolatile memory is divided into two independent banks but encapsulated in the same macro, the embedded flash memory interface only supports reading in one bank while writing or erasing is executed in the other bank. This feature is called read-while-write capability (RWW). It does not support write-while-write or read-while-read. Same is valid for the flash data area.

In all cases, the sequences are described in *Section 6.3.4*, *Section 6.3.5*, and *Section 6.3.6*.

6.3.8 Flash memory error protections

Error correction codes (ECC)

The FLASH supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detect double errors.

This mechanism uses 9 ECC bits per 128-bit FLASH word, and applies to user and system memory.

For read-only, OTP, and user flash data area, a stronger 6 ECC bits per 16-bit word is used. A double ECC error is generated for an OTP or flash data area virgin word (for example a word with 22 bits at 1). When this OTP or flash data area word is no more virgin, the ECC error disappears.

More specifically, during each read operation from a 128-bit FLASH word, the FLASH retrieves the 9-bit ECC information, computes the ECC of the FLASH word, and compares the result with the reference value. If they do not match, the corresponding ECC error is raised as described in *Section 6.8.5*.

During each program operation, a 9-bit ECC code is associated to each 128-bit data FLASH word, and the resulting 137-bit FLASH word information is written in nonvolatile memory.

A similar mechanism applies to read-only, OTP, and user flash data area but with 6-bit ECC for 16-bit data.

6.3.9 OTP and RO memory access

OTP and RO memory are accessed through the main AHB interface. The OTP is accessible at the address 0x08FF E000 to 0x08FF F1FF, and the read only section is accessible from 0x08FF F800 to 0x08FF FDFF.

They are stored in a distinct way as data or user flash, filling first 4 bytes of a page, then 5th to 8th and finally 9th to 12th as columns. It does not impact addressing nor locking mechanism but requires caution to decode ECC double error or operation interruption. Indeed for OTP or RO the ECC address returned in ADDR_ECC bitfield indicate FLASH line.

In case of double error detection, the corrupted access can be identified thanks to DATA_ADDR_ECC bitfield returning OTP position on the line.

They are stored in a different way than user data, each sector being filled vertically 32-bit wise as described in the table below.

Table 21. OTP first page organization

FLASH line	OTP position on FLASH line					
	0b000	**0b001**	**0b010**	**0b011**	**0b100**	**0b101**
0x00	OTP0 0x08FF E000	OTP1 0x08FF E002	OTP256 0x08FF E200	OTP257 0x08FF E202	OTP512 0x08FF E400	OTP513 0x08FF E402
0x01	OTP2 0x08FF E004	OTP3 0x08FF E006	OTP258 0x08FF E204	OTP259 0x08FF E206	OTP514 0x08FF E404	OTP515 0x08FF E406
...	...		...		...	
0x7E	OTP252 0x08FF E1F8	OTP253 0x08FF E1FA	OTP508 0x08FF E3F8	OTP509 0x08FF E3FA	OTP764 0x08FF E5F8	OTP765 0x08FF E5FA
0x7F	OTP254 0x08FF E1FC	OTP255 0x08FF E1FE	OTP510 0x08FF E3FC	OTP511 0x08FF E3FE	OTP766 0x08FF E5FC	OTP767 0x08FF E5FE

FLASH one-time programmable area

The FLASH offers a 4608-byte memory area dedicated to application nonconfidential, one-time programmable data (OTP). This area is composed of 2304 words of 16 bits (plus 6 bits of ECC). It cannot be erased, and can be written only once. The OTP area can be accessed through the main AHB interface from address 0x08FF E000 to 0x08FF F1FE (last whole readable 16-bit word).

OTP data can be programmed by the application software by chunks of 16 bits. Overwriting an already programmed 16-bit half-word can lead to data and ECC errors and is therefore not supported.

Note: The OTP area is virgin when the device is delivered by STMicroelectronics.

When reading OTP data with a single error corrected or a double error detected, the FLASH reports read errors, as described in *Section 6.8.5*.

When reading OTP data not written by the application software (such as virgin OTP), the ECC correction reports a double-error detection (ECCD), and the data are to be found in FLASH_ECCDR register. ECCD implies a NMI raised, unless setting in SBS prevents that.

OTP write protection

OTP data are organized as 24 blocks of 96 OTP words, as shown in *Table 22*. An entire OTP block can be protected (locked) from write accesses by setting the LOCKBLi (i = 0 to 23) bit corresponding to each OTP block (i = 0 to 23) in FLASH_OTPBLR. A block can be write-protected whether or not it has been programmed (even partially).

The OTP block locking operation is irreversible and independent from the product life state.

Note: The OTP area can only be accessed in read mode.

Table 22. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF E000	OTP0001	OTP0000	LOCKBL0
	0x08FF E004	OTP0003	OTP0002	
	...			
	0x08FF E0BC	OTP0095	OTP0094	
Block 1	0x08FF E0C0	OTP0097	OTP0096	LOCKBL1
	0x08FF E0C4	OTP0099	OTP0098	
	...			
	0x08FF E17C	OTP0191	OTP0190	
Block 2	0x08FF E180	OTP0193	OTP0192	LOCKBL2
	0x08FF E184	OTP0195	OTP0194	
	...			
	0x08FF E23C	OTP0287	OTP0286	
...				
Block 23	0x08FF F140	OTP2209	OTP2208	LOCKBL23
	0x08FF F144	OTP2211	OTP2210	
	...			
	0x08FF F1FC	OTP2303	OTP2302	

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check that no flash memory operation is ongoing by checking the BSY bit in FLASH_SR register, and that the data buffer is empty by checking the DBNE bit in the same register.
2. Check and clear all the error flags due to previous programming/erase operation.
3. Set PG bit in FLASH_CR.
4. Check the protection status of the target OTP word (see *Table 22*). The corresponding LOCKBLi bit must not be set to 1.
5. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 22*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one
6. Wait for the BSY bit to be cleared in FLASH_SR.
7. Clear PG bit in FLASH_CR if there is not any programming request anymore in the bank.
8. Optionally, lock the OTP block using LOCKBLi to prevent further data changes.

Note: Do not write twice an OTP 16-bit word, otherwise an ECC error can be generated.

Writing OTP data at byte level is not supported and generates a bus error.

To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting an option change.

FLASH read-only area

The FLASH offers a 1.5-Kbyte memory area to store read-only data, also referred to as RO. This area is mapped as described in *Table 23*. It can be accessed through the AHB main port. This read-only area is protected by a robust ECC scheme, as explained in *Section 6.3.8*.

The read-only information that can be used by the application software are described in the table below. This information is programmed by STMicroelectronics.

Table 23. Read-only public data organization

Read-only data name	Address	Comment
Unique device ID	0x08FF F800	U_ID[31:0]
	0x08FF F804	U_ID[63:32]
	0x08FF F808	U_ID[96:64]
Flash memory size/ package	0x08FF F80C	Flash memory size[15:0] || Package code[15:0]
Factory calibration	0x08FF F810	Vrefint calibration value[31:0]
	0x08FF F814	TS_CAL1[31:0]
	0x08FF F818	TS_CAL2[31:0]
Reserved	0x08FF F81C to 0x08FF FDFF	Reserved information

6.3.10 FLASH data area

The FLASH offers 64 Kbytes to store extra code, data or emulate EEPROM in 16 EDATA pages per bank. Based on value of EDATA_EN option bit this area is one of the following:

- Protected by a robust 6-bit ECC, which allows a write granularity of 16 or 32 bits at the expense of having page size shrunk to 1.5 Kbytes. This area is the FLASH data area and the memory can be accessed through the AHB system port from address 0x0900 0000 to 0x0900 BFFF.
- Page size of 2 Kbytes with write granularity of 128 bits protected by a robust 9-bit ECC. This area is part of user main flash memory and instructions can be fetched from addresses 0x0840 0000 to 0x0840 FFFF (see *Figure 13*).

Caution: This area cannot be used as a boot location in BOOTADD.

For greater efficiency, it is always recommended to use page on the other bank for the FLASH data area, so that the application benefits from RWW capability of the dual-bank arrangement.

When SWAP_BANK feature is enabled, the banks are swapped: the flash data area in bank 2 are accessible from 0x0900 000 to 0x0900 5FFF, and the data in bank 1 are accessible from 0x0900 6000 to 0x0900 BFFF.

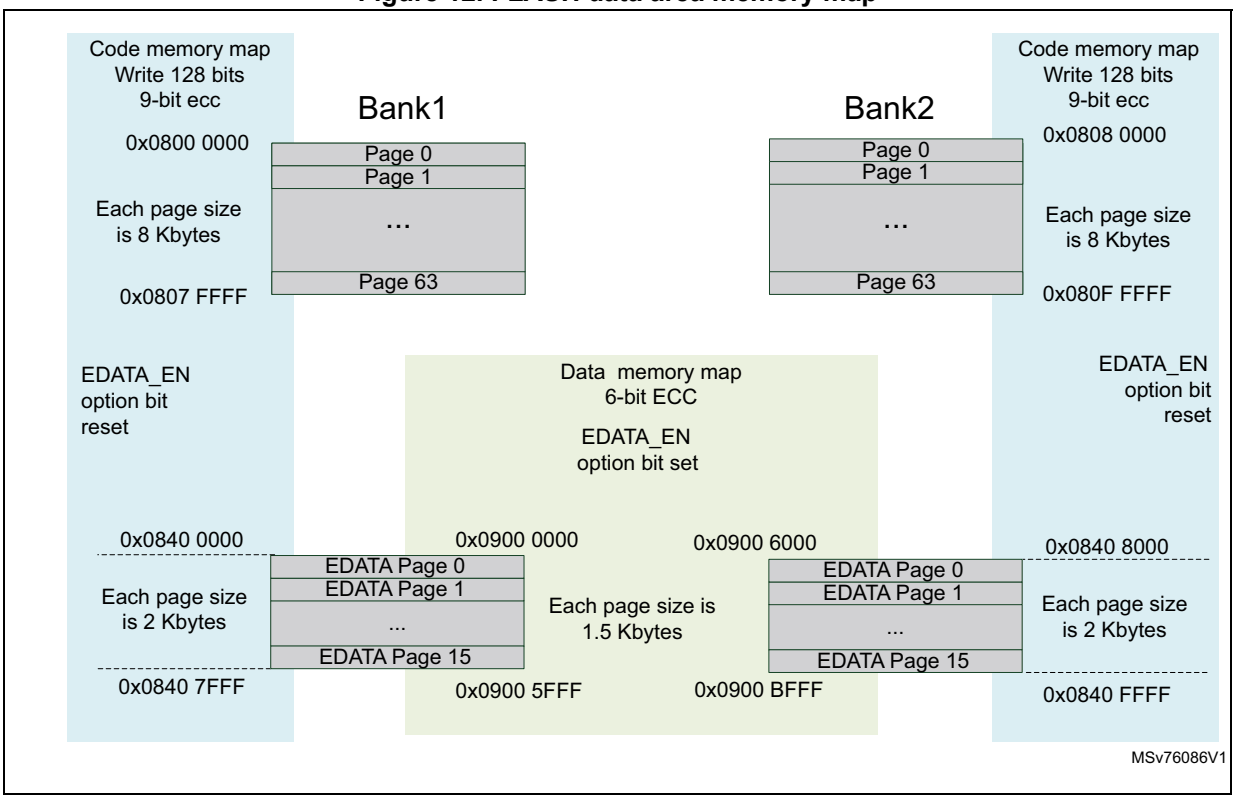
A bus error is generated on:

- Attempt to access one of the following address
  - Between 0x0900 0000 to 0x0900 BFFF, and this address is not a data FLASH valid page.
  - Between 0x0840 0000 to 0x0840 FFFF, and this address is not a user memory valid page.
- Attempt to fetch instructions from data FLASH area (fetch from 0x0900 0000 to 0x0900 BFFF result in HardFault).

Erasing these EDATA pages is possible by setting the EDATASEL bit and following a page erase request. The EDATA page erasure is not taking account EDATA_EN bit.

Protections and security of data FLASH area are detailed in *Section 6.5*.

Figure 12. FLASH data area memory map



6.3.11 FLASH bank swapping

The FLASH bank1 and bank2 can be swapped for the user FLASH. This feature can be used after a firmware upgrade to restart the device on the new firmware. Bank swapping is a user option-byte flag controlled by the SWAP_BANK bit in FLASH_OPTCR register.

Bank specific settings for data area and security attributes follow the original bank and its contents. The control bit BKSEL always refers to physical bank, not the SWAP_BANK setting.

Table 24 shows the memory map that can be accessed depending on the SWAP_BANK bit configuration.

Table 24. Memory map and the swapping option (STM32C53x/542 devices)

The SWAP_BANK bit in FLASH_OPTCR register is loaded from the SWAP_BANK option bit only after system reset or POR.

To change the SWAP_BANK bit (for example to apply a new firmware update), respect the sequence below:

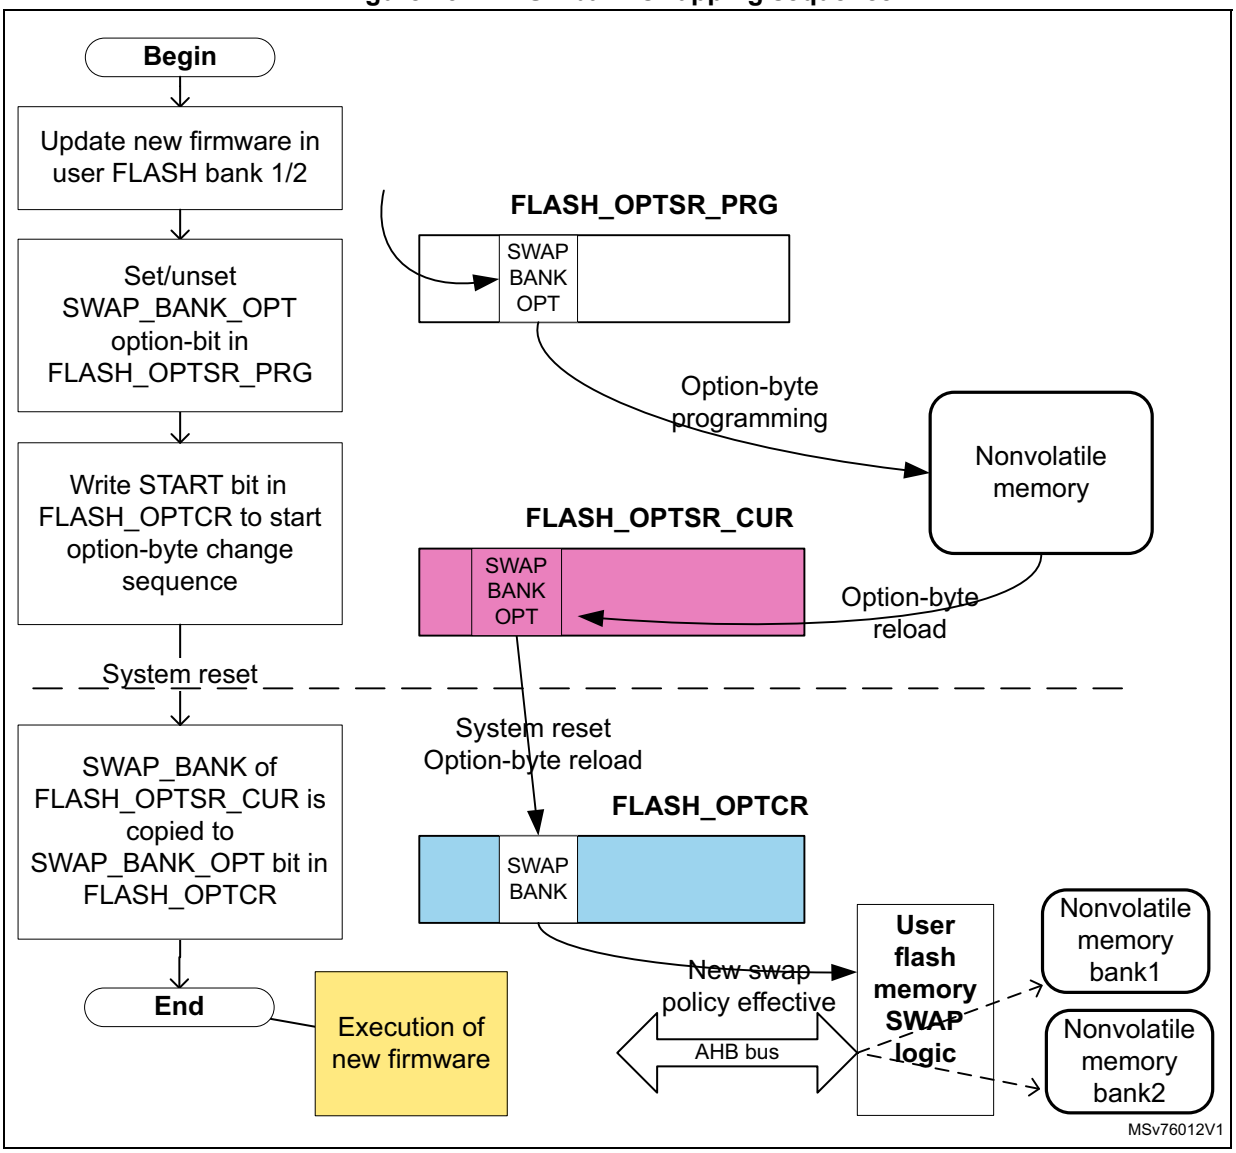
1. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in FLASH_SR, and that the write buffer is empty by checking the WBNE bit in the same register.
2. Clear all error flags due to a previous operation.
3. Unlock OPTLOCK bit, if not already unlocked.
4. Set the new desired SWAP_BANK value in the FLASH_OPTSR_PRG register.
5. Start the option-byte change sequence by setting the OPTSTRT bit in FLASH_OPTCR.
6. Once the option-byte change has completed, FLASH_OPTSR_CUR contains the expected SWAP_BANK value, but SWAP_BANK bit in FLASH_OPTCR has not yet been modified, and the bank swapping is not yet effective
7. Force a system reset or a POR. When the reset rises up, the bank swapping is effective (SWAP_BANK value updated in FLASH_OPTCR) and the new firmware must be executed.

Note: The SWAP_BANK bit in FLASH_OPTCR is read-only and cannot be modified by the application software.

The SWAP_BANK option bit in FLASH_OPTSR_PRG can be modified whatever the RDP level. Instead of being locked by RDP_LEVEL, it is locked by BOOT_LOCK User OB.

The figure below gives an overview of the bank swapping sequence.

Figure 13. FLASH bank swapping sequence



6.3.12 FLASH reset and clocks

Reset management

The FLASH can be reset by a core domain reset, driven by the reset and clock control (RCC). The main effects of this reset are the following:

- All registers, except for option-byte registers, are cleared, including read and write latencies. If the bank swapping option is changed, it is applied.
- Most control registers are automatically protected against write operations. To unprotect them, new unlock sequences must be used as described in *Section 6.5.4*.

The FLASH can be reset by a power-on core domain reset, driven by the RCC. When the reset falls, all option-byte registers are reset. When the reset rises up, the option bytes are

loaded, potentially applying new features. During this loading sequence, the device remains under reset and the FLASH is not accessible.

Reset occurring during FLASH operation

If a reset occurs during a FLASH operation (programing, erase, or option change), the content of the flash memory is not guaranteed. It is mandatory for flash memory integrity than user restarts the operation. The status register FLASH_OPSR gives information if any FLASH operation has been interrupted by a reset.

FLASH_OPSR.CODE_OP gives opcode of operation. The table below indicates how to use FLASH_OPSR and which operation is required.

Table 27. Recommended reactions to FLASH_OPSR contents

CODE_OP	Operation interrupted	OTP_OP	BK_OP	DATA_OP	Flash memory area	ADDR_OP min	ADDR_OP max	Recommended action
0b000	No operation ongoing while reset	0	0	0	-(1)	-	-	No extra action
0b001	Write operation	0	0/1	0	User flash	0x0000	0x7FFF(2)	Erase page and rewrite
		1	1	0	OTP(3)	0x0200	0x037F	
		0	0/1	1	EDATA Page(4)	0x0000	0x07FF(2)	
0b011	Page erase(5)	0	0/1	0	User flash	0x0000	0x7FFF	Relaunch page erase
		0	0/1	1	EDATA Page	0x0000	0x07FF	
0b100	Bank erase	0	0/1	0	User flash	-	-	Relaunch bank erase
0b101	Mass erase	0	0	0		-	-	Relaunch mass erase
0b110	Option change	0	0	0	User configuration	-	-	New attempt on option change

1. '-' = does not matter.
2. ADDR_OP maximum depends on the flash memory size of the device.
3. OTP are organized per column, refer to *Section 6.3.9*.
4. Depends on EDATA setting in the OB.
5. Addresses indicated are aligned to page start, data area pages are erased by erase request to corresponding user flash memory page.

Clock management

The FLASH uses the microcontroller AHB interface clock HCLK.

6.4 FLASH option bytes

6.4.1 About option bytes

The FLASH includes a set of nonvolatile option bytes. They are loaded at power-on reset and can be read and modified only through configuration registers.

This section documents:

- When option bytes are loaded.
- How application software can modify them.
- The detailed list of option bytes, together with their initial values (before the first option byte change, user default configuration).

6.4.2 Option-byte loading

There are multiple ways of loading the option bytes into the FLASH:

1. Power-on wake-up

   When the device is first powered, the FLASH automatically loads all the option bytes. During the option-byte loading (OBL) sequence, the device remains under reset, and the FLASH cannot be accessed.

2. Wake-up from system Standby mode

   When the core power domain, which contains the FLASH, is switched from Standby mode to Run mode, the FLASH behaves as during a power-on sequence. During OBL time, the device is not under reset, unlike power-on sequence.

3. Dedicated option-byte reloading by the application

   When the user application successfully modifies the option-byte content through the FLASH registers, the nonvolatile option bytes are programmed, and the FLASH automatically reloads all option bytes to update the option registers.

Note: The option-byte read sequence is protected by error correction code.

In case of error, the option bytes are loaded with default values (see Section 6.4.3). This value differs from the initial values (user default configuration), and tends to be more restrictive.

6.4.3 Option-byte modification

Changing user option bytes

A user-option-byte change operation can be used to modify the configuration and the protection settings saved in the nonvolatile option byte area.

There are numerous rules enforced when attempting to change a user option byte, they are all summarized in *Section 6.4.9*. Failing to stick to these rules usually results in error, described in *Section 6.8.6*.

The FLASH features two sets of option-byte registers:

- The first register set contains the current values of the option bytes. Their names have the _CUR extension. All "_CUR" registers are read-only. Their values are automatically loaded from the nonvolatile memory after power-on reset, wake-up from system Standby mode, or after an option-byte change operation.
- The second register set allows the modification of the option bytes. Their names contain the _PRG extension. All "_PRG" registers can be accessed in read/write mode.

When the OPTLOCK bit in FLASH_OPTCR is set, modifying the FLASH_XXX_PRG registers is not possible.

When OPTSTRT bit is set to 1, the FLASH checks the programming sequence (PGSERR), and the conditions described in *Section 6.4.9* (OPTCHANGEERR). If no error has been detected (PGSERR/OPTCHANGEERR), the FLASH launches the option-byte modification in its nonvolatile memory, and updates the option-byte registers with _CUR extension.

If one of the condition described in *Section 6.4.9*, *Section 6.8.6*, or *Section 6.8.2* is not respected, the FLASH aborts the option-byte change operation. In this case, FLASH_XXX_PRG registers are not overwritten by current option value. The user application can check what was wrong in their configuration.

Unlocking the option-byte modification

After reset, the OPTLOCK bit is set to 1 and FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option bytes. FLASH_OPTCR unlock sequence is described in *Section 6.5.4*.

Option-byte modification sequence

To modify user option bytes, follow the sequence below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in FLASH_SR, and that the write buffer is empty by checking the WBNE bit in the same register.
2. Check the data buffer is empty (DBNE = 0) in FLASH_SR.
3. Clear all error flags due to a previous operation.
4. Unlock FLASH_OPTCR register as described in *Section 6.5.4*, unless the register is already unlocked.
5. Write the desired new option byte values in the corresponding option registers (FLASH_XXX_PRG).
6. Set the option byte start change OPTSTRT bit to 1 in FLASH_OPTCR.
7. Wait until BSY bit is cleared in FLASH_SR.
8. OPTSTRT bit is cleared automatically at the end of the sequence (or in case of error).

9. Perform a system reset if the RDP level, SWAP_BANK, or BOOTADD options have been changed. A system reset is also recommended if other option bytes have been modified.

Note: If a reset or a power-down occurs while the option-byte modification is ongoing, the original option-byte value is kept. A new option-byte modification sequence is required to program the new value

6.4.4 Option-byte overview

Table 28 lists all the user option bytes managed through the FLASH registers, as well as initial values before the first option-byte change (user default configuration).

6.4.5 Description of user and system option bytes

The general-purpose option bytes that can be used by the application are listed below:

- Bank management
  - SWAP_BANK: bank swapping option, set to 1 to swap user FLASH banks after boot (see *Section 6.3.11*).
  - SINGLE_BANK: this bit is applicable for:
    - STM32C53x/542 with 128 Kbytes of flash
    - STM32C55x/562 with 256 Kbytes of flash
    - STM32C59x/5A3 with 512 Kbytes of flash

    If SINGLE_BANK = 1, the available user memory is located in a single bank. Otherwise, the device works in dual-bank mode. In any case, the address range is kept linear.
- Watchdog management
  - IWDG_STOP: independent watchdog IWDG counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_STDBY: independent watchdog IWDG counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_SW and WWDG_SW: hardware (0) or software (1) IWDG watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STDBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode, respectively. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - NRST_STDBY: generates a reset when entering Standby mode if cleared to 0.
  - NRST_STOP: generates a reset when entering Stop mode if cleared to 0.

Note: Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STDBY (respectively NRST_STOP) is cleared to 0.

- Bootloader configuration

  After reset, if the STMicroelectronics bootloader is selected as boot location, it reads the contents of BL_COM_CFG, and only attempts to establish communication on selected interfaces. This setting allows using the bootloader safely in applications where it otherwise may cause trouble by reconfiguring some GPIOs.

When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- Watchdog management
  - IWDG active in Standby and Stop modes (option value = 0x1)
  - IWDG not automatically enabled at power-on (option byte value = 0x1)
- Reset management:
  - A reset is not generated when the device enters Standby or Stop low-power mode (option byte value = 0x1)

Refer to *Section 6.10* for details.

6.4.6 Description of data protection option bytes

The option bytes that can be used to enhance data protection are listed below:

- RDP_LEVEL[7:0]: product lifecycle state (see *Section 6.5.8* for details)
- WRP1/2: write-protection option of pages in bank1 (respectively bank2). It is active low. Refer to *Section 6.5.5* for details.

Table 29. Write-protection management

WRP bit number	Write-protected pages	
	STM32C53x/542/55x/562	STM32C59x/5A3
Bit 0	Page 0	Page [0 to 1]
Bit 1	Page 1	Page [2 to 3]
…	…	…
Bit N	Page N	Page [2 x N to 2 x N +1]

- HDPx: HDPL exclusive area control in the user flash memory.

When factory programmed, values of the data-protection option bytes are the following:

- Read-out protection level: L0 (Open)
- Write protection disabled (all option byte bits set to 1)

Refer to *Section 6.10* for details.

6.4.7 Description of data FLASH option bytes

The option bytes that can be used to address the data FLASH pages are:

- EDATA_EN: activate data FLASH area for this device (see *Section 6.3.10* for details).

6.4.8 Description of boot-address option byte

Below the list of option bytes that can be used to configure the appropriate boot address for an application:

- RDP_LEVEL: Influences the boot sequence indirectly.
- BOOTADD: Selects default boot address.
- BOOT_LOCK: Protects the boot configuration from further modification attempts.
- SWAP_BANK: bank swapping option, set to 1 to swap user FLASH banks after boot (see *Section 6.3.11*). If BOOT_LOCK is active, the value in SWAP_BANK is fixed, read-only.
- BOOT0 management
  - BOOT0: This option bit is the value of BOOT0 used depending on BOOT_SEL to select boot location. BOOTLOADER (1) or User code(0).
  - BOOT_SEL: BOOT0 value is taken from option bit (0) or from BOOT0 pin (1)

When STMicroelectronics delivers the device, the RDP_LEVEL is L0, BOOT_LOCK is not set (0xC3). Address BOOTADD is 0x0800 0000.

Refer to *Section 6.10* for details.

6.4.9 Specific rules for modifying option bytes

Besides the OPTLOCK bit and register access rules, there are additional protection means for selected security-sensitive option byte fields.

Multiple option bytes can be modified simultaneously, but if they rely on each other for protection, both states are checked.

With few exceptions listed in this section, failing to uphold the rules results in raising OPTCHANGEERR flag (*Section 6.8.6* for additional details).

Table 30. Specific OB modifying rules overview

OB	HDPL	Value	RDP level
RDP_LEVEL	-	Set of possible transitions	Set of possible transitions (*Table 36*)
HDP	1(1)	-	-
BOOTADD	-	-	L0 open
LOCKBL	-	One way switch(1)	-
SWAP_BANK	-	BOOT_LOCK can restrict this change	-
BOOT_LOCK	-	-	L0 open

1. No OPTCHANGEERR is raised in violation of this.

Even in the closed RDP_LEVEL progression, some OBs can still be modified, if all the other constraints are satisfied. An overview is presented in the table below.

Table 31. OBs modifiable in L2 product

RDP_LEVEL	OBs that can be modified
L2_wBS or L2	SWAP_BANK, LOCKBL, RDP_LEVEL

Specific rules must be respected to update the following OBs:

- **RDP_LEVEL:** its transitions follow a state machine with two types of transition. Locking down the product is allowed without restriction. Opening the product is only possible under the condition that OEM key were provisioned ahead. The regression to L0 RDP_LEVEL results in the erasing of the protected content (see *Section 6.5.8*).
- **HDP:** Can only be modified in HDPL0 and HDPL1.
- **BOOTADD:** Can only be changed in Open RDP L0 (open).
- **LOCKBL:** Can only be changed freely in one direction. A permanent irreversible switch.
- **SWAP_BANK:** Cannot be modified when BOOT_LOCK is active (0xB4).
- **BOOT_LOCK:** Can only be changed freely in locking direction. Unlock is possible in L0.

Note: For all user option bytes above, default values are loaded and Tamper is signaled when a double ECC error occurs during OBL.

6.5 FLASH security and protections

Since sensitive information are stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of immutable pages, or malicious flash memory erasing.

For that purpose, the flash memory implements the following protection mechanisms:

- Temporal isolation protection (HDP)
- Configuration protection
- User FLASH write protection
- Device boot state management
- OTP locking

This section provides a detailed description of all these security mechanisms.

The flash memory interface evaluates the access restrictions in the following order:

1. Write protection (for write access)
2. HDP

6.5.1 Hide protection (HDP)

A nonvolatile hide-protection (HDP) area per bank can be defined with a page granularity. Access to the hide-protection area can be denied by progressing the HDPL level in the SBS.

When the HDPL = 1, no user FLASH is protected by the HDP. With HDPL ≥ 2, the user OB defined HDP area in each bank is closed. No read, write, fetch, or erase is allowed in the HDP area.

The HDP area can be extended. The extension setting is only a register value, not stored in the OB. With HDPL = 3, the HDP area remains activated and the extension is added. If an extension is added while the base user OB defined area is not active, the extension covers one more page, because HDPx_END page is also protected.

The HDPL level can be only cleared by a system reset, there is no means to deactivate the HDP area.

The protected HDP area is defined by setting its size using start and end pages .

The size of the inaccessible area can be extended using register FLASH_HDPEXTR values HDPx_EXT. The value HDPx_EXT is a number of pages added to the HDP area (past the HDPx_END page). The volatile HDPx_EXT value in the register can be increased, but cannot decrement.

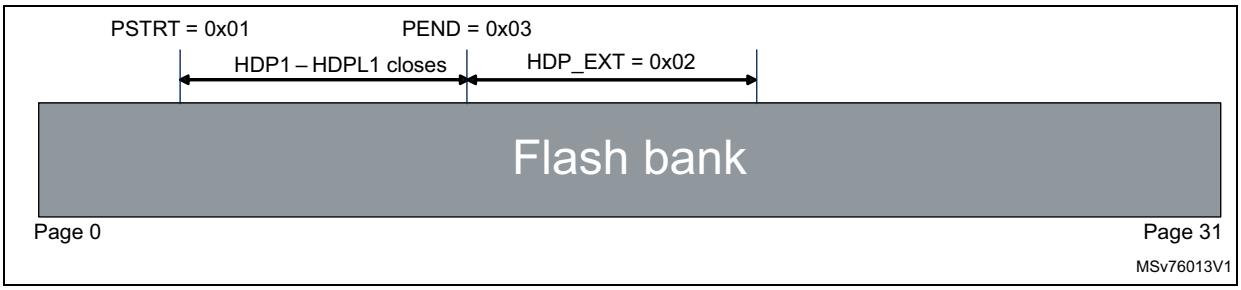
In case of HDPx_STRT > HDPx_END, the extension covers (HDPx_EXT + 1) size area between pages marked by HDPx_END and HDPx_END + HDPx_EXT.

By default, the HDPx_END is set to zero and HDPx_STRT is set to one. This means that the HDP area in user FLASH is zero size, and extends from the FLASH start address (first page).

For example, to protect area by HDP from 0x0800 2000 (included) to 0x0800 7FFF (included):

- For physical bank1, the option-byte registers must be programmed with:
  - HDP1_STRT = 0x01,
  - HDP1_END = 0x03.

Figure 14. HDP in user flash memory



- Once the HDPL is incremented to 2, the marked area becomes inaccessible.
  The HDPL = 2 code then sets the extension size to 2. Once the HDPL is incremented to 3, the extension area becomes also inaccessible.

  Alternatively, if:
  - HDP1_END = 0
  - HDP1_START = 1
  - HDPx_EXT = 1

  Page 0 and page 1 are HDP protected.

  Or a rather unusual example:
  - HDP1_END = 2
  - HDP1_START = 7
  - HDPx_EXT = 3
- Pages 2 until 5 are HDP protected. Here the user must know that, if the application needs pages 2 until 4 only as HDP area, HDPx_EXT must be programmed at 2 instead of 3.
- If the two banks are swapped, the protection defined to physical bank1 remains on the physical bank1, unaffected by swapping. Separate protection applies to physical bank2 and the option bytes registers must also be programmed with:
  - HDP2_STRT = 0x01
  - HDP2_END = 0x03

Note: For more details on the bank-swapping mechanism, refer to Section 6.5.3.

Table 32. Secure hide protection

HDPx watermark option byte values (x = 1, 2)		Hide protection area
HDPL = 1	-	No inaccessible HDP area in user flash memory
HDPL = 2	HDPx_END < HDPx_STRT	No inaccessible HDP area in user flash memory
	HDPx_END = HDPx_STRT	Exactly one page is protected by HDP
	HDPx_END > HDPx_STRT	The area between HDPx_STRT and HDPx_END is HDP protected.
HDPL = 3	HDPx_END < HDPx_STRT and HDPx_EXT = 0	No inaccessible HDP area in user flash memory
	HDPx_END < HDPx_STRT and HDPx_EXT > 0	The area betwen (HDPx_END + HDPx_EXT) is HDP protected
	HDPx_END ≥ HDPx_STRT and HDPx_EXT > 0	The area between min (HDPx_STRT, HDPx_END) and (HDPx_END + HDPx_EXT) is HDP protected

Table 33. HDP protections summary

HDP protection	User flash memory			
	Access to OB HDP area		Access to EXT HDP area	
	HDPL 2 or 3	HDPL1	HDPL3	HDPL1 or HDPL 2
Fetch	BUS ERROR	OK	BUS ERROR	OK
Read	RAZ		RAZ	
Write	WI, WRPERR	If WRP disabled: OK else: WI, WRPERR	WI, WRPERR	If not WRP: OK Else: WI, WRPERR
Erase (mass erase)				

6.5.2 Flash memory register privileged and unprivileged modes

The FLASH registers can be read and written by privileged and unprivileged accesses, depending on the PRIV bit in FLASH_PRIVCFGR.

- When the PRIV bit is reset, all flash memory registers can be read and written by both privileged or unprivileged access.
- When the PRIV bit is set, all flash memory registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

6.5.3 Flash memory banks attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, FLASH bank1 is mapped at the lower address range. When SWAP_BANK is set, FLASH bank1 is mapped at the higher address range. FLASH

bank attributes follow their bank contents so there is no need to modify their setting registers when swapping banks:

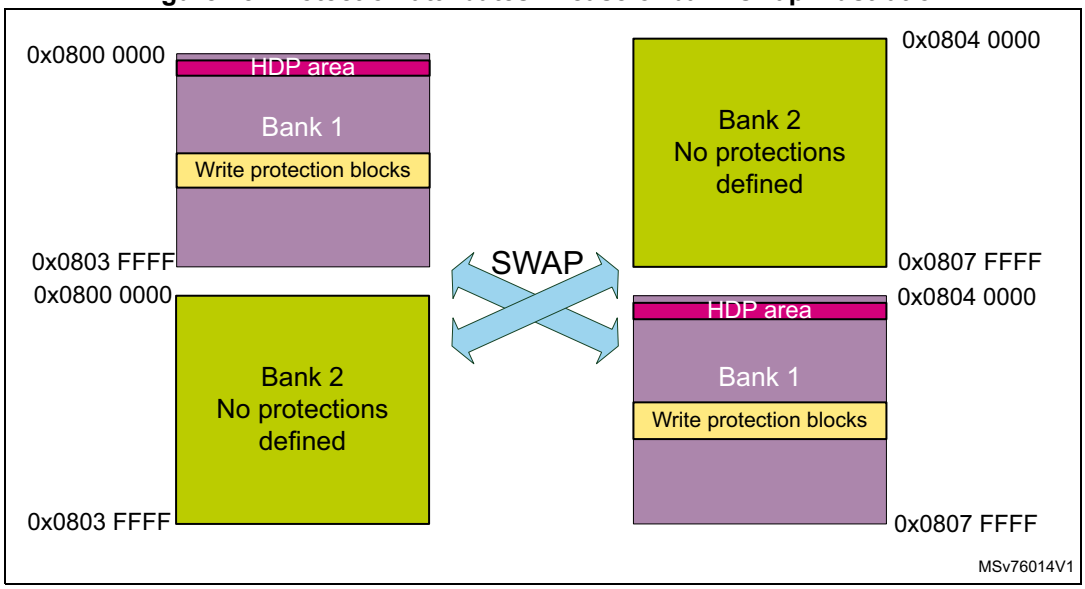
- FLASH write protection page FLASH_WRPG (refer to *Section 6.5.5*)
- Hide protection in FLASH_HDPx registers

The SWAP_BANK is rendered immutable by setting BOOT_LOCK.

Note: The BK_ECC bit in FLASH_OEMKEYR2_CUR and FLASH_ECCDETR, BKSEL bit in FLASH_CR always refers to bank1 (respectively bank2) when it is low (respectively high), regardless of the SWAP_BANK value.

The figure below shows how security attributes and protections behave in case of bank swap.

Figure 15. Protection attributes in case of bank swap illustration



6.5.4 Flash memory configuration protection

The FLASH uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (such as software bugs):

- Option-byte changes
- Write operations
- Erase commands
- Interrupt masking

The FLASH configuration registers protection is summarized in *Table 34*. Registers not present in this table are not protected by a key.

Table 34. FLASH interface register protection summary

Register name	Unlocking register	Protected asset
FLASH_CR	FLASH_KEYR	Write/erase control
FLASH_OPTCR	FLASH_OPTKEYR	FLASH bank option-byte words change

6.5.5 Write protection

The purpose of FLASH write protection is to prevent unwanted modifications to embedded nonvolatile code and/or data.

A write-protected group of pages can neither be erased nor programmed. As a result, a bank erase cannot be performed if some page is write-protected, unless a RDP level transition to L0 is triggered (erasing the whole user flash memory).

Note: Write protection errors are documented in Section 6.8.

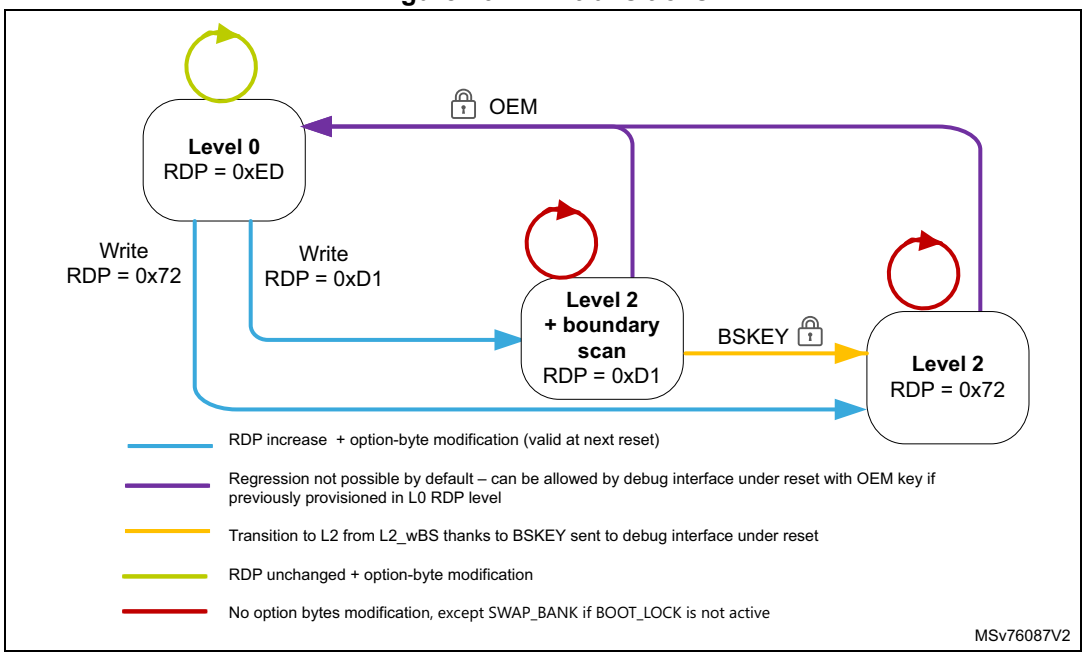
6.5.6 FLASH data area protections

The FLASH can be configured to have 64-Kbyte (or 48-Kbyte if EDATA_EN is set) memory area to store data and emulate EEPROM (see *Section 6.3.10: FLASH data area*). These pages can not be protected by HDP or WRPGS whatever the setting of EDATA_EN.

6.5.7 RDP protection and life cycle management

Nonvolatile states, or debug states, are determined by the RDP levels set by user option bytes. Debug possibility and possibility to change selected security settings are related to this state. While the state is stored in the OB, it is the SBS that controls the debug policy.

Figure 16. RDP transitions



HDP works equally regardless of the RDP level.

Table 35. RDP levels description

RDP_LEVEL	Code in OB	Description
L0 (Open)	0xED	– Full debug capabilities – Read/Write/Erase Flash is possible – Read/Modify the option bytes – Boot in bootloader or user flash based on BOOT0 pin or option bytes – Boundary scan available under reset
L2_wBS (Closed + boundary scan)	0xD1	– No debug capabilities – Read/Write/Erase Flash is possible – All option bytes Read by user code – SWAP_BANK (depending on BOOT_LOCK) & LOCKBL (for OTP) option bytes can be modified – Boot in user flash only – Boundary Scan available under reset
L2 (Closed)	0x72	– No debug capabilities – Read/Write/Erase Flash is possible – All option bytes Read by user code – SWAP_BANK (depending on BOOT_LOCK) & LOCKBL (for OTP) option bytes can be modified – Boot in user flash only

Caution: STMicroelectronics cannot functionally analyze parts with level 2 protection enabled. Regress parts to RDP level 0 before returning them for analysis (refer to OEM RDP lock mechanism).

6.5.8 RDP level transitions

Progressing to more closed levels is the normal product life cycle, that does not require security measures. Transition in direction to open level (RDP Level 0) is a regression, and is possible only thanks to the OEM Key.

There is no restriction on reading the current RDP level.

Transitions to L2 with boundary scan (L2_wBS) or L2 (L2) closed states

Transition from L0 to L2 with or without boundary scan is managed either by software running on the device, or directly, using a debug interface. By software, it is assumed that transitions are triggered by the bootloader, but generally any software running on the device can do a progress transition.

Caution: The new RDP Level will only be valid after next system or power reset.

Transition from L2 with boundary scan to L2 is only feasible thanks the BSKEY option-byte key:

- If the BSKEY key have not been modified under L0 state, the default value apply.
- If the BSKEY key have been modified under L0 state, the user must apply the key populated.

This key must be written under reset and L2 with boundary scan thanks to JTAG in order to progress to L2 RDP level.

Regression to L0 open debug level

This transition is a full regression, possible from either L2_wBS or L2 if an OEM key has been provisioned. The debug tools are used to provide the OEM key, if the key matches the one provisioned under L0, the device regresses securely in RDP L0.

The regression has the following consequences:

- RDP level updated
- User options updated (security settings reset)
- Flash memory mass erase (even write protected pages)

Table 36. RDP levels transitions

From	To(1)		
	L0	L2_wBS	L2
L0	-	OB update thanks to debug or bootloader	
L2_wBS	OEM key regression	-	BSKEY
L2	OEM key regression	X	-

1. ‘X’ = transitions that are not permitted (OPTCHANGEERR raised). ‘-’ = no change.

An attempt to make a illegal transition results in the OPTCHANGEERR.

An incorrect RDP_LEVEL (on OBL) is interpreted as L2.

6.5.9 OEM key management

The OEM 128-bit key (OEMKEY) can be defined in order to permit the RDP regression.

OEM lock activation

The 128-bit key is coded on four registers: FLASH_OEMKEYR1 to FLASH_OEMKEYR4. OEMKEY and BSKEY cannot be read through these registers. They are read as zero.

Caution: OEMKEY can only be modified in readout protection level 0.

In order to activate OEM regression mechanism, the following steps are needed:

1. Check that the RDP is at L0.
2. Write a 128-bit key in FLASH_OEMKEYR1 to FLASH_OEMKEYR4.
3. Launch option modification by setting the OPTSTRT bit in FLASH_CR.
4. Wait for the BSY bit to be cleared and check that OPTWERR is not set.
5. Check that OEMLOCK is set.

Note: Once the OEM KEY has been programmed a first time, the OEMLOCK bit remains set. The user can reprogram the key, but cannot erase it.

OEM key validation mechanism

The OEM RDP lock mechanism is active when the OEMLOCK bit is set. The OEMKEY, can

be validated while in RDP L0.

- Shift OEMKEY[31:0], then OEMKEY[63:32], then OEMKEY[95:64], then OEMKEY[127:96] through JTAG or SWD under reset in DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEMKEY value:
  - A status bit in DBGMCU_DBG_VALR indicates that the adequate key has been successfully entered, a power sequence is required to clear the validation status bit. Omitting this step will prevent to enter RDP Level 2.
- If the key does not match the OEMKEY value, a power sequence is required to clear the validation status bit and retry.

OEM RDP regression mechanism

The OEM RDP lock mechanism is active when the OEMLOCK bit is set. It authorizes RDP L2 to RDP L0 regression.

- Shift OEMKEY[31:0,] then OEMKEY[63:32], then OEMKEY[95:64], then OEMKEY[127:96] through JTAG or SWD under reset in DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEMKEY value:
  - The RDP regression is launched by hardware when the reset is released (it is not possible to execute instructions when the key is matching).
  - A power-on reset must be applied (cycle V_{DD} power supply off and on).
- If the key does not match the OEMKEY value, the RDP regression is blocked until next power-on reset.

6.5.10 BS key management

The BS key is used to transition from RDP L2_wBS to L2. This key is coded in FLASH_BSKEYR, and can be modified only under RDP L0. During production, the value 0xAAAA AAAA is preprogrammed in BSKEY option bytes.
In order to personalize BSKEY transition mechanism, the following steps are needed:

1. Check that the RDP is at L0.
2. Write the desired key in FLASH_BSKEYR.
3. Launch option modification by setting the OPTSTRT bit in FLASH_CR.
4. Wait for the BSY bit to be cleared and check that OPTWERR is not set.
5. Check that BSLOCK bit has been set.

BSKEY RDP transition mechanism

In order to transition from RDP L2_wBS to L2 follow these steps:

1. Provide BSKEY[31:0] through JTAG or SWD under reset in DBGMCU_BSKEY_PWD. The key is 0xAAAA AAAA if not updated under L0, otherwise it is the value provisioned in BSKEYR.
2. If this key matches the BSKEY value:
   - The RDP transition is launched by hardware (it is not possible to execute instructions when the key is matching).
   - A power-on reset is applied (cycle V_{DD} power supply off and on).

if the key does not match the BSKEY value, the RDP transition and any access to the flash memory are blocked until a next power-on reset.

6.5.11 One-time-programmable and read-only memory protections

OTP/RO in the flash memory are detailed in *Section 6.3.9*. There is no protection provided by the FLASH interface other than the dedicated write protection.

No write is possible to the RO area, once it was established in manufacturing. *OTP write protection* describes a method of locking out the OTP area.

The access conditions are summarized in the table below.

Table 37. OTP/RO access constraints

-	**Undefined addresses**	**4.5-Kbyte page dedicated to OTP**	**1.5-Kbyte page dedicated to RO**
	0x08FF_F200 - F7FF 0x08FF_FE00 - FFFF	**0x08FF_E000 - F1FF OTP**	**0x08FF_F800 - FDFF RO**
X	Bus error	Bus error	
R		If correct size OK, else bus error	
W		Bus error if incorrect size. WRPERR if block is protected by LOCKBL, else OK.	If correct size WI, else bus error
erase	Not applicable		

6.6 System memory

6.6.1 System memory introduction

System memory stores bootloader firmware that is programmed by ST during production. The bootloader provides runtime services to user firmware. These services are described hereafter in this section.

6.6.2 Bootloader user functions

As other microcontroller peripherals features and mapping, the bootloader library functions are exposed to user within the CMSIS device header file provided by the STM32CubeC5 firmware package. Refer to the online HAL/LL drivers documentation to get more details regarding STM32CubeC5 firmware package. Bootloader library provides runtime services through prefixed EXITHDP functions.

Table 38. C defined macro for HDP services

C defined macro	Location in flash memory
EXITHDP_PFUNC	0x0BF883E0

EXITHDPLIB

The user firmware calls EXITHDPLIB functions using EXITHDPLIB_PFUNC C defined macro, that points to a location within system memory.

Table 39. EXITHDPlib interface function list

Library	Function
EXITHDP_PFUNC	JumpHDPLvl2
	JumpHDPLvl3

The EXITHDPLIB functions are described within section hereafter.

a) JumpHDPLvl2

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
EXITHDPLIB_PFUNC->JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:

Input parameter, address of the next vector table to apply.

The vector table format is the one used by the Cortex-M33 core.

- MPUIndex:

Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the Reset Handler of the vector table. The vector table Reset Handler function shall belong to the MPU region.

Descriptions:

User calls JumpHDPLvl2 to:

- Close user Flash HDPL1 area by incrementing HDPL to 2
- Jump to the reset handler embedded within the Vector Table which address is passed as input parameter

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed Vector Table and jumps to the Reset Handler function supported by the Vector Table too. JumpHDPLvl2 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

Errors:

In case of failure (bad input parameter value), EXITHDPLIB_Sec_JumpHDPLvl2 returns 0xF5F5F5F5.

b) JumpHDPLvl3

Prototype

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
EXITHDPLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  Input parameter, address of the next vector table to apply.
  The vector table format is the one used by the Cortex-M33 core.
- MPUIndex:
  Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the Reset Handler of the vector table. The vector table Reset Handler function shall belong to the MPU region.

Descriptions:

User calls JumpHDPLvl3 to:

- Close user Flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3
- Then jump to the reset handler embedded within the Vector Table which address is passed as input parameter

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed Vector Table and jumps to the Reset Handler function supported by the Vector Table too. JumpHDPLvl3 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

Errors:

In case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

6.7 FLASH low-power modes

The table below summarizes the FLASH behavior in STM32 low-power modes. The FLASH belongs to the core domain.

Table 40. Effect of low-power modes on the FLASH

Power mode	Allowed if FLASH busy	FLASH power mode
Run/Sleep	Yes	Run
Stop (clock stopped)	No	Clock gated (in normal or low-power mode)
Standby	No	Off

The procedure to switch the FLASH into various power mode (run, clock gated, stopped, off) is described hereafter.

Note: For more information on microcontroller power states, refer to Section 8: Power control (PWR).

Managing FLASH domain switching to Stop or Standby mode

As explain in *Table 40*, if the FLASH informs the RCC that it is busy (BSY, DBNE, WBNE is set), the microcontroller cannot switch the core domain to Stop or Standby mode.

There are two ways to release the FLASH:

- Reset the WBNE busy flag in FLASH_SR by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling the missing data by activating the FW bit in FLASH_CR. This forces all missing data “high”.
- Poll BSY busy bits in FLASH_SR until they are cleared. This indicates that all recorded write, erase, and option change operations are complete.

The microcontroller can then switch the domain to Stop or Standby mode.

6.8 FLASH error management

The FLASH automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- Write protection error (WRPERR) (*Section 6.8.1*)
- Programming sequence error (PGSERR) (*Section 6.8.2*)
- Error correction code error (ECCC/ECCD) (*Section 6.8.3*)
- Option-byte change error (OPTCHANGEERR) (*Section 6.8.4*)

The application software can individually enable the interrupt for each error, as detailed in *Section 6.9*.

Note: For all errors, the application software must clear the error flag before attempting a new modify operation.

Since there is just one write buffer and only one operation is allowed at a time, the write control bits and status bits are shared by both banks:

- Write control bits (PG, FW, EOPIE, WRPERRIE, PGSERRIE, STRBERRIE, INCERRIE, CLR_EOP, CLR_WRPERR, CLR_STRBERR, CLR_INCERR, CLR_PGSERR) controls bank1 and 2 at the same time.
- Write status flag reports (WBNE, DBNE, EOP, WRPERR, PGSERR, STRBERR, INCERR, BSY) error for bank1 and 2 at the same time.

6.8.1 Write protection error (WRPERR)

When an illegal erase/program operation is attempted to the nonvolatile memory, the FLASH sets the write protection error flag WRPERR in FLASH_SR.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A page write-protected with WRP.
- An HDP area while the HDPL has made it inaccessible.

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- The system flash memory
- A user page write-protected with WRP
- An OTP block, locked with LOCKBL
- A reserved area

When WRPERR flag is raised, the operation is rejected and nothing is changed in the corresponding bank.

If this error is detected the write buffer is invalidated.

Note: WRPERR flag has to be cleared before any erase/program operation.

WRPERR flag is cleared by setting CLR_WRPERR bit to 1 in FLASH_CCR.

If WRPERRIE bit in FLASH_CR is set to 1, an interrupt is generated when WRPERR flag is raised (see *Section 6.9* for details).

6.8.2 Programming sequence error (PGSERR)

When the programming sequence is incorrect, the FLASH interface sets the programming sequence error flag PGSERR in FLASH_SR.

More specifically, PGSERR flag is set when one of below conditions is met:

- An error like INCERR, WRPERR, PGSERR, STRBERR, OPTCHANGEERR have not been cleared before requesting a new write or erase operation or options change.
- For erase, PGSERR is set:
  - If missing erase operation (FLASH_CR): STRT = 1 with (MER = 0, PER = 0, and BER = 0)
  - If page and bank erase requested at the same time (STRT and more than one of MER, PER and BER)
  - If PG is set during erase operation (it ensures that no erase request and write request happen at the same time): (STRT = 1) with (PG = 1)
  - If an erase operation is started while write buffer is waiting for next data: (STRT = 1) with WBNE = 1.
  - If an erase operation is started while DBNE = 1.

- For programming, PGSERR is set:
  - If missing write flag: A write operation is requested but the program enable bit PG has not been set in FLASH_CR prior to the request.
  - If a write operation to flash data area is requested but PG = 0.
  - If an AHB write request is received and (PER = 1, BER = 1, or MER = 1)
  - If a 16-bit data access requested while WBNE = 1.
- For options change, PGSERR is set:
  - If an option change is started while write buffer is waiting for next data: OPTSTRT = 1 with WBNE = 1
  - If OPTSTRT is set with DBNE = 1.

When PGSERR flag is raised as consequence of failed write attempt (FLASH programming), the current program operation is aborted, and nothing is changed in the corresponding bank. The write data buffer is also invalidated.

Note: When PGSERR flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERR, and to verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERR flag also blocks any new program operation. This means that PGSERR must be cleared before starting a new program operation.

PGSERR flag is cleared by setting CLR_PGSERR bit to 1 in FLASH_CCR.

If PGSERRIE bit in FLASH_CR is set to 1, an interrupt is generated when PGSERR flag is raised (see *Section 6.9* for details).

6.8.3 Strobe error (STRBERR)

When the application software writes several times to the same byte in the write buffer, the FLASH sets the strobe error flag STRBERR in FLASH_SR, whatever the target bank of the write access.

When STRBERR is raised, the current program operation is aborted and the write buffer is invalidated.

STRBERR is cleared by setting CLR_STRBERR bit to 1 in FLASH_CCR.

If STRBERRIE bit in FLASH_CR is set to 1, an interrupt is generated when STRBERR flag is raised (see *Section 6.9* for details).

6.8.4 Inconsistency error (INCERR)

When a programming inconsistency is detected, the FLASH sets the inconsistency error flag INCERR in FLASH_SR.

More specifically, INCERR flag is set when the following condition is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.

Note: INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow the sequence below to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when INCERR flag is raised.
2. Stop all write requests to FLASH.
3. Clear INCERR bit.
4. Restart the write operations where they have been interrupted.

INCERR flag is cleared by setting CLR_INCERR bit to 1 in FLASH_CCR.

If INCERRIE bit in FLASH_CR register is set to 1, an interrupt is generated when INCERR flag is raised (see *Section 6.9* for details).

6.8.5 Error correction code error (ECCC/ECCD)

When a single-error correction is detected during a read, the FLASH interface sets the single-error correction flag ECCC in FLASH_ECCCORR.

When two ECC errors are detected during a read, the FLASH interface sets the double error detection flag ECCD in FLASH_ECCDETR.

When ECCC flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations. When ECCD flag is raised a NMI is generated. The software must invalidate the instruction cache (CACHEINV = 1) in the NMI interrupt service routine when the ECCD flag is set. This NMI can be masked in SBS registers *Section 12.5.12: SBS ECC NMI mask register (SBS_ECCNMIR)* for data access (OTP, data area, RO data).

When ECCC or ECCD flag is raised, the address of the FLASH word that generated the error is saved in the FLASH_ECCCORR (FLASH_ECCDETR). If the address corresponds to a read-only area, to a EDATA page (in user mode or in FLASH data area mode) or to an OTP area, the OTP_ECC or SYSF_ECC or EDATA_ECC bit is also set to 1 in FLASH_ECCCORRR (FLASHBS_ECCDETR). This register is automatically cleared when the associated flag that generated the error is reset.

A BK_ECC flag indicates in which FLASH bank the error occurred.

A SYSF_ECC flag indicates error detected in the system FLASH area.

Table 41. Locating ECC failure

OTP_ECC	SYSF_ECC	BK_ECC	DATA_ECC	FLASH area	ADDR_ECC min	ADDR_ECC max
0	0	0/1	0	User FLASH	0x0000	0x7FFF(1)
0	1	0/1	0	System FLASH	0x0000	0x0FFF
1	0	1	0	OTP	0x0200	0x037F
0	0	0/1	1	EDATA page 0	0x0000	0x007F
0	0	0/1	1	EDATA page 1	0x0080	0x00FF
0	0	0/1	1	EDATA page 2	0x0100	0x017F

Table 41. Locating ECC failure (continued)

OTP_ECC	SYSF_ECC	BK_ECC	DATA_ECC	FLASH area	ADDR_ECC min	ADDR_ECC max
0	0	0/1	1	EDATA page 3	0x0180	0x01FF
0	0	0/1	1	EDATA page 4	0x0200	0x027F
0	0	0/1	1	EDATA page 5	0x0280	0x02FF
0	0	0/1	1	EDATA page 6	0x0300	0x037F
0	0	0/1	1	EDATA page 7	0x0380	0x03FF
0	0	0/1	1	EDATA page 8	0x0400	0x047F
0	0	0/1	1	EDATA page 9	0x0480	0x04FF
0	0	0/1	1	EDATA page 10	0x0500	0x057F
0	0	0/1	1	EDATA page 11	0x0580	0x05FF
0	0	0/1	1	EDATA page 12	0x0600	0x067F
0	0	0/1	1	EDATA page 13	0x0680	0x06FF
0	0	0/1	1	EDATA page 14	0x0700	0x077F
0	0	0/1	1	EDATA page 15	0x0780	0x07FF

1. ADDR_ECC maximum depends on the flash memory size of the product.

Note: In case of successive single correction or double detection errors, only the address corresponding to the first error is stored in FLASH_ECCCORR (FLASH_ECCDETR).

It is mandatory to clear ECCC or ECCD flags before starting a new read operation.

As the ECC interface is shared by the two banks, if the same error is registered simultaneously, a physical bank1 error is registered. Both errors are registered if one bank reports ECCD and the other bank ECCC.

ADDR_ECC value indicates the FLASH line where the ECC error occurred.

If the EDATA_EN option bit is set, the EDATA sectors are programmed and read as 16-bit accesses, (memory row being 137 bits long: 128-bit + 9-bit ECC). Consequently, the arrangement of the memory is modified. The first 32 bits of each row of a sector are filled first, then the bits from 32 to 63 and finally from 64 to 96 (the rest of the memory row contains ECC code). The ADDR_ECC indicates the memory line holding the failure. To identify the data corrupted on the line, DATA_ADDR_ECC bitfield value can be used to

discriminate which column holds the failed data (only in case of error relative to data area or OTP).

Example: ADDR_ECC = 0x0312 and DATA_ADDR_ECC = 0x3.

- With ADDR_ECC between 0x0300 and 0x037F, the address of failure is in page 6, starting at 0x0900 2400.
- DATA_ADDR_ECC = 0b01X indicates the concerned column is the second, starting from 0x0900 2600.
- ADDR_ECC ending with 0xXX12 means the concerned row in memory is 0x12. With 4 bytes per column, this gives the 32-bit address as 0x0900 2648.
- DATA_ADDR_ECC = 0b0X1 indicates the concerned final address is the second 16-bit data, so 0x0900 264A.

ECCC (respectively ECCD) flag is cleared by setting to 1 the ECCC bit (respectively ECCD bit) in FLASH_ECCCORR (FLASH_ECCDETR).

If ECCC bit in FLASH_ECCCORR is set to 1, an interrupt is generated when ECCC flag is raised. Only NMI is generated for the ECCD (see *Section 6.9* for details).

6.8.6 Option-byte change error (OPTCHANGEERR)

When the FLASH finds an error during an option-byte change operation, it aborts the operation, and sets the option-byte change error flag OPTCHANGEERR in FLASH_SR.

The error is raised after OPTSTRT bit set if one of the following occurs:

- Any forbidden RDP_LEVEL transition (*Table 36*).
- SWAP_BANK is locked out by BOOT_LOCK.
- Attempt to modify OB with invalid value not recognized by the specification (enumerated magic numbers only)
- Attempt to modify OB in RDP level where it is not allowed (usually a state open for debug is required for change)

Note: Exceptions and details provided in the OB description (see Section 6.4.9).

OPTCHANGEERR flag is cleared by setting CLR_OPTCHANGEERR bit to 1 in FLASH_CCR.

If OPTCHANGEERRIE bit in FLASH_CR is set to 1, an interrupt is generated when OPTCHANGEERR flag is raised (see *Section 6.9* for details).

It is mandatory to clean the OPTCHANGEERR flag before starting a new operation (option change, erase, or write).

6.8.7 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On main AHB system bus for access targeting code and data with 9-bit ECC.
  - Access to invalid address (including data addresses forbidden for code use)
  - Fetching from HDP area with incorrect HDPL value
  - Fetching from privilege area in unprivileged mode
- On AHB configuration or system bus for accesses targeting OTP/RO (all addresses using 6-bits ECC):
  - Wrong key input to FLASH_KEYR or FLASH_OPTKEYR
  - 8-bit accesses to system AHB interface
  - Wrong unlock sequence on a register

6.9 FLASH interrupts

The FLASH can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see *Section 6.8*)
  - Single ECC error correction during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Option-byte change operation error
- Security errors (see *Section 6.8*)
  - Write protection error
- Miscellaneous events (described below)
  - End of programming

A NMI is raised on double-ECC-error detection during read operation.

The user can individually enable or disable FLASH interrupt sources by changing the mask bits in FLASH_CR, FLASH_ECCCORR, and FLASH_ECCDETR. Setting the appropriate mask bit to 1 enables the interrupt.

Note: Before writing, FLASH_CR must be unlocked as explained in Section 6.5.4.

The table below summarizes the available FLASH interrupt features. As mentioned, some flags need to be cleared before a new operation is triggered.

Table 42. FLASH interrupt request

Interrupt event flag	Error flag label in register	Enable control bit	Clear flag to resume operation
End of operation event	EOP	EOPIE	N/A
Write protection error	WRPERR	WRPERRIE	Yes
Programming sequence error	PGSERR	PGSERRIE	Yes
Strobe error	STRBERR	STRBERRIE	Yes

Table 42. FLASH interrupt request (continued)

Interrupt event flag	Error flag label in register	Enable control bit	Clear flag to resume operation
Inconsistency error	INCERR	INCERRIE	Yes
Option byte error	OPTCHANGEERR	-	Yes
ECC single error correction event	ECCC	ECCCIE	No
ECC double error detection event(1)	ECCD	Disabled	No

1. NMI.

The status of the individual maskable interrupt sources described in *Table 42* (except for option-byte error and ECC) can be read in FLASH_SR register. They can be cleared by setting to 1 the adequate bit in FLASH_CCR.

Note: No unlocking mechanism is required to clear an interrupt.

End of operation event

Setting the end of operation interrupt enable bit (EOPIE) in FLASH_CR enables the generation of an interrupt at the end of an erase operation, a program operation, or an option-byte change.

Setting CLR_EOP bit to 1 in FLASH_CCR clears EOP flag.

6.10 FLASH registers

Each register is assigned a offset address and a reset value. In case of registers representing option-byte value, the reset value is determined by the OBL process. In case of success, the reset value is loaded from OB. In case of OBL failure, a highly restrictive default value is set.

6.10.1 FLASH access control register (FLASH_ACR)

Address offset: 0x000

Reset value: 0x000X 0027

Bit 16 not reset by system reset

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. For more details, refer to *Section 6.3.4* and *Section 6.3.5*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EMPTY
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRFTEN	Res.	Res.	WRHIGHFREQ[1:0]		LATENCY[3:0]			
							rw			rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **EMPTY**: Main flash memory area empty (not reset by system reset)

Set and reset by software. This bit indicates whether the boot location of the main flash memory area (indicated by BOOT_ADD) is erased or has a programmed value.

0: Boot address in main flash memory area programmed

1: Boot address in main flash memory area empty

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **PRFTEN**: Prefetch enable

When this bit value is modified, the user must read back this register to be sure PRFTEN has been taken into account. This bit is used to control the prefetch.

0: Prefetch disabled

1: Prefetch enabled when latency is at least 1 wait-state

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: FLASH signal delay

These bits are used to control the delay between nonvolatile memory signals during programming operations. The application software has to program them to the correct value depending on the FLASH frequency. Refer to *Table 20* for details.

Note: No check is performed to verify that the configuration is correct.

Two WRHIGHFREQ values can be selected for some frequencies.

Bits 3:0 **LATENCY[3:0]**: Read latency

These bits are used to control the number of wait states used during read operations on both nonvolatile memory banks. The application software has to program them to the correct value depending on the FLASH frequency and voltage conditions.

0000: 0 wait state

0001: 1 wait state

0010: 2 wait states

0011-1111: {v} wait states

Note: No check is performed by hardware to verify that the configuration is correct.

6.10.2 FLASH key register (FLASH_KEYR)

Address offset: 0x004

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is write-only.

The following values must be programmed consecutively to unlock FLASH_CR and to allow programming/erasing it. A wrong sequence locks FLASH_CR until next system reset.

1st key = 0x4567 0123

2nd key = 0xCDEF 89AB

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Nonvolatile memory configuration access unlock key

6.10.3 FLASH option key register (FLASH_OPTKEYR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.This register is write-only.

The following values must be programmed consecutively to unlock FLASH_OPTCR. A wrong sequence locks FLASH_OPTCR until next system reset.

1st key = 0x0819 2A3B

2nd key = 0x4C5D 6E7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPTKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPTKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OPTKEY[31:0]**: FLASH option-byte control access unlock key

6.10.4 FLASH operation status register (FLASH_OPSR)

Address offset: 0x018

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CODE_OP[2:0]			Res.	Res.	Res.	Res.	OTP_OP	Res.	BK_OP	DATA_OP	Res.	Res.	Res.	Res.	Res.

ADDR_OP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 **CODE_OP[2:0]**: Flash memory operation code
- 000: No FLASH operation ongoing during previous reset
- 001: Single write operation interrupted
- 010: Reserved
- 011: Page erase operation interrupted
- 100: Bank erase operation interrupted
- 101: Mass erase operation interrupted
- 110: Option change operation interrupted
- 111: Reserved

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **OTP_OP**: OTP operation interrupted
This bit indicates that a reset interrupted an ongoing operation in the OTP area.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **BK_OP**: Interrupted operation bank
This bit indicates which bank was concerned by operation. (Refer to *Section Table 24.: Memory map and the swapping option (STM32C53x/542 devices)*)

Bit 21 **DATA_OP**: FLASH data area operation interrupted
This bit indicates if user data FLASH area is concerned by an operation.

Bits 20:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_OP[15:0]**: Interrupted operation address

6.10.5 FLASH option control register (FLASH_OPTCR)

Address offset: 0x01C

Reset value: 0xX000 0001

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Access: No wait state when no flash memory operation is ongoing.

This register is not accessible in write mode when the BSY bit is set. Any attempt to write to it while the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPTSTRT	OPTLOCK
														rw	rs

Bit 31 **SWAP_BANK**: Bank-swapping option configuration bit

SWAP_BANK controls whether bank1 and bank2 are swapped or not. This bit is loaded with the SWAP_BANK bit of FLASH_OPTSR_CUR register only after reset or POR.

0: Bank1 and bank2 not swapped

1: Bank1 and bank2 swapped

Bits 30:2 Reserved, must be kept at reset value.

Bit 1 **OPTSTRT**: Option-byte start change option configuration bit

OPTSTRT triggers an option byte change operation. The user can set OPTSTRT only when the OPTLOCK bit is cleared to 0. It is set only by software and cleared when the option-byte change is completed or an error occurs (PGSERR or OPTCHANGEERR). It is reset at the same time as BSY bit.

The user application cannot modify any FLASH_XXX_PRG register until the option change operation has been completed.

Before setting this bit, the user has to write the required values in FLASH_XXX_PRG. FLASH_XXX_PRG registers are locked until the option-byte change operation has been executed in nonvolatile memory.

Bit 0 **OPTLOCK**: FLASH_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH_OPTCR register as well as all _PRG registers. The correct write sequence to FLASH_OPTKEYR register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_OPTKEYR is performed twice, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from 0 to 1, the others bits of FLASH_OPTCR register do not change.

0: FLASH_OPTCR register unlocked

1: FLASH_OPTCR register locked.

6.10.6 FLASH status register (FLASH_SR)

Address offset: 0x020

Reset value: 0x0000 000X

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPTCHANGEERR	Res.	Res.	INCERR	STRBERR	PGSERR	WRPERR	EOP
								r			r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	BSLOCK	OEMLOCK	Res.	Res.	Res.	Res.	DBNE	Res.	WBNE	BSY
						r	r					r		r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERR**: Option-byte change error flag

This flag indicates that an error occurred during an option-byte change operation. When This bit is set to 1, the option-byte change operation did not successfully complete. An interrupt is generated when this flag is raised if OPTCHANGEERRIE in FLASH_NSCR is set to 1.

Writing 1 to CLR_OPTCHANGEERR in FLASH_CCR clears OPTCHANGEERR.

0: No option-byte change errors occurred.

1: One or more errors occurred during an option-byte change operation.

Note: OPTSTRT in FLASH_OPTCR cannot be set while OPTCHANGEERR is set.

Bits 22:21 Reserved, must be kept at reset value.

Bit 20 **INCERR:** Inconsistency error flag

This flag is raised when an inconsistency error occurs. An interrupt is generated if INCERRIE is set to 1. Writing 1 to CLR_INCERR in FLASH_CCR clears INCERR.

0: No inconsistency error occurred.

1: An inconsistency error occurred.

Bit 19 **STRBERR:** Strobe error flag

This flag is raised when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if STRBERRIE is set to 1. Writing 1 to CLR_STRBERR in FLASH_CCR clears STRBERR.

0: No strobe error occurred.

1: A strobe error occurred.

Bit 18 **PGSERR:** Programming sequence error flag

This flag is raised when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set to 1. Writing 1 to CLR_PGSERR in FLASH_CCR clears PGSERR.

0: No sequence error occurred.

1: A sequence error occurred.

Bit 17 **WRPERR**: Write protection error flag

This flag is raised when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set to 1. Writing 1 to CLR_WRPERR bit in FLASH_CCR clears WRPERR.

0: No write-protection error occurred.

1: A write-protection error occurred.

Bit 16 **EOP**: End of operation flag

This flag is set when an operation (program/erase) completes. An interrupt is generated if EOPIE is set to 1. It is not necessary to reset EOP before starting a new operation. EOP bit is cleared by writing 1 to CLR_EOP in FLASH_CCR.

0: No operation completed.

1: An operation completed.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **BSLOCK**: BS lock

This bit indicates that the BS key read during the option byte loading is not default (default is 0xAAAA AAAA).

When set, the BS personalized key mechanism to transition to L2 from L2_wBS is active.

Bit 8 **OEMLOCK**: OEM lock

This bit indicates that the OEM key read during the OBL is not virgin. When set, the OEM RDP lock mechanism is active. The lock mechanism allows the user to regress from RDP L2_wBS or L2 to L0. This bit is set once a 128-bit password is written in OEMKEYRx registers and written in memory. It cannot be cleared.

0: Lock mechanism is not active, progressing to RDP L2_wBS or L2 is irrevocable.

1: Lock mechanism is active, a key exist to regress to RDP L0.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DBNE**: Data buffer not empty flag

This flag is set when the FLASH is processing 6-bit ECC data (OTP or EDATA area when EDATA_EN option bit set) in a dedicated buffer. This bit cannot be cleared by software. The hardware resets it once the buffer is free.

0: Data buffer not used

1: Data buffer used, wait

Bit 2 Reserved, must be kept at reset value.

Bit 1 **WBNE**: Write buffer not empty flag

This flag is set when the FLASH is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- The application software forces the write operation using FW bit in FLASH_CR.
- The FLASH detects an error that involves data loss.

This bit cannot be reset by software writing 0 directly. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: Write buffer empty or full

1: Write buffer waiting data to complete

Bit 0 **BSY**: Busy flag

This flag indicates that a flash memory is busy by an operation (write, erase, option-byte change). It is set at the beginning of a flash memory operation, and cleared when the operation finishes or an error occurs.

0: No programming, erase, or option-byte change operation being executed

1: Programming, erase, or option byte change operation being executed

6.10.7 FLASH control register (FLASH_CR)

Address offset: 0x028

Reset value: 0x0000 0001

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Access: No wait state when no flash memory operation is ongoing.

This register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BKSEL	Res.	EDATASEL	Res.	Res.	Res.	Res.	Res.	OPTCHANGEERRIE	Res.	Res.	INCERRIE	STRBERRIE	PGSERRIE	WRPERRIE	EOPIE
rw		rw						rw			rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MER	Res.	Res.	PNB[6:0]							STRT	FW	BER	PER	PG	LOCK
rw			rw	rw	rw	rw	rw	rw	rw	rs	rw	rw	rw	rw	rs

Bit 31 **BKSEL**: Bank selector bit

This bit can only be programmed when LOCK is cleared to 0. This bit selects physical bank, SWAP_BANK setting is ignored.

0: Bank1 is selected for bank erase (BER)/page erase (PER)/interrupt enable.

1: Bank2 is selected for BER/PER.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **EDATASEL**: EDATA erase selector bit

This bit can only be programmed when LOCK is cleared to 0. This bit selects if page erased concern EDATA page or User main flash pages. This bit has no effect if PER bit is reset.

0: Main FLASH page erase

1: FLASH data area EDATA page erase

Note: During a bank erase, the user and the EDATA sectors are always erased, regardless of this bit setting.

Bits 28:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERRIE**: Option-byte change error interrupt enable bit

This bit controls if an interrupt has to be generated when an error occurs during an option-byte change. This bit can be programmed only when LOCK bit is cleared to 0.

0: No interrupt is generated when an error occurs during an option-byte change.

1: An interrupt is generated when and error occurs during an option-byte change.

Bits 22:21 Reserved, must be kept at reset value.

Bit 20 **INCERRIE**: Inconsistency error interrupt enable bit

When INCERRIE bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation. INCERRIE can be programmed only when LOCK is cleared to 0.

0: No interrupt generated when a inconsistency error occurs.

1: Interrupt generated when a inconsistency error occurs.

Bit 19 **STRBERRIE**: Strobe error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation. STRBERRIE can be programmed only when LOCK is cleared to 0.

0: No interrupt generated when a strobe error occurs.

1: Interrupt generated when strobe error occurs.

Bit 18 **PGSERRIE**: Programming sequence error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation. PGSERRIE can be programmed only when LOCK is cleared to 0.

0: No interrupt generated when a sequence error occurs.

1: Interrupt generated when sequence error occurs.

Bit 17 **WRPERRIE**: Write protection error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a protection error occurs during a program operation. WRPERRIE can be programmed only when LOCK is cleared to 0.

0: No interrupt generated when a protection error occurs.

1: Interrupt generated when a protection error occurs.

Bit 16 **EOPIE**: End of operation interrupt control bit

Setting this bit to 1 enables the generation of an interrupt at the end of a program or erase operation. EOPIE can be programmed only when LOCK is cleared to 0.

0: No interrupt generated at the end of operation.

1: Interrupt enabled when at the end of operation.

Bit 15 **MER**: Mass erase request

Setting this bit to 1 requests a mass erase operation (user flash memory only). MER can be programmed only when LOCK is cleared to 0. If BER or PER are both set, a PGSERR is raised.

0: Mass erase not requested

1: Mass erase requested

Note: An error is triggered when a mass erase is required and some pages are protected.

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:6 **PNB[6:0]**: Page erase selection number

These bits are used to select the target page for an erase operation (they are unused otherwise). PNB can be programmed only when LOCK is cleared to 0.

0x00: Page 0 selected

0x01: Page 1 selected

0x02-0x3F: Page {v} selected

Note: Values corresponding to addresses outside the main memory are not allowed. Refer to Table 24: Memory map and the swapping option (STM32C53x/542 devices), Table 25: Memory map and the swapping option (STM32C55x/562 devices), and Table 26: Memory map and the swapping option (STM32C59x/5A3 devices)

Bit 5 **STRT**: Erase start control bit

This bit is used to start a page erase or a bank erase operation. STRT can be programmed only when LOCK is cleared to 0.

This bit is reset at the end of the operation or when an error occurs. It cannot be reseted by software.

Bit 4 **FW:** Write forcing control bit

This bit forces a write operation even if the write buffer is not full. In this case, all bits not written are set to 1 by hardware. FW can be programmed only when LOCK is cleared to 0. The FLASH resets this bit when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it leads to permanent ECC error.

Write forcing is effective only if the write buffer is not empty (in particular, FW does not start several write operations when the force-write operations are performed consecutively). Since there is just one write buffer, FW can force a write in bank1 or bank2.

Bit 3 **BER**: Bank-erase request

Setting this bit to 1 requests a bank erase operation (user flash memory only). BER can be programmed only when LOCK is cleared to 0. If MER and PER are also set, a PGSERR is raised.

0: Bank erase not requested

1: Bank erase requested

Note: Write protection error is triggered when a bank erase is required and some pages are protected.

Bit 2 **PER**: Page-erase request

Setting this bit to 1 requests a sector erase. PER can be programmed only when LOCK is cleared to 0. If MER and PER are also set, a PGSERR is raised.

0: Page erase not requested

1: Page erase requested

Bit 1 **PG**: Programming control bit

This bit can be programmed only when LOCK is cleared to 0. It allows programming in bank1 and bank2.

0: Programming disabled

1: Programming enabled

Bit 0 **LOCK**: Configuration lock bit

This bit locks FLASH_CR. The correct write sequence to FLASH_KEYR unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_KEYR is performed twice, this bit remains locked until the next system reset.

LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_CR register do not change.

0: FLASH_CR unlocked

1: FLASH_CR locked

6.10.8 FLASH clear control register (FLASH_CCR)

Address offset: 0x030

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLR_OPTCHANGEERR	Res.	Res.	CLR_INCERR	CLR_STRBERR	CLR_PGSERR	CLR_WRPERR	CLR_EOP

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CLR_OPTCHANGEERR:** OPTCHANGEERR clear bit
Setting this bit to 1 clears the corresponding flag in FLASH_SR.

Bits 22:21 Reserved, must be kept at reset value.

Bit 20 **CLR_INCERR**: INCERR flag clear bit
Setting this bit to 1 resets to 0 INCERR flag in FLASH_SR.

Bit 19 **CLR_STRBERR**: STRBERR flag clear bit
Setting this bit to 1 resets to 0 STRBERR flag in FLASH_SR.

Bit 18 **CLR_PGSERR**: PGSERR flag clear bit
Setting this bit to 1 resets to 0 PGSERR flag in FLASH_SR.

Bit 17 **CLR_WRPERR**: WRPERR flag clear bit
Setting this bit to 1 resets to 0 WRPERR flag in FLASH_SR.

Bit 16 **CLR_EOP**: EOP flag clear bit
Setting this bit to 1 resets to 0 EOP flag in FLASH_SR.

Bits 15:0 Reserved, must be kept at reset value.

6.10.9 FLASH privilege configuration register (FLASH_PRIVCFGR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register can be read by both privileged and unprivileged access. It can only be written by privileged mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PRIV**: Privilege attribute
0: Access to registers is always granted.
1: Access to registers is denied in case of unprivileged access.

Bit 0 Reserved, must be kept at reset value.

6.10.10 FLASH HDP extension register (FLASH_HDPEXTR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. The register can only be modified in HDPL ≤ 2.

The values in this register cannot be decremented. Attempt to write a lower value that current is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP2_EXT[5:0]					
										rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_EXT[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **HDP2_EXT[5:0]:** HDP area extension in 8-Kbyte pages in bank2
Extension is added after the HDP2_END page (included).

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **HDP1_EXT[5:0]**: HDP area extension in 8-Kbyte pages in bank1
Extension is added after the HDP1_END page (included).

6.10.11 FLASH option status register (FLASH_OPTSR_CUR)

Address offset: 0x050

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0x20B0 72D8 (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This read-only register reflects the current values of corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	SINGLE_BANK	EDATA_EN	Res.	Res.	Res.	Res.	Res.	BOOT0	BOOT_SEL	IWDG_STDBY	IWDG_STOP	Res.	Res.	Res.	Res.
r	r	r						r	r	r	r				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDP_LEVEL[7:0]								NRST_STDBY	NRST_STOP	Res.	WWDG_SW	IWDG_SW	Res.	Res.	Res.
r	r	r	r	r	r	r	r	r	r		r	r			

Bit 31 **SWAP_BANK**: Bank-swapping option status bit
SWAP_BANK reflects whether bank1 and bank2 are swapped or not.
SWAP_BANK is loaded to SWAP_BANK in FLASH_OPTCR after a reset.
0: Bank1 and bank2 not swapped
1: Bank1 and bank2 swapped

Bit 30 **SINGLE_BANK**: Dual-bank selection option status bit
For products:
- STM32C53x/542 with 128-Kbyte user memory
- STM32C55x/562 with 256-Kbyte user memory
- STM32C59x/5A3 with 512-Kbyte user memory

SINGLE_BANK reflects single or dual-bank memory selection.
0: User flash is split between bank 1 and bank 2
1: User flash is located in one bank
Note: This bit has no impact on EDATA sectors.

Bit 29 **EDATA_EN:** FLASH data area enable
0: No FLASH data area (EDATA pages are 128-bit writable)
1: FLASH data area is enabled (EDATA pages are 16/32-bit writable)

Bits 28:24 Reserved, must be kept at reset value.

Bit 23 **BOOT0**: Boot 0 option bit
0: BOOT0 = 0
1: BOOT0 = 1

Bit 22 **BOOT_SEL**: Boot 0 source selection
0: BOOT0 signal is defined by the BOOT0 option bit.
1: BOOT0 signal is defined by BOOT0 pin value (legacy mode).

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option status bit
When this bit is set, the IWDG is frozen in system Standby mode.
0: IWDG frozen in Standby mode
1: IWDG keeps running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option status bit
When set the independent watchdog IWDG is in system Stop mode.
0: IWDG frozen in system Stop mode
1: IWDG keeps running in system Stop mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:8 **RDP_LEVEL[7:0]**: RDP level code (based on Hamming 8,4)
See *Section 6.5.8*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option status bit
0: A reset is generated when entering Standby mode on core domain.
1: No reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option status bit
0: A reset is generated when entering Stop mode on core domain.
1: No reset generated when entering Stop mode on core domain..

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option status bit
0: WWDG controlled by hardware
1: WWDG controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option status bit
0: IWDG controlled by hardware
1: IWDG controlled by software

Bits 2:0 Reserved, must be kept at reset value.

6.10.12 FLASH option status register (FLASH_OPTSR_PRG)

Address offset: 0x054

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	SINGLE_BANK	EDATA_EN	Res.	Res.	Res.	Res.	Res.	BOOT0	BOOT_SEL	IWDG_STDBY	IWDG_STOP	Res.	Res.	Res.	Res.
rw	rw	rw						rw	rw	rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDP_LEVEL[7:0]								NRST_STDBY	NRST_STOP	Res.	WWDG_SW	IWDG_SW	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw			

Bit 31 **SWAP_BANK**: Bank-swapping option configuration bit
This bit is used to configure whether the bank1 and bank2 are swapped or not. This bit is loaded with SWAP_BANK in FLASH_OPTSR_CUR after a reset.
0: Bank1 and bank2 not swapped
1: Bank1 and bank2 swapped

Bit 30 **SINGLE_BANK**: Dual-bank option configuration bit
For products:
- STM32C53x/542 with 128-Kbyte user memory
- STM32C55x/562 with 256-Kbyte user memory
- STM32C59x/5A3 with 512-Kbyte user memory

This bit configures memory as single or dual bank. This bit is loaded with SINGLE_BANK in FLASH_OPTSR_CUR after a reset.
0: User flash is split between bank 1 and bank 2
1: User flash is located in one bank

Bit 29 **EDATA_EN:** FLASH data area enable
0: No FLASH data area
1: FLASH data area enabled

Bits 28:24 Reserved, must be kept at reset value.

Bit 23 **BOOT0**: Boot 0 option bit
0: BOOT0 = 0
1: BOOT0 = 1

Bit 22 **BOOT_SEL**: Boot 0 source configuration
0: BOOT0 signal is defined by the BOOT0 option bit.
1: BOOT0 signal is defined by BOOT0 pin value (legacy mode).

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option configuration bit
When this bit is set, the IWDG is frozen in system Standby mode.
0: IWDG frozen in Standby mode
1: IWDG keeps running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option configuration bit
When this bit is set, the IWDG is frozen in system Stop mode.
0: IWDG frozen in system Stop mode
1: IWDG keeps running in system Stop mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:8 **RDP_LEVEL[7:0]**: RDP level code (based on Hamming 8,4)
See *Section 6.5.8*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option configuration bit
0: A reset is generated when entering Standby mode on core domain.
1: No reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option configuration bit
0: A reset is generated when entering Stop mode on core domain.
1: No reset generated when entering Stop mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option configuration bit
0: WWDG controlled by hardware
1: WWDG controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option configuration bit
0: IWDG controlled by hardware
1: IWDG controlled by software

Bits 2:0 Reserved, must be kept at reset value.

6.10.13 FLASH option status register 2 (FLASH_OPTSR2_CUR)

Address offset: 0x070

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0x0000 0010 (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This read-only register reflects the current values of corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM2_ECC	Res.	Res.	SRAM2_RST	SRAM1_RST
											r			r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **SRAM2_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs

Bit 0 **SRAM1_RST**: SRAM1 erase upon system reset
0: SRAM1 erased when a system reset occurs
1: SRAM1 not erased when a system reset occurs

6.10.14 FLASH option status register 2 (FLASH_OPTSR2_PRG)

Address offset: 0x074

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM2_ECC	Res.	Res.	SRAM2_RST	SRAM1_RST
											rw			rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
- 0: SRAM2 ECC check enabled
- 1: SRAM2 ECC check disabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **SRAM2_RST**: SRAM2 erase when system reset
- 0: SRAM2 erased when a system reset occurs
- 1: SRAM2 not erased when a system reset occurs.

Note: SRAM erase is triggered by option-byte change operation, when enabling this feature.

Bit 0 **SRAM1_RST**: SRAM1 erase upon system reset
- 0: SRAM1 erased when a system reset occurs
- 1: SRAM1 not erased when a system reset occurs

Note: SRAM erase is triggered by option-byte change operation, when enabling this feature.

6.10.15 FLASH unique boot entry register (FLASH_BOOTR_CUR)

Address offset: 0x080

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0xFFFF FFB4 (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This register reflects the current values of corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOTADD[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTADD[7:0]								BOOT_LOCK[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:8 **BOOTADD[23:0]**: Unique boot-entry address
These bits reflect the user memory boot address.

Caution: The BOOTADD must be a valid address within user main flash area. Otherwise, the boot stalls, and the flash memory becomes unreadable.

Note: The SRAM or EDATA areas cannot be selected as BOOTADD.

Bits 7:0 **BOOT_LOCK[7:0]**: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD option settings lock
0xC3: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD can still be modified following their individual rules.
0xB4: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD are frozen.

6.10.16 FLASH unique boot entry address (FLASH_BOOTR_PRG)

Address offset: 0x084

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in corresponding option bits.

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOTADD[23:8]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTADD[7:0]								BOOT_LOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **BOOTADD[23:0]**: Unique boot entry address
These bits reflect the user memory boot address.

Bits 7:0 **BOOT_LOCK[7:0]**: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD option settings lock
0xC3: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD can still be modified following their individual rules.
0xB4: BOOT0, BOOT_SEL, SWAP_BANK, and BOOTADD are frozen.

6.10.17 FLASH OTP block lock (FLASH_OTPBLR_CUR)

Address offset: 0x090

Reset value: 0x00XX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0xFFFF FFFF (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKBL[23:16]							
								r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **LOCKBL[23:0]**: OTP block lock
Block *n* corresponds to OTP 16-bit word 96 x *n* to 96 x *n* + 95.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP block *n* are locked and attempt to program them results in WRPERR.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP block *n* are not locked.
When one block is locked, it is not possible to remove the write protection.
Also if not locked, it is not possible to erase OTP words.

6.10.18 FLASH OTP block lock (FLASH_OTPBLR_PRG)

Address offset: 0x094

Reset value: 0x00XX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKBL[23:16]							
								rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **LOCKBL[23:0]**: OTP block lock

Block *n* corresponds to OTP 16-bit word 96 x *n* to 96 x *n* + 95.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP block *n* are locked and attempt to program them results in WRPERR.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP block *n* are not locked.
When one block is locked, it is not possible to remove the write protection.
LOCKBL bits can be set if the corresponding bit in FLASH_OTPBLR_CUR is cleared.

6.10.19 FLASH bootloader interface selection (FLASH_BL_COM_CFG_CUR)

Address offset: 0x098

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0xFFFF FFFF (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BL_COM_CFG[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BL_COM_CFG[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **BL_COM_CFG[31:0]**: Bootloader interface selection/configuration
This register is used to configure the set of interfaces on which the ST bootloader is active.
BL_COM_CFG[n] = 1 indicates that the corresponding interface is used by the bootloader.
BL_COM_CFG[n] = 0 indicates that the corresponding interface is not used by the bootloader. The GPIO remains in default state.

Note: For assignment of interfaces to register bits, see the bootloader documentation.

6.10.20 FLASH bootloader interface selection (FLASH_BL_COM_CFG_PRG)

Address offset: 0x09C

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in the corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BL_COM_CFG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BL_COM_CFG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **BL_COM_CFG[31:0]**: Bootloader interface selection/configuration
This register is used to configure the set of interfaces on which the ST bootloader is active.
BL_COM_CFG[n] = 1 indicates that the corresponding interface is used by the bootloader.
BL_COM_CFG[n] = 0 indicates that the corresponding interface is not used by the bootloader. The GPIO remains in default state.

Note: For assignment of interfaces to register bits see the bootloader documentation.

6.10.21 FLASH OEM key register 1 (FLASH_OEMKEYR1_PRG)

Address offset: 0xA4

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is read as zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OEMKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OEMKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OEMKEY[31:0]:** Least significants bytes of OEMKEY

6.10.22 FLASH OEM key register 2 (FLASH_OEMKEYR2_PRG)

Address offset: 0xAC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is read as zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OEMKEY[63:48]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

OEMKEY[47:32]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OEMKEY[63:32]:** Mid-least significants bytes of OEMKEY

6.10.23 FLASH OEM key register 3 (FLASH_OEMKEYR3_PRG)

Address offset: 0xB4

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is read as zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OEMKEY[95:80]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OEMKEY[79:64]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OEMKEY[95:64]:** Mid-most significants bytes of OEMKEY

6.10.24 FLASH OEM key register 4 (FLASH_OEMKEYR4_PRG)

Address offset: 0xBC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is read as zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OEMKEY[127:112]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OEMKEY[111:96]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OEMKEY[127:96]:** Most significants bytes of OEMKEY

6.10.25 FLASH boundary scan key register (FLASH_BSKEYR_PRG)

Address offset: 0xC4

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is read as zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BSKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BSKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **BSKEY[31:0]:** Boundary scan key

6.10.26 FLASH write page protection for bank1 (FLASH_WRP1R_CUR)

Address offset: 0x0E8

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0x0000 0000 (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSG1[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSG1[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRPSG1[31:0]**: Bank1 page protection option status byte
Each bit reflects the write protection status of the corresponding group of pages in Bank1.
0: Write protected
1: Not write protected

Note: Refer to Table 29: Write-protection management for group definition.

6.10.27 FLASH write-page protection for bank1 (FLASH_WRP1R_PRG)

Address offset: 0x0EC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSG1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSG1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRPSG1[31:0]**: Bank1 page protection option status byte
Setting these bits to 0 write-protects the corresponding pages in bank 1
0: Write protected
1: Not write protected
Note: Refer to Table 29: Write-protection management for group definition.

6.10.28 FLASH HDP bank1 register (FLASH_HDP1R_CUR)

Address offset: 0x0F8

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is initially loaded with the values of corresponding option bits.

Default value: 0x000F 0000 (value in case of double ECC issue during OBL) for STM32C53x/542.

Default value: 0x001F 0000 (value in case of double ECC issue during OBL) for STM32C55x/562.

Default value: 0x003F 0000 (value in case of double ECC issue during OBL) for STM32C59x/5A3.

ST production value: refer to *Table 28: Option-byte organization*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_END[5:0]					
										r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_STRT[5:0]					
										r	r	r	r	r	r

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **HDP1_END[5:0]:** HDPL barrier end set in number of 8-Kbyte pages

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **HDP1_STRT[5:0]:** HDPL barrier start set in number of 8-Kbyte pages

6.10.29 FLASH HDP bank1 register (FLASH_HDP1R_PRG)

Address offset: 0x0FC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR. Register is accessible only in HDPL1. In HDPL=2 or 3 it is WI, RAZ.

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_END[5:0]					
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_STRT[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **HDP1_END[5:0]:** Bank 1 HDPL barrier end set in number of 8-Kbyte pages

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **HDP1_STRT[5:0]:** Bank 1 HDPL barrier start set in number of 8-Kbyte pages

6.10.30 FLASH ECC correction register (FLASH_ECCCORR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ECCC	Res.	Res.	Res.	Res.	ECCCIE	OTP_ECC	SYSF_ECC	BK_EC C	EDATA _ECC	Res.	Res.	Res.	Res.	Res.
	rw					rw	r	r	r	r					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ECCC:** ECC correction
Set by hardware when single ECC error has been detected and corrected.
Cleared by writing 1.

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **ECCCIE**: ECC single-correction error interrupt enable bit
When this bit is set to 1, an interrupt is generated when an ECC single-correction error occurs during a read operation.
0: No interrupt generated when an ECC single-correction error occurs.
1: Interrupt generated when an ECC single-correction error occurs.

Bit 24 **OTP_ECC**: OTP ECC error bit
This bit is set to 1 when one ECC single-correction occurred during the last successful read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC flag for corrected ECC error in system FLASH
This bit indicates if system flash memory is concerned by an ECC error.

Bit 22 **BK_ECC**: ECC bank flag for corrected ECC error
This bit indicates which bank is concerned by an ECC error .

Bit 21 **EDATA_ECC**: ECC fail for corrected ECC error in FLASH data area
This bit indicates if FLASH data area is concerned by an ECC error.

Bits 20:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address
When an ECC error occurs (for single correction) during a read operation, this bitfield contains the address that generated the error. It is reset when the flag error is reset.
The FLASH programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.
The address in ADDR_ECC is relative to the FLASH area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

6.10.31 FLASH ECC detection register (FLASH_ECCDETR)

Address offset: 0x104

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECCD	Res.	Res.	Res.	Res.	Res.	Res.	OTP_ECC	SYSF_ECC	BK_ECC	EDATA_ECC	Res.	Res.	Res.	Res.	Res.
rc_w1							r	r	r	r					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ECCD:** ECC detection set by hardware when two ECC errors have been detected
When this bit is set, a NMI is generated. This bit is cleared by writing 1. Needs to be cleared in order to detect subsequent double ECC errors.

Bits 30:25 Reserved, must be kept at reset value.

Bit 24 **OTP_ECC**: OTP ECC error bit
This bit is set to 1 when a double ECC detection occurred during the last read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC fail for double ECC error in system flash memory
This bit indicates if system flash memory is concerned by an ECC error.

Bit 22 **BK_ECC**: ECC fail bank for double ECC Error
This bit indicates which bank is concerned by an ECC error.

Bit 21 **EDATA_ECC**: ECC fail for double ECC error in FLASH data area
This bit indicates if FLASH EDATA sector is concerned by an ECC error.

Bits 20:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address
When an ECC error occurs (double detection) during a read operation, this bitfield contains the address that generated the error. It is reset when the flag error is reset.
The FLASH programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an double ECC error is saved. The address in ADDR_ECC is relative to the flash memory area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

6.10.32 FLASH ECC data (FLASH_ECCDR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATA_ADDR_ECC[2:0]		
													r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **DATA_ADDR_ECC[2:0]**: DATA ECC error address
When a double detection ECC error occurs on special areas with 6-bit ECC on 16-bit data (data area, read-only/OTP area), the position of the failing word on the FLASH line can be read to this register.
000: Double error on first 16-bit data or first 32-bit data accessed on the FLASH line
001: Double error on second 16-bit data accessed on the FLASH line
010: Double error on third 16-bit data or second 32-bit data accessed on the FLASH line
011: Double error on fourth 16-bit data accessed on the FLASH line
100: Double error on fifth 16-bit data or third 32-bit data accessed on the FLASH line
101: Double error on sixth 16-bit data
Note: If the data access was 16 bits, the corrupted word can be fully located. If access was 32 bits, use DATA_ECC value to discriminate which one of the two 16-bit word is faulty.

Bits 15:0 **DATA_ECC[15:0]**: ECC error data
When a double detection ECC error occurs on special areas with 6-bit ECC on 16-bit data (data area, read-only/OTP area), the failing data is read to this register.
By checking if it is possible to determine whether the failure was on a real data, or due to access to uninitialized memory.

6.10.33 FLASH write page protection for bank2 (FLASH_WRP2R_CUR)

Address offset: 0x1E8

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0x0000 0000 (value in case of double ECC issue during OBL).

ST production value: refer to *Table 28: Option-byte organization*

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSG2[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSG2[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRPSG2[31:0]**: Bank2 page protection option status byte

Each bit reflects the write protection status of the corresponding group of pages in Bank2.

0: Write protected

1: Not write protected

Note: Refer to Table 29: Write-protection management group definition.

6.10.34 FLASH write page protection for bank2 (FLASH_WRP2R_PRG)

Address offset: 0x1EC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSG2[31:16]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSG2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRPSG2[31:0]**: Bank2 page protection option status byte

Setting WRPSG2 bits to 0 write protects the corresponding pages in bank 2

0: write protected;

1: not write protected

Note: Refer to Table 29: Write-protection management group definition.

6.10.35 FLASH HDP bank2 register (FLASH_HDP2R_CUR)

Address offset: 0x1F8

Reset value: 0xXXXX XXXX

This register is initially loaded with the values of corresponding option bits.

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Default value: 0x000F 0000 (value in case of double ECC issue during OBL) for STM32C53x/542.

Default value: 0x001F 0000 (value in case of double ECC issue during OBL) for STM32C55x/562.

Default value: 0x003F 0000 (value in case of double ECC issue during OBL) for STM32C59x/5A3.

ST production value: refer to *Table 28: Option-byte organization*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP2_STRT[5:0]					
										r	r	r	r	r	r

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **HDP2_END[5:0]:** Bank 2 HDPL barrier end set in number of 8-Kbyte pages

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **HDP2_STRT[5:0]:** Bank 2 HDPL barrier start set in number of 8-Kbyte pages

6.10.36 FLASH HDP bank2 register (FLASH_HDP2R_PRG)

Address offset: 0x1FC

Reset value: 0xXXXX XXXX

This register can be protected against unprivileged access when PRIV = 1 in FLASH_PRIVCFGR.

Register is accessible only in HDPL0 and HDPL1. In HDPL=2 or 3 it is WI, RAZ.

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP2_END[5:0]

7 Instruction cache (ICACHE)

7.1 ICACHE introduction

The instruction cache (ICACHE) is implemented on the C-AHB code bus of the Cortex®-M33 processor to improve performance when fetching instructions and data from internal and external memories (the latter only on STM32C59x/5A3 devices).

Some specific features, like dual master ports (second master port only on STM32C59x/5A3 devices), hit-under-miss, and critical-word-first refill policy, result in close to zero-wait-state performance in most use cases.

7.2 ICACHE main features

The main features of ICACHE are listed below:

- Bus interface
  - One 32-bit AHB slave port, the execution port (input from Cortex®-M33 C-AHB code interface)
  - Two AHB master ports: master1 and master2 ports, with outputs to Fast and Slow buses of main AHB bus matrix, respectively (master2 port only on STM32C59x/5A3STM32C5P1xx/5Q1xx devices)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master (only on STM32C59x/5A3 devices) access: feature used to decouple the traffic according to targeted memory. For example, the ICACHE assigns fast traffic (addressing flash memories and SRAMs) to the AHB master1 port, and slow traffic (addressing external memories) to the AHB master2 port, thus preventing processor stalls on line refills from external memories. This allows ISR (interrupt service routine) fetching on internal flash memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, **w**, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Memory address remap
  - Possibility to remap input address falling into up to four memory regions (used only on STM32C59x/5A3 devices to remap aliased code in external memories to the code region, for execution from the C-AHB code interface)
- Replacement and refill
  - pLRU-t (pseudo-least-recently-used, based on binary tree) replacement policy, algorithm with best complexity/performance balance

  - Critical-word-first refill policy, minimizing processor stalls
  - Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error, and optionally, to raise an interrupt
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, noninterruptible

7.3 ICACHE implementation

Table 44. ICACHE features for STM32C5 devices

Feature	ICACHE1
Number of ways	2
Cache size	8 Kbytes
Cache line width	16 bytes
Range granularity of memory regions to be remapped	2 Mbytes
Number of regions to remap	4
Data size of AHB slave interface	32 bits
Data size of AHB fast master1 interface	128 bits
Data size of AHB slow master2 interface(1)	32 bits

1. Only on STM32C59x/5A3 devices.

7.4 ICACHE functional description

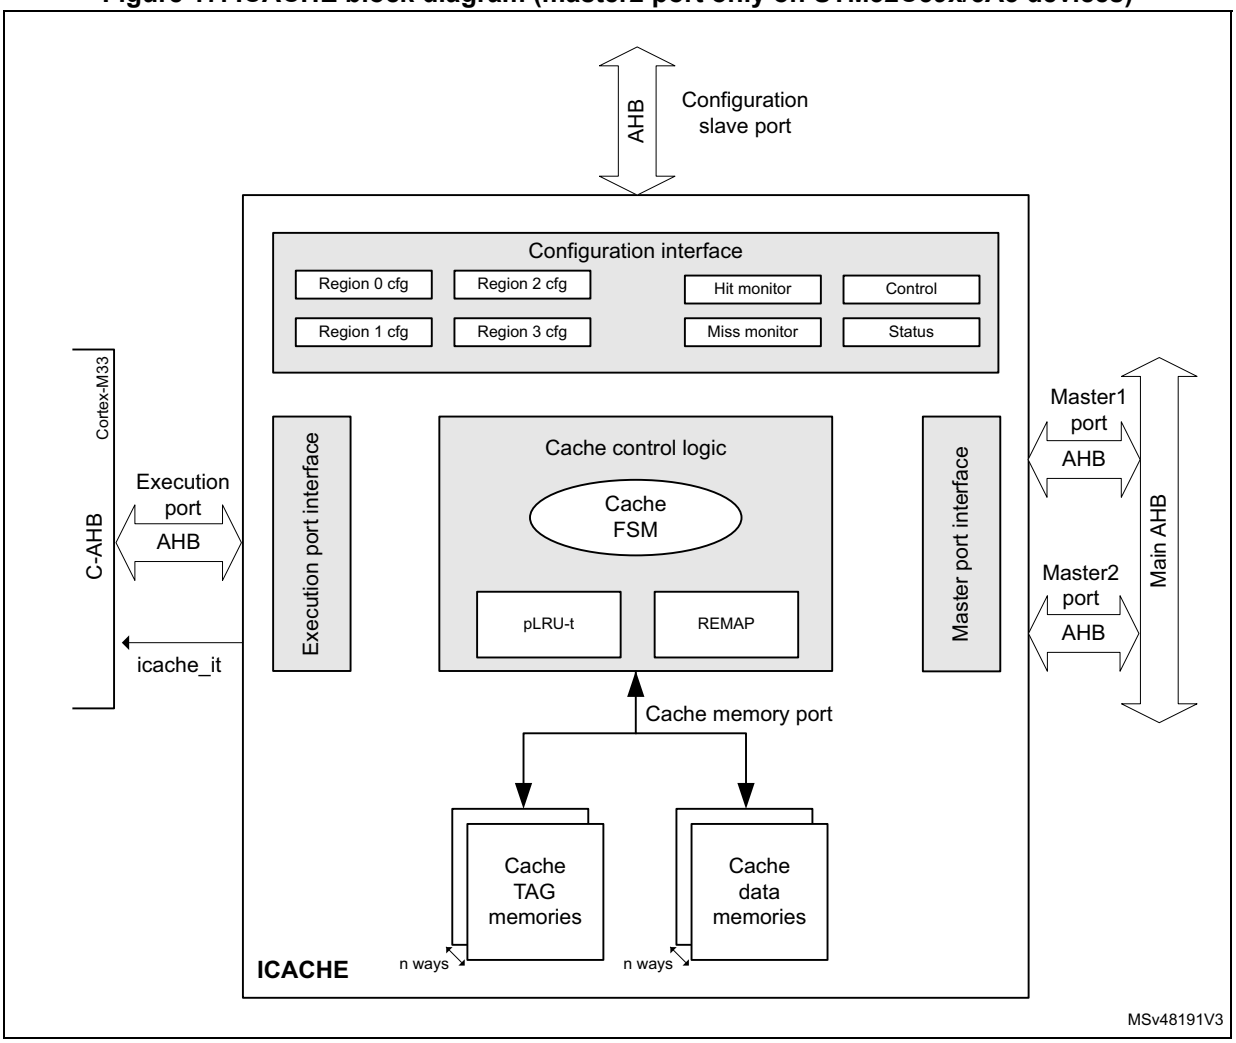
The purpose of this block is to cache instruction fetches or instruction memories loads, coming from the processor. As such, the ICACHE manages only cacheable read transactions, and does not manage cacheable write transactions.

The noncacheable transactions (both read and write) bypass the ICACHE.

For the error management purpose, if a write cacheable transaction is presented (this happens only in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

7.4.1 ICACHE block diagram

Figure 17. ICACHE block diagram (master2 port only on STM32C59x/5A3 devices)



7.4.2 ICACHE reset and clocks

The ICACHE is clocked on the Cortex®-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (= 0).

Note: When disabled, the ICACHE is bypassed, except the remapping mechanism that is still functional: slave input requests (remapped or not) are forwarded to the master port(s).

7.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags indicating which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 45* for B and W definitions):

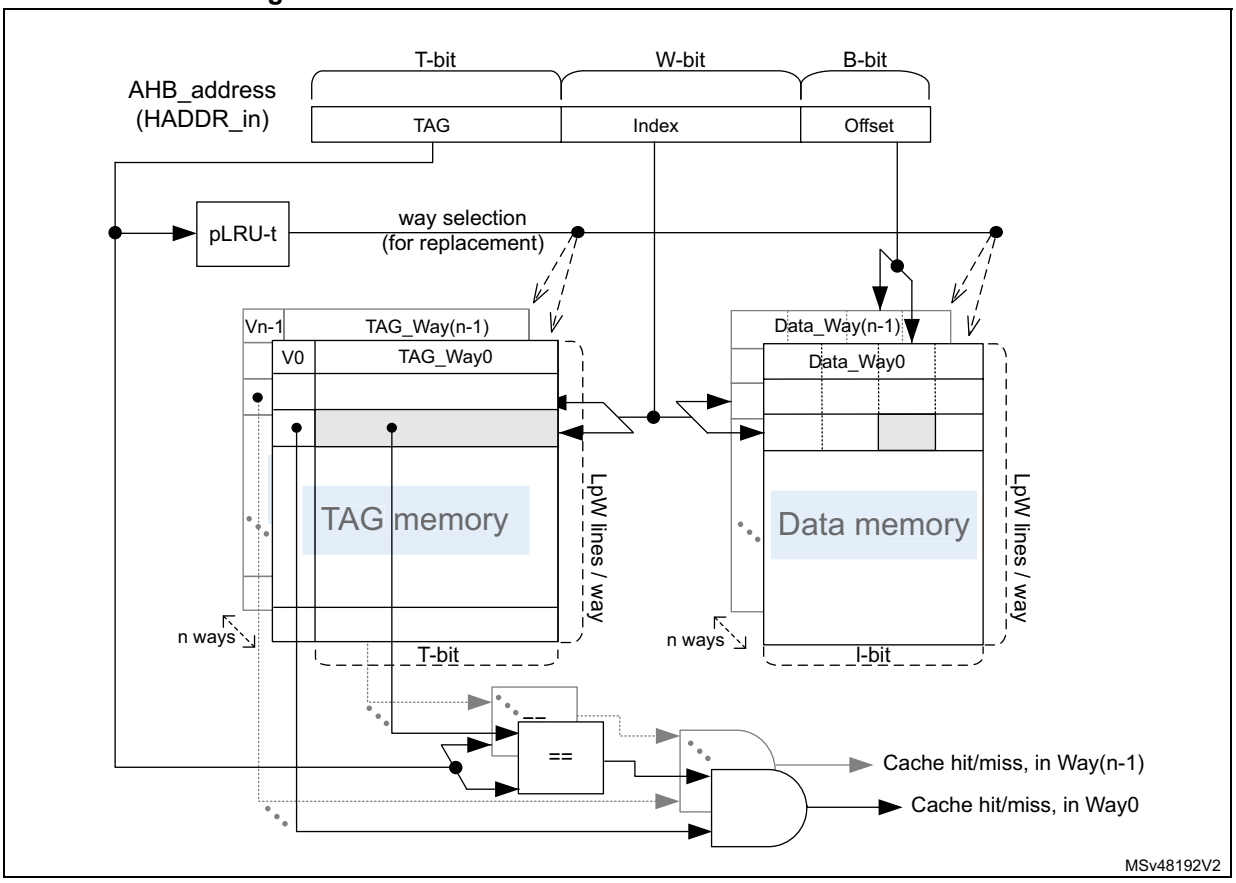
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. *Figure 18* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 45. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 18. ICACHE TAG and data memories functional view



7.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 46. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, remapping, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 7.4.8*): only one way (the unique one) is possible for any data refill.

7.4.5 ICACHE enable

To activate the ICACHE, the EN bit in ICACHE_CR must be set to 1.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave to the master port(s) in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether the ICACHE is enabled or not, if the input transaction address falls into the memory regions defined and enabled in ICACHE_CRRx (see *Figure 19*).

The ICACHE is, by default, disabled at boot.

7.4.6 Cacheable and noncacheable traffic

The ICACHE is developed for the Cortex®-M33 core. It is placed on the C-AHB bus, and thus caches the code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

To make other memory regions cacheable, the ICACHE supports a memory region remapping feature, used (only for STM32C59x/5A3 devices) to define up to four external memory regions, whose addresses have an alias in the code region. Addressing these memory regions through their code alias address allows the memory request to be routed to the C-AHB bus, and to be managed by the ICACHE.

Any external memory space physically mapped at an address in the range [0x6000 0000:0xAFFF FFFF] can be aliased with an address in the range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the code region, the ICACHE implements the address remapping functionality first. If aliased, it is the remapped address, which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for noncacheable traffic, and when the cache is disabled.

Additional details on address remapping are provided in *Section 7.4.7*.

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 47*. This AHB attribute depends on the MPU (memory protection unit) programming for the addressed region.

Table 47. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Noncacheable

In the case of a noncacheable access (read or write), the ICACHE is bypassed. The AHB transaction is propagated unchanged to the master output port, except the transaction address, which may be modified due to the address remapping feature (see *Section 7.4.7*).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in *Section 7.4.8*.

Cacheable memory regions are defined and programmed by the user in the MPU responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

Table 48 summarizes programmable configurations of various memories.

Table 48. Memory configurations

Memory	Cacheable (MPU programming)	Remapped in the ICACHE (ICACHE_CRRx programming)
Flash	Yes or no	Not required
SRAM	Not recommended	Not required
External memories	Yes	Required
	No	Required if the user wants code in external memories fetched on C-AHB bus (else on S-AHB bus)

7.4.7 Address remapping

The ICACHE allows an alias address to be defined in the code region for up to four external memory regions (only for STM32C59x/5A3 devices).

The address remapping is applied on the code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx (x = 0 to 3, number of remapped regions). This programming can be done only when the ICACHE is disabled.

Each region x can be individually enabled with REN in ICACHE_CRRx. Once enabled, the remap operation occurs even if the ICACHE is disabled, or if the transaction is noncacheable.

Remap regions can have different size: each can be programmed in RSIZE of its ICACHE_CRRx. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum of 2 Mbytes, and a maximum of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given code subregion base-address, and the modification of this address into its (remapped) physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code subregion base-address programmed in BASEADDR of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = $\log_2$ (region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region).
- If the region x is enabled, the master port output AHB address (HADDR_out) is composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs

Figure 19 describes the matching and the output address generation.

Figure 19. ICACHE remapping address mechanism

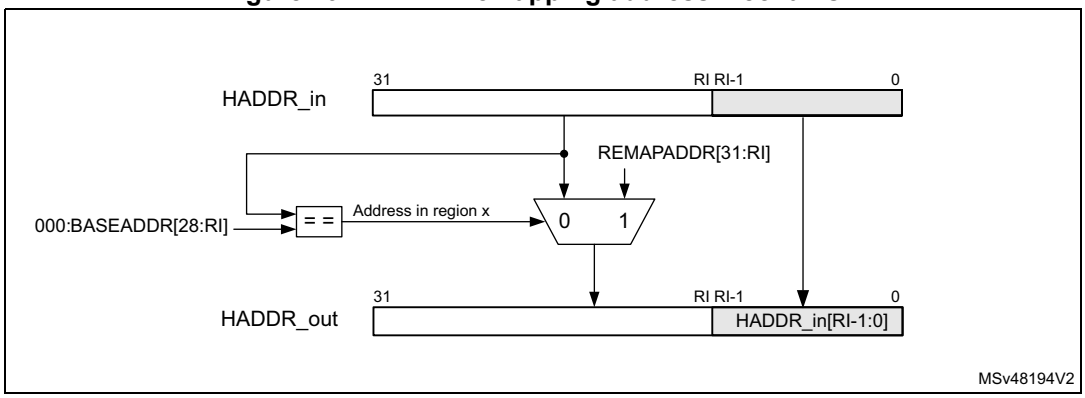


Table 49 summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending upon RSIZE.

Table 49. ICACHE remap region size, base address, and remap address

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
2	8	11
4	7	10
8	6	9
16	5	8
32	4	7
64	3	6
128	2	5

Care must be taken while programming BASEADDR and REMAPADDR in ICACHE_CRRx: if the programmed value is bigger than expected (number of MSBs, see *Table 49*), the unneeded extra LSBs are ignored.

Typical remapping example: a 128-Mbyte external RAM region physically located in the external address range [0x9000 0000:0x97FF FFFF], remapped in the code section range [0x1800 0000:0x1FFF FFFF]:

- REMAPADDR[31:21] = 0x480
- BASEADDR[28:21] = 0xC0
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], while HADDR_in and BASEADDR[26:21] are ignored.

If the comparison matches:

- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst generated by the ICACHE master ports on the bus matrix (for cache line refill), by setting HBURST in ICACHE_CRRx with:

- WRAP for remapped external memories accessed through interfaces that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through the interfaces that do not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming the MPU (memory protection unit) attributes for both the external regions and their aliased code subregions.

7.4.8 Cacheable accesses

When the ICACHE receives a cacheable transaction from the Cortex®-M33, it checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy ensures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words) if no address remap occurs. If an address remap occurs, the kind of burst depends upon the HBURST programmed in corresponding ICACHE_CRRx.

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port selected for the line refill (master1 port, or master2 port if available, as for STM32C59x/5A3 devices).

- The address is not present in TAG memory, but belongs to the refill burst from the main memory currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as data are available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

7.4.9 Dual-master cache

The ICACHE implements a dual-port AHB master on the main AHB bus matrix: master1 and master2 ports (master2 port on STM32C59x/5A3 devices only). This is used to split the traffic going to different destination memories.

The nonremapped traffic goes systematically to master1 port. The remapped traffic can be routed on the master2 port by programming MSTSEL in ICACHE_CRRx (on a region basis).

The code can typically be fetched as follows:

- internal flash memory and internal SRAM on master1 port (Fast bus)
- external flash memory/RAM on master2 port (Slow bus)

For systems not implementing external memories, the traffic to the internal flash memory can be decoupled from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual-master feature allows the processor to have an alternative path in case of fetching from different memories.

7.4.10 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

7.4.11 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 7.4.8*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

7.4.12 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

The code remapping at boot is not needed for a Cortex®-M33 as it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

7.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with lower performance profile (in terms of hit ratio) and stringent power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 18*). The power consumption is reduced by accessing, for each request, only the necessary cut of TAG and data memories. The cache effect still improves fetch performance, even if for most code execution, it is less efficient than with an n-way set associative cache mode.

7.6 ICACHE error management and interrupts

If an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 50. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as address decoding issues) from the master1 or master2 port back to the execution port.

7.7 ICACHE registers

7.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISS MRST	HITM RST	MISS MEN	HITM EN
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAY SEL	CACHE INV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

7.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	BSYENDF	BUSYF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

7.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	BSYENDIE	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end

Set by software to enable an interrupt generation at the end of a cache invalidate operation.

0: interrupt disabled on busy end

1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

7.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	CBSYENDF	Res.
													w	w	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CERRF**: clear cache error flag

Set by software.

0: no effect

1: clears ERRF flag in ICACHE_SR

Bit 1 **CBSYENDF**: clear busy end flag

Set by software.

0: no effect

1: clears BSYENDF flag in ICACHE_SR.

Bit 0 Reserved, must be kept at reset value.

7.7.5 ICACHE hit monitor register (ICACHE_HMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HITMON[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HITMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **HITMON[31:0]**: cache hit monitor counter

7.7.6 ICACHE miss monitor register (ICACHE_MMONR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MISSMON[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISSMON[15:0]**: cache miss monitor counter

7.7.7 ICACHE region x configuration register (ICACHE_CRRx)

Address offset: 0x020 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0200

Define an alias address in the code region for other regions, making them cacheable.

BASEDADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	MSTSEL	Res.	REMAPADDR[31:21]										
rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REN	Res.	Res.	Res.	RSIZE[2:0]			Res.	BASEADDR[28:21]							
rw				rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 7.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 7.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

7.7.8 ICACHE register map

Table 51. ICACHE register map and reset values

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

8 Power control (PWR)

8.1 PWR introduction

The power controller manages the device power supplies and power modes transitions.

8.2 PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain (V_{CORE})
  - V_{DD} domain
  - RTC domain (V_{RTC})
  - Analog domain (V_{DDA})
  - V_{DDUSB} for USB transceiver
- System supply voltage regulation
  - Linear voltage regulator (LDO)
- Power supply supervision
  - POR/PDR monitor
  - PVD monitor
- Power management
  - Low-power modes
- Privileged protection

8.3 PWR pins and internal signals

Table 52. PWR input/output pins

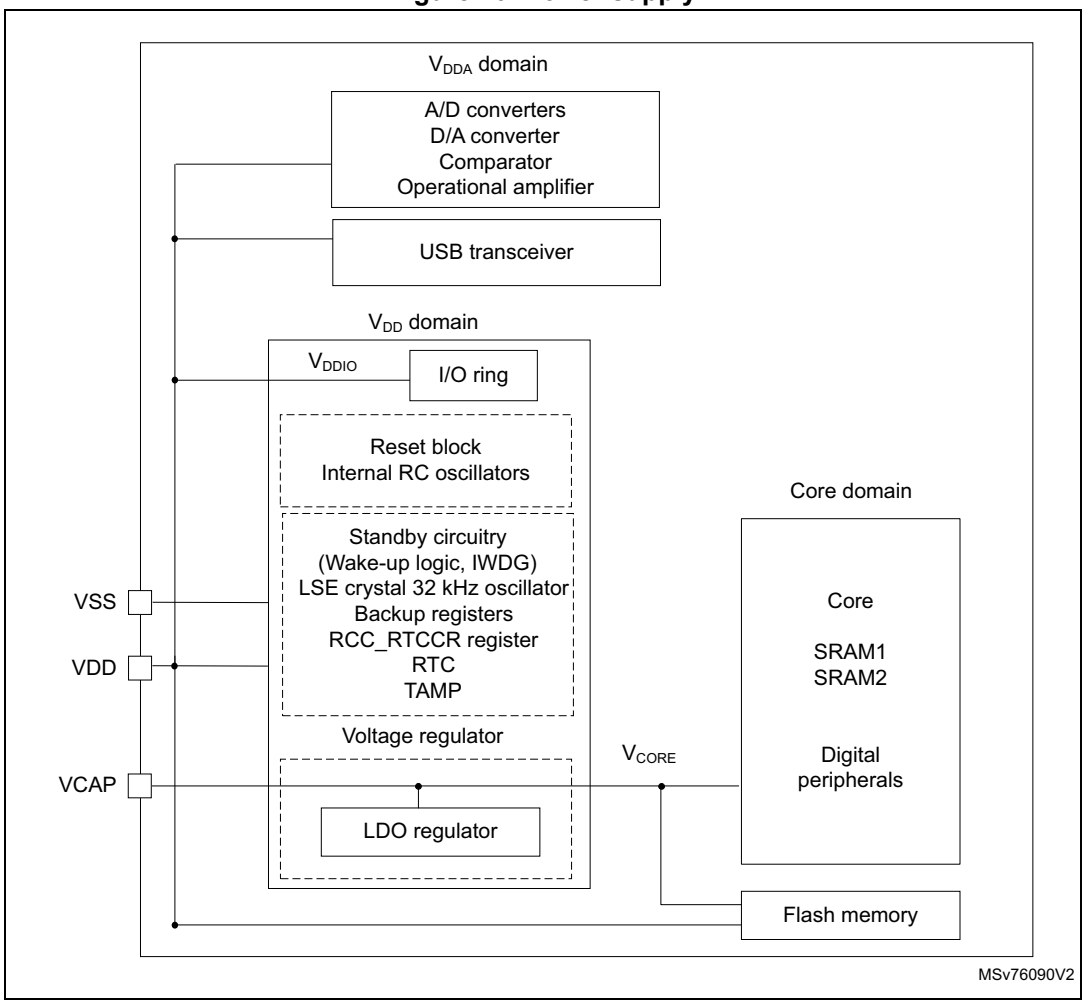
Pin name	Signal type	Description
VDD	Supply	Main supply
GND	Supply	Main ground
VDDA	Supply	Analog peripherals supply
VSSA	Supply	Analog peripherals ground
VCAP	Supply	Logic supply (V_{CORE})
VREF+	Supply	ADC/DAC high reference voltage
VREF-	Supply	ADC/DAC low reference voltage
WKUPx (x = 1 to 7)	Input	Wake-up pins
CSLEEP	Output	MCU in Sleep mode
CSTOP	Output	CPU in Stop modes

Table 53. PWR internal input/output signals

Internal signal name	Signal type	Description
WKUPx (x = 1 to 7)	Input	Wake-up event source

8.4 PWR power supplies and supply domains

Figure 20. Power supply



8.4.1 External power supplies

The devices require a 2.7 to 3.6 V operating voltage supply V_{DD}:

- V_{DD} = 2.7 to 3.6 V

  V_{DD} is the external power supply for the I/Os, the internal regulator, and the system analog (such as reset, power management, and internal clocks). It is provided externally through the VDD pins.

- V_{DDA} = 2.7 V (ADCs, DAC, COMP, and OPAMP) to 3.6 V

  V_{DDA} is the external analog power supply for A/D converters, D/A converters, operational amplifier, and the analog comparator. The V_{DDA} voltage domain is

physically connected to the V_{DD} voltage.

- V_{CAP} = 0.9 to 1.25 V: digital core domain supply
  This power supply is independent from all the other power supplies:
- V_{RTC} = 2.7 to 3.6 V
  V_{RTC} is the power supply for RTC, external clock 32 kHz oscillator, and backup registers. The V_{RTC} voltage level is physically connected to the V_{DD} voltage.
- V_{REF-}, V_{REF+}
  V_{REF+} is the input reference voltage for ADCs and DAC.
  V_{REF+} can be grounded when ADC and DAC are not active.
  VREF- and VREF+ pins are not available on all packages. When not available, they are bonded to VSS and VDD, respectively.
  V_{REF-} must always be equal to V_{SSA}.

8.4.2 Internal regulator

The devices embed an LDO regulator to provide the V_{CORE} supply for digital peripherals, SRAMs, and embedded flash memory. The LDO generates this voltage on VCAP, with a total external capacitance of 2.2 µF (typical). The LDO regulator is always enabled in Run mode and Stop mode, generating Vcore at 1.2 V in Run and Stop 0 mode and at 0.95 V in Stop 1 mode.

8.4.3 Independent analog peripherals supply

To improve ADC and DAC conversion and OPAMP accuracy, the analog peripherals have an independent power supply that can be filtered and shielded from noise on the PCB:

- The voltage supply input of the analog peripherals is available on VDDA pin.
- An isolated supply ground connection is provided on the VSSA pin.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+, a separate reference voltage lower than V_{DDA}. V_{REF+} is the highest voltage, represented by the full-scale value, for an analog input (ADC) or output (DAC) signal.

Note: The VREF+ and VREF- pins are not available on all packages. When not available, they are internally connected, respectively to VDD and VSS).

8.4.4 RTC domain

To retain the content of the backup registers and to supply the RTC function when the device enters Standby mode.

The RTC domain powers the RTC unit and the LSE oscillator, allowing the RTC to operate even when the core supply domain is switched off.

RTC domain access

After a system reset, the RTC domain (RCC RTC domain control register RCC_RTCCR, RTC registers, TAMP registers, and backup registers) is protected against possible unwanted write accesses. To enable access to the RTC domain, set the DRTCP bit in PWR_RTCCR.

8.5 PWR system supply voltage regulation

8.5.1 Embedded voltage regulator operating modes

There are three different power modes: Run, Stop mode (Stop 0 and Stop 1), and Standby modes.

Run mode

The voltage regulator provides full power to the V_{CORE} domain (core, memories, and digital peripherals). The regulator output voltage is 1.2 V and is stabilized thanks the VCAP capacitance.

Stop mode

The voltage regulator supplies the V_{CORE} domain to retain the content of registers and internal memories. The regulator under Stop 1 mode is configured to output 0.95 V to V_{CORE} domain.

Standby mode

The regulator is OFF and the V_{CORE} domain is powered down. The content of the registers and memories is lost except for the Standby circuitry in the RTC domain.

8.6 PWR power supply and temperature supervision

Power supply level monitoring is available on the following supplies:

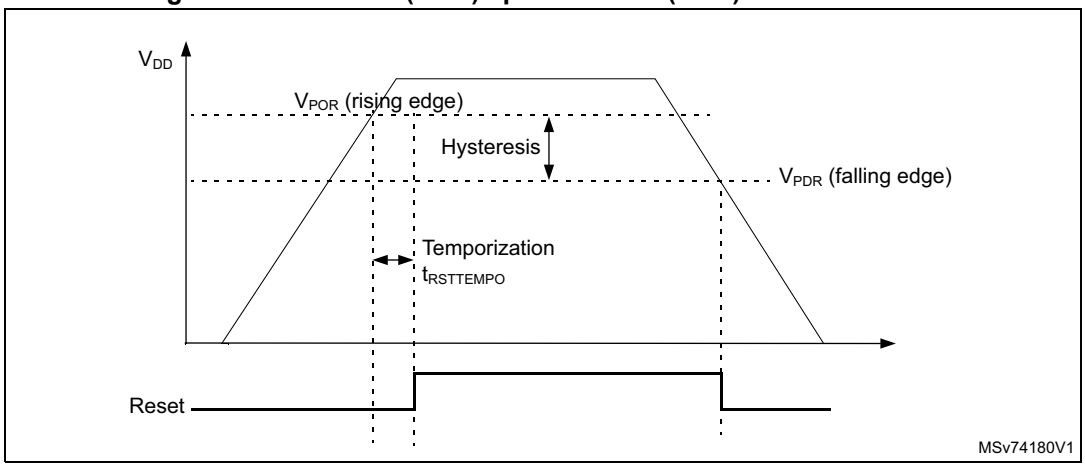
- V_{DD} via POR/PDR (see *Section 8.6.1*) and PVD monitor (see *Section 8.6.2*)
- Temperature monitoring (see *Section 21.4.30*)

8.6.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in reset mode when V_{DD} is below a specified VPOR threshold, without the need for an external reset circuit. Once the supply level is above the VPOR threshold, the system is taken out of reset (see figure below). For more details concerning the reset thresholds refer to the electrical characteristics section of the datasheets.

Figure 21. Power-on (POR) / power-down (PDR) reset waveform



1. For thresholds and hysteresis values refer to the datasheets.

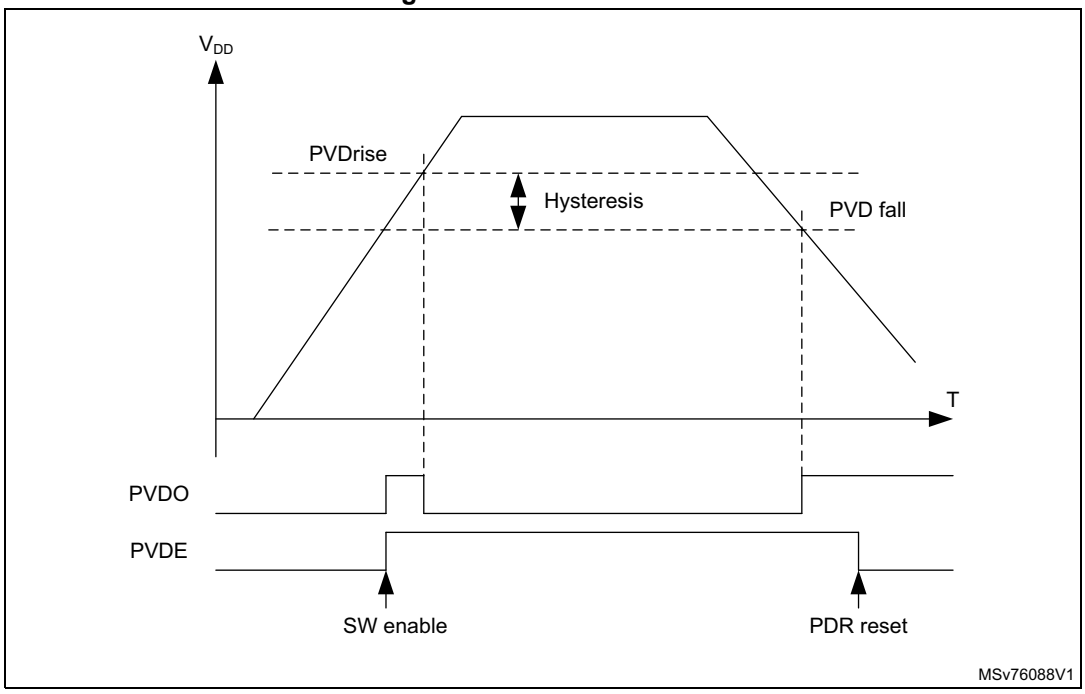
8.6.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a defined threshold.

The PVD is enabled by setting the PVDE bit in PWR_VMCR.

A PVDO flag is available in PWR_VMSR to indicate if V_{DD} voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, provided it has been enabled through the EXTI registers. The rising/falling edge sensitivity of the EXTI line must be configured according to PVD output behavior. As an example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when V_{DD} voltage drops below the PVD threshold. The service routine can then start an emergency shutdown.

Figure 22. PVD thresholds



1. For thresholds and hysteresis values, refer to the product datasheet.

8.7 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Three low-power modes are available to reduce consumption when there is no need to keep the CPU running, for example when waiting for an external event. The user can select the mode that gives the best compromise between low-power consumption, short startup time, and wake-up sources.

The device features the following low-power modes:

- Sleep mode

  CPU clock off, peripherals such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to *Section 8.7.4*.

- Stop 0 and Stop 1 modes

  Achieve the lowest power consumption, while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The HSE crystal oscillators, HSI (except if HSIKERON is set), PSI (except if PSIKERON is set) are disabled. The LSE or LSI is still running. Under Stop 0, the LDO regulator supplies VCORE at 1.2 V while under Stop 1 VCORE voltage is decreased down to 0.9 V. Consequently wake up sources are reduced and wake up time increased, refer to *Section Table 54.*

  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

  When exiting from Stop mode, the system clock is HSI clock at 144 MHz or 48 MHz based STOPWUCK value.

  Refer to *Section 8.7.5*.

- Standby mode

  This mode achieves the lowest power consumption. The internal regulator is switched

off so that the core domain is powered off. The HSI, PSI, and the HSE crystal oscillators are also switched off.

The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

The power-on reset and power-down reset (POR/PDR) remains active.

The state of the I/O (except I/Os used by Standby mode) during Standby mode can be retained.

After entering Standby mode, SRAMs and register contents are lost except for registers in the RTC domain and Standby circuitry.

The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), an RTC event occurs (alarm, periodic wake-up, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.

The system clock after wake-up is HSI at 48 MHz.

The table below shows the power modes overview.

Table 54. Low-power mode summary

Mode name	Entry	Wake-up source(1)	Wake-up system clock	Effect on clocks
Sleep (Sleep-now or Sleep-on-exit)	WFI or Return from ISR	Any interrupt	Same as before entering Sleep mode	– CPU clock OFF – No effect on other clocks or analog clock sources
	WFE	Wake-up event		
Stop 0	LPMS = 00 + SLEEPDEEP bit + WFI or Return from ISR or WFE	– Any EXTI line (configured in the EXTI registers) – Specific peripherals events(2)	– HSI clock at 144 MHz or 48 MHz based STOPWUCK value	– All clocks OFF except LSI and LSE – HSI or PSI can be enabled temporarily when requested by software or kept ON thanks to HSIKERON/PSIKERON bits
Stop 1	LPMS = 01 + SLEEPDEEP bit + WFI or Return from ISR or WFE	– Any GPIO EXTI line and EXTI from PVD, COMP, RTC, LPUART or LPTIM (configured in the EXTI registers)		– All clocks OFF except LSI and LSE
Standby	LPMS = 10 + SLEEPDEEP bit + WFI or Return from ISR or WFE	WKUP pin edge, RTC event, IWDG reset, external reset in NRST pin	HSI clock at 48 MHz	All clocks OFF except LSI and LSE

1. Refer to *Table 55*.
2. Peripherals able to wake up the system from Stop mode.

EXTI	O	O	O	O	O	-	-

1. Y = yes (enabled). O = optional (disabled by default, can be enabled by software). - = not available. HSI or PSI are available as kernel clock for peripherals only in STOP 0.
2. The memory can be configured in low-power mode. By default, it is not in Low-power mode during Stop.
3. The SRAM clock can be gated on or off independently. By default clock is enabled in Run and Sleep modes.
4. Wake-up with internal tamper.
5. GPIOs state can be retained during Standby mode. By default GPIOs states are not retained.
6. 7 pins are capable of wake-up from Standby mode: PA0, PA2, PB7, PC1, PC13, PD2, and PE6.

In addition, the power consumption in Run mode can be reduced by slowing down the system clocks and by gating the clocks to the APB and AHB peripherals when they are not used.

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 49.2.5: Debug and low-power modes*.

8.7.1 Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to *Section 9: Reset and clock control (RCC)*.

8.7.2 Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, or Stop 0 mode the peripheral clocks can be disabled before executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripheral clocks in Sleep mode or Stop 0 mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxLPENR and RCC_APBxLPENR registers.

8.7.3 Low-power modes

Entering into a low-power mode

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on return from ISR.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Exiting a low-power mode

The MCU exits the Sleep or Stop mode according to how the low-power mode was entered:

- If the WFI instruction or return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  - An NVIC IRQ interrupt:
    - When SEVONPEND = 0 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear

pending register) must be cleared. Only NVIC interrupts with high enough priority can wake up and interrupt the MCU.

> When SEVONPEND = 1 in the Cortex-M33 system control register
By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority can wake up and interrupt the MCU.

– An event:

> Configuring an EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit, as the pending bits corresponding to the event line are not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Standby mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see *Figure 561: RTC block diagram*).

After waking up from Standby mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

Caution: When the device is in Stop 0 mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device could remain in Stop mode with clock ON.

8.7.4 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The MCU enters the Sleep mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting the Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see the table below for details on how to exit the Sleep mode).

Table 56. Sleep mode

Sleep mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) pending Refer to the Cortex-M33 system control register.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 – No interrupt pending Refer to the Cortex-M33 system control register.
Mode exit	If WFI or Return from ISR was used for entry Interrupt (see *Table 100: STM32C5 vector table*) If WFE was used for entry and SEVONPEND = 0: Wake-up event (see *Section 16.3: EXTI functional description* If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC (see *Table 100: STM32C5 vector table*) or wake-up event (see *Section 16.3: EXTI functional description*)
Wake-up latency	None

8.7.5 Stop 0 mode

The Stop 0 mode is based on the Cortex-M33 Deepsleep mode combined with the peripheral clock gating. In Stop mode, all clocks in the core domain are stopped. The HSI, PSI, and HSE oscillators are disabled.

It is possible to keep the HSI or PSI clock enabled during Stop mode, to be quickly available as kernel clock for peripherals.

All register contents are preserved. SRAMs can be preserved or powered down, depending on the SRAMxPDSx bits in PWR_PMCR.

Table 57. Memory power down block selection

Selection bit	Power down block in Stop mode		
	STM32C53x/542	STM32C55x/562	STM32C59x/5A3
SRAM1PDS	SRAM1 block from 0 to 32 Kbytes	SRAM1 block from 0 to 64 Kbytes	SRAM1 block from 0 to 128 Kbytes
SRAM2PDS1	SRAM2 block from 0 to 16 Kbytes		
SRAM2PDS2	SRAM2 block from 16 to 32 Kbytes	SRAM2 block from 16 to 64 Kbytes	SRAM2 block from 16 to 64 Kbytes
SRAM2PDS3	-	-	SRAM2 block from 64 to 128 Kbytes

The power-down reset is always available in Stop 0 mode.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 0 mode

The MCU enters the Stop mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 54* for details on how to enter the Stop mode).

If the flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 37.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in RCC_RTCCR.
- The internal RC oscillator LSI clock is configured by the LSION bit in RCC_RTCCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_RTCCR.

The PVD can be used in Stop mode. If not needed, it must be disabled by software to save power consumption.

The ADCx (x = 1 to 3) and the DAC1 can consume power during the Stop mode, unless they are disabled before entering this mode.

Exiting the Stop 0 mode

The MCU exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered. Some peripherals are able to wake up the system (refer to *Table 103: EXTI line connections*) from Stop mode.

When exiting Stop 0 mode by issuing an interrupt or a wake-up event, HSI is selected as system clock. The MCU exits Stop 0 mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered.

Table 58. Stop 0 mode

Stop mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 00 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 00 in PWR_PMCR
	Note: To enter Stop 0 mode, all EXTI line pending bits (in Section 16.6.4: EXTI rising edge pending register (EXTI_RPR1) and Section 16.6.10: EXTI rising edge pending register 2 (EXTI_RPR2)), and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and the program execution continues.
Mode exit	If WFI or Return from ISR was used for entry: – any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 100: STM32C5 vector table*). – any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: – any EXTI line configured in event mode (see *Section 16.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: – any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 100: STM32C5 vector table*). – any EXTI line is configured in event mode (see *Section 16.3: EXTI functional description*)
	Note: All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN and [PERIPH]LPEN bits must be set in the RCC, and a functional independent clock must be selected).
Wake-up latency	Longest wake-up time between: HSI wake-up time and flash memory wake-up time from Stop mode.

8.7.6 Stop 1 mode

The Stop 1 mode is based on the Cortex-M33 Deep sleep mode combined with the peripheral clock gating. In comparison to Stop 0, the voltage regulator is configured to Low voltage retention at 0.9 V. All clocks in the core domain are stopped. The HSI, PSI, and HSE oscillators are disabled.

All register contents are preserved. SRAMs can be preserved or powered down, depending on SRAMxPDSx bits in PWR_PMCR. Refer to *Table 57: Memory power down block selection* for details.

The power-down reset is always available in Stop mode.

I/O states in Stop 1 mode

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 1 mode

The MCU enters the Stop 1 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 54* for details on how to enter the Stop mode).

If the flash memory programming is ongoing, the Stop 1 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 1 mode entry is delayed until the APB access is finished.

In Stop 1 mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 37.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in RCC_RTCCR.
- The internal RC oscillator LSI clock is configured by the LSION bit in RCC_RTCCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_RTCCR.

The PVD can be used in Stop mode. If not needed, it must be disabled by software to save power consumption.

The ADCx (x = 1 to 3) and the DAC1 can consume power during the Stop 1 mode, unless they are disabled before entering this mode.

Exiting the Stop 1 mode

The MCU exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered.

When exiting Stop mode by issuing an interrupt or a wake-up event, HSI is selected as system clock. The MCU exits Stop 1 mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered.

Table 59. Stop 1 mode

Stop mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 01 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 01 in PWR_PMCR
	Note: To enter Stop mode, all EXTI line pending bits (in Section 16.6.4: EXTI rising edge pending register (EXTI_RPR1) and Section 16.6.10: EXTI rising edge pending register 2 (EXTI_RPR2)), and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.
Mode exit	If WFI or Return from ISR was used for entry: – any GPIO EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source must be external interrupts with wake-up capability (see *Table 100: STM32C5 vector table*). If WFE was used for entry and SEVONPEND = 0: – any GPIO EXTI line configured in event mode (see *Section 16.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: – any GPIO EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source must be external interrupts with wake-up capability (see *Table 100: STM32C5 vector table*). – any GPIO EXTI line is configured in event mode (see *Section 16.3: EXTI functional description*)
Wake-up latency	Longest wake-up time between: HSI wake-up time, regulator stabilization from 0.9 V to 1.2 V and flash memory wake-up time from Stop mode.

8.7.7 Standby mode

The lowest power mode in which the POR/PDR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled. The HSI, PSI, and HSE oscillators are also switched off.

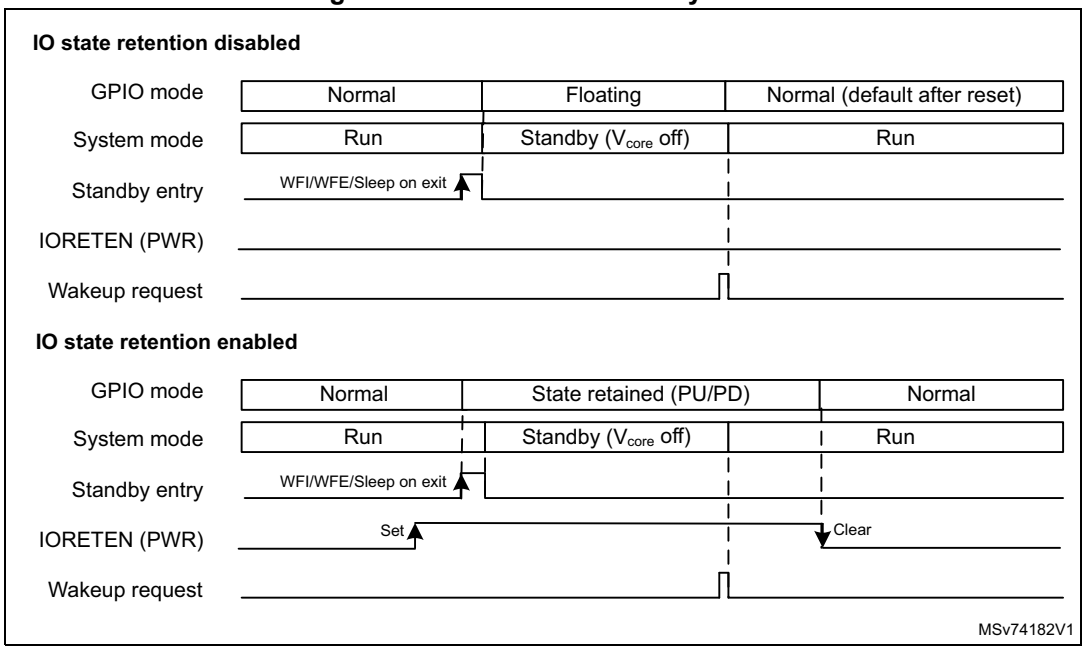
The SRAMs and register contents are lost except for registers in the backup domain and Standby circuitry (see *Figure 23*).

I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If the IORETEN bit in the PWR_IORETR register is set, the I/Os output state is retained. I/O retention mode is enabled for all I/Os except those supporting the standby functionality and JTAG I/Os (PA13, PA14, PA15, and PB4). When entering into Standby mode, the state of the output is sampled, and pull-up or pull-down resistors are set to maintain the I/O output during Standby mode.

If the JTAGIORETEN bit in the PWR_IORETR register is set, the I/Os output state is retained. I/O retention mode is enabled for PA13, PA14, PA15, and PB4 (default JTAG pull-up/pull-down after wake-up is not enabled).

Figure 23. I/O states in Standby mode



After wake-up from Standby mode, as long as IORETEN (or JTAGIORETEN for JTAG I/Os) is set, the retained state (pull-up/pull-down) remains applied.

The GPIO pin state before standby can be identified with GPIO_IDR register (when both GPIO port clock and input buffer are enabled).

The application can release the I/O state (clear the retained Pull-up/Pull-down) by clearing the IORETEN (or JTAGIORETEN for JTAG I/Os) bit, before or after reconfiguring the GPIOs and related peripherals. The GPIOs can then be configured in a known state before releasing the retained state.

The RTC output on PC13 is functional in Standby mode. PC14 and PC15 used for LSE are also functional. Up to seven wake-up (WKUPx, x = 1 to 7) and three RTC tamper pins are available.

Entering Standby mode

The MCU enters the Standby mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 60* for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 37.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in RCC_RTCCR.
- The internal RC oscillator LSI clock is configured by the LSION bit in RCC_RTCCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_RTCCR.
- The I/Os retention is configured by the IORETEN bit in the PWR_IORETR register.

Exiting Standby mode

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in PWR_PMSR) indicates that the MCU was in Standby mode. All registers are reset after wake-up from Standby except for PWR_RTCCR and PWR_IORETR *(see Table 60* for more details on how to exit Standby mode).

When exiting Standby mode, I/Os output state that were retained during Standby through IORETEN bit, keep this configuration upon exiting Standby mode until the IORETEN bit in PWR_IORETR register is cleared. Once IORETEN is cleared, the I/Os are configured to their reset values, or to the pull-up/pull-down state according to the GPIOx_PUPDR registers.

For I/Os, with a pull-up or pull-down predefined after reset (some JTAG/SWD I/Os), in case those pull-up or pull-downs are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Also in case the GPIOx_PUPDR values programed after exiting from Standby are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Table 60. Standby mode

Standby mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 10 in PWR_PMCR – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 10 in PWR_PMCR – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared
Mode exit	WKUPx pin edge, RTC event, external reset in NRST pin, IWDG reset
Wake-up latency	Reset phase

8.7.8 Power mode output pins

In order to help the debug, two signals are available as device pins alternate functions:

- **CSLEEP**

  When set, CSLEEP indicates that the system is in Sleep mode: WFI or WFE has been executed.

  When cleared, CSLEEP indicates that the system is in Run mode.

- **CSTOP**

  When set, CSTOP indicates that the system is in Stop mode, meaning that the following conditions are fulfilled:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  – No AHB/APB clock is running.

  When cleared, CSTOP indicates that the system is not in Stop mode: AHB/APB clocks are running.

The table below explains the MCU power mode depending on these signal states.

Table 61. Power mode output states versus MCU power modes

CSLEEP	CSTOP	MCU power modes(1)
0	0	Run mode
1	0	Sleep mode
1	1	Stop mode

1. CSLEEP and CSTOP are generated in core domain, consequently they are not driven in Standby mode.

8.8 PWR privileged protection

By default, after a reset, all registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR, which can be written only with privileged access. PWR_PRIVCFGR can be read by privileged and unprivileged accesses.

The PRIV bit of PWR_PRIVCFGR can be written only with privileged access. It configures the privileged access of all PWR functions (defined by RCC, or GPIO).
When the PRIV bit is set in PWR_PRIVCFGR:

- The PWR bits can be written only with privileged access.
- The PWR bits can be read only with privileged access except PWR_PRIVCFGR, which can be read by privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as 0, and the write to these bits is ignored (RAZ/WI).

8.9 PWR interrupts

The table below gives a summary of the interrupt sources and the way to control them.

Table 62. PWR interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop mode	Exit Standby mode
PVD output	Programmable voltage detector through EXTI line 16	PVDO	EXTI line 16 enabled	Write EXTI PIF16 = 1	Yes	No

8.10 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

For the actual availability of some peripherals/features and their related bits, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved, and keep them at reset value

8.10.1 PWR power mode control register (PWR_PMCR)

Address offset: 0x000

Reset value: 0x0000 0000

This register is protected against unprivileged access when PRIV = 1 in PWR_PRIVCFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	FLPS	Res.	CSSF	Res.	Res.	Res.	Res.	Res.	LPMS[1:0]	
						rw		rw						rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SRAM1PDS**: AHB SRAM1 block power down in Stop mode
0: AHB RAM1 content is kept in Stop mode.
1: AHB RAM1 content is lost in Stop mode.

Bit 25 **SRAM2PDS2**: AHB SRAM2 block 2 power down in Stop mode
0: AHB RAM2 block 2 content is kept in Stop mode.
1: AHB RAM2 block 2 content is lost in Stop mode.
Note: For block definition, refer to *Table 57: Memory power down block selection*.

Bit 24 **SRAM2PDS1**: AHB SRAM2 block 1 power down in Stop mode
0: AHB RAM2 block 1 content is kept in Stop mode.
1: AHB RAM2 block 1 content is lost in Stop mode.
Note: For block definition, refer to *Table 57: Memory power down block selection*.

Bit 23 **SRAM2PDS3**: AHB SRAM2 block 3 power down in Stop mode
0: AHB RAM2 block 3 content is kept in Stop mode.
1: AHB RAM2 block 3 content is lost in Stop mode.
Note: For block definition, refer to *Table 57: Memory power down block selection*.

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FLPS**: Flash memory low-power mode in Stop mode
This bit is used to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.
When it is set, the flash memory enters low-power mode when the system is in Stop mode.
0: Flash memory remains in normal mode when the system enters Stop mode (quick restart time).
1: Flash memory enters low-power mode when the system enters Stop mode (low-power consumption).

Bit 8 Reserved, must be kept at reset value.

Bit 7 **CSSF**: Clear Standby and Stop flags (always read as 0)
This bit is cleared to 0 by hardware.
0: No effect
1: STOPF and SBF flags cleared

Bits 6:2 Reserved, must be kept at reset value.

Bits 1:0 **LPMS[1:0]**: low-power mode selection
This bits define the Deepsleep mode.
00: Stop 0 mode when entering DeepSleep.
01: Stop 1 mode when entering DeepSleep.
10: Standby mode when entering DeepSleep.
11: Reserved

8.10.2 PWR status register (PWR_PMSR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.
									r	r					

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SBF**: System standby flag
This bit is set by hardware and cleared only by a POR or by setting the CSSF bit.
0: System has not been in Standby mode.
1: System has been in Standby mode.

Bit 5 **STOPF**: Stop flag
This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.
0: System has not been in Stop mode.
1: System has been in Stop mode.

Bits 4:0 Reserved, must be kept at reset value.

8.10.3 PWR RTC domain control register (PWR_RTCCR)

Address offset: 0x24

Reset value: 0x0000 0000

This register is protected against unprivileged access when PRIV = 1 in PWR_PRIVCFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DRTCP
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DRTCP**: Disable RTC domain write protection

In reset state, all registers in RTC domain are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Write access to RTC domain disabled

1: Write access to RTC domain enabled

8.10.4 PWR voltage monitor control register (PWR_VMCR)

Address offset: 0x034

Reset value: 0x0000 0000

This register is protected against unprivileged access when PRIV = 1 in PWR_PRIVCFGR register.

The PVDE bit is protected by lock mechanism. The lock control is in the SBS module controlled by PVDL bit in SBS_CFGR2 register. By default, the PVDE is unlocked.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PVDO**: programmable voltage detect output

This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.

0: V_{DD} is equal or higher than the PVD threshold.

1: V_{DD} is lower than the PVD threshold.

Note: Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bits 21:0 Reserved, must be kept at reset value.

8.10.6 PWR wake-up status clear register (PWR_WUSCR)

Address offset: 0x040

Reset value: 0x0000 0000

Each register bit CWUFx (x = 1 to 7) is protected against unprivileged access when PRIV = 1 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

									w	w	w	w	w	w	w

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **CWUFx**: clear wake-up pin flag for WUFx (x = 7 to 1)

These bits are always read as 0.

0: No effect

1: Writing 1 clears the WUFx wake-up pin flag (bit is cleared to 0 by hardware).

8.10.7 PWR wake-up status register (PWR_WUSR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **WUFx**: wake-up pin WUFx flag (x = 7 to 1)

This bit is set by hardware and cleared only by a RESET pin or by setting the CWUFx bit in PWR_WUSCR register or by hardware when WUPENx = 0.

0: No wake-up event occurred.

1: Wake-up event received from WUFx pin.

8.10.8 PWR wake-up configuration register (PWR_WUCR)

Address offset: 0x048

Reset value: 0x0000 0000

Each WUPPUPDx (x = 1 to 7), WUPPx (x = 1 to 7), and WUPENx (x = 1 to 7) is protected against unprivileged access when PRIV = 1 in PWR_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	WUPPUPD7[1:0]		WUPPUPD6[1:0]		WUPPUPD5[1:0]		WUPPUPD4[1:0]		WUPPUPD3[1:0]		WUPPUPD2[1:0]		WUPPUPD1[1:0]	
		rw	rw	rw	rw	rw	w	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	WUPP 7	WUPP 6	WUPP 5	WUPP 4	WUPP 3	WUPP 2	WUPP 1	Res.	WUPE N7	WUPE N6	WUPE N5	WUPE N4	WUPE N3	WUPE N2	WUPE N1
	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **WUPPUPDx[1:0]**: Wake-up pin pull configuration for WKUPx (x = 7 to 1)

These bits define the I/O pad pull configuration used when WUPENx = 1. The associated GPIO port pull configuration must be set to the same value or to 00. The wake-up pin pull configuration is kept in Standby mode.

00: No pull-up

01: Pull-up

10: Pull-down

11: Reserved

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **WUPPx**: Wake-up pin polarity bit for WKUPx (x = 7 to 1)

These bits define the polarity used for event detection on WUPx external wake-up pin.

0: Detection on high level (rising edge)

1: Detection on low level (falling edge)

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **WUPENx**: Enable wake-up pin WKUPx (x = 7 to 1)

These bits are set and cleared by software.

0: An event on WUPx pin does not wake-up the system from Standby mode.

1: A rising or falling edge on WUPx pin wakes up the system from Standby mode.

Note: An additional wake-up event is detected if WUPx pin is enabled (by setting the WUPENx bit) when WUPx pin level is already high when WUPPx selects rising edge, or low when WUPPx selects falling edge.

8.10.9 PWR I/O retention register (PWR_IORETR)

Address offset: 0x050

Reset value: 0x0000 0000

This register is protected against unprivileged access PRIV = 1 in the PWR_PRIVCFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IORETEN
															rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **JTAGIORETEN**: IO retention enable for JTAG I/Os

0: I/O retention mode is disabled.

1: I/O retention mode is enabling for PA13, PA14, PA15, and PB4.

When entering Standby mode, the output is sampled, and apply to the output I/O during the Standby power mode.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **IORETEN**: IO retention enable

0: I/O retention mode is disabled.

1: I/O retention mode is enabling for all I/Os except the I/O support the standby functionality and PA13, PA14, PA15, and PB4.

When entering Standby mode, the output is sampled, and apply to the output I/O during the Standby power mode.

Note: The I/O state is not retained if the DBG_STANDBY bit is set in DBGMCU_CR register.

8.10.10 PWR privilege configuration register (PWR_PRIVCFGR)

Address offset: 0x104

Reset value: 0x0000 0000

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PRIV**: PWR functions privilege configuration

Set and reset by software. This bit can be written only by privileged access.

0: Read and write to PWR functions can be done by privileged or unprivileged access.

1: Read and write to PWR functions can be done by privileged access only.

Bit 0 Reserved, must be kept at reset value.

Refer to *Section 2.2* for the register boundary addresses.

9 Reset and clock control (RCC)

9.1 RCC introduction

The reset and clock control (RCC) manages the different resets, and generates the clocks for the bus and peripheral.

9.2 RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

Table 64. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO	O	Output clock for external devices
LSCO	O	Low-speed output clock for external devices
AUDIOCLK	I	External kernel clock input for I2S1, I2S2, and I2S3

9.3 RCC reset functional description

There are three types of reset:

- A system reset
- A power reset
- A RTC domain reset

9.3.1 Power reset

A power reset is generated when one of the following events occurs:

- A power-on or power-down reset (POR/PDR)
- When exiting Standby mode

A power-on or power-down reset (POR/PDR) sets all registers to their reset values.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, WKUP, IWDG, and GPIO pull-up/pull-down configuration during Standby and Standby mode exit) are not impacted.

9.3.2 System reset

A system reset sets all registers to their reset values, except the reset flags in RCC_RSR, and the registers in the RTC domain.

A system reset is generated when one of the following events occurs:

- A low level on the NRST pin (external reset)
- A window watchdog event (WWDG reset)
- An independent watchdog event (IWDG reset)
- A software reset (SW reset) (see *Software reset*)
- A low-power mode security reset (see *Low-power mode security reset*)
- A POR reset

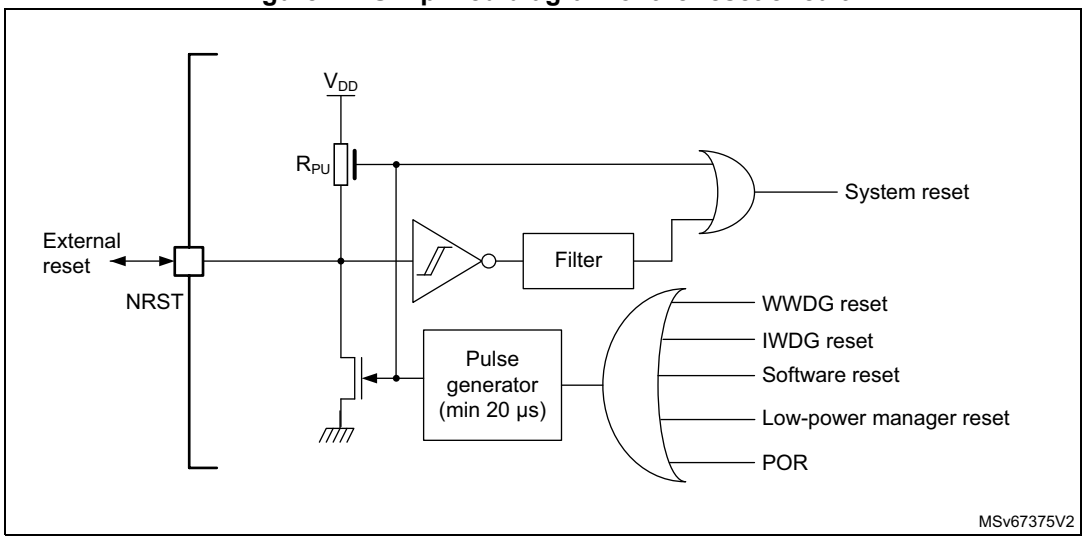
The reset source can be identified by checking the reset flags in RCC_RSR.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected depending on RDP level, on Boot option bytes or on both.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case of an internal reset, the internal pull-up R_{PU} is deactivated to save the power consumption through the pull-up resistor.

Figure 24. Simplified diagram of the reset circuit



Software reset

The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.

Low-power mode security reset

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- Entering Standby mode: this type of reset is enabled by resetting NRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Entering Stop mode: this type of reset is enabled by resetting NRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

For further information on the user option bytes, refer to *Section 6.4: FLASH option bytes*.

9.3.3 RTC domain reset

The RTC domain has two specific resets, generated when one of the following events occurs:

- A software reset, is triggered by setting the RTCDRST bit in RCC_RTCCR. Write access to this domain must be enabled before setting RTCDRST bit to perform the reset.
- A V_{DD} power on

An RTC domain reset affects the LSE oscillator, the RTC, the backup registers, and the RCC_RTCCR register.

9.3.4 Reset source identification

The application can identify the reset source by checking the reset flags in the RCC_RSR register.

The software can reset the flags by setting the RMVF bit.

The table below shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs, if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 65. Reset source identification (RCC_RSR)(1)

	Reset	LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	PORRSTF	PINRSTF
1	Power-on reset	0	0	0	0	1	1
2	Pin/pad reset	0	0	0	0	0	1
3	System reset generated by CPU	0	0	0	1	0	1
4	WWDG reset	0	1	0	0	0	1
5	IWDG reset	0	0	1	0	0	1
6	Illegal stop entry reset	1	0	0	0	0	1

1. Gray cells highlight the register bits that are set.

9.4 RCC clocks functional description

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSIS: high-speed internal clock at 144 MHz
  - and HSIDIV3: high-speed internal clock is divided by 3; at 48 MHz
- PSIS: programmable speed internal clock up to 160MHz (max SYSCLK is 144 MHz)
- HSE: high-speed external crystal or clock, from 4 to 50 MHz

The HSIDIV3 is used as a the system clock source after startup from reset, at 48 MHz.

Note: If HSE or PSIS with HSE as reference are used as SYSCLK and the HSE CSS detect a failure, HSIDIV3 is automatically set as SYSCLK. Adequate wait state supporting both frequencies must be configured in this case.

The device has the following additional clock sources:

- HSIK: high-speed internal clock divided by 1;1.5; 2;...; 7.5; 8
- PSIDIV3: programmable speed internal clock divided by 3
- PSIK: programmable speed internal clock divided by 1;1.5; 2;...; 7.5; 8
- LSI: 32 kHz low-speed internal RC that drives the independent watchdog and optionally the RTC used for auto-wake-up from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB and APB frequencies. The maximum frequency of the AHB and APB domains is 144 MHz.

The peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2 or PCLK3), except those that receive an independent kernel clock. This kernel clock can be selected by software between several sources thanks to RCC_CCIPRx registers (x = 1 to 3).

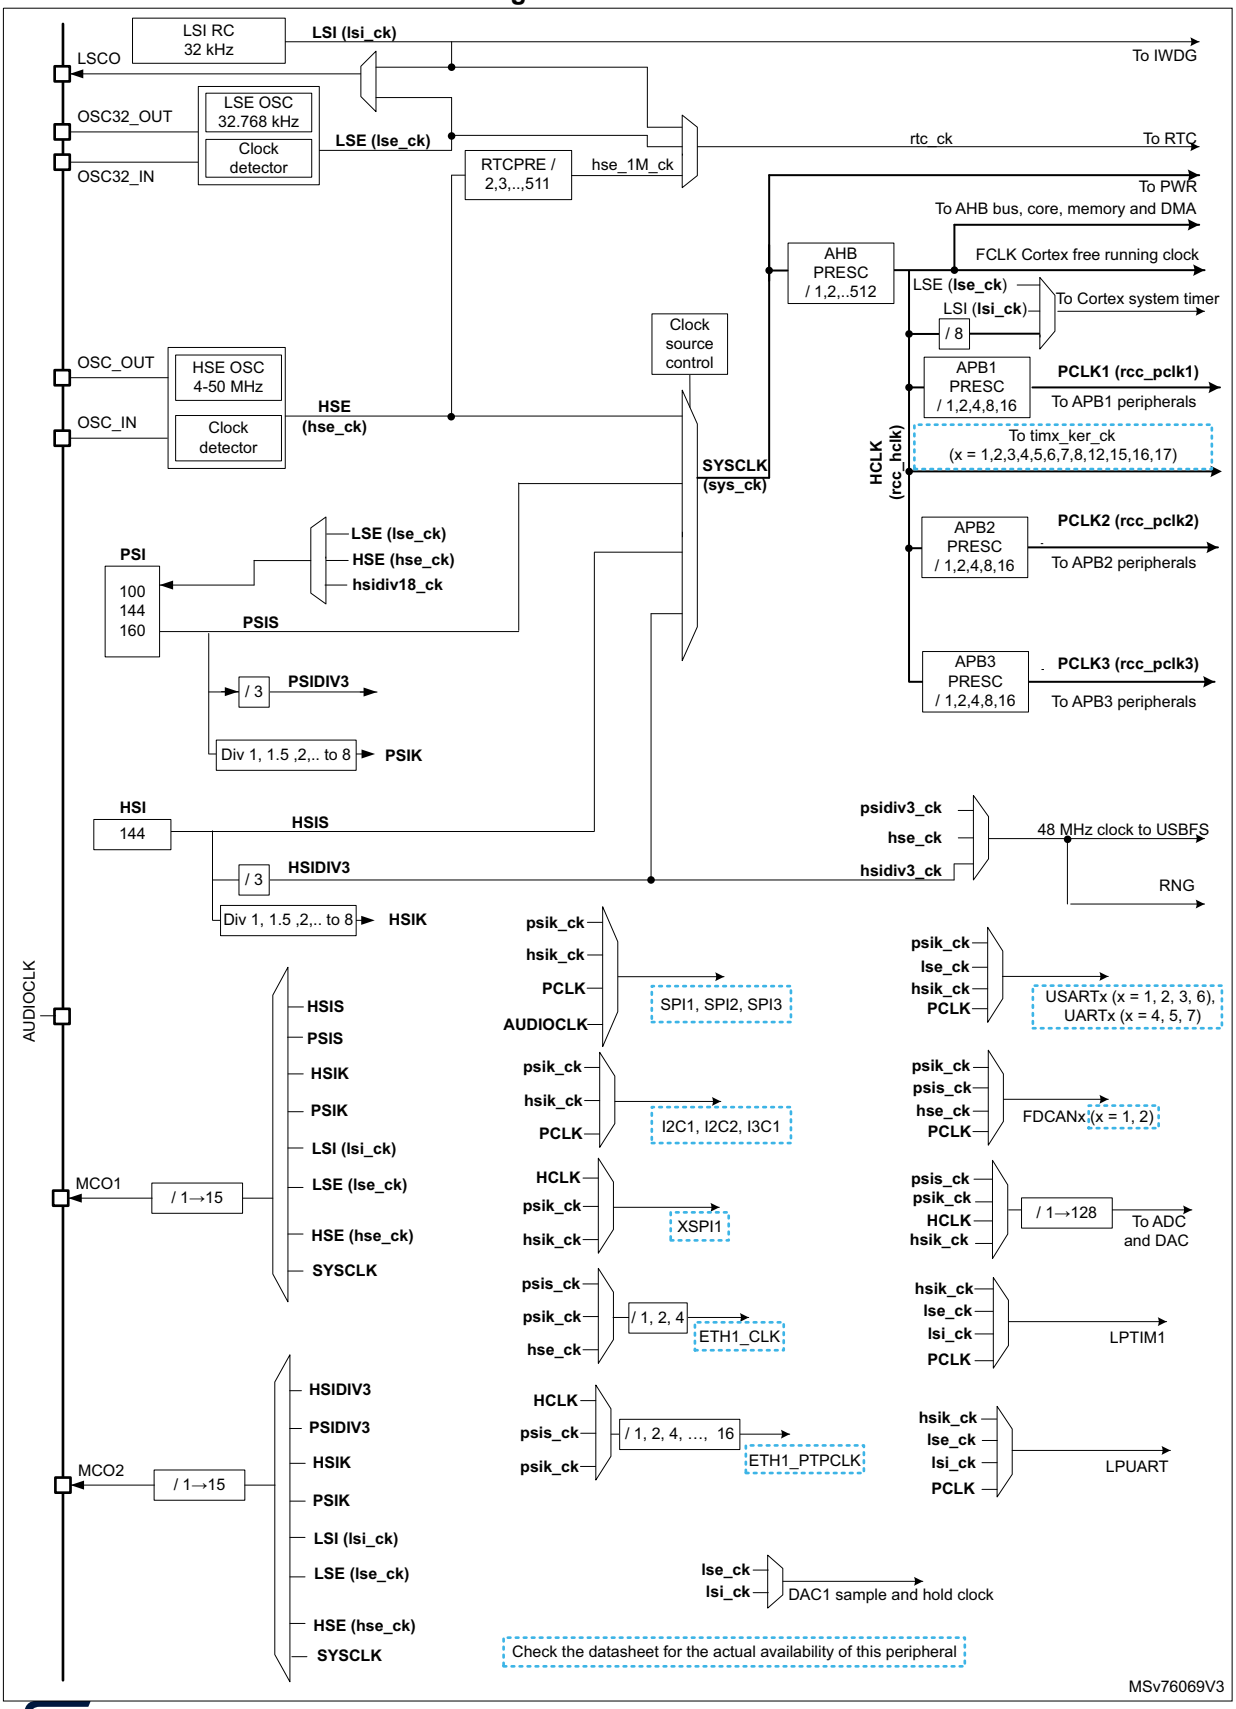
Note: All timers (except LPTIM) are clocked by HCLK, independently of their respective PCLK.

In addition, the RTC kernel clock is selected by software in RCC_RTCCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the Cortex system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE or LSI. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as a a Cortex-M33 free-running clock.

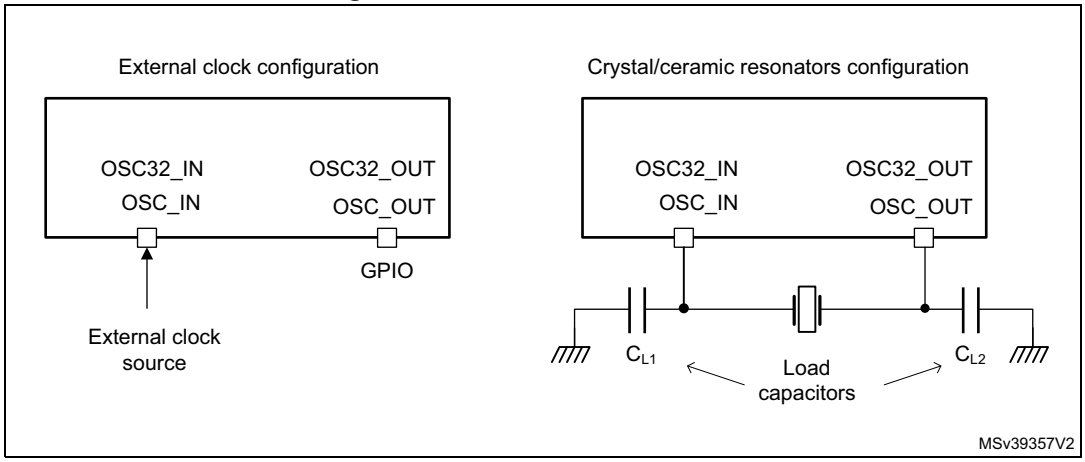
Figure 25. Clock tree



9.4.1 HSE clock

The HSE block can generate a clock from an external crystal/ceramic resonator, or from an external clock source.

Figure 26. HSE/ LSE clock sources



External clock source (HSE bypass)

In this mode, an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital. If this clock is directly used by a peripheral, the duty cycle requirement is defined by the peripheral and the application (refer to datasheet for more details).

In case of an analog clock (low swing) the HSEBYP and HSEON bits must be set to 1 in RCC_CR1.

In case of a digital clock, the HSEBYP and the HSEEXT bits must be set to 1 followed by setting the HSEON bit to 1 in RCC_CR1.

External crystal/ceramic resonator

The oscillator is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

The HSE can be used when the product requires a very accurate high-speed clock.

The associated hardware configuration is shown in *Figure 26*: the resonator and the load capacitors must be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in RCC_CR1 indicates whether the HSE oscillator is stable or not. At startup, the hse_ck clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

The HSE can be switched on and off through the HSEON bit.

Note: The HSE cannot be switched off if one of the following two conditions is met:

- the HSE is used directly (through software multiplexer) as a system clock
- the HSE is selected as the reference clock for PSI, with PSI enabled and selected to provide the system clock (through software multiplexer).

In that case the hardware does not allow programming the HSEON bit to 0.

The HSE is automatically disabled by hardware when the system enters Stop or Standby mode. It can be kept on under Stop 0 mode if PSIKERON is set and PSI needs HSE as a reference clock.

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as a clock source for other application components.

9.4.2 HSI oscillator and HSIS clock

The HSI block provides the default clocks to the product.

The HSI is a high-speed internal oscillator that can be used as a system clock or peripheral clock offering a 144MHz clock available at startup and upon wake-up from low power modes. The HSI oscillator can produce 3 output clocks; HSIS, HSIDIV3, and HSIK.

Two output dividers let you extent the available frequencies for the device. One configurable divider by 1.5, 2, 2.5, ... 7.5 or 8 is configured thanks to HSIKDIV[3:0] generating HSIK clock and a second divided by 3 intended for system clock and USB generating HSIDIV3.

The HSI advantages are the following:

- Low-cost clock source, as no external crystal is required
- Faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

HSI oscillator can be switched on and off using the HSISON bit, the HSIDIV3ON bit, and the HSIKON bit. Only the enabled clock output is generated.

Note: The HSI cannot be switched off if the HSI is used directly (via SW mux) as a system clock. In that case the hardware does not allow clearing the HSISON bit or HSIDIV3ON bit to 0.

The HSISRDY, HSIKRDY, and HSIDIV3RDY flags indicate if the HSI is stable or not. At startup, the HSIS output clock is not released until HSISRDY is set by hardware.

The HSIDIV3 clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *Section 9.4.10: Clock security system (CSS)*).

In addition, the HSI clocks can be driven to the MCO1 or MCO2 outputs and used as clock source for other application components.

Care must be taken when the HSIK is used as a kernel clock for communication peripherals, the application must take in account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available
- the frequency accuracy.

Note: The HSI can remain enabled when the system is in Stop 0 mode thanks to HSIKERON bit. In this case, the HSI and its clocks outputs HSIK, HSIDIV3, or HSIS, are kept active if their respective HSIKON, HSIDIV3ON, and HSISON are set. The states of these bits are consequently maintained exiting Stop 0 if HSIKERON bit is set.

HSI calibration

HSI oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACCHSI (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded. If the application is subject to voltage or temperature variations, this may affect the oscillator frequency. The user application can trim the HSI frequency using the TRIM[6:0] bits in the CRS_CR register.

The clock recovery system can be used to perform this calibration. It requires an accurate reference that can be HSE (through HSE_1MHz connection), LSE, USB Start of Frame, or an external signal.

9.4.3 PSI oscillator and PSIS clock

The PSI oscillator provides a 100 MHz, 144 MHz, or 160 MHz frequency, selected thanks to PSIFREQ[1:0] bitfield, to the product on condition that an adequate reference clock is available. This programmable speed internal oscillator can be used as a system clock or peripheral clock. The PSI oscillator can produce three output clocks; PSIS, PSIDIV3, and PSIK.

The PSI is only operational when receiving a reference clock of 32.768 kHz, 8 MHz, or 8.33 MHz (25 MHz divided by 3) as input. The PSIREF[2:0] bitfield helps you get the required input frequency depending on your chosen external clock. This external clock is selected thanks to PSIREFSRC[1:0] multiplexer between LSE, HSE, or HSI divided by 18. Details of possible settings are listed in the table below.

Table 66. PSI frequency settings

PSIFREQ[1:0]	PSIREFSRC[1:0]	PSIREF[2:0]
160	HSE	48
		32
		24
		16
		8
	HSI/18	8
	LSE	0.032768
144	HSE	48
		32
		24
		16
		8
	HSI/18	8
	LSE	0.032768

Table 66. PSI frequency settings (continued)

PSIFREQ[1:0]	PSIREFSRC[1:0]	PSIREF[2:0]
100	HSE	50
		48
		32
		25
		24
		16
		8
	HSI/18	8
	LSE	0.032768

Note: If LSE is used as reference, an intrinsic error must be anticipated on the output frequency (100.016 MHz, 144.015 MHz, and 160.006 MHz)

Two output dividers can be used to extent the available frequencies for the device. One configurable divider by 1.5, 2, 2.5, 3, 3.5, ... , 7.5, or 8, configured thanks to PSIKDIV[3:0] generating PSIK clock and a second dividing by 3 generating PSIDIV3 clock, intended for USB.

The PSI advantages are the following:

- Programmable high-speed clock source based on a reference clock
- Configurable output frequencies (100 MHz, 144 MHz, 160 MHz)

The PSI frequency accuracy is directly related to the accuracy of its reference clock (for more details regarding the specification of this oscillator, refer to product datasheet).

PSI oscillator can be switched on and off using the PSISON bit, the PSIDIV3ON bit, or the PSIKON bit. Only the enabled clock output is generated.

Note: The PSI cannot be switched off if used (via SW mux) as a system clock. In that case, the hardware does not allow programming the PSISON bit to 0.

The PSISRDY, PSIKRDY, and PSIDIV3RDY flags indicate if the oscillator is stable or not.

In addition, the PSI clocks can be driven to the MCO1 or MCO2 outputs, and used as clock source for other application components.

Care must be taken when the PSI is used as a kernel clock for communication peripherals; the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available

Note: The PSI can remain enabled when the system is in Stop 0 mode thanks to PSIKERON bit. In this case the PSI and its clock outputs PSIK, PSIKDIV3, or PSIS are kept enabled if their respective PSIKON, PSIDIV3ON, and PSISON are set. The states of those bits are maintained exiting Stop 0 if the HSIKERON bit is set.

9.4.4 HSIDIV3 and PSIDIV3 clock

The HSIDIV3 clock signal is generated from the internal 144 MHz RC oscillator, divided by 3 to be used directly for USB and for random number generator (RNG).

This internal 48 MHz clock is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE, or an external signal to automatically and quickly adjust the oscillator frequency on-the-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI oscillator runs on its default frequency, subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to *Section 10: Clock recovery system (CRS)*.

The HSIDIV3RDY flag in the RCC_CR register indicates whether the HSIDIV3 clock is stable or not. At startup, the HSIDIV3 output clock is not released until this bit is set by the hardware.

The HSIDIV3 clock signal can be switched on and off using the HSIDIV3ON bit in the RCC_CR register.

The PSIDIV3 clock signal is generated from the internal 144 MHz RC oscillator, divided by 3 to be used directly for USB and for random number generator (RNG). It benefits from the accuracy of the HSE or LSE thanks to its operation in PLL mode. Similarly to HSIDIV3, it is disabled in Stop or Standby mode, ready once PSIDIV3RDY is set and enabled thanks to PSIDIV3ON bit is set.

9.4.5 HSIK and PSIK clock

THE HSIK and PSIK are two clock outputs offering frequency flexibility to the user. These dividers can be configured thanks to HSIKDIV[3:0] and PSIKDIV[3:0] bitfields respectively with division factors of 1, 1.5, 2, 2.5 ... 7.5, and 8. This allow to create a 96 MHz clock source derived from a 144 MHz for example if divided by 1.5, useful for FDCAN operation, or 64 MHz out of the 160 MHz divided by 2.5 to tune your DAC output sample frequency.

The HSIKRDY and PSIKRDY flags in the RCC_CR register indicate whether the HSIK and PSIK clocks are stable or not. At startup, the HSIK, and PSIK output clocks are not released until this bit is set by hardware.

The HSIK and PSIK clock signals can be switched on and off using the HSIKON and PSIKON bits in the RCC_CR register.

Table 67. PSIK and HSIK output frequency

PSIKDIV[3:0]/ HSIKDIV[3:0] division factor	PSIK frequency if PSI 160MHz	PSIK frequency if PSI 144MHz and hsik frequency	PSIK frequency if PSI 100MHz
1	160 MHz	144 MHz	100 MHz
1.5	106. 67 MHz	96 MHz	66.67 MHz
2	80 MHz	72 MHz	50 MHz
2.5	64 MHz	57.6 MHz	40 MHz
3	53.33 MHz	48 MHz	33.33 MHz
3.5	45.71 MHz	41.14 MHz	28.57 MHz

Table 67. PSIK and HSIK output frequency (continued)

PSIKDIV[3:0]/ HSIKDIV[3:0] division factor	PSIK frequency if PSI 160MHz	PSIK frequency if PSI 144MHz and hsik frequency	PSIK frequency if PSI 100MHz
4	40 MHz	36 MHz	25 MHz
4.5	35.56 MHz	32 MHz	22.22 MHz
5	32 MHz	28.8 MHz	20 MHz
5.5	29.09 MHz	26.18 MHz	18.18 MHz
6	26.67 MHz	24 MHZ	16.67 MHz
6.5	24.62 MHz	22.15 MHz	15.38 MHz
7	22.86 MHz	20.57 MHz	14.28 MHz
7.5	21.33 MHz	19.2 MHz	13.33 MHz
8	20 MHz	18 MHz	12.5 MHz

Caution: 160 MHz is above the maximum frequency supported by the product. It must not be propagated to the kernel clock of peripherals.

9.4.6 LSE clock

The LSE block can generate a clock from an external crystal/ceramic resonator, or from an external user clock.

External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32_IN pin. The input clock can have a frequency up to 1 MHz, and be low swing (analog) or digital. A duty cycle close to 50% is recommended.

This external clock is provided to the OSC32_IN pin while the OSC32_OUT pin must be left high-Z (see *Figure 25*).

In case of an analog clock (low swing), the LSEBYP, and LSEON bits must be set to 1 in RCC_RTCCR.

In case of a digital clock, the LSEBYP and the LSEEXT bits must be set to 1 followed by setting the LSEON bit to 1 in RCC_RTCCR.

External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power, highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions.

The LSERDY flag in RCC_RTCCR indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by the hardware. An interrupt can be generated if enabled in RCC_CIER.

The LSE oscillator is switched on and off using the LSEON bit. The LSE remains enabled when the system enters Stop or Standby mode.

In addition, the LSE clock can be driven to the MCO1 and MCO2 output and used as a clock source for other application components.

The LSE also offers a programmable driving capability (LSEDRV[1:0]), which can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to ensure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

9.4.7 LSI clock

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wake-up unit (AWU).

The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched on and off using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced on and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode.

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in RCC_CIER.

In addition, the LSI clock can be driven to the MCO1 and MCO2 output, and used as a clock source for other application components.

Note: LSION and LSIRDY are located in RCC_RTCCR.

9.4.8 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator, through HSIS clock
- HSI oscillator divided by 3, through HSIDIV3 clock source
- PSI oscillator, through PSIS clock
- HSE oscillator

The system clock maximum frequency is 144 MHz. After a system reset (or after leaving Standby mode), the HSI oscillator divided by 3, at 48 MHz, is selected as the system clock. When a clock source is used directly or through PSI as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay). If a clock source not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in RCC_CR1 indicate which clocks are ready, and which clock is currently used as a system clock.

9.4.9 Handling clock generators in Stop and Standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped, as well as the following clock sources:

- HSI oscillator
- PSI oscillator
- HSE

Note: In Stop 0 mode, if HSIKERON or PSIKERON are set, HSI, PSI, or HSE may be kept running depending on clock output enable bits (HSISON, HSIDIV3ON, HSIKON, PSISON, PSIDIV3ON, PSIKON) and PSI reference clock source setting. in Stop 1 mode, HSIKERON, and PSIKERON have no effect.

The content of the RCC registers is not altered except for HSEON set to 0.

Exiting Stop mode

When the system exits this mode via a wake-up event, the application restarts on HSI oscillator and HSIS or HSIDIV3 clock depending on STOPWUCK bit value.

During Stop mode

There are two specific cases where the HSI can be enabled during this mode.

- When a dedicated peripheral requests the kernel clock the peripheral receives the HSIS, HSIK or HSIDIV3 according to the kernel clock source selected for this peripheral (using the RCC kernel clock configuration register RCC_CCIPRx)).
- When the HSIKERON bit in RCC_CR1 is set, the HSI is kept running under Stop 0 mode. If a clock is enabled thanks to HSISON, HSIDIV3ON or HSIKON it is available immediately when the system exits Stop 0 mode, or when a peripheral requests the kernel clock (see *Table 68* for details). The same applies to the PSI thanks to PSIKERON bit. In this case, its reference clock is also kept on.

Table 68. HSIKERON and PSIKERON behavior

HSIKERON (PSIKERON)	HSI (PSI) state during Stop mode	HSI (PSI) state setting time
0	Off	$t_{su(HSI)}$ $t_{su(PSI)}$ (1)
1	Running and gated if enabled	Immediate

1. $t_{su(HSI)}$ and $t_{su(PSI)}$ are the startup times of, respectively, the HSI and PSI oscillators (refer to the product datasheet for the values of these parameters).

When the microcontroller exits Standby mode, HSIDIV3 is selected as the system clock. The RCC registers are reset to their initial values, except for RCC_RSR and RCC_RTCCR.

Note: The HSI and PSI oscillators provide three clock paths respectively:

- One path for the system clock (hsis_ck or psis_ck)

- One path for the peripheral kernel clock (hsik_ck or psik_ck)

- One path for the peripheral kernel clock divided by 3 (hsidiv3_ck or psidiv3_ck)

When a peripheral requests the kernel clock in system Stop mode, only the path providing the hsik_ck, psik_ck or hsidiv3_ck, psidiv3_ck is activated.

9.4.10 Clock security system (CSS)

Clock security system on HSE

The clock security system can be enabled by software via the HSECSSON bit, which can be set even when the HSEON is cleared.

The CSS on HSE is enabled by the hardware when the HSE is enabled and ready, and HSECSSON set to 1.

The CSS on HSE is disabled when the HSE is disabled. It is not possible to clear directly the HSECSSON bit by software.

The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode.

If a failure is detected on the HSE clock while it is used as a system clock, the system automatically switches to the HSIDIV3, to provide a safe clock. The HSE is then automatically disabled, a clock failure event is sent to the break inputs of the advanced-control timer (TIM1, TIM8, TIM15, TIM16, and TIM17), and an NMI is automatically generated to inform the application about the failure, allowing the MCU to perform rescue operations. If the HSE output was used as clock source for the PSI reference clock when the failure occurred, the oscillator is also disabled.

If an HSE clock failure occurs when the CSS is enabled, the CSS generates an interrupt that causes the automatic generation of an NMI. The HSECSSF flag in RCC_CIFR is set to 1 to allow the application to identify the failure source. The NMI routine is executed indefinitely until the HSECSSF bit is cleared. As a consequence, the application must clear the HSECSSF flag in the NMI ISR by setting the HSECSSC bit in RCC_CICR.

Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in RCC_RTCCR. This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes. It also works under system reset (excluding power-on reset).

The clock security system on the LSE detects when the LSE disappears or in case of over frequency.

If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC, but no hardware action is made to the registers.

Note: If the LSECSS is enabled and the LSE clock fails, the LSECSSI occurs and an NMI is automatically generated. The NMI is executed infinitely unless the LSECSSF interrupt pending bit is cleared. It is therefore necessary that the NMI ISR clears the LSECSSI by setting the LSECSSC bit in the clock interrupt clear register (RCC_CICR).

In case of CSS on LSE detection event (LSECSSD = 1 in the RCC_RTCCR), the software must change the RTC clock source (no clock or LSI or HSE, with RTCSEL bitfield modification only possible while LSECSSD = 1) then disable the LSECSSON bit that clears the LSECSSD, stop the defective 32 kHz oscillator (disabling LSEON), or act to secure the application.

Refer to the datasheet for CSS on LSE electrical characteristics.

9.4.11 Clock output generation (MCO1/MCO2/LSCO)

Two microcontroller clock output pins (MCO1 and MCO2) are available. A clock source can be selected for each output. The selected clock can be divided thanks to a configurable prescaler (refer to *Figure 25* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0], and MCO2[2:0], located in RCC_CFGR1.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the product datasheet for information on the supported speed). Under Stop 0, only PSIK, HSIK, and PSIDIV3 can be output on MCOx if they are kept enabled thanks to HSIKERON or PSIKERON.

Another output (LSCO) allows one of the low-speed clocks (LSI, LSE) to be output onto the external LSCO pin. This output is available in Stop mode, not available in Standby mode. The selection is controlled by the LSCOSEL bit, and enabled by the LSCOEN bit in RCC_RTCCR.

The MCO clock output requires the corresponding alternate function selected on the MCO pin. The LSCO pin must be left in the default POR state.

9.4.12 Kernel clock selection

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (ckg_bus_perx clock)
- a clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose an optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral. The user application can thus change the bus frequency without reprogramming the peripherals. As an example, an ongoing transfer with UART is not disturbed if its APB clock is changed on-the-fly.

The table below shows the kernel clock that the RCC can deliver to the peripherals. Each row represents a multiplexer and the peripherals connected to its output.

Table 69. Kernel clock distribution overview

Peripherals	Clock multiplexer control bits	Bus clocks(1)	psis_ck	psidiv3_ck	psik_ck	hsis_ck	hsidiv3_ck	hsik_ck	hse_ck	lse_ck	lsi_ck	AUDIOCLK	hse_1M_ck	Disabled
XSPI1	XSPI1SEL	0(2)	-	-	1	-	-	2	-	-	-	-	-	-
FDCANx	FDCANSEL	0	1	-	2	-	-	-	3	-	-	-	-	-
I2Cx	I2CxSEL	0	-	-	1	-	-	2	-	-	-	-	-	-
I3C1	I3C1SEL	0	-	-	1	-	-	2	-	-	-	-	-	-
LPTIM1	LPTIM1SEL	0	-	-	-	-	-	1	-	2	3	-	-	-
SPI(I2S)x	SPIxSEL	0	-	-	1	-	-	2	-	-	-	3	-	-
USARTx	USARTxSEL	0	-	-	1	-	-	2	-	3	-	-	-	-
UARTx	UARTxSEL	0	-	-	1	-	-	2	-	3	-	-	-	-
LPUART1	LPUART1SEL	0	-	-	-	-	-	1	-	2	3	-	-	-
USB(CK48)	CK48SEL	-	-	1	-	-	2	-	3	-	-	-	-	0
ADCDAC	ADCDACSEL	0(2)	1	-	2	-	-	3	-	-	-	-	-	-

Table 69. Kernel clock distribution overview (continued)

Peripherals	Clock multiplexer control bits	Bus clocks(1)	psis_ck	psidiv3_ck	psik_ck	hsis_ck	hsidiv3_ck	hsik_ck	hse_ck	lse_ck	lsi_ck	AUDIOCLK	hse_1M_ck	Disabled
DAC	DACSEL	-	-	-	-	-	-	-	-	0	1	-	-	-
RTC/AWU	RTCSEL	-	-	-	-	-	-	-	-	1	2	-	3	0
ETH1_CLK	ETH1CLKSEL	-	1	-	2	-	-	-	3	-	-	-	-	0
ETH1_PTP	ETH1PTPCLKSEL	1	2	-	3	-	-	-	-	-	-	-	-	0

1. The bus (APB or AHB) clocks are the bus interface clocks to whom the peripherals are connected.
2. When SYSCLK is divided by 2 or more, the AHB prescaler does not maintain the 50% duty cycle required by the ADC and XSPI in DDR mode. To achieve a 50% duty cycle, the ADCDACPRE or XSPI peripheral prescalers must divide HCLK by a factor of 2 or higher.

Peripherals dedicated to control and data transfer

Peripherals such as SPIs, I2Cs, UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the required bit clock on the serial interface. For that purpose the source can be selected among the following ones:

- HSIS or HSIK if the clock must quickly be available upon Stop mode exit.
- PSIS or PSIK if an HSE clock is available and accuracy must be controlled over temperature or if a ratio of 100 MHz or 160 MHz is mandatory for some protocols.

Note: UARTs also can use the LSE clock when high baud rates are not required.

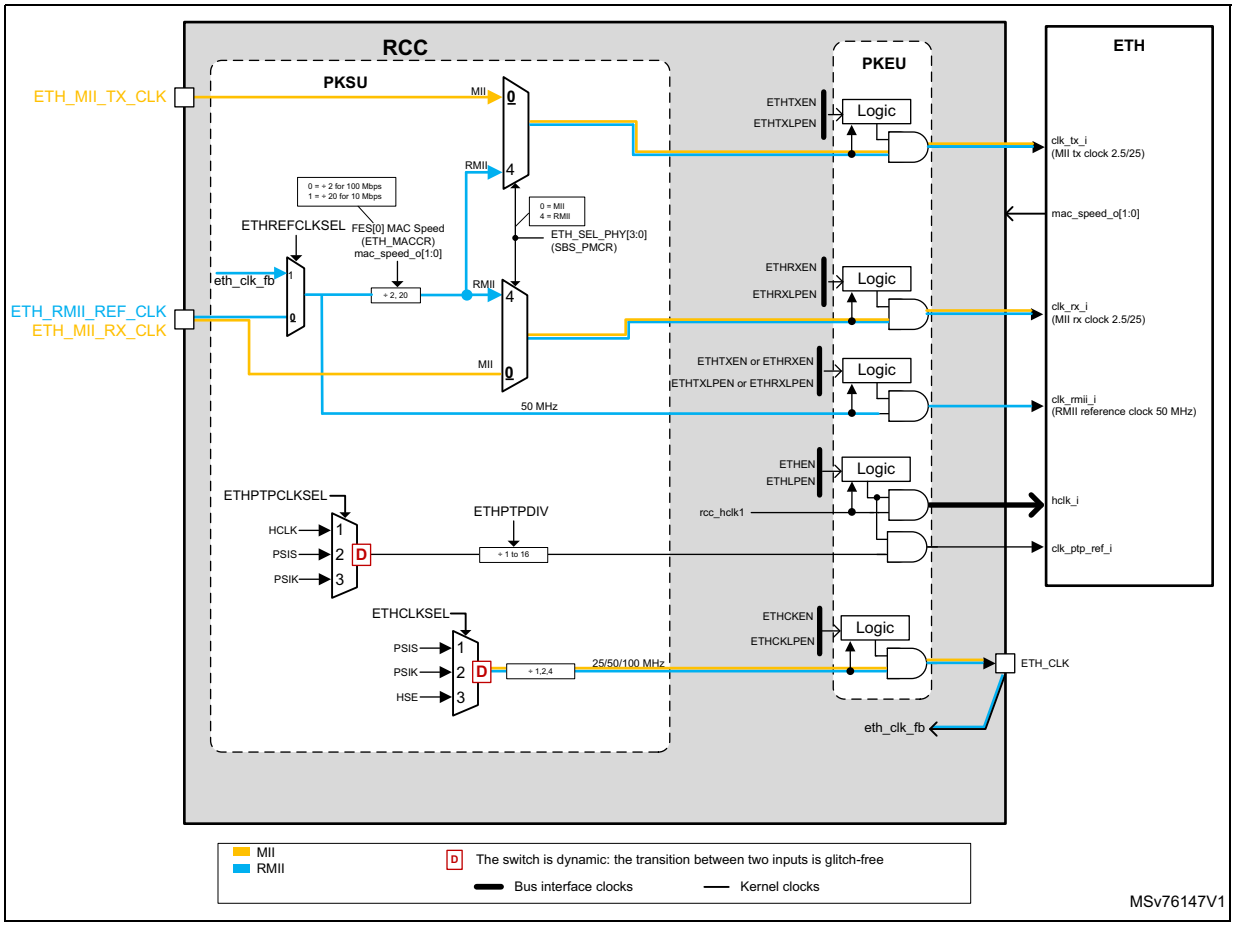
Clock distribution for ETH1

The Ethernet clocks provided by the RCC are available on ETH1_CLK pad. The application can select if the ETH1_CLK is generated from the PSIS, PSIK or from the HSE.

The RCC also provides the bus clock and the reference clock for the PTP function. The bus and PTP clocks generation are controlled via ETH1EN and ETH1LPEN bits.

The Ethernet transmit and receive clocks must be provided from an external Ethernet PHY.

Figure 27. Clock distribution for ETH



The signal ETH1_SEL_PHY is provided by the SBS block and defines the interface type:

- In MII mode (yellow path):
  - The transmit clock is received from the external PHY via the pad ETH_MII_TX_CLK.
  - The receive clock is received from the external PHY via the pad ETH_MII_RX_CLK.
  - The clock frequency is 2.5 (or 25) MHz for Ethernet at 10 (or 100) Mbps.
- In RMII mode (blue path):
  - The reference clock (50MHz) can be selected between two sources, this selection is controlled through ETH1REFCLKSEL.
  - The ETH_RMII_REF_CLK pad, if the reference clock is provided by the PHY.
  - The ETH1_CLK feedback clock (eth_clk_fb) if the RCC is providing the reference clock to the PHY.
- In RMII mode:
  - A clock must be provided to clk_rx_i and clk_tx_i inputs.
  - The clock frequency at clk_rx_i and clk_tx_i inputs is 2.5 MHz (division by 20) for Ethernet at 10 Mbps, and 25 MHz (division 2) for Ethernet at 100 Mbps.

- The transmit and receive clock frequency can be adjusted dynamically to 2.5 to 25 MHz according to the signal mac_speed_o[0] (controlled by FES bit in ETH_MACCR register) provided by the ETH block.
- The clock can be provided by RCC to be used by the external ETH PHY through ETH1_CLK output. This clock can be selected between three sources, this selection is controlled via ETH1CLKSEL.

Clock distribution for cryptographic subsystem

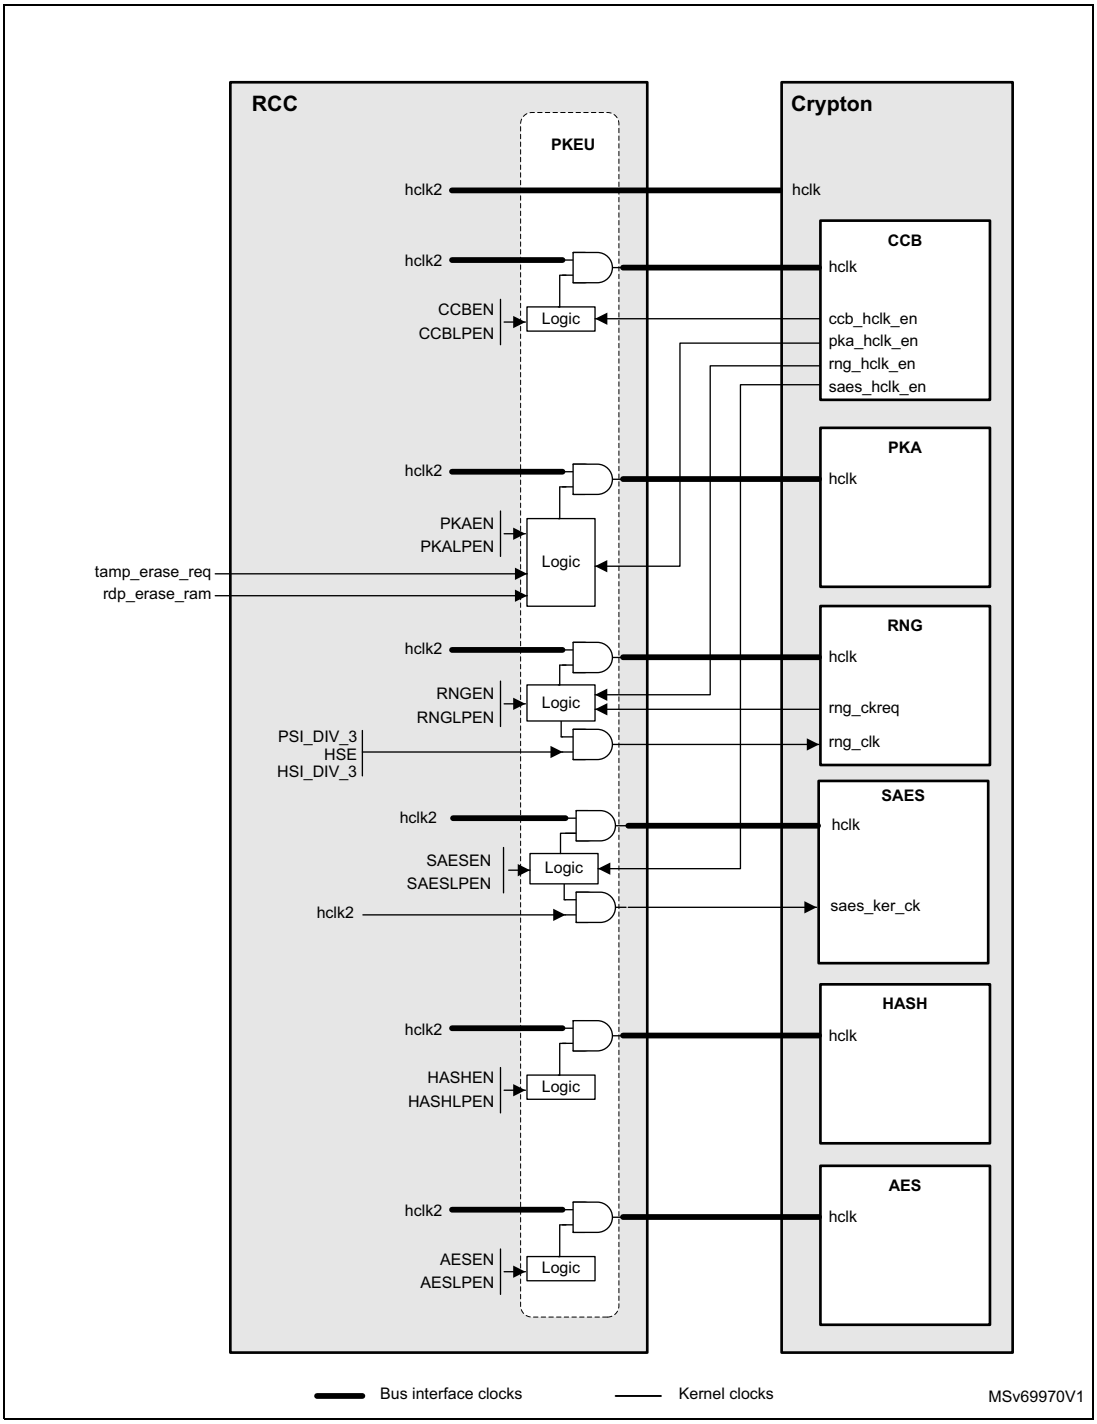
This subsection is only available for STM32C59x/5A3.

Figure 28 shows the clock distribution for the cryptographic subsystem.

Note: All the peripheral clocks of the cryptographic subsystem must be disabled before issuing a software reset to any CCB/PKA/RNG/SAES/HASH/AES peripheral of this subsystem.

For any CCB/PKA/RNG/SAES/HASH/AES peripheral of this subsystem, the software must ensure that the peripheral is not busy (by polling on the BUSY bit flag of the related CCB/PKA/RNG/SAES/HASH/AES peripheral) before disabling the peripheral clock.

Figure 28. Clock distribution for Crypton subsystem



RTC/AWU clock

The rtc_ck clock source can be one of the following:

- The hse_1M_ck (hse_ck divided by a programmable prescaler)
- The lse_ck
- The lsi_ck clock

The source clock is selected by programming the RTCSEL[1:0] bits in RCC_RTCCR and the RTCPRE[8:0] bits in RCC_CFGR1.

This selection cannot be modified without resetting the RTC domain.

The rtc_ck clock is enabled through the RTCEN bit in RCC_RTCCR.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB3ENR/LPENR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise, a third read access must be performed.

Watchdog clocks

The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced on and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

Clock frequency measurement using TIMx

The HSI is not operating on a reference clock as the PSI. If the PSI cannot be the source to blocks requiring accurate frequency, it can be interesting to calibrate HSI thanks to timers or CRS. Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI. This requires to use the HSI as the system clock source directly. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

  The basic concept consists in providing a relative measurement (such as HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

  The HSI oscillator have dedicated user-accessible calibration bits for this purpose (see RCC_CFGR1).

- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process

deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

Clock frequency measurement using CRS

The HSI is as well directly connected to CRS block that can handle its TRIM automatically on HSE, LSE, USB SOF signal or external reference clock.

9.4.13 RTC and TAMP clock

The RTCCLK clock source is used by RTC and TAMP, and can be either the HSE_1MHz, LSE, or LSI clock. It is selected by programming the RTCSEL[1:0] bits in RCC_RTCCR. This selection cannot be modified without resetting the RTC domain. The system must always be configured so as to get a PCLK frequency greater than or equal to the RTCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to *Section 40: Tamper and backup registers (TAMP)* for more details).

The LSE is in the RTC domain, whereas the HSE and LSI clocks are not.

Consequently, if the HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the internal voltage regulator is powered off (removing power from the core domain) during Standby mode for example. Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

9.4.14 Timer clock

The timer clock frequencies (excluding LPTIM) are fixed and equal to HCLK.

9.4.15 Peripherals clock gating

Peripherals clock gating in Run mode

Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENR registers.

When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, there the clock is active after 2 cycles of the peripheral bus clock.

Caution: Just after enabling the clock for a peripheral, the software must wait for these 2 clock cycles before accessing the peripheral registers.

Peripherals clock gating in Sleep mode

When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral LPEN bit in the RCC_AHBxLPENR and

RCC_APBxLPENR registers. Both EN and LPEN bit of the peripheral must be set to keep the clock on in Sleep mode.

9.5 RCC privilege functional description

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access except RCC_PRIVCFGR that can be written with privileged access only. RCC_PRIVCFGR can be read by privileged and unprivileged access.

The PRIV bit in RCC_PRIVCFGR can be written with privileged access only. This bit configures the privileged access of all RCC functions.

When the PRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC bits is possible only with privileged access.
- The RCC bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

9.6 RCC low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (flash memory, cache, and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop 0 mode stops all the clocks in the core domain and disable the HSI, PSI, and HSE oscillators. However, HSI and PSI can be kept on (if HSIKERON or PSIKERON are set) or HSI can be started by a peripheral to generate a wake-up interrupt. LSI and LSE remain active in Stop 0 mode.
- Stop 1 mode stops all the clocks in the core domain and disable the HSI, PSI, and HSE oscillators. LSI and LSE remain active in Stop 1 mode.
- Standby mode stops all the clocks in the core domain and disable the HSI, the PSI, and HSE oscillators.

The CPU DeepSleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

When exiting Stop mode, the system clock can be HSIS or HSIDIV3 based on the STOPWUCK value. The frequency (user trim) and the setting of the HSIK and PSIK prescaler are the one configured before entering Stop mode.

When leaving Standby mode, the system clock is HSIDIV3 (48 MHz). The user trim is lost.

If a flash memory programming operation is ongoing, a Stop or Standby mode entry is delayed until the flash memory interface access is finished. If an access to the APB domain is ongoing, a Stop or Standby mode entry is delayed until the APB access is finished.

9.7 RCC interrupts

The table below summarizes the interrupt sources and the way to control them.

Table 70. Interrupt sources and control

Interrupt vector	Interrupt event flag	Description	Enable control bits	Interrupt clear method	Exit Sleep mode	Exit Stop and Standby modes
RCC	LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to 1	Yes	No
	LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to 1	Yes	No
	PSISRDYF	PSIS ready	PSISRDYIE	Set PSISRDYC to 1	Yes	No
	PSIDIV3RDYF	PSIDIV3 ready	PSIDIV3RDYIE	Set PSIDIV3RDYC to 1	Yes	No
	HSIKRDYF	HSIK ready	HSIKRDYIE	Set HSIKRDYC to 1	Yes	No
	HSISRDYF	HSIS ready	HSISRDYIE	Set HSISRDYC to 1	Yes	No
	HSIDIV3RDYF	HSIDIV3 ready	HSIDIV3RDYIE	Set HSIDIV3RDYC to 1	Yes	No
	HSIKRDYF	HSIK ready	HSIKRDYIE	Set HSIKRDYC to 1	Yes	No
	HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to 1	Yes	No
TAMP	ITAMP3F(1)	LSE CSS failure	LSECSSON and ITAMP3E(1) and ITAMP3IE(1)	Set CITAMP3F(1) to 1	Yes	Yes
NMI	LSECSSF	LSE CSS failure	LSECSSON(2)	Set LSECSSC to 1	Yes	Yes
	HSECSSF	HSE CSS failure	HSECSSON(3)	Set HSECSSC to 1	Yes	No

1. The LSE CSS failure event (LSECSSD) is connected to TAMP internal tamper 3. To get the interrupt associated with this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. The ITAMP3F, ITAMP3E, ITAMP3IE, and CITAMP3F bits are in the TAMP peripheral.
2. It is not possible to mask this interrupt when the security system feature is enabled (LSECSSON = 1).
3. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

9.8 RCC registers

For the actual availability of some peripherals and their related bits, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them reserved, and keep them at the reset value.

9.8.1 RCC clock control register (RCC_CR1)

Address offset: 0x000

Reset value: 0x0000 0022

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSEEXT	HSECSSON	HSEBYP	HSERDY	HSEON
											rw	rs	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	PSIKRDY	PSIDIV3RDY	PSISRDY	PSIKERON	PSIKON	PSIDIV3ON	PSISON	Res.	HSIKRDY	HSIDIV3RDY	HSISRDY	HSIKERON	HSIKON	HSIDIV3ON	HSISON
	r	r	r	rw	rw	rw	rw		r	r	r	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: External high speed clock type in Bypass mode

This bit is set and reset by software to select the external clock type (analog or digital). The external clock must be enabled with the HSEON bit to be used by the device. The HSEEXT bit can be written only if the HSE oscillator is disabled.

0: HSE in analog mode (default after reset)

1: HSE in digital mode

Bit 19 **HSECSSON**: HSE clock security system enable

This bit is set by software to enable clock security system on HSE. This bit is “set only” (disabled by a system reset or when the system enters in Standby mode). When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.

0: CSS on HSE off (clock detector off) (default after reset)

1: CSS on HSE on (clock detector on if the HSE oscillator is stable, off if not).

Bit 18 **HSEBYP**: HSE clock bypass

This bit is set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

This bit is set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock not ready (default after reset)

1: HSE clock ready

Bit 16 **HSEON**: HSE clock enable

This bit is set and cleared by software. It is cleared by hardware to stop the HSE when entering Stop or Standby mode. This bit cannot be cleared if the HSE is used directly or indirectly (via SW mux) as system clock, or if the HSE is selected as reference clock for PSI with PSI enabled (PSISON bit or PSIDIV3ON bit or PSIKON bit set to 1).

0: HSE off (default after reset)

1: HSE on

Bit 15 Reserved, must be kept at reset value.

Bit 14 **PSIKRDY**: PSIK clock ready flag

This bit is set by hardware to indicate that the PSI oscillator divided clock is stable.

0: PSIK clock not ready (default after reset)

1: PSIK clock ready

Bit 13 **PSIDIV3RDY**: PSIDIV3 clock ready flag

This bit is set by hardware to indicate that the PSI oscillator divided by 3 clock is stable.

0: PSIDIV3 clock not ready (default after reset)

1: PSIDIV3 clock ready

Bit 12 **PSISRDY**: PSIS clock ready flag

This bit is set by hardware to indicate that the PSIS clock is stable.

0: PSIS clock not ready (default after reset)

1: PSIS clock ready

Bit 11 **PSIKERON**: PSI clock enable in Stop mode

This bit is set and cleared by software to force maintain PSI enabled in Stop 0 mode, to be quickly available as kernel clock for some peripherals. This bit only impacts PSI if PSISON, PSIDIV3ON, or PSIKON is set.

0: No effect on PSI (default after reset)

1: PSI keep ON even in Stop 0 mode

Bit 10 **PSIKON**: PSIK clock enable

This bit is set and reset by software to enable/disable PSIK clock for peripheral. This bit value is kept under Stop 0 if PSIKERON is set, otherwise it is cleared.

0: PSIK off (default after reset)

1: PSIK on

Bit 9 **PSIDIV3ON**: PSIDIV3 clock enable

This bit is set and reset by software to enable/disable PSIDIV3 clock for peripheral.
This bit value is kept under Stop 0 if PSIKERON is set, otherwise it is cleared.

0: PSIDIV3 off (default after reset)

1: PSIDIV3 on

Bit 8 **PSISON**: PSIS clock enable

This bit is set and reset by software to enable/disable PSIS clock for peripheral and system. This bit value is kept under Stop 0 if PSIKERON is set, otherwise it is cleared. This bit cannot be cleared if the PSIS is used (via SW mux) as system clock.

0: PSIS off (default after reset)

1: PSIS on

Bit 7 Reserved, must be kept at reset value.

Bit 6 **HSIKRDY**: HSIK clock ready flag

This bit is set by hardware to indicate that the HSIK divided clock is stable.

0: HSIK clock not ready (default after reset)

1: HSIK clock ready

Bit 5 **HSIDIV3RDY**: HSIDIV3 clock ready flag

This bit is set by hardware to indicate that the HSI oscillator divided by 3 clock is stable.

0: HSIDIV3 clock not ready (default after reset)

1: HSIDIV3 clock ready

Bit 4 **HSISRDY**: HSIS clock ready flag

This bit is set by hardware to indicate that the HSIS clock is stable.

0: HSIS clock not ready (default after reset)

1: HSIS clock ready

Bit 3 **HSIKERON**: HSI clock enable in Stop mode

This bit is set and cleared by software to maintain HSI enabled in Stop 0 mode, to be quickly available as kernel clock for some peripherals. This bit only impact HSI if HSISON, HSIDIV3ON or HSIKON are set.

0: No effect on HSI (default after reset)

1: HSI keep ON in Stop 0 mode

Bit 2 **HSIKON**: HSIK clock enable

This bit is set and reset by software to enable/disable HSIK clock for peripheral. This bit value is kept under Stop 0 mode if HSIKERON is set, otherwise it is cleared.

0: HSIK off (default after reset)

1: HSIK on

Bit 1 **HSIDIV3ON**: HSIDIV3 clock enable

This bit is set and reset by software to enable/disable HSIDIV3 clock for system or peripheral. It is set by hardware to force the HSIDIV3 to on when product exit Standby mode, or in case of a failure of the HSE which is used directly or indirectly as the system clock source. This bit cannot be cleared if the HSIDIV3 is used directly (via SW mux) as system clock. This bit value is kept under Stop 0 mode if HSIKERON is set, otherwise it is cleared. This bit is set by hardware to force the HSIDIV3 to on when the system leaves Stop mode, if STOPWUCK = 0.

0: HSIDIV3 off

1: HSIDIV3 on (default after reset)

Bit 0 **HSISON**: HSIS clock enable

This bit is set and cleared by software to enable/disable HSIS clock for system and peripheral. This bit is set by hardware to force the HSI to on when the product leaves Stop mode, if STOPWUCK = 1. This bit value is kept under Stop 0 mode if HSIKERON is set, otherwise it is cleared. This bit cannot be cleared if the HSIS is used directly or indirectly (via SW mux) as system clock.

0: HSIS off (default after reset)

1: HSIS on

9.8.2 RCC clock control register (RCC_CR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PSIFREQ[1:0]		Res.	Res.	Res.	Res.	Res.	PSIREF[2:0]			Res.	Res.	PSIREFSRC[1:0]	
		rw	rw						rw	rw	rw			rw	rw

Res.	Res.	Res.	Res.	PSIKDIV[3:0]				Res.	Res.	Res.	Res.	HSIKDIV[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **PSIFREQ[1:0]**: PSI target frequency configuration

This bitfield is set and reset by software to configure the PSI oscillator target frequency. Each bit can be written only if the PSI oscillator is disabled.

00: PSI nominal frequency = 100 MHz

01: PSI nominal frequency = 144 MHz

1x: PSI nominal frequency = 160 MHz

Bits 27:23 Reserved, must be kept at reset value.

Bits 22:20 **PSIREF[2:0]**: PSI reference clock frequency selection

This bitfield is set and cleared by software to indicate the adequate reference frequency connected to the PSI oscillator. Each bit can be written only if the PSI oscillator is disabled.

000: 32.768 kHz

001: 8 MHz

010: 16 MHz

011: 24 MHz

100: 25 MHz

101: 32 MHz

110: 48 MHz

111: 50 MHz

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **PSIREFSRC[1:0]**: PSI reference clock source selection

This bitfield is set and cleared by software to indicate the adequate reference clock source connected to the PSI oscillator. Each bit can be written only if the PSI oscillator is disabled.

00: HSE clock used as reference for PSI

01: LSE clock used as reference for PSI

10: HSI clock divided by 18 used as reference for PSI

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PSIKDIV[3:0]**: PSI clock out divider factor

This bitfield is set and cleared by software to configure the PSIK clock based on PSI and its division factor.

0000: PSI clock divided by 1
0001: PSI clock divided by 1
0010: PSI clock divided by 1.5
0011: PSI clock divided by 2
0100: PSI clock divided by 2.5
....
1110: PSI clock divided by 7.5
1111: PSI clock divided by 8

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **HSIKDIV[3:0]**: HSI clock out divider factor

This bitfield is set and cleared by software to configure the HSIK clock based on HSI and its division factor.

0000: HSI clock divided by 1
0001: HSI clock divided by 1
0010: HSI clock divided by 1.5
0011: HSI clock divided by 2
0100: HSI clock divided by 2.5
....
1110: HSI clock divided by 7.5
1111: HSI clock divided by 8

9.8.3 RCC clock configuration register1 (RCC_CFGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word and half-word access

One or two wait states are inserted only if the access occurs during the clock source switch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		r	r		rw	rw

Bits 31:29 **MCO2SEL[2:0]**: Microcontroller clock output 2

This bitfield is set and cleared by software. Clock source selection may generate glitches on MCO2. It is highly recommended to configure these bits only after reset, before enabling the external oscillators.

000: system clock selected (sys_ck) (default after reset)

001: HSE clock selected (hse_ck)

010: LSE clock selected (lse_ck)

011: LSI clock selected (lsi_ck)

100: PSIK clock selected (psik_ck)

101: HSIK clock selected (hsik_ck)

110: PSIDIV3 clock selected (psidiv3_ck)

111: HSIDIV3 clock selected (hsidiv3_ck): if this clock is retained by HSIKERON, it is not visible on MCO output under the Stop 0 mode.

Other: Reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

This bitfield is set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: Prescaler disabled (default after reset)

0001: Division by 1 (bypass)

0010: Division by 2

0011: Division by 3

0100: Division by 4

...

1111: Division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1

This bitfield is set and cleared by software. Clock source selection may generate glitches on MCO1. It is highly recommended to configure these bits only after reset, before enabling the external oscillators.

000: System clock selected (sys_ck) (default after reset)

001: HSE clock selected (hse_ck)

010: LSE clock selected (lse_ck)

011: LSI clock selected (lsi_ck)

100: PSIK clock selected (psik_ck)

101: HSIK clock selected (hsik_ck)

110: PSIS clock selected (psis_ck), if this clock is retained by PSIKERON, it is not visible on MCO output under the Stop 0 mode.

111: HSIS clock selected (hsis_ck), if this clock is retained by HSIKERON, it is not visible on MCO output under the Stop 0 mode.

Other: Reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

This bitfield is set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: Prescaler disabled (default after reset)

0001: Division by 1 (bypass)

0010: Division by 2

0011: Division by 3

0100: Division by 4

...

1111: Division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bits 15:7 **RTCPRE[8:0]**: HSE division factor for RTC clock (source of HSE_1MHz clock)

This bitfield is set and cleared by software to divide the HSE to generate a clock for RTC.

Caution: Software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000000: No clock (default after reset)

000000001: No clock

000000010: HSE/2

000000011: HSE/3

000000100: HSE/4

...

111111110: HSE/510

111111111: HSE/511

Bit 6 **STOPWUCK**: System clock selection after a wake-up from system Stop mode

This bit is set and reset by software to select the system wake-up clock from system Stop.

0: HSIDIV3 selected as wake-up clock from system Stop mode (default after reset)

1: HSIS selected as wake-up clock from system Stop mode

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SWS[1:0]**: System clock switch status

This bitfield is set and reset by hardware to indicate which clock source is used as system clock.

00: HSIDIV3 used as system clock (hsidiv3_ck) (default after reset).

01: HSIS used as system clock (hsis_ck)

10: HSE used as system clock (hse_ck)

11: PSIS used as system clock (psis_ck)

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SW[1:0]**: System clock and trace clock switch

This bitfield is set and reset by software to select system clock and trace clock sources (sys_ck). It is set by hardware to force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode, and to force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock

00: HSIDIV3 selected as system clock (hsidiv3_ck) (default after reset)

01: HSIS selected as system clock (hsis_ck)

10: HSE selected as system clock (hse_ck)

11: PSIS selected as system clock (psis_ck)

9.8.4 RCC CPU domain clock configuration register 2 (RCC_CFGR2)

Address offset: 0x020

Reset value: 0x0000 0000

1 or 2 wait states are inserted only if the access occurs during the clock source switch.

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is ongoing.

	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **APB3DIS**: APB3 clock disable value.Set and cleared by software

This bit can be set to further reduce power consumption, when none of the APB3 peripherals are used, and when their clocks are disabled in RCC_APB3ENR. When this bit is set, all the APB3 peripheral clocks are off.

0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB3 clock disabled

Bit 21 **APB2DIS**: APB2 clock disable value

This bit can be set to further reduce power consumption, when none of the APB2 peripherals are used, and when their clocks are disabled in RCC_APB2ENR. When this bit is set, all the APB2 peripheral clocks are off.

0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB2 clock disabled

Bit 20 **APB1DIS**: APB1 clock disable value

This bit can be set to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used, and when their clocks are disabled in RCC_APB1ENR. When this bit is set, all the APB1 peripheral clocks are off, except for IWDG.

0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB1 clock disabled

Bit 19 **AHB4DIS**: AHB4 clock disable value

This bit can be set to further reduce power consumption, when none of the AHB4 peripherals from RCC_AHB4ENR are used, and when their clocks are disabled in RCC_AHB4ENR. When this bit is set, all the AHB4 peripheral clocks are off.

0: AHB4 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB4 clock disabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 **AHB2DIS**: AHB2 clock disable

This bit can be set to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR are used, and when their clocks are disabled in RCC_AHB2ENR. When this bit is set, all the AHB2 peripheral clocks are off.

0: AHB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB2 clock disabled

Bit 16 **AHB1DIS**: AHB1 clock disable

This bit can be set to further reduce power consumption, when none of the AHB1 peripherals from RCC_AHB1ENR are used, and when their clocks are disabled in RCC_AHB1ENR. When this bit is set, all the AHB1 peripheral clocks are off, except for FLASH, ICACHE, SRAM1, and SRAM2.

0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB1 clock disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE3[2:0]**: APB low-speed prescaler (APB3)

This bitfield is set and reset by software to control APB low-speed clocks division factor. The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE3 write.

0xx: rcc_pclk3 = rcc_hclk1

100: rcc_pclk3 = rcc_hclk1 / 2

101: rcc_pclk3 = rcc_hclk1 / 4

110: rcc_pclk3 = rcc_hclk1 / 8

111: rcc_pclk3 = rcc_hclk1 / 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB high-speed prescaler (APB2)

This bitfield is set and reset by software to control APB high-speed clocks division factor. The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE2 write.

0xx: rcc_pclk2 = rcc_hclk1

100: rcc_pclk2 = rcc_hclk1 / 2

101: rcc_pclk2 = rcc_hclk1 / 4

110: rcc_pclk2 = rcc_hclk1 / 8

111: rcc_pclk2 = rcc_hclk1 / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE1[2:0]**: APB low-speed prescaler (APB1)

This bitfield is set and reset by software to control the division factor of rcc_pclk1. The clock is divided by the new prescaler factor from 1 to 16 cycles of rcc_hclk after PPRE write.

0xx: rcc_pclk1 = rcc_hclk1 (default after reset)

100: rcc_pclk1 = rcc_hclk1 / 2

101: rcc_pclk1 = rcc_hclk1 / 4

110: rcc_pclk1 = rcc_hclk1 / 8

111: rcc_pclk1 = rcc_hclk1 / 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler

This bitfield is set and reset by software to control the division factor of rcc_hclk. Changing this division ratio has an impact on the frequency of all bus matrix clocks

0xxx: rcc_hclk = sys_ck (default after reset)

1000: rcc_hclk = sys_ck / 2

1001: rcc_hclk = sys_ck / 4

1010: rcc_hclk = sys_ck / 8

1011: rcc_hclk = sys_ck / 16

1100: rcc_hclk = sys_ck / 64

1101: rcc_hclk = sys_ck / 128

1110: rcc_hclk = sys_ck / 256

1111: rcc_hclk = sys_ck / 512

9.8.5 RCC clock source interrupt enable register (RCC_CIER)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **HSERDYIE**: HSE ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.

0: HSE ready interrupt disabled (default after reset)

1: HSE ready interrupt enabled

Bit 7 **PSIKRDYIE**: PSIK ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the PSIK clock stabilization.

0: PSIK ready interrupt disabled (default after reset)

1: PSIK ready interrupt enabled

Bit 6 **PSIDIV3RDYIE**: PSIDIV3 ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the PSIDIV3 clock stabilization.

0: PSIDIV3 ready interrupt disabled (default after reset)

1: PSIDIV3 ready interrupt enabled

Bit 5 **PSISRDYIE**: PSIS ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the PSIS clock stabilization.

0: PSI ready interrupt disabled (default after reset)

1: PSI ready interrupt enabled

Bit 4 **HSIKRDYIE**: HSIK ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the HSIK clock stabilization.

0: HSIK ready interrupt disabled (default after reset)

1: HSIK ready interrupt enabled

Bit 3 **HSIDIV3RDYIE**: HSIDIV3 ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the HSIDIV3 clock stabilization.

0: HSIDIV3 ready interrupt disabled (default after reset)

1: HSIDIV3 ready interrupt enabled

Bit 2 **HSISRDYIE**: HSIS ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the HSIS clock stabilization.

0: HSI ready interrupt disabled (default after reset)

1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.

0: LSE ready interrupt disabled (default after reset)

1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable

This bit is set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.

0: LSI ready interrupt disabled (default after reset)

1: LSI ready interrupt enabled

9.8.6 RCC clock source interrupt flag register (RCC_CIFR)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				r	r		r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **LSECSSF**: LSE clock security system interrupt flag
Reset by software by writing LSECSSC bit. Set by hardware in case of LSE clock failure.
0: No clock security interrupt caused by LSE clock failure (default after reset)
1: Clock security interrupt caused by LSE clock failure

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Reset by software by writing HSECSSC bit. Set by hardware in case of HSE clock failure.
0: No clock security interrupt caused by HSE clock failure (default after reset)
1: Clock security interrupt caused by HSE clock failure

Bit 9 Reserved, must be kept at reset value.

Bit 8 **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit. Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE

Bit 7 **PSIKRDYF**: PSIK ready interrupt flag
Reset by software by writing PSIKRDYC bit.
Set by hardware when the PSIK clock becomes stable and PSIKDYIE is set.
0: No clock ready interrupt caused by PSIK (default after reset)
1: Clock ready interrupt caused by PSIK

Bit 6 **PSIDIV3RDYF**: PSIDIV3 ready interrupt flag
Reset by software by writing PSIDIV3RDYC bit.
Set by hardware when the PSIDIV3 clock becomes stable and PSIDIV3DYIE is set.
0: No clock ready interrupt caused by PSIDIV3 (default after reset)
1: Clock ready interrupt caused by PSIDIV3

Bit 5 **PSISRDYF**: PSIS ready interrupt flag
Reset by software by writing PSISRDYC bit.
Set by hardware when the PSIS clock becomes stable and PSISDYIE is set.
0: No clock ready interrupt caused by PSIS (default after reset)
1: Clock ready interrupt caused by PSIS

Bit 4 **HSIKRDYF**: HSIK ready interrupt flag
Reset by software by writing HSIKRDYC bit.
Set by hardware when the HSIK clock becomes stable and HSIKDYIE is set.
0: No clock ready interrupt caused by HSIK (default after reset)
1: Clock ready interrupt caused by HSIK

Bit 3 **HSIDIV3RDYF**: HSIDIV3 ready interrupt flag
Reset by software by writing HSIDIV3RDYC bit.
Set by hardware when the HSIDIV3 clock becomes stable and HSIDIV3DYIE is set.
0: No clock ready interrupt caused by HSIDIV3 (default after reset)
1: Clock ready interrupt caused by HSIDIV3

Bit 2 **HSISRDYF**: HSIS ready interrupt flag
Reset by software by writing HSISRDYC bit.
Set by hardware when the HSIS clock becomes stable and HSISDYIE is set.
0: No clock ready interrupt caused by HSIS (default after reset)
1: Clock ready interrupt caused by HSIS

Bit 1 **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: No clock ready interrupt caused by the LSE (default after reset)
1: Clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: No clock ready interrupt caused by the LSI (default after reset)
1: Clock ready interrupt caused by the LSI

9.8.7 RCC clock source interrupt clear register (RCC_CICR)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rc_w1	rc_w1		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **LSECSSC**: LSE clock security system interrupt clear
Set by software to clear LSECSSF. Reset by hardware when clear done.
0: LSECSSF no effect (default after reset)
1: LSECSSF cleared

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF. Reset by hardware when clear done.
0: HSECSSF no effect (default after reset)
1: HSECSSF cleared

Bit 9 Reserved, must be kept at reset value.

Bit 8 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF. Reset by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 7 **PSIKRDYC**: PSIK ready interrupt clear
Set by software to clear PSIKRDYF. Reset by hardware when clear done.
0: PSIKRDYF no effect (default after reset)
1: PSIKRDYF cleared

Bit 6 **PSIDIV3RDYC**: PSIDIV3 ready interrupt clear
Set by software to clear PSIDIV3RDYF. Reset by hardware when clear done.
0: PSIDIV3RDYF no effect (default after reset)
1: PSIDIV3RDYF cleared

Bit 5 **PSISRDYC**: PSIS ready interrupt clear
Set by software to clear PSISRDYF. Reset by hardware when clear done.
0: PSISRDYF no effect (default after reset)
1: PSISRDYF cleared

Bit 4 **HSIKRDYC**: HSIK ready interrupt clear
Set by software to clear HSIKRDYF. Reset by hardware when clear done.
0: HSIKRDYF no effect (default after reset)
1: HSIKRDYF cleared

Bit 3 **HSIDIV3RDYC**: HSIDIV3 ready interrupt clear
Set by software to clear HSIDIV3RDYF. Reset by hardware when clear done.
0: HSIDIV3RDYF no effect (default after reset)
1: HSIDIV3RDYF cleared

Bit 2 **HSISRDYC**: HSIS ready interrupt clear
Set by software to clear HSIRDYF. Reset by hardware when clear done.
0: HSISRDYF no effect (default after reset)
1: HSISRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF. Reset by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF. Reset by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared

9.8.8 RCC AHB1 reset register (RCC_AHB1RSTR)

Address offset: 0x060

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **ETH1RST**: ETHERNET reset
Set and reset by software.
0: ETHERNET not reset (default after reset)
1: ETHERNET reset

Bit 18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGRST**: RAMCFG reset
Set and reset by software.
0: RAMCFG not reset (default after reset)
1: RAMCFG reset

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **CORDICRST**: CORDIC reset
Set and reset by software.
0: CORDIC not reset (default after reset)
1: CORDIC reset

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCRST**: CRC reset
Set and reset by software.
0: CRC not reset (default after reset)
1: CRC reset

Bits 11:2 Reserved, must be kept at reset value.

Bit 1 **LPDMA2RST**: LPDMA2 reset
Set and reset by software.
0: LPDMA2 not reset (default after reset)
1: LPDMA2 reset

Bit 0 **LPDMA1RST**: LPDMA1 reset
Set and reset by software.
0: LPDMA1 not reset (default after reset)
1: LPDMA1 reset

9.8.9 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x064

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ADC3RST**: ADC3 reset
Set and reset by software.
0: ADC3 not reset (default after reset)
1: ADC3 reset

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCBRST**: CCB reset
Set and reset by software.
0: CCB not reset (default after reset)
1: CCB reset

Bit 20 **SAESRST**: SAES reset
Set and reset by software.
0: SAES not reset (default after reset)
1: SAES reset

Bit 19 **PKARST**: PKA reset
Set and reset by software.
0: PKA not reset (default after reset)
1: PKA reset

Bit 18 **RNGRST**: RNG reset
Set and reset by software.
0: RNG not reset (default after reset)
1: RNG reset

Bit 17 **HASHRST**: HASH reset
Set and reset by software.
0: HASH not reset (default after reset)
1: HASH reset

Bit 16 **AESRST**: AES reset
Set and reset by software.
0: AES not reset (default after reset)
1: AES reset

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **DAC1RST**: DAC reset
Set and reset by software.
0: DAC1 not reset (default after reset)
1: DAC1 reset

Bit 10 **ADC12RST**: ADC1 and ADC2 reset
Set and reset by software.
0: ADC1 and ADC2 not reset (default after reset)
1: ADC1 and ADC2 reset

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHRST**: GPIOH reset
Set and reset by software.
0: GPIOH not reset (default after reset)
1: GPIOH reset

Bit 6 **GPIOGRST**: GPIOG reset
Set and reset by software.
0: GPIOG not reset (default after reset)
1: GPIOG reset

Bit 5 **GPIOFRST**: GPIOF reset
Set and reset by software.
0: GPIOF not reset (default after reset)
1: GPIOF reset

Bit 4 **GPIOERST**: GPIOE reset
Set and reset by software.
0: GPIOE not reset (default after reset)
1: GPIOE reset

Bit 3 **GPIODRST**: GPIOD reset
Set and reset by software.
0: e GPIOD not reset (default after reset)
1: GPIOD reset

Bit 2 **GPIOCRST**: GPIOC reset
Set and reset by software.
0: GPIOC not reset (default after reset)
1: GPIOC reset

Bit 1 **GPIOBRST**: GPIOB reset
Set and reset by software.
0: GPIOB not reset (default after reset)
1: GPIOB reset

Bit 0 **GPIOARST**: GPIOA reset
Set and reset by software.
0: GPIOA not reset (default after reset)
1: GPIOA reset

9.8.10 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x06C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **XSPI1RST**: XSPI1 reset
Set and reset by software.
0: XSPI1 not reset (default after reset)
1: XSPI1 reset

Bits 19:0 Reserved, must be kept at reset value.

9.8.11 RCC APB1 peripheral low reset register (RCC_APB1LRSTR)

Address offset: 0x074

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw							rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **UART7RST**: UART7 reset
Set and reset by software.
0: UART7 not reset (default after reset)
1: UART7 reset

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **USART6RST**: USART6 reset
Set and reset by software.
0: USART6 not reset (default after reset)
1: USART6 reset

Bit 24 **CRSRST**: CRS reset
Set and reset by software.
0: CRS not reset (default after reset)
1: CRS reset

Bit 23 **I3C1RST**: I3C1 block reset
Set and reset by software.
0: I3C1 not reset (default after reset)
1: I3C1 reset

Bit 22 **I2C2RST**: I2C2 reset
Set and reset by software.
0: I2C2 not reset (default after reset)
1: I2C2 reset

Bit 21 **I2C1RST**: I2C1 reset
Set and reset by software.
0: I2C1 not reset (default after reset)
1: I2C1 reset

Bit 20 **UART5RST**: UART5 reset
Set and reset by software.
0: UART5 not reset (default after reset)
1: UART5 reset

Bit 19 **UART4RST**: UART4 reset
Set and reset by software.
0: UART4 not reset (default after reset)
1: UART4 reset

Bit 18 **USART3RST**: USART3 reset
Set and reset by software.
0: USART3 not reset (default after reset)
1: USART3 reset

Bit 17 **USART2RST**: USART2 reset
Set and reset by software.
0: USART2 not reset (default after reset)
1: USART2 reset

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3RST**: SPI3 reset
Set and reset by software.
0: SPI3 not reset (default after reset)
1: SPI3 reset

Bit 14 **SPI2RST**: SPI2 reset
Set and reset by software.
0: SPI2 not reset (default after reset)
1: SPI2 reset

Bit 13 **OPAMP1RST**: OPAMP1 reset
Set and reset by software.
0: OPAMP1 not reset (default after reset)
1: OPAMP1 reset

Bits 12:7 Reserved, must be kept at reset value.

Bit 6 **TIM12RST**: TIM12 reset
Set and reset by software.
0: TIM12 not reset (default after reset)
1: TIM12 reset

Bit 5 **TIM7RST**: TIM7 reset
Set and reset by software.
0: TIM7 not reset (default after reset)
1: TIM7 reset

Bit 4 **TIM6RST**: TIM6 reset
Set and reset by software.
0: TIM6 not reset (default after reset)
1: TIM6 reset

Bit 3 **TIM5RST**: TIM5 reset
Set and reset by software.
0: TIM5 not reset (default after reset)
1: TIM5 reset

Bit 2 **TIM4RST**: TIM4 reset
Set and reset by software.
0: TIM4 not reset (default after reset)
1: TIM4 reset

Bit 1 **TIM3RST**: TIM3 reset
Set and reset by software.
0: TIM3 not reset (default after reset)
1: TIM3 reset

Bit 0 **TIM2RST**: TIM2 reset
Set and reset by software.
0: TIM2 not reset (default after reset)
1: TIM2 reset

9.8.12 RCC APB1 peripheral high reset register (RCC_APB1HRSTR)

Address offset: 0x078

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw						rw			

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **FDCANRST**: FDCAN1 and FDCAN2 reset
Set and reset by software.
0: FDCAN1 and FDCAN2 not reset (default after reset)
1: FDCAN1 and FDCAN2 reset

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **COMPRST**: COMP reset
Set and reset by software.
0: COMP not reset (default after reset)
1: COMP reset

Bits 2:0 Reserved, must be kept at reset value.

9.8.13 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw											

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBRST**: USB reset
Set and reset by software.
0: USB not reset (default after reset)
1: USB reset

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **TIM17RST**: TIM17 reset
Set and reset by software.
0: TIM17 not reset (default after reset)
1: TIM17 reset

Bit 17 **TIM16RST**: TIM16 reset
Set and reset by software.
0: TIM16 not reset (default after reset)
1: TIM16 reset

Bit 16 **TIM15RST**: TIM15 reset
Set and reset by software.
0: TIM15 not reset (default after reset)
1: TIM15 reset

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1RST**: USART1 reset
Set and reset by software.
0: USART1 not reset (default after reset)
1: USART1 reset

Bit 13 **TIM8RST**: TIM8 reset
Set and reset by software.
0: TIM8 not reset (default after reset)
1: TIM8 reset

Bit 12 **SPI1RST**: SPI1 reset
Set and reset by software.
0: SPI1 not reset (default after reset)
1: SPI1 reset

Bit 11 **TIM1RST**: TIM1 reset
Set and reset by software.
0: TIM1 not reset (default after reset)
1: TIM1 reset

Bits 10:0 Reserved, must be kept at reset value.

9.8.14 RCC APB3 peripheral reset register (RCC_APB3RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw					rw					rw	

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1RST**: LPTIM1 reset
Set and reset by software.
0: LPTIM1 not reset (default after reset)
1: LPTIM1 reset

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **LPUART1RST**: LPUART1 reset
Set and reset by software.
0: LPUART1 not reset (default after reset)
1: LPUART1 reset

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **SBSRST**: SBS reset
Set and reset by software.
0: SBS not reset (default after reset)
1: SBS reset

Bit 0 Reserved, must be kept at reset value.

9.8.15 RCC AHB1 peripheral clock register (RCC_AHB1ENR)

Address offset: 0x088

Reset value: 0xC000 0100

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **SRAM1EN**:SRAM1 clock enable
Set and reset by software.
0: SRAM1 clock disabled
1: SRAM1 clock enabled (default after reset)

Bit 30 **SRAM2EN**:SRAM2 clock enable
Set and reset by software.
0: SRAM2 clock disabled
1: SRAM2 clock enabled (default after reset)

Bits 29:22 Reserved, must be kept at reset value.

Bit 21 **ETH1RXEN**: ETH1RX clock enable
Set and reset by software.
0: ETH1RX clock disabled (default after reset)
1: ETH1RX clock enabled

Bit 20 **ETH1TXEN**: ETH1TX clock enable
Set and reset by software.
0: ETH1TX clock disabled (default after reset)
1: ETH1TX clock enabled

Bit 19 **ETH1EN**: ETH1 clock enable
Set and reset by software.
0: ETH1 clock disabled (default after reset)
1: ETH1 clock enabled

Bit 18 **ETH1CKEN**: ETH1 internal clock enable
Set and reset by software.
0: ETH1 internal clock disabled (default after reset)
1: ETH1 internal clock enabled

Bit 17 **RAMCFGEN**: RAMCFG clock enable
Set and reset by software.
0: RAMCFG clock disabled (default after reset)
1: RAMCFG clock enabled

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC clock disabled (default after reset)
1: CORDIC clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCEN**: CRC clock enable
Set and reset by software.
0: CRC clock disabled (default after reset)
1: CRC clock enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHEN**: Flash interface clock enable
Set and reset by software.
0: FLASH clock disabled
1: FLASH clock enabled (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **LPDMA2EN**: LPDMA2 clock enable
Set and reset by software.
0: LPDMA2 clock disabled (default after reset)
1: LPDMA2 clock enabled

Bit 0 **LPDMA1EN**: LPDMA1 clock enable
Set and reset by software.
0: LPDMA1 clock disabled (default after reset)
1: LPDMA1 clock enabled

9.8.16 RCC AHB2 peripheral clock register (RCC_AHB2ENR)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ADC3EN**: ADC3 clock enable
Set and reset by software.
0: ADC3 clock disabled (default after reset)
1: ADC3 clock enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCBEN**: CCB clock enable
Set and reset by software.
0: CCB clock disabled (default after reset)
1: CCB clock enabled

Bit 20 **SAESEN**: SAES clock enable
Set and reset by software.
0: SAES clock disabled (default after reset)
1: SAES clock enabled

Bit 19 **PKAEN**: PKA clock enable
Set and reset by software.
0: PKA clock disabled (default after reset)
1: PKA clock enabled

Bit 18 **RNGEN**: RNG clock enable
Set and reset by software.
0: RNG clock disabled (default after reset)
1: RNG clock enabled

Bit 17 **HASHEN**: HASH clock enable
Set and reset by software.
0: HASH clock disabled (default after reset)
1: HASH clock enabled

Bit 16 **AESEN**: AES clock enable
Set and reset by software.
0: AES clock disabled (default after reset)
1: AES clock enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **DAC1EN**: DAC clock enable
Set and reset by software.
0: DAC1 clock disabled (default after reset)
1: DAC1 clock enabled

Bit 10 **ADC12EN**: ADC1 and ADC2 clock enable
Set and reset by software.
0: ADC1 and ADC2 clock disabled (default after reset)
1: ADC1 and ADC2 clock enabled

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHEN**: GPIOH clock enable
Set and reset by software.
0: GPIOH clock disabled (default after reset)
1: GPIOH clock enabled

Bit 6 **GPIOGEN**: GPIOG clock enable
Set and reset by software.
0: GPIOG clock disabled (default after reset)
1: GPIOG clock enabled

Bit 5 **GPIOFEN**: GPIOF clock enable
Set and reset by software.
0: GPIOF clock disabled (default after reset)
1: GPIOF clock enabled

Bit 4 **GPIOEEN**: GPIOE clock enable
Set and reset by software.
0: GPIOE clock disabled (default after reset)
1: GPIOE clock enabled

Bit 3 **GPIODEN**: GPIOD clock enable
Set and reset by software.
0: GPIOD clock disabled (default after reset)
1: GPIOD clock enabled

Bit 2 **GPIOCEN**: GPIOC clock enable
Set and reset by software.
0: GPIOC clock disabled (default after reset)
1: GPIOC clock enabled

Bit 1 **GPIOBEN**: GPIOB clock enable
Set and reset by software.
0: GPIOB clock disabled (default after reset)
1: GPIOB clock enabled

Bit 0 **GPIOAEN**: GPIOA clock enable
Set and reset by software.
0: GPIOA clock disabled (default after reset)
1: GPIOA clock enabled

9.8.17 RCC AHB4 peripheral clock register (RCC_AHB4ENR)

Address offset: 0x094

Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bit 30 **UART7EN**: UART7 clock enable
Set and reset by software.
0: UART7 clock disabled (default after reset)
1: UART7 clock enabled

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **USART6EN**: USART6 clock enable
Set and reset by software.
0: USART6 clock disabled (default after reset)
1: USART6 clock enabled

Bit 24 **CRSEN**: CRS clock enable
Set and reset by software.
0: CRS clock disabled (default after reset)
1: CRS clock enabled

Bit 23 **I3C1EN**: I3C1 clock enable
Set and reset by software.
0: I3C1 clock disabled (default after reset)
1: I3C1 clock enabled

Bit 22 **I2C2EN**: I2C2 clock enable
Set and reset by software.
0: I2C2 clock disabled (default after reset)
1: I2C2 clock enabled

Bit 21 **I2C1EN**: I2C1 clock enable
Set and reset by software.
0: I2C1 clock disabled (default after reset)
1: I2C1 clock enabled

Bit 20 **UART5EN**: UART5 clock enable
Set and reset by software.
0: UART5 clock disabled (default after reset)
1: UART5 clock enabled

Bit 19 **UART4EN**: UART4 clock enable
Set and reset by software.
0: UART4 clock disabled (default after reset)
1: UART4 clock enabled

Bit 18 **USART3EN**: USART3 clock enable
Set and reset by software.
0: USART3 clock disabled (default after reset)
1: USART3 clock enabled

Bit 17 **USART2EN**: USART2 clock enable
Set and reset by software.
0: USART2 clock disabled (default after reset)
1: USART2 clock enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3EN**: SPI3 clock enable
Set and reset by software.
0: SPI3 clock disabled (default after reset)
1: SPI3 clock enabled

Bit 14 **SPI2EN**: SPI2 clock enable
Set and reset by software.
0: SPI2 clock disabled (default after reset)
1: SPI2 clock enabled

Bit 13 **OPAMP1EN**: OPAMP1 clock enable
Set and reset by software.
0: OPAMP1 clock disabled (default after reset)
1: OPAMP1 clock enabled

Bit 12 Reserved, must be kept at reset value.

Bit 11 **WWDGEN**: WWDG clock enable
Set by software and reset by hardware system reset.
0: WWDG clock disabled (default after reset)
1: WWDG clock enabled

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **TIM12EN**: TIM12 clock enable
Set and reset by software.
0: TIM12 clock disabled (default after reset)
1: TIM12 clock enabled

Bit 5 **TIM7EN**: TIM7 clock enable
Set and reset by software.
0: TIM7 clock disabled (default after reset)
1: TIM7 clock enabled

Bit 4 **TIM6EN**: TIM6 clock enable
Set and reset by software.
0: TIM6 clock disabled (default after reset)
1: TIM6 clock enabled

Bit 3 **TIM5EN**: TIM5 clock enable
Set and reset by software.
0: TIM5 clock disabled (default after reset)
1: TIM5 clock enabled

Bit 2 **TIM4EN**: TIM4 clock enable
Set and reset by software.
0: TIM4 clock disabled (default after reset)
1: TIM4 clock enabled

Bit 1 **TIM3EN**: TIM3 clock enable
Set and reset by software.
0: TIM3 clock disabled (default after reset)
1: TIM3 clock enabled

Bit 0 **TIM2EN**: TIM2 clock enable
Set and reset by software.
0: TIM2 clock disabled (default after reset)
1: TIM2 clock enabled

9.8.19 RCC APB1 peripheral clock register (RCC_APB1HENR)

Address offset: 0x0A0

Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBEN**: RTC APB interface clock enable
Set and reset by software.
0: RTC APB interface clock disabled (default after reset)
1: RTC APB interface clock enabled

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1EN**: LPTIM1 clock enable
Set and reset by software.
0: LPTIM1 clock disabled (default after reset)
1: LPTIM1 clock enabled

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **LPUART1EN**: LPUART1 clock enable
Set and reset by software.
0: LPUART1 clock disabled (default after reset)
1: LPUART1 clock enabled

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **SBSEN**: SBS clock enable
Set and reset by software.
0: SBS clock disabled (default after reset)
1: SBS clock enabled

Bit 0 Reserved, must be kept at reset value.

9.8.22 RCC AHB1 sleep clock register (RCC_AHB1LPENR)

Address offset: 0x0B0

Reset value: 0xC402 5103 (for STM32C53x/542/55x/562)

Reset value: 0xC43E 5103 (for STM32C59x/5A3)

Bit 31 **SRAM1LPEN**: SRAM1 clock enable during Sleep mode
Set and reset by software
0: SRAM1 clock disabled during Sleep mode
1: SRAM1 clock enabled during Sleep mode (default after reset)

Bit 30 **SRAM2LPEN**: SRAM2 clock enable during Sleep mode
Set and reset by software
0: SRAM2 clock disabled during Sleep mode
1: SRAM2 clock enabled during Sleep mode (default after reset)

Bits 29:27 Reserved, must be kept at reset value.

Bit 26 **ICACHELPEN**: ICACHE clock enable during Sleep mode
Set and reset by software.
0: ICACHE clock disabled during Sleep mode
1: ICACHE clock enabled during Sleep mode (default after reset)

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **ETH1RXLPEN**: ETH1RX clock enable during Sleep mode
Set and reset by software.
0: ETH1RX clock disabled during Sleep mode
1: ETH1RX clock enabled during Sleep mode (default after reset)

Bit 20 **ETH1TXLPEN**: ETH1TX clock enable during Sleep mode
Set and reset by software.
0: ETH1TX clock disabled during Sleep mode
1: ETH1TX clock enabled during Sleep mode (default after reset)

Bit 19 **ETH1LPEN**: ETH1 clock enable during Sleep mode
Set and reset by software.
0: ETH1 clock disabled during Sleep mode
1: ETH1 clock enabled during Sleep mode (default after reset)

Bit 18 **ETH1CLKLPEN**: ETH1 internal clock enable during Sleep mode
Set and reset by software.
0: ETH1 internal clock disabled during Sleep mode
1: ETH1 internal clock enabled during Sleep mode (default after reset)

Bit 17 **RAMCFGLPEN**: RAMCFG clock enable during Sleep mode
Set and reset by software.
0: RAMCFG clock disabled during Sleep mode
1: RAMCFG clock enabled during Sleep mode (default after reset)

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **CORDICLPEN**: CORDIC clock enable during Sleep mode
Set and reset by software.
0: CORDIC clock disabled during Sleep mode
1: CORDIC clock enabled during Sleep mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode
Set and reset by software.
0: CRC clock disabled during Sleep mode
1: CRC clock enabled during Sleep mode (default after reset)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHLPEN**: Flash interface clock enable during Sleep mode
Set and reset by software.
0: FLASH clock disabled during Sleep mode
1: FLASH clock enabled during Sleep mode (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **LPDMA2LPEN**: LPDMA2 clock enable during Sleep mode
Set and reset by software.
0: LPDMA2 clock disabled during Sleep mode
1: LPDMA2 clock enabled during Sleep mode (default after reset)

Bit 0 **LPDMA1LPEN**: LPDMA1 clock enable during Sleep mode
Set and reset by software.
0: LPDMA1 clock disabled during Sleep mode
1: LPDMA1 clock enabled during Sleep mode (default after reset)

9.8.23 RCC AHB2 sleep clock register (RCC_AHB2LPENR)

Address offset: 0x0B4

Reset value: 0x0007 0C9F (for STM32C53x/C542/C55x/C562)

Reset value: 0x013F 0CFF (for STM32C59x/C5A3)

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ADC3LPEN**: ADC3 clock enable during Sleep mode
Set and reset by software.
0: ADC3 clock disabled during Sleep mode
1: ADC3 clock enabled during Sleep mode (default after reset)

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCBLPEN**: CCB clock enable during Sleep mode
Set and reset by software.
0: CCB clock disabled during Sleep mode
1: CCB clock enabled during Sleep mode (default after reset)

Bit 20 **SAESLPEN**: SAES clock enable during Sleep mode
Set and reset by software.
0: SAES clock disabled during Sleep mode
1: SAES clock enabled during Sleep mode (default after reset)

Bit 19 **PKALPEN**: PKA clock enable during Sleep mode
Set and reset by software.
0: PKAclock disabled during Sleep mode
1: PKA clock enabled during Sleep mode (default after reset)

Bit 18 **RNGLPEN**: RNG clock enable during Sleep mode
Set and reset by software.
0: RNG clock disabled during Sleep mode
1: RNG clock enabled during Sleep mode (default after reset)

Bit 17 **HASHLPEN**: HASH clock enable during Sleep mode
Set and reset by software.
0: HASH clock disabled during Sleep mode
1: HASH clock enabled during Sleep mode (default after reset)

Bit 16 **AESLPEN**: AES clock enable during Sleep mode
Set and reset by software.
0: AES clock disabled during Sleep mode
1: AES clock enabled during Sleep mode (default after reset)

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **DAC1LPEN**: DAC clock enable during Sleep mode
Set and reset by software.
0: DAC1 clock disabled during Sleep mode
1: DAC1 clock enabled during Sleep mode (default after reset)

Bit 10 **ADC12LPEN**: ADC1 and ADC2 clock enable during Sleep mode
Set and reset by software.
0: ADC1 and ADC2 clock disabled during Sleep mode
1: ADC1 and ADC2 clock enabled during Sleep mode (default after reset)

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHLPEN**: GPIOH clock enable during Sleep mode
Set and reset by software.
0: GPIOH clock disabled during Sleep mode
1: GPIOH clock enabled during Sleep mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG clock enable during Sleep mode
Set and reset by software.
0: GPIOG clock disabled during Sleep mode
1: GPIOG clock enabled during Sleep mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF clock enable during Sleep mode
Set and reset by software.
0: GPIOF clock disabled during Sleep mode
1: GPIOF clock enabled during Sleep mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE clock enable during Sleep mode
Set and reset by software.
0: GPIOE clock disabled during Sleep mode
1: GPIOE clock enabled during Sleep mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD clock enable during Sleep mode
Set and reset by software.
0: GPIOD clock disabled during Sleep mode
1: GPIOD clock enabled during Sleep mode (default after reset)

Bit 2 **GPIOCLPEN**: GPIOC clock enable during Sleep mode
Set and reset by software.
0: GPIOC clock disabled during Sleep mode
1: GPIOC clock enabled during Sleep mode (default after reset)

Bit 1 **GPIOBLPEN**: GPIOB clock enable during Sleep mode
Set and reset by software.
0: GPIOB clock disabled during Sleep mode
1: GPIOB clock enabled during Sleep mode (default after reset)

Bit 0 **GPIOALPEN**: GPIOA clock enable during Sleep mode
Set and reset by software.
0: GPIOA clock disabled during Sleep mode
1: GPIOA clock enabled during Sleep mode (default after reset)

9.8.24 RCC AHB4 peripheral sleep clock register (RCC_AHB4LPENR)

Address offset: 0x0BC

Reset value: 0x0010 0000

Bit 31 Reserved, must be kept at reset value.

Bit 30 **UART7LPEN**: UART7 clock enable during Sleep mode
Set and reset by software.
0: UART7 clock disabled during Sleep mode
1: UART7 clock enabled during Sleep mode (default after reset)

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **USART6LPEN**: USART6 clock enable during Sleep mode
Set and reset by software.
0: USART6 clock disabled during Sleep mode
1: USART6 clock enabled during Sleep mode (default after reset)

Bit 24 **CRSLPEN**: CRS clock enable during Sleep mode
Set and reset by software.
0: CRS clock disabled during Sleep mode
1: CRS clock enabled during Sleep mode (default after reset)

Bit 23 **I3C1LPEN**: I3C1 clock enable during Sleep mode
Set and reset by software.
0: I3C1 clock disabled during Sleep mode
1: I3C1 clock enabled during Sleep mode (default after reset)

Bit 22 **I2C2LPEN**: I2C2 clock enable during Sleep mode
Set and reset by software.
0: I2C2 clock disabled during Sleep mode
1: I2C2 clock enabled during Sleep mode (default after reset)

Bit 21 **I2C1LPEN**: I2C1 clock enable during Sleep mode
Set and reset by software.
0: I2C1 clock disabled during Sleep mode
1: I2C1 clock enabled during Sleep mode (default after reset)

Bit 20 **UART5LPEN**: UART5 clock enable during Sleep mode
Set and reset by software.
0: UART5 clock disabled during Sleep mode
1: UART5 clock enabled during Sleep mode (default after reset)

Bit 19 **UART4LPEN**: UART4 clock enable during Sleep mode
Set and reset by software.
0: UART4 clock disabled during Sleep mode
1: UART4 clock enabled during Sleep mode (default after reset)

Bit 18 **USART3LPEN**: USART3 clock enable during Sleep mode
Set and reset by software.
0: USART3 clock disabled during Sleep mode
1: USART3 clock enabled during Sleep mode (default after reset)

Bit 17 **USART2LPEN**: USART2 clock enable during Sleep mode
Set and reset by software.
0: USART2 clock disabled during Sleep mode
1: USART2 clock enabled during Sleep mode (default after reset)

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3LPEN**: SPI3 clock enable during Sleep mode
Set and reset by software.
0: SPI3 clock disabled during Sleep mode
1: SPI3 clock enabled during Sleep mode (default after reset)

Bit 14 **SPI2LPEN**: SPI2 clock enable during Sleep mode
Set and reset by software.
0: SPI2 clock disabled during Sleep mode
1: SPI2 clock enabled during Sleep mode (default after reset)

Bit 13 **OPAMP1LPEN**: OPAMP1 clock enable during Sleep mode
Set and reset by software.
0: OPAMP1 clock disabled during Sleep mode
1: OPAMP1 clock enabled during Sleep mode (default after reset)

Bit 12 Reserved, must be kept at reset value.

Bit 11 **WWDGLPEN**: WWDG clock enable during Sleep mode
Set and reset by software.
0: WWDG clock disabled during Sleep mode
1: WWDG clock enabled during Sleep mode (default after reset)

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **TIM12LPEN**: TIM12 clock enable during Sleep mode
Set and reset by software.
0: TIM12 clock disabled during Sleep mode
1: TIM12 clock enabled during Sleep mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 clock enable during Sleep mode
Set and reset by software.
0: TIM7 clock disabled during Sleep mode
1: TIM7 clock enabled during Sleep mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 clock enable during Sleep mode
Set and reset by software.
0: TIM6 clock disabled during Sleep mode
1: TIM6 clock enabled during Sleep mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 clock enable during Sleep mode
Set and reset by software.
0: TIM5 clock disabled during Sleep mode
1: TIM5 clock enabled during Sleep mode (default after reset)

Bit 2 **TIM4LPEN**: TIM4 clock enable during Sleep mode
Set and reset by software.
0: TIM4 clock disabled during Sleep mode
1: TIM4 clock enabled during Sleep mode (default after reset)

Bit 1 **TIM3LPEN**: TIM3 clock enable during Sleep mode
Set and reset by software.
0: TIM3 clock disabled during Sleep mode
1: TIM3 clock enabled during Sleep mode (default after reset)

Bit 0 **TIM2LPEN**: TIM2 clock enable during Sleep mode
Set and reset by software.
0: TIM2 clock disabled during Sleep mode
1: TIM2 clock enabled during Sleep mode (default after reset)

9.8.26 RCC APB1 sleep clock register (RCC_APB1HLPENR)

Address offset: 0x0C8

Reset value: 0x4000 0208

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBLPEN**: USB clock enable during Sleep mode
Set and reset by software.
0: USB clock disabled during Sleep mode
1: USB clock enabled during Sleep mode (default after reset)

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **TIM17LPEN**: TIM17 clock enable during Sleep mode
Set and reset by software.
0: TIM17 clock disabled during Sleep mode
1: TIM17 clock enabled during Sleep mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 clock enable during Sleep mode
Set and reset by software.
0: TIM16 clock disabled during Sleep mode
1: TIM16 clock enabled during Sleep mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 clock enable during Sleep mode
Set and reset by software.
0: TIM15 clock disabled during Sleep mode
1: TIM15 clock enabled during Sleep mode (default after reset)

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1LPEN**: USART1 clock enable during Sleep mode
Set and reset by software.
0: USART1 clock disabled during Sleep mode
1: USART1 clock enabled during Sleep mode (default after reset)

Bit 13 **TIM8LPEN**: TIM8 clock enable during Sleep mode
Set and reset by software.
0: TIM8 clock disabled during Sleep mode
1: TIM8 clock enabled during Sleep mode (default after reset)

Bit 12 **SPI1LPEN**: SPI1 clock enable during Sleep mode
Set and reset by software.
0: SPI1 clock disabled during Sleep mode
1: SPI1 clock enabled during Sleep mode (default after reset)

Bit 11 **TIM1LPEN**: TIM1 clock enable during Sleep mode
Set and reset by software.
0: TIM1 clock disabled during Sleep mode
1: TIM1 clock enabled during Sleep mode (default after reset)

Bits 10:0 Reserved, must be kept at reset value.

9.8.28 RCC APB3 sleep clock register (RCC_APB3LPENR)

Address offset: 0x0D0

Reset value: 0x0020 0842

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBLPEN**: RTC APB interface clock enable during Sleep mode
Set and reset by software.
0: RTC APB interface clock disabled during Sleep mode
1: RTC APB interface clock enabled during Sleep mode (default after reset)

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1LPEN**: LPTIM1 clock enable during Sleep mode
Set and reset by software.
0: LPTIM1 clock disabled during Sleep mode
1: LPTIM1 clock enabled during Sleep mode (default after reset)

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **LPUART1LPEN**: LPUART1 clock enable during Sleep mode
Set and reset by software.
0: LPUART1 clock disabled during Sleep mode
1: LPUART1 clock enabled during Sleep mode (default after reset)

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **SBSLPEN**: SBS clock enable during Sleep mode
Set and reset by software.
0: SBS clock disabled during Sleep mode
1: SBS clock enabled during Sleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

9.8.29 RCC kernel clock configuration register (RCC_CCIPR1)

Address offset: 0x0D8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

- 01: hsik_ck selected as kernel clock
- 10: lse_ck selected as kernel clock
- 11: lsi_ck selected as kernel clock

Bits 13:12 **UART7SEL[1:0]**: UART7 kernel clock source selection
- 00: rcc_pclk1 selected as kernel clock (default after reset)
- 01: psik_ck selected as kernel clock
- 10: hsik_ck selected as kernel clock
- 11: lse_ck selected as kernel clock

Bits 11:10 **USART6SEL[1:0]**: UART6 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

Bits 9:8 **UART5SEL[1:0]**: UART5 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

Bits 7:6 **UART4SEL[1:0]**: UART4 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

Bits 5:4 **USART3SEL[1:0]**: UART3 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

Bits 3:2 **USART2SEL[1:0]**: USART2 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

Bits 1:0 **USART1SEL[1:0]**: USART1 kernel clock source selection
00: rcc_pclk2 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
11: lse_ck selected as kernel clock

9.8.30 RCC kernel clock configuration register (RCC_CCIPR2)

Address offset: 0x0DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYSTICKSEL[1:0]		Res.	Res.	Res.	Res.	CK48SEL[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	LPTIM1SEL[1:0]

rw	rw	rw	rw	rw	rw			rw	rw			rw	rw	rw	rw

Bits 31:30 **SYSTICKSEL[1:0]**: SYSTICK clock source selection
00: rcc_hclk/8 selected as clock source (default after reset)
01: lsi_ker_ck[1] selected as clock source
10: lse_ck[1] selected as clock source
11: reserved, the kernel clock is disabled
*Note: rcc_hclk frequency must be four times higher than lsi_ker_ck/lse_ck, that is, period (LSI/LSE) ≥ 4 * period (HCLK).*

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **CK48SEL[1:0]**: CK48 clock source selection
01: psi_div_3_ck selected as kernel clock
10: hsi_div_3_ck selected as kernel clock
11: hse_ck selected as kernel clock
Other: Reserved, kernel clock disabled (default after reset)

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **LPTIM1SEL[1:0]**: LPTIM1 kernel clock source selection
00: rcc_pclk3 selected as kernel clock (default after reset)
01: hsik_ck selected as kernel clock
10: lse_ck selected as kernel clock
11: lsi_ck selected as kernel clock

Bit 15 **DACSEL**: DAC sample and hold clock
0: lse_ck selected as sample and hold clock (default after reset)
1: lsi_ck selected as sample and hold clock

Bits 14:12 **ADCDACPRE[2:0]**: ADC and DAC prescaler for kernel clock source selection
ADCDACPRE bitfield must not be changed when ADC or DAC are enabled.
000: ADC and DAC kernel clock are not divided (default after reset)
001: ADC and DAC kernel clock divided by 2
010: ADC and DAC kernel clock divided by 4
011: ADC and DAC kernel clock divided by 8
100: ADC and DAC kernel clock divided by 16
101: ADC and DAC kernel clock divided by 32
110: ADC and DAC kernel clock divided by 64
111: ADC and DAC kernel clock divided by 128

Bits 11:10 **ADCDACSEL[1:0]**: ADC and DAC kernel clock source selection
This bitfield must not be changed when ADC or DAC are enabled.
00: rcc_hclk selected as kernel clock
01: psis_ck selected as kernel clock (default after reset)
10: psik_ck selected as kernel clock
11: hsik_ck selected as kernel clock

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:6 **I3C1SEL[1:0]**: I3C1 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
Others: reserved, the kernel clock is disabled

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:2 **I2C2SEL[1:0]**: I2C2 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
Other: Reserved, kernel clock disabled

Bits 1:0 **I2C1SEL[1:0]**: I2C1 kernel clock source selection
00: rcc_pclk1 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
Other: Reserved, kernel clock disabled

9.8.31 RCC kernel clock configuration register (RCC_CCIPR3)

Address offset: 0x0E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ETH1PTPDIV[3:0]				ETH1CLKDIV[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw										
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	rw	rw		rw	rw		rw							rw	rw

Bits 31:28 **ETH1PTPDIV[3:0]**: Ethernet PTP clock division
This field selects the division factor of the PTP clock.
0000: divided by 1(default after reset)
0001: divided by 2
0010-1111: divided by {v+1}

Bits 27:26 **ETH1CLKDIV[1:0]**: Ethernet clock division
This field selects the division factor of the ETH1 clock.
00: divided by 1(default after reset)
01: divided by 2
10: divided by 4
11: Reserved

Bits 25:15 Reserved, must be kept at reset value.

Bits 14:13 **ETH1CLKSEL[1:0]**: ETH1 clock source selection
This field selects the reference clock of the PAD ETH1_CLK.
Set and reset by software.
00: kernel clock disabled (default after reset)
01: psis_ck selected as kernel clock
10: psik_ck selected as kernel clock
11: hse_ck selected as kernel clock

Bit 12 Reserved, must be kept at reset value.

Bits 11:10 **ETH1PTPCLKSEL[1:0]**: ETH1 PTP clock source selection
Set and reset by software.
00: kernel clock disabled (default after reset)
01: rcc_hclk1 selected as kernel clock
10: psis_ck selected as kernel clock
11: psik_ck selected as kernel clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **ETH1REFCLKSEL**: ETH1 RMII reference clock source selection
This bit selects the reference clock of the Ethernet for RMII mode. It must be set to 0 in any other mode than RMII.
0: ETH1_RMII_REF_CLK (default after reset)
1: eth_clk_fb

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **XSPI1SEL[1:0]**: XSPI1 kernel clock source selection
00: rcc_hclk4 selected as kernel clock (default after reset)
01: psik_ck selected as kernel clock
10: hsik_ck selected as kernel clock
Other: Reserved, kernel clock disabled

9.8.32 RCC RTC domain control register (RCC_RTCCR)

Address offset: 0x0F0

Reset value: 0x0000 0000

Reset by RTC domain reset.

Access: 0 ≤ wait state ≤ 3, word, half-word, and byte access.

Wait states are inserted in case of successive accesses to this register.

Note: After a system reset, this register is write-protected (except bits 27:26 and bit 16). To modify the RTC domain bits, the DRTCP bit in PWR_RTCCR must be set to 1. All bits (except bits 27:26 and bit 16) are reset only after an RTC domain reset (see Section 9.3.3). Other resets do not affect these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	LSIRDY	LSION	LSCOSEL	LSCOEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTCDRST
				r	rw	rw	rw								rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	Res.	Res.	Res.	RTCSEL[1:0]		LSEEXT	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw						rw	rw	rw	r	rw	rw	rw	rw	r	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **LSIRDY**: LSI oscillator ready
Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles.
This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.
0: LSI oscillator not ready
1: LSI oscillator ready

Bit 26 **LSION**: LSI oscillator enable
Set and cleared by software.
0: LSI oscillator off
1: LSI oscillator on

Bit 25 **LSCOSEL**: Low-speed clock output selection
Set and cleared by software.
0: LSI clock selected
1: LSE clock selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
Set and cleared by software.
0: LSCO output disabled
1: LSCO output enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **RTCDRST**: RTC domain software reset
Set and reset by software.
0: reset not activated (default after RTC domain reset)
1: resets the entire VSW domain

Bit 15 **RTCEN**: RTC clock enable
Set and reset by software.
0: rtc_ck disabled (default after RTC domain reset)
1: rtc_ck enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection
Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The RTCDRST bit can be used to reset them, then it can be written one time again. If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).
00: No clock (default after RTC domain reset)
01: LSE selected as RTC clock
10: LSI selected as RTC clock
11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 **LSEEXT**: Low-speed external clock type in bypass mode
Set and reset by software to select the external clock type (analog or digital). The external clock must be enabled with the LSEON bit, to be used by the device. The LSEEXT bit can be written only if the LSE oscillator is disabled.
0: LSE in analog mode (default after RTC domain reset)
1: LSE in digital mode

Bit 6 **LSECSSD**: LSE clock security system failure detection
Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator. Clearing LSECSSON (only possible after failure detection) also clears this bit.
0: No failure detected on 32 kHz oscillator (default after RTC domain reset)
1: Failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable

Set by software to enable the clock security system on 32 kHz oscillator. This bit must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after RTCSEL is selected.

Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case, software must disable LSECSSON.

0: CSS on 32 kHz oscillator off (default after RTC domain reset)

1: CSS on 32 kHz oscillator on

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.

These bits can be written only if LSE oscillator is disabled (LSEON = 0 and LSERDY = 0).

00: Lowest drive (default after RTC domain reset)

01: Medium-low drive

10: Medium-high drive

11: Highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and reset by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = 1)

0: LSE oscillator not bypassed (default after RTC domain reset)

1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of lse_ck clock to fall down after LSEON has been set to 0.

0: LSE oscillator not ready (default after RTC domain reset)

1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled

Set and reset by software. This bit cannot be cleared if the LSE is selected as reference clock for PSI with PSI enabled (PSISON bit or PSIDIV3ON bit or PSIKON bit set to 1).

0: LSE oscillator off (default after RTC domain reset)

1: LSE oscillator on

9.8.33 RCC reset status register (RCC_RSR)

Address offset: 0x0F4

Reset value: 0xXX00 0000

Reset by power-on reset only.

Access: 0 ≤ wait state ≤ 3, word, half-word, and byte access.

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	BORRSTF	PINRSTF	Res.	Res.	RMVF	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 **LPWRRSTF**: Low-power reset flag

Set by hardware when a reset occurs due to Stop or Standby mode entry, whereas the corresponding NRST_STOP, NRST_STBY option bit is cleared.
Cleared by writing to the RMVF bit.
0: No illegal low-power mode reset occurred
1: An illegal low-power mode reset occurred

Bit 30 **WWDGRSTF**: Window watchdog reset flag

Reset by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: No WWDG reset occurred (default after power-on reset)
1: A WWDG reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag

Reset by software by writing the RMVF bit. Set by hardware when an IWDG reset occurs.
0: No IWDG reset occurred (default after power-on reset)
1: An IWDG reset occurred

Bit 28 **SFTRSTF**: System reset from CPU reset flag

Reset by software by writing the RMVF bit. Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the Cortex-M33.
0: No CPU software reset occurred (default after power-on reset)
1: A system reset has been generated by the CPU.

Bit 27 **BORRSTF**: POR reset flag

Reset by software by writing the RMVF bit. Set by hardware when a POR reset occurs (pwr_por_rst).
0: No POR reset occurred
1: A POR reset occurred (default after power-on reset)

Bit 26 **PINRSTF**: Pin reset flag (NRST)

Reset by software by writing the RMVF bit. Set by hardware when a reset from pin occurs.
0: No reset from pin occurred
1: A reset from pin occurred (default after power-on reset)

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag

Set and reset by software to reset the value of the reset flags.
0: Reset of the reset flags not activated (default after power-on reset)
1: Reset the value of the reset flags

Bits 22:0 Reserved, must be kept at reset value.

9.8.34 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x114

Reset value: 0x0000 0000

Access: no wait state; word, half-word, and byte access

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PRIV**: RCC function privileged configuration
Set and reset by software. This bit can be written only by privileged access.
0: Read and write to RCC functions can be done by privileged or unprivileged access.
1: Read and write to RCC functions can be done by privileged access only

Bit 0 Reserved, must be kept at reset value.

9.8.35 RCC register map

Table 71. RCC register map and reset values

10 Clock recovery system (CRS)

10.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI144. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

10.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 10.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

10.3 CRS implementation

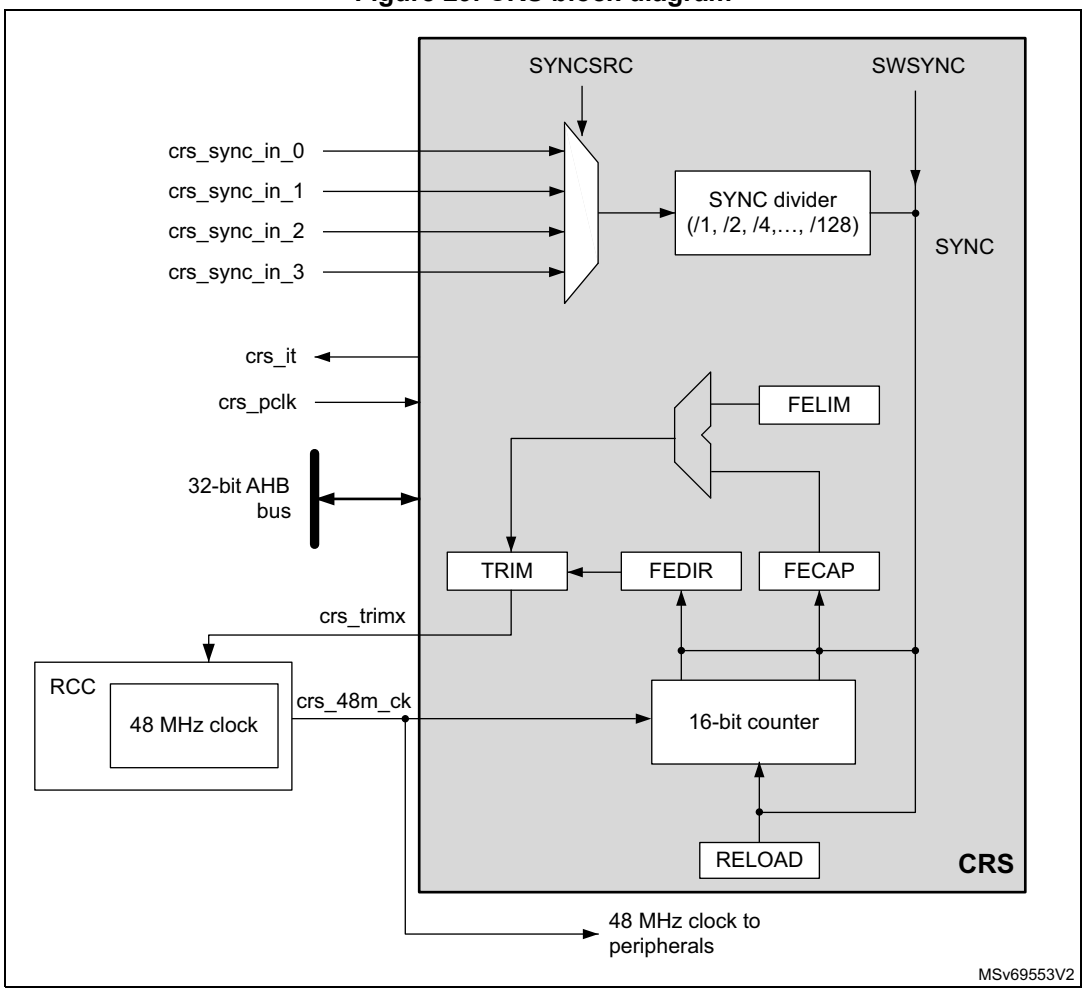
Table 72. CRS features

Feature	CRS
TRIM width	7 bits

10.4 CRS functional description

10.4.1 CRS block diagram

Figure 29. CRS block diagram



10.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 73. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSIDIV3 48 MHz clock
crs_trim[0:6]	Digital output	HSI144 oscillator smooth trimming value

Table 73. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 74. CRS interconnection

Internal signal name	Description
crs_sync_in_0	GPIO AF selected as SYNC signal source
crs_sync_in_1	LSE selected as SYNC signal source
crs_sync_in_2	USB SOF selected as SYNC signal source (default)
crs_sync_in_3	HSE_1MHz clock (output of RTCPRE) selected as SYNC signal source

10.4.3 Synchronization input

The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 10.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

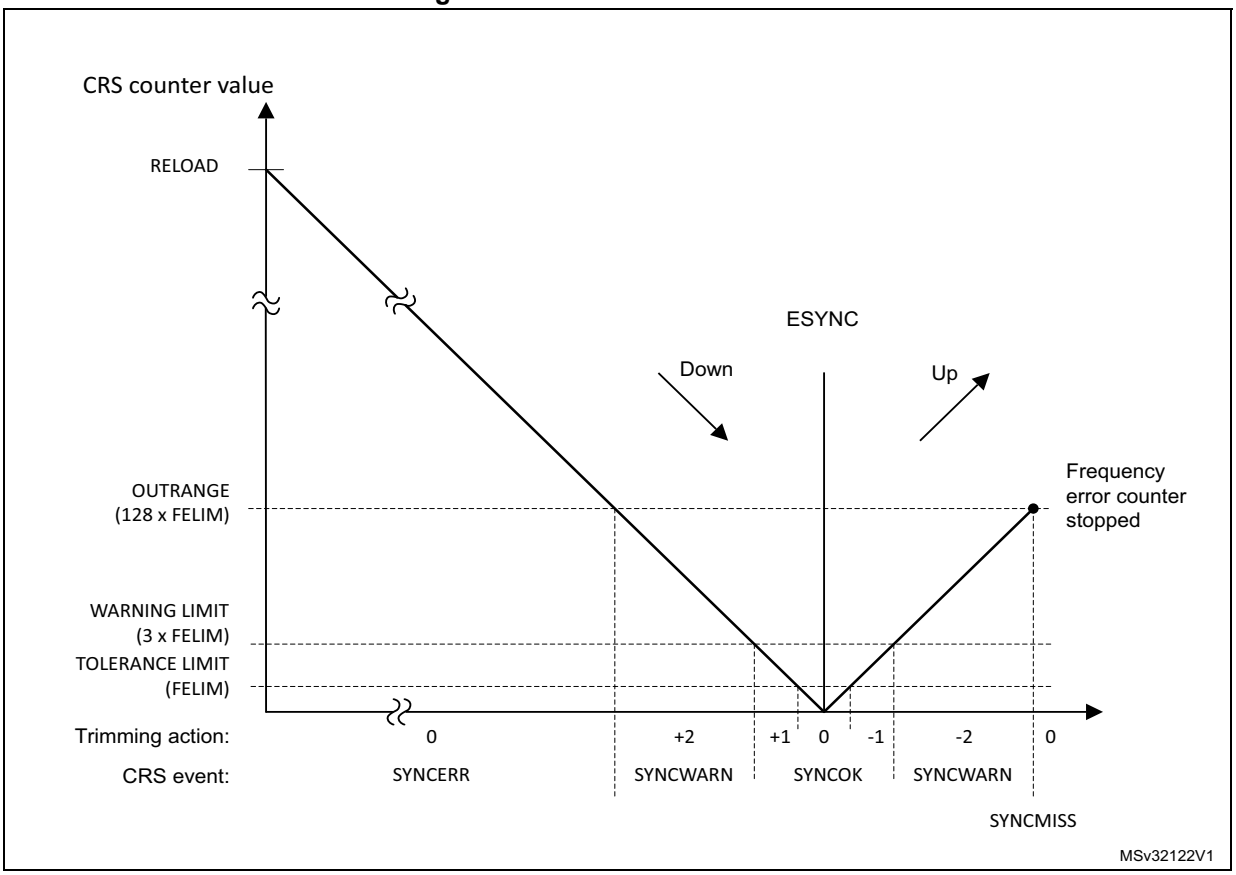
10.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual

frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 30. CRS counter behavior



10.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated

  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

10.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI144 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

10.5 CRS in low-power modes

Table 75. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI144 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.

10.6 CRS interrupts

Table 76. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

10.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

10.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 3000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TRIM[6:0]							SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
	rw	rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **TRIM[6:0]**: HSI144 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI144 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value of the HSI144 oscillator smooth trimming is 48, for a complete TRIM range of 128 steps.

The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 10.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

10.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.

0: SYNC active on rising edge (default)

1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 10.4.2: CRS internal signals*).

00: crs_sync_in_0 selected as SYNC signal source

01: crs_sync_in_1 selected as SYNC signal source

10: crs_sync_in_2 selected as SYNC signal source

11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.

000: SYNC not divided (default)

001: SYNC divided by 2

010: SYNC divided by 4

011: SYNC divided by 8

100: SYNC divided by 16

101: SYNC divided by 32

110: SYNC divided by 64

111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 10.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 10.4.4* for more details about counter behavior.

10.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 10.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

10.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

11 General-purpose I/Os (GPIO)

11.1 GPIO introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16-bit reset register (GPIOx_BRR), and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

11.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bit-wise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- I/Os state retention during Standby mode

11.3 GPIO functional description

Based on the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

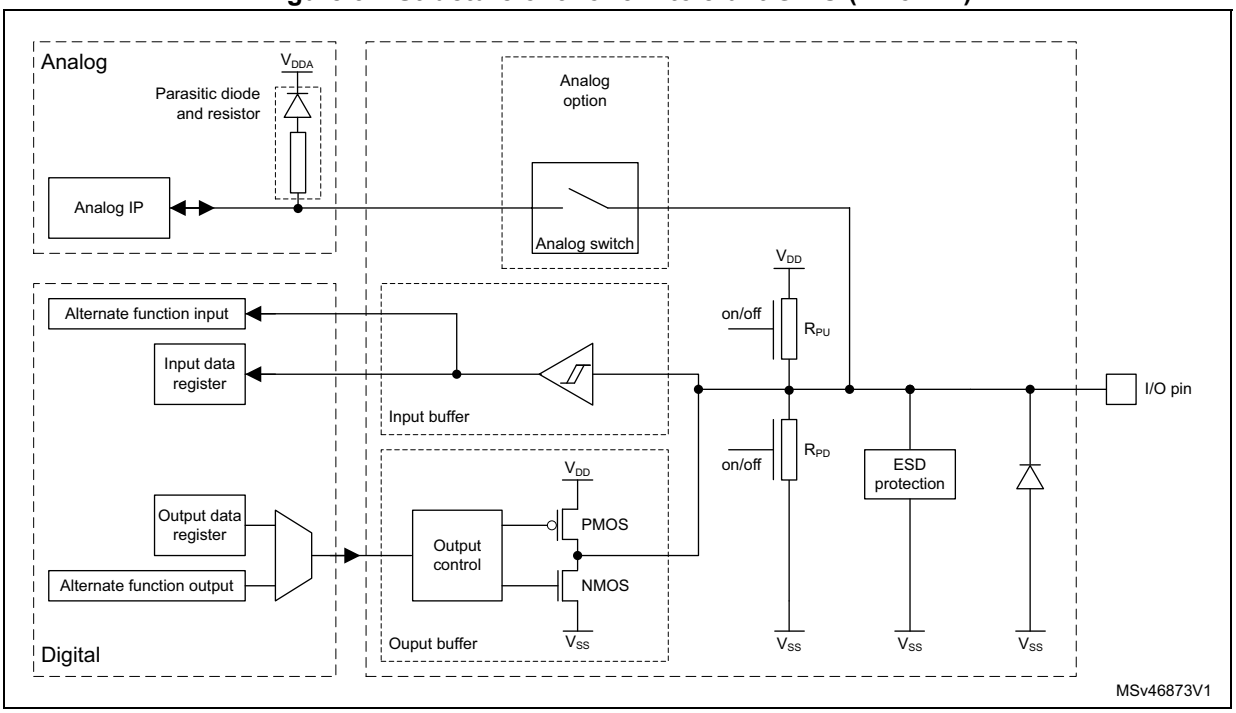
- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow

atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a 3- or 5-V tolerant GPIO (TT or FT). *Table 78* gives the possible port bit configurations.

Figure 31. Structure of 3- or 5-V tolerant GPIO (TT or FT)



Note: On a TT GPIO, the analog switch is not present, it is replaced by a direct connection. The analog bloc parasitic circuitry does not allow 5-V tolerance.

Table 78. Port bit configuration(1)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]	PUPD(i)[1:0]		I/O configuration	
01	0	SPEED[1:0]	0	0	GP output	PP
	0		0	1	GP output	PP + PU
	0		1	0	GP output	PP + PD
	0		1	1	Reserved	
	1		0	0	GP output	OD
	1		0	1	GP output	OD + PU
	1		1	0	GP output	OD + PD
	1		1	1	Reserved (GP output OD)	

Table 78. Port bit configuration[1] (continued)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]		PUPD(i)[1:0]		I/O configuration	
10	0	SPEED[1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0	Input/output	Analog
	x	x	x	1	1	Reserved	

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

11.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see *Section 11.3.15*).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, the high level is high-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not, depending upon the value in the GPIOx_PUPDR register.

11.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through the GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- Debug function: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- GPIO: configure the desired I/O as output, input, or analog in the GPIOx_MODER register.
- Alternate function:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down, and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
  - The Cortex-M33 output EVENTOUT signal can be output as alternate function on several I/Os. An event can be indicated through the configured pin after executing SEV instruction.
  - The EVENTOUT signal can be used internally as a trigger for some peripherals (see *Section 13: Peripherals interconnect matrix*)
- Additional functions:
  - For the ADC, DAC, COMP, and OPAMP configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, COMP, and OPAMP registers.
  - For the additional functions like RTC, WKUPx, LSCO, and oscillators, configure the required function in the related RTC, PWR, and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

11.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type

(push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

11.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR (x = A to H)).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data entered through the I/Os are stored into the input data register (GPIOx_IDR), a read-only register.

11.3.5 I/O data bitwise handling

GPIOx_BSRR is a 32-bit register that allows the application to set and reset each individual bit in GPIOx_ODR. The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the corresponding ODR(i) bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

11.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can be performed only using a word (32-bit long) access to the GPIOx_LCKR register, because GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

11.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that some peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

11.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output, or alternate function mode (the port must not be configured in analog mode). Refer to *Section 16: Extended interrupts and event controller (EXTI)*.

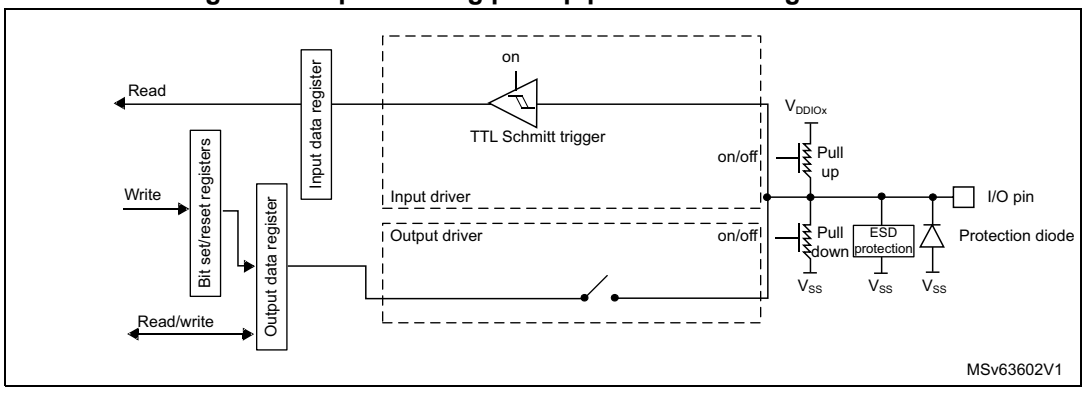
11.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 32. Input floating/pull-up/pull-down configurations



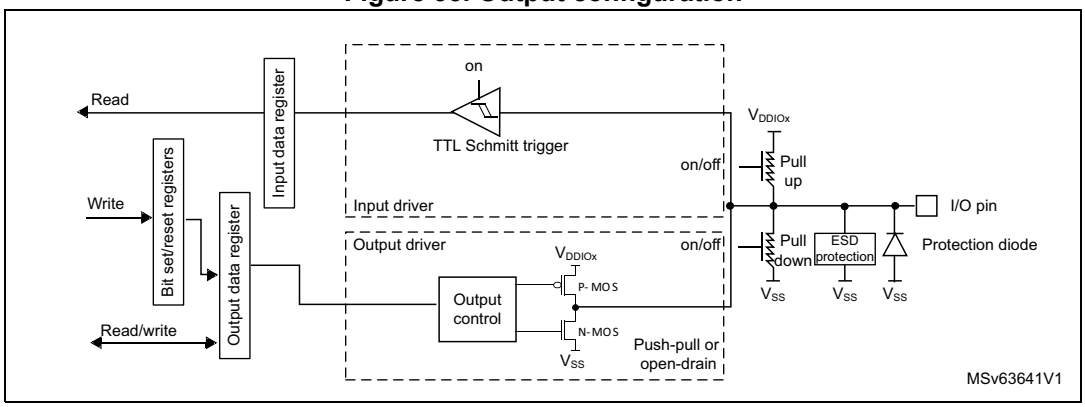
11.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in high-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 33. Output configuration



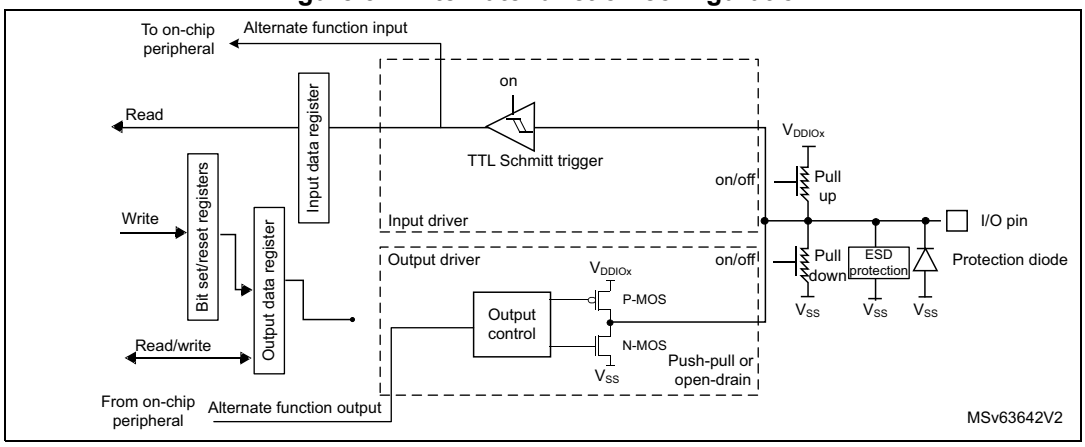
11.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 34. Alternate function configuration



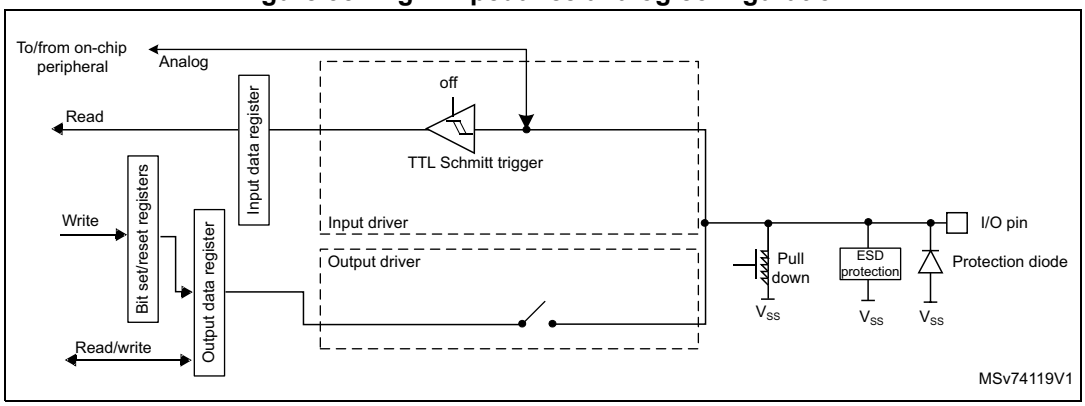
11.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up is disabled by hardware. The weak pull-down is configurable.
- Read access to the input data register gets the value 0.

The figure below shows the high-Z, analog-input configuration of the I/O port bits.

Figure 35. High-impedance analog configuration



11.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CR1 register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

11.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 39.3: RTC functional description*.

11.3.15 I/Os state retention during standby mode

In the Standby mode, the I/Os are by default in floating state.

If the IORETEN bit in the PWR_IORETR register is set, the I/Os state is sampled during standby entry. The state of I/Os is applied to the pin via pull-up and pull-down resistors. The pull-up and pull-down resistors remains applied after Standby wake-up until the IORETEN bit in the PWR_IORETR register is cleared by software.

11.3.16 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses.

11.3.17 I/O compensation cell

The I/O commutation slew rate (tfall / trise) can be adapted by software depending on process, voltage and temperatures conditions, to reduce the I/O noise on power supply. Refer to*Section 12: System configuration, boot, and security (SBS)* for more details.

11.4 GPIO registers

This section gives a detailed description of the GPIO registers. The peripheral registers can be written in word, half word, or byte mode.

For the actual availability of GPIO ports and their related bits, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved, and keep them at reset value.

11.4.1 GPIO port mode register (GPIOx_MODER) (x = A to H)

Address offset:0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFF3F FEBF (for port B)

Reset value: 0xFFFF FFFF (for the other ports)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

11.4.5 GPIO port input data register (GPIOx_IDR) (x = A to H)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID15	ID14	ID13	ID12	ID11	ID10	ID9	ID8	ID7	ID6	ID5	ID4	ID3	ID2	ID1	ID0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

11.4.6 GPIO port output data register (GPIOx_ODR) (x = A to H)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to H).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

11.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to H)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

11.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to H)

Address offset: 0x1C

Reset value: 0x0000 0000

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each bit freezes a specific configuration register (control and alternate function registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

11.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to H)

Address offset: 0x20

Reset value: 0x0000 0000

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

12 System configuration, boot, and security (SBS)

12.1 SBS introduction

The STM32C5 devices feature a set of configuration registers located in the SBS. On top of various device configurations, this SBS peripheral controls key boot and security features, including debug control.

12.2 SBS main features

- System configuration
  - Manage robustness feature.
  - Manage ADC input channel remap.
  - Manage the I/O compensation cell.
  - Configure register security access.
- Boot control
  - Upon system reset, configure the Cortex-M33 boot address and the temporal isolation level depending on the current configuration (such as RDP_LEVEL (sbs_rdp_level).
  - Manage the temporal isolation feature implemented thanks to the hide protect level (HDPL) monotonic counter.

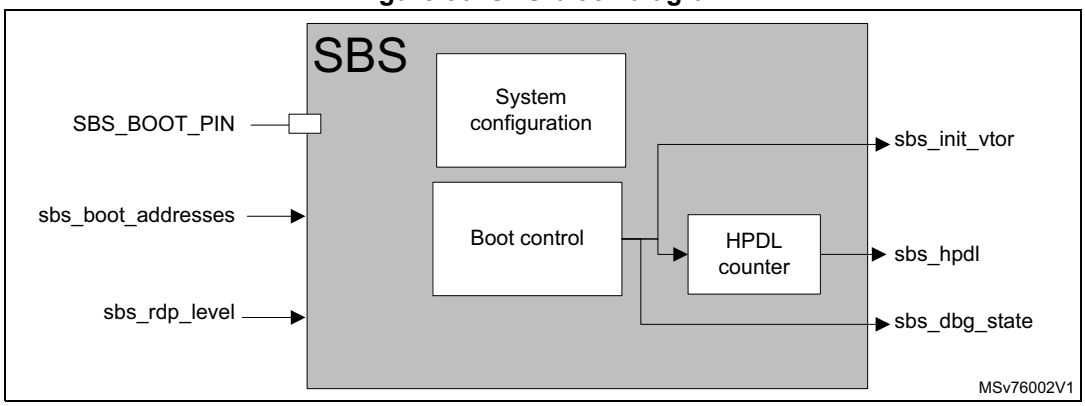
12.3 SBS functional description

12.3.1 SBS block diagram

The figure below shows the SBS block diagram, including the following main functions:

- System configuration
- Boot control

Figure 36. SBS block diagram



12.3.2 SBS signals

The following table details the user-relevant internal signals that interface the SBS.

Table 80. SBS internal input/output signals

Signal name	Type	Description
SBS_BOOT_PIN	Input	Select booting on user flash memory or bootloader
sbs_boot_addresses		List of addresses defined by the flash memory: – BOOT_ADDR: boot address
sbs_rdp_level		Signal based on the RDP_LEVEL option byte to activate the different security mechanisms depending on the product use. Expected values are described in *Section 6: Embedded flash memory (FLASH)*.
sbs_init_vtor	Output	Vector address for Cortex-M33
sbs_hdpl		HDPL (temporal isolation level, ID of the boot level, used to isolate boot levels) This signal reflects a monotonic counter that can be incremented from 0 to 3, and that is reset to zero only on software reset or POR.
sbs_ap_unlocked		Control the Cortex-M33 access port.

12.3.3 SBS reset and clocks

The SBS configuration port is clocked by the AHB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.

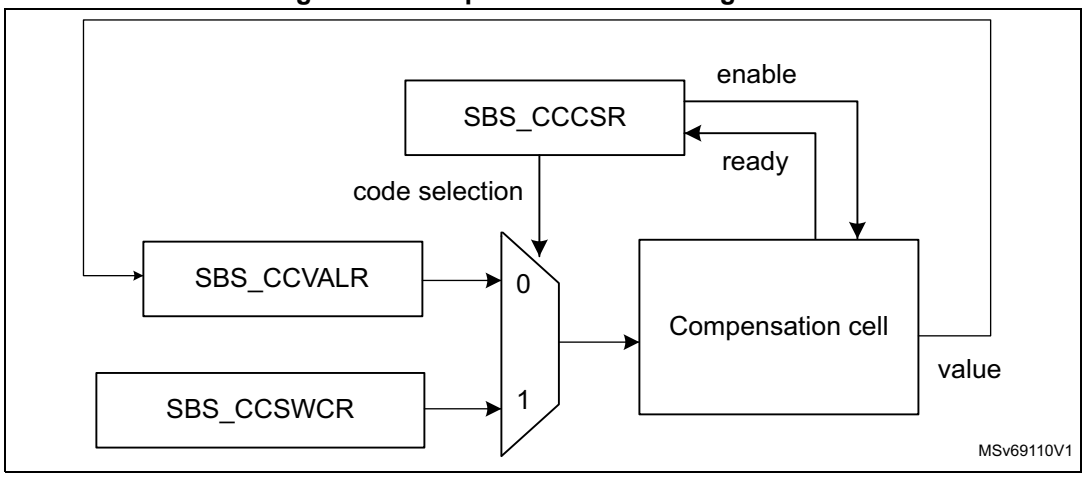
12.3.4 SBS I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer: 4 bits for N-MOS and 4 bits for P-MOS. This value depends on the process, voltage, temperature (PVT) operating conditions. These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the t_{fall} and t_{rise} time), in order to reduce the I/O noise on the power supply.

As shown in *Figure 37*, the compensation cell is split in two blocks:

- One block to provide an optimal code for the current PVT
- One block to drive the block controlled by software

Figure 37. Compensation cell management

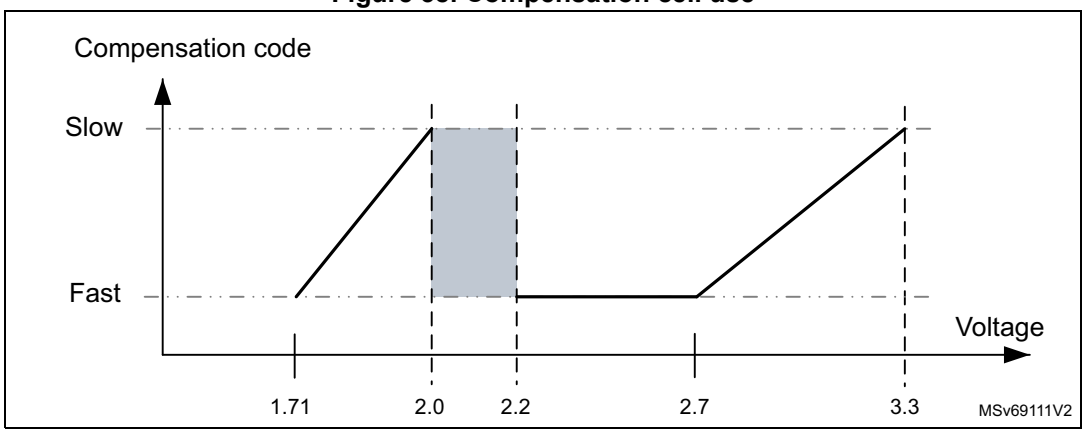


The compensation cell value can be read when the READY flag is set in SBS_CCCSR. With CODESEL in SBS_CCCSR, the application can select the value to apply between two options: the code from the cell, or the code from SBS_CCSWCR.

By default, the compensation cells are disabled, and a fixed code is applied to all I/Os.

The compensation cell can be used only when the HSI oscillator is enabled, see Section 9: Reset and clock control (RCC) for more details on the HSI oscillator.

Figure 38. Compensation cell use



12.3.5 SBS boot control

The SBS can be used to control the boot entry points considering the product settings. The main boot control actions are listed below:

- Select boot between the bootloader or the user flash memory boot.
- Initialize the HDPL boot value.

Note: For more details on STM32C5xx BOOT control, refer to Section 4: Boot modes.

SBS HDPL (temporal isolation level) management

The HDPL is a monotonic counter incremented during the boot stages. The HDPL is reset to its default value only after a power-on or a system reset. This default value is 1.

The devices use HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HPDL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

The HDPL is used by the user flash memory. See *Section 6: Embedded flash memory (FLASH)* for more details.

The HDPL can take the value from 1 to 3. When reaching the value 3, HDPL keeps this value until reset. The current HDPL value is readable in HDPL bitfield of SBS_HDPLSR.

To increment the HDPL by one, the application must write 0x6A to INCR_HDPL in SBS_HDPLCR. After such increment, and before doing any subsequent action, the user must check that the HDPL has effectively been incremented reading SBS_HDPLSR.

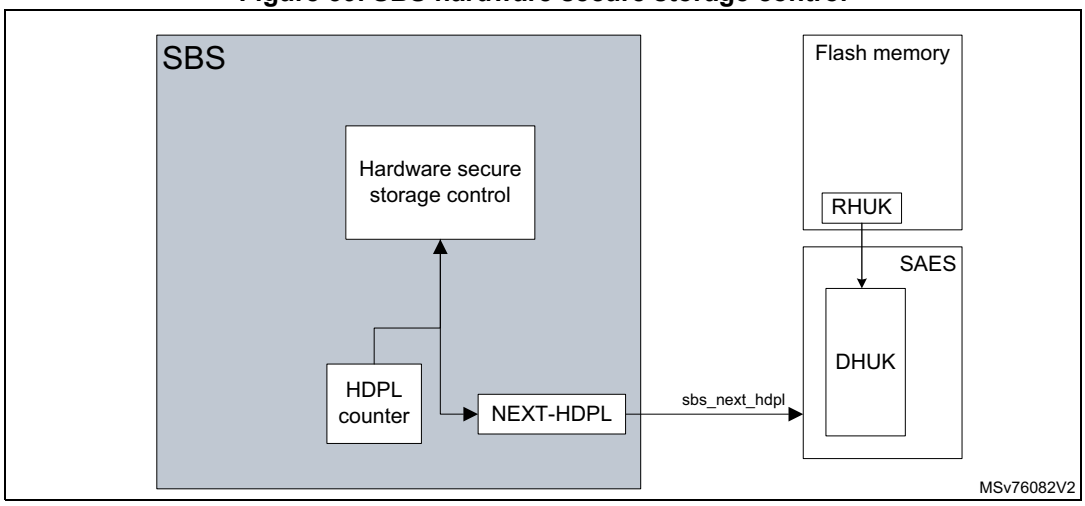
Table 81. HDPL encoded values

HDPL	Code
1	0x51
2	0x8A
3	0x6F
	All other values

12.3.6 SBS hardware secure storage control

This feature ensures the isolation of keys including the key derivation (DHUK) mechanism protecting data using a hardware key different for the identified domains.

Figure 39. SBS hardware secure storage control



- sbs_next_hdpl: select secure storage context for current HDPL, or greater ones. This signal is set thanks to the SBS_NEXTHDPLCR register. This information is used by the SAES when processing the derived key to generate a key derived related to HDPL context.

All keys encrypted using the SAES/DHUK inherit of the RHUK property: unique per device.

The table below gives the value of HDPL function of NEXTHDPL value.

Table 82. NEXT-HDPL logic

HDPL[7:0] in SBS_HDPLSR	NEXTHDPL[1:0]			
	0	1	2	3
1 (0x51)	0x51	0x8A	0x6F

12.4 SBS interrupts

SBS does not support interrupts.

12.5 SBS registers

For the actual availability of some peripherals/features and their related bits, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved, and keep them at reset value.

12.5.1 SBS temporal isolation control register (SBS_HDPLCR)

Address offset: 0x010

Reset value: 0x0000 00B4

Reset: system reset

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **INCR_HDPL[7:0]**: HDPL value increment
0xB4: No increment
0x6A: Recommended value to increment HDPL level by one
Other: All other values allow an HDPL level increment.

12.5.2 SBS temporal isolation status register (SBS_HDPLSR)

Address offset: 0x014

Reset value: 0x0000 0051

Reset: system reset

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]**: Temporal isolation level

This bitfield returns the current temporal isolation level.

0x51: HDPL1, hide protection level to be used to execute and protect an immutable root of trust (IROT) stage. First code to be executed at each reset of the platform. To ensure secure boot, this code must be immutable)

0x8A: HDPL2, hide protection level to be used to execute and protect an updatable Root of Trust (UROT) stage. UROT is executed from IROT to complete the immutable root of trust execution during boot stages

0x6F: HDPL3, hide protection level to be used to execute the application. It is a temporal isolation level that can be used to run the application when it has to be isolated from IROT and UROT)

12.5.3 SBS next HDPL control register (SBS_NEXTHDPLCR)

Note: This section applies only to STM32C59xx/C5Axx devices.

Address offset: 0x018

Reset value: 0x0000 0000

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NEXTHDPL[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **NEXTHDPL[1:0]**: Index to point to a higher HDPL than the current one
This bitfield is used to add the increment to HDPL to access to the next secure storage areas through NEXT-HDPL.
00: NEXT-HDPL = HDPL
01: NEXT-HDPL = HDPL + 1
10: NEXT-HDPL = HDPL + 2
11: NEXT-HDPL = HDPL + 3

12.5.4 SBS product mode and configuration register (SBS_PMCR)

Address offset: 0x100

Reset value: 0x8000 0000

Reset: system reset

Register security: there is no access restriction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ETH1TXLPI	ETH1PDACK	ETH1INTPOL	ETH1_SEL_PHY[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	r	r	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADC1_IN7_REMAP	ADC1_IN6_REMAP	ADC1_IN5_REMAP	ADC1_IN2_REMAP
												rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ETH1TXLPI**: Ethernet TxLPI status
This bit is set and reset by hardware.
When set, this bit indicates that the MAC has entered Tx LPI mode.

Bit 29 **ETH1PDACK**: Ethernet power-down acknowledge
This bit is set and reset by hardware.
When set, this bit indicates that the Ethernet controller has complete its power-down sequence and its clock can be stopped.
0: Ethernet functional / power-down sequence not yet completed
1: Ethernet power-down sequence completed

Bit 28 **ETH1INTPOL**: Ethernet external PHY interrupt polarity configuration
0: active high
1: active low

Bits 27:24 **ETH1_SEL_PHY[3:0]**: Ethernet PHY interface selection
0000: GMII or MII
0100: RMII
Other: reserved

Bits 23:4 Reserved, must be kept at reset value.

Bit 3 **ADC1_IN7_REMAP**: ADC1 channel IN7 remap
0: ADC1_IN7 is mapped on PA7
1: ADC1_IN7 is mapped on PB1
Note: This bit is only available for STM32C53x/542 device.

Bit 2 **ADC1_IN6_REMAP**: ADC1 channel IN6 remap
0: ADC1_IN6 is mapped on PA6
1: ADC1_IN6 is mapped on PB0
Note: This bit is only available for STM32C53x/542 device.

Bit 1 **ADC1_IN5_REMAP**: ADC1 channel IN5 remap
0: ADC1_IN5 is mapped on PA5
1: ADC1_IN5 is mapped on PC5
Note: This bit is only available for STM32C53x/542 device.

Bit 0 **ADC1_IN2_REMAP**: ADC1 channel IN2 remap
0: ADC1_IN2 is mapped on PA2
1: ADC1_IN2 is mapped on PC4
Note: This bit is only available for STM32C53x/542 device.

12.5.5 SBS FPU interrupt mask register (SBS_FPUIMR)

Address offset: 0x104

Reset value: 0x0000 001F

Reset: system reset

This register is only accessible through a privilege transaction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: FPU interrupt enable
This bitfield is set and cleared by software to enable the Cortex-M33 FPU interrupts.
FPU_IE[5]: Inexact interrupt enable (interrupt disabled at reset)
FPU_IE[4]: Input abnormal interrupt enable
FPU_IE[3]: Overflow interrupt enable
FPU_IE[2]: Underflow interrupt enable
FPU_IE[1]: Divide-by-zero interrupt enable
FPU_IE[0]: Invalid operation interrupt enable

12.5.6 SBS memory erase status register (SBS_MESR)

Address offset: 0x108

Reset value: 0x000X 000X

Note: Bits 0 and 16 are not affected by system reset.

Register security: always accessible

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPMEE
															rc_w1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCLR
															rc_w1

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE erase status

This bit is set by hardware when an ICACHE erase is completed after potential tamper detection, or a product state regression (refer to *Section 40: Tamper and backup registers (TAMP)* for more details). This bit is cleared by software by writing 1 to it.

0: ICACHE erase ongoing

1: ICACHE erase ended

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: Device memories erase status

This bit is set by hardware when a SRAM2 and ICACHE erase is completed after power-on reset or tamper detection, or product state regression (refer to *Section 40: Tamper and backup registers (TAMP)* for more details).

This bit is not reset by system reset and is cleared by software by writing 1 to it.

0: Memory erase ongoing if not yet cleared by software

1: Memory erase done

12.5.7 SBS compensation cell for I/Os control and status register (SBS_CCCSR)

Address offset: 0x110

Reset value: 0x0000 0002

Reset: system reset

Register security: always accessible

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDY1	Res.	Res.	Res.	Res.	Res.	Res.	CS1	EN1
							r							rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **RDY1**: VDDIO compensation cell ready flag
This bit provides the status of the compensation cell.
0: VDDIO compensation cell not ready
1: VDDIO compensation cell ready (code value provided by the cell can be used)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CS1**: Code selection for VDDIO power rail (reset value set to 1)
This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from SBS_CCWCR

Bit 0 **EN**1: Enable compensation cell for VDDIO power rail
This bit enables the I/O compensation cell.
0: I/O compensation cell disabled
1: I/O compensation cell enabled

12.5.8 SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114

Reset value: 0x0000 00XX

Reset: system reset

Register security: always accessible

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APSRC1[3:0]				ANSRC1[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **APSRC1[3:0]**: Compensation value for the PMOS transistor
This value is provided by the cell ,and the processor must interpret it to compensate the slew rate in the functional range.

Bits 3:0 **ANSRC1[3:0]**: Compensation value for the NMOS transistor
This value is provided by the cell, and the processor must interpret it to compensate the slew rate in the functional range.

12.5.9 SBS compensation cell for I/Os software code register (SBS_CCSWCR)

Address offset: 0x118

Reset value: 0x0000 0078

Reset: system reset

Register security: always accessible

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW_APSRC1[3:0]				SW_ANSRC1[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **SW_APSRC1[3:0]**: PMOS compensation code for the VDD power rails
This bitfield is written by software to define an I/O compensation cell code for PMOS transistors of the VDDIO power rail. This code is applied to the I/O when CS1 is set in SBS_CCSR.

Bits 3:0 **SW_ANSRC1[3:0]**: NMOS compensation code for VDD power rails
This bitfield is written by software to define an I/O compensation cell code for NMOS transistors of the VDD power rail. This code is applied to the I/O when CS1 is set in SBS_CCSR.

12.5.10 SBS Class B register (SBS_CFGR2)

Address offset: 0x120

Reset value: 0x0000 0000

Reset: system reset

Register security: always accessible

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCL	PVDL	SEL	CLL
												rw	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCL**: ECC lock
This bit is set and cleared by software. It can be used to enable and lock the flash memory double ECC error with break input of TIM1/8/15/16/17.
0: Double ECC error flag disconnected to timer break inputs
1: Double ECC error flag connected to timer break inputs

Bit 2 **PVDL**: PVD lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection with TIM1/8/15/16/17 break inputs.

0: PVD interrupt disconnected from timer break inputs. PVD_EN and PVD_SEL[2:0] in PWR registers are read/write.

1: PVD interrupt is connected to timer break inputs. PVD_EN and PVD_SEL[2:0] in PWR registers are read only

Bit 1 **SEL**: SRAM ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM double ECC error signal with break input of TIM1/8/15/16/17.

0: SRAM double ECC error flag disconnected from timer break inputs

1: SRAM double ECC error flag connected to timer break inputs

Bit 0 **CLL**: Core lockup lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the lockup (HardFault) output of the Cortex-M33 with TIM1/8/15/16/17 break inputs.

0: Lockup output disconnected from timer break inputs

1: Lockup output connected to timer break inputs

12.5.11 SBS CPU lock register (SBS_CLCKR)

Address offset: 0x144

Reset value: 0x0000 0000

Reset: system reset

Register security: This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

This register is used to lock the configuration of the MPU and VTOR registers of the Cortex-M33.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKMPU	LOCKVTOR
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LOCKMPU**: MPU register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to MPU_CTRL, MPU_RNR, and MPU_RBAR registers.

0: MPU registers write enabled

1: MPU registers write disabled

Bit 0 **LOCKVTOR**: VTOR register lock

This bit is set by software and cleared only by a system reset.

0: VTOR register write enabled

1: VTOR register write disabled

12.5.12 SBS ECC NMI mask register (SBS_ECCNMIR)

Address offset: 0x14C

Reset value: 0x0000 0000

Reset: system reset

Register security: This register is only accessible through a privilege transaction.

This register sets up the expected behavior on NMI regarding double ECC errors from the flash memory.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

13 Peripherals interconnect matrix

13.1 Interconnect matrix introduction

Several peripherals have direct connections between them, enabling autonomous communication and/or synchronization: this approach saves CPU resources and power supply consumption. In addition, these hardware connections remove software latency and help the design of a predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, and Stop modes.

13.2 Connection summary

There are several types of connections.

- Asynchronous connections (A)

  The source output signal is sampled by the destination clock, leading to introduction of a possible jitter in the latency between the source output event and the destination event detection
- Synchronous connections (S)

  Both source and destination are synchronous (they run on the same clock), and the latency from the source to the destination is deterministic. No jitter is introduced.
- Immediate connections (I)

  Either the source or the destination is an analog signal.
- Break/fault connection for TIM outputs (B)

  The source output signal disables the timer outputs through a pure combinational logic path, without any latency.

Table 84. Peripherals interconnect matrix(1)(2)

Source	Destination																
	TIM1	TIM2	TIM5	TIM6	TIM7	TIM8	TIM12	TIM15	TIM16	TIM17	LPTIM1	CRS	LPDMA1	LPDMA2	ADC	DAC	COMP

14 Low-power direct memory access controller (LPDMA)

14.1 LPDMA introduction

The low-power direct memory access (LPDMA) controller is a bus master and system peripheral.

The LPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

14.2 LPDMA main features

- Single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Transfers arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half-transfer complete, data transfer error, user setting error, link transfer error, completed suspension and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- Up to 8 concurrent LPDMA1 channels, up to 8 concurrent LPDMA2 channels:
  - Intra-channel LPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel LPDMA transfers chaining via programmable LPDMA input triggers connection to LPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive single transfers
  - Programmable LPDMA request and trigger selection
  - Programmable LPDMA half-transfer and transfer-complete events generation

  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the LPDMA linked-list control registers
- Debug:
  - Channel suspend and resume support
  - Channel status reporting and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged LPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

14.3 LPDMA implementation

14.3.1 LPDMA instances

The number of available channels per instance are given in *Table 86: LPDMA1/2 channels implementation*. *Section 14.8: LPDMA registers* reflects the LPDMA registers, with x = 0 to 7 for the channel number.

LPDMA instances have the same registers, excepted for those with x = 4 to 7.

Any LPDMA instance is connected to the same requests and triggers.

Table 86.LPDMA1/2 channels implementation

LPDMA instance	STM32C53xxx/542xx	STM32C55xxx/562xx	STM32C59xxx/5A3xx
LPDMA1	x = 0 to 3	x = 0 to 7	x = 0 to 7
LPDMA2	x = 0 to 3	x = 0 to 3	x = 0 to 7

14.3.2 LPDMA channels

A given LPDMA channel x is implemented with the hardware parameters as per the table below.

Table 87.LPDMA1 channels implementation

Channel x	Hardware parameters		Features
	dma_fifo_ size[x]	dma_ addressing[x]	
x = 0 to 7	0	0	Channel x (x = 0 to 7) is implemented with: – no FIFO. Only a single source transfer cell is internally registered. – fixed/contiguously incremented addressing

Table 88.LPDMA2 channels implementation

Channel x	Hardware parameters		Features
	dma_fifo_ size[x]	dma_ addressing[x]	
x = 0 to 7	0	0	Channel x (x = 0 to 7) is implemented with: – no FIFO. Only a single source transfer cell is internally registered. – fixed/contiguously incremented addressing

14.3.3 LPDMA in low-power modes

The LPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 89. LPDMA1/2 autonomous mode and wake-up in low-power modes

Feature	Low-power modes
Wake-up	LPDMA1/2 in Sleep mode

14.3.4 LPDMA requests

A LPDMA request from a peripheral can be assigned to a LPDMA channel x, via the REQSEL[6:0] field in the *LPDMA channel x transfer register 2 (LPDMA_CxTR2)*, provided that SWREQ = 0.

The LPDMA requests mapping is specified in the table below.

Table 90. Programmed LPDMA1/2 request

14.3.5 LPDMA block requests

Some LPDMA requests must be programmed as a block request, and not as a single request. Then the BREQ bit in *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* must be set for a correct LPDMA execution of the requested peripheral transfer at the hardware level.

The LPDMA block requests are listed in the table below.

Table 91. Programmed LPDMA1/2 request as a block request

LPDMA block requests
lptim1_ue_dma

14.3.6 LPDMA channels with peripheral early termination

A LPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 92. LPDMA1/2 channel with peripheral early termination

LPDMA channel x with peripheral early termination
LPDMA1: x = 0 and x = 7 LPDMA2: x = 0 and x = 7

This LPDMA support is activated when the channel x is programmed with LPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before the LPDMA has transferred the whole block (see *Section 14.4.14* for more details).

Table 93. Programmed LPDMA1/2 request with peripheral early termination

14.3.7 LPDMA triggers

A LPDMA trigger can be assigned to a LPDMA channel x, via the TRIGSEL[5:0] field in the *LPDMA channel x transfer register 2 (LPDMA_CxTR2)*, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The LPDMA triggers mapping is specified in the table below.

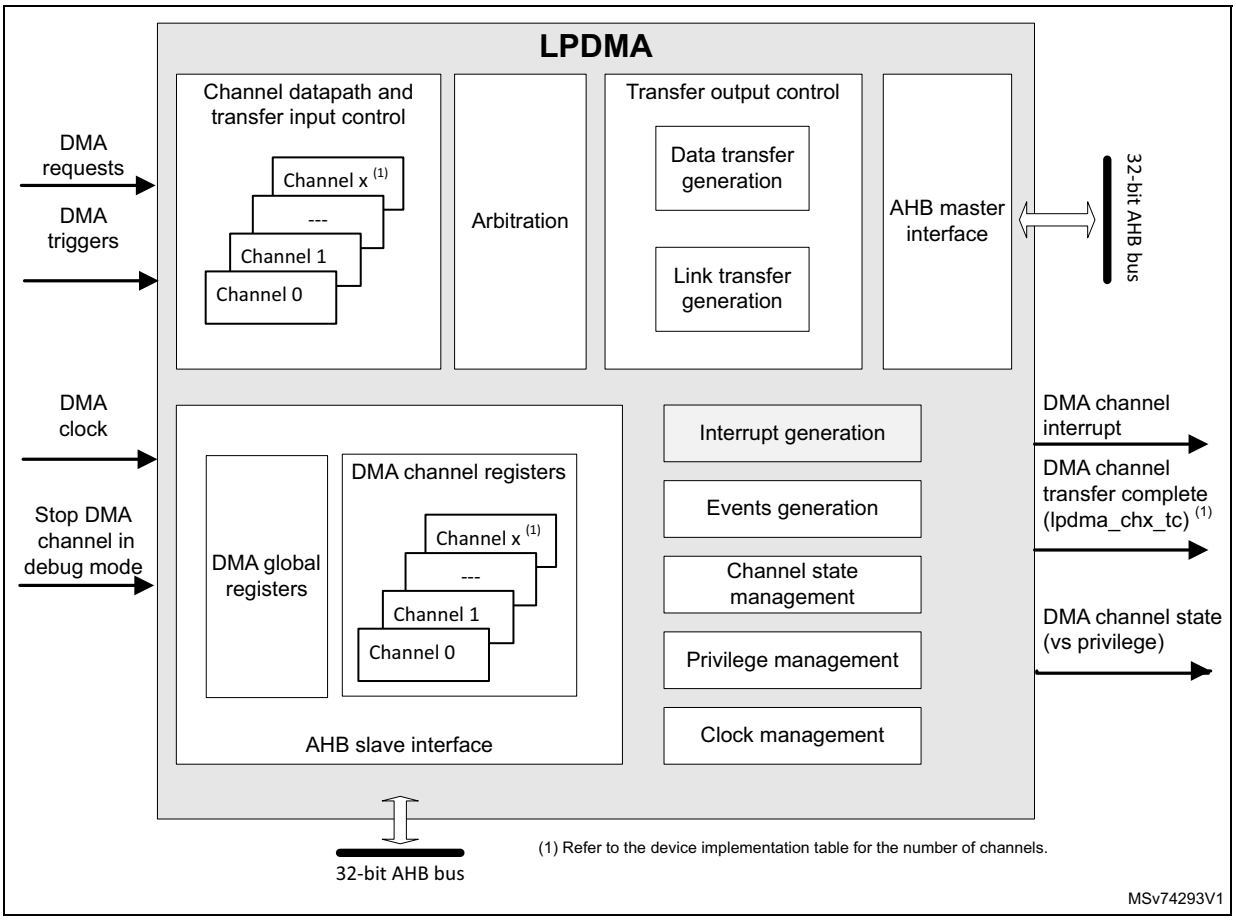
14.4 LPDMA functional description

14.4.1 LPDMA block diagram

The LPDMA block diagram is illustrated in the figure below.

Figure 40. LPDMA block diagram



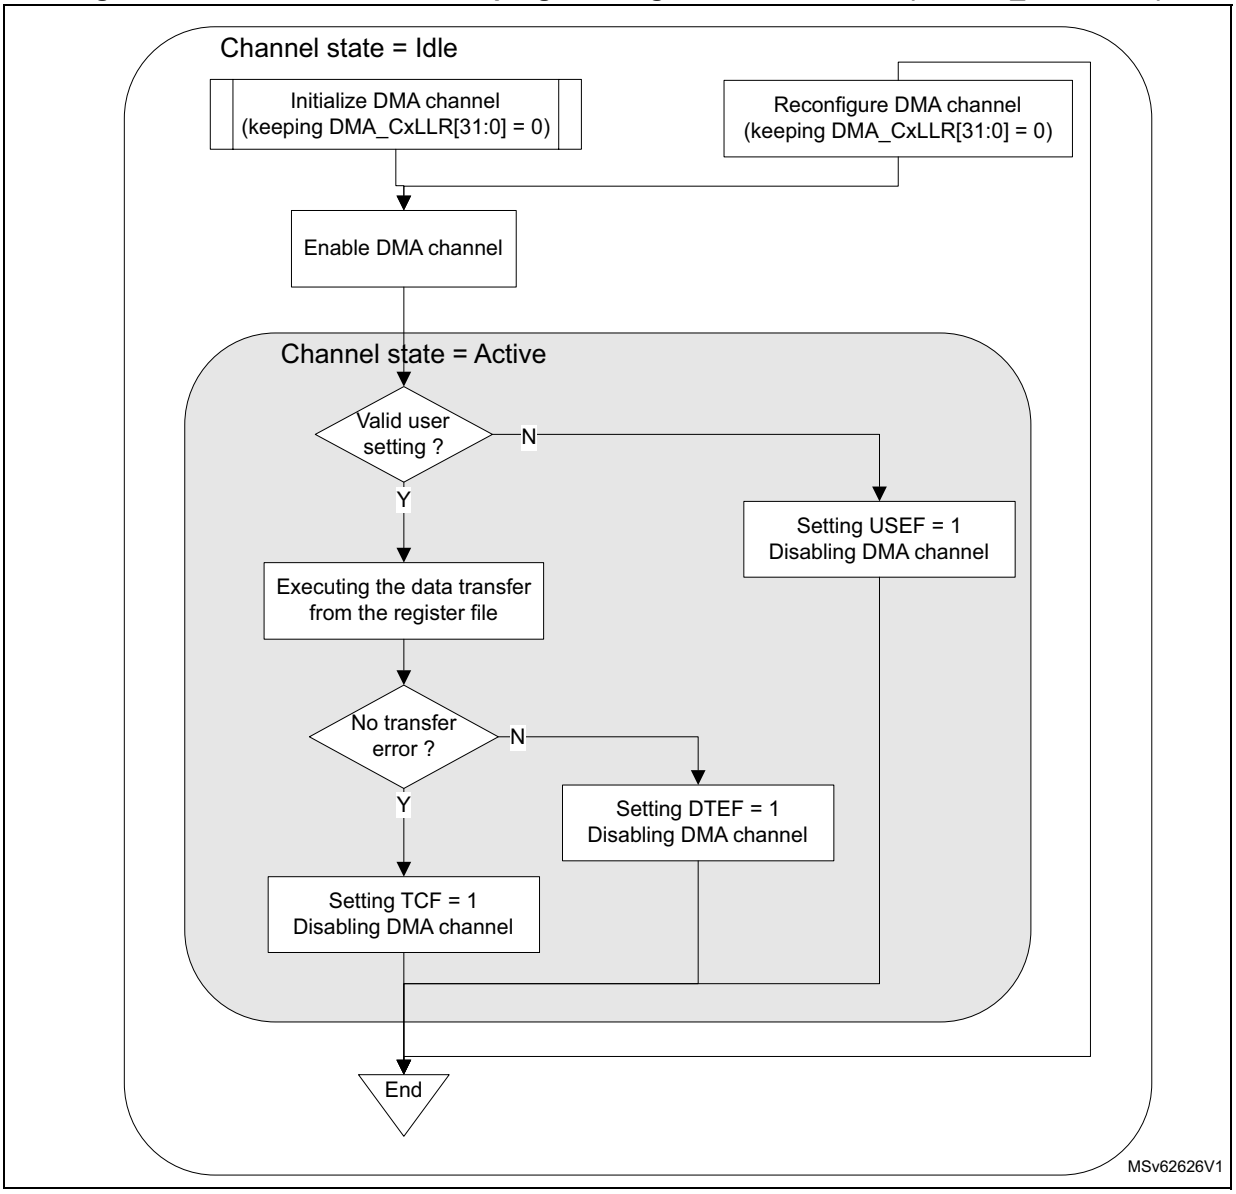
14.4.2 LPDMA channel state and direct programming without any linked-list

After a LPDMA reset, a LPDMA channel x is in idle state. When the software writes 1 into the in LPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (LPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a LPDMA channel transfer by writing 1 into the LPDMA_CxCR.EN bit, a LPDMA channel interrupt on a complete transfer notifies the software that the LPDMA channel is back in idle state (EN is then de-asserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this LPDMA direct programming without any linked-list (LPDMA_CxLLR = 0).

Figure 41. LPDMA channel direct programming without linked-list (LPDMA_CxLLR = 0)



14.4.3 LPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of

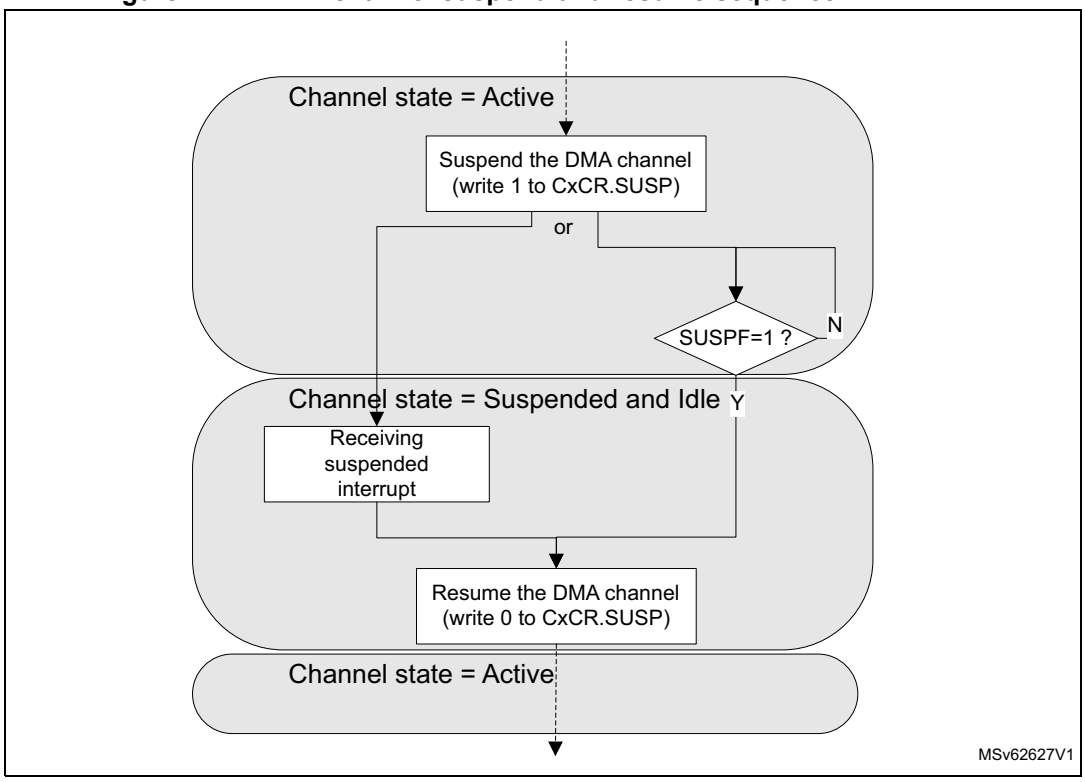
any ongoing LPDMA transfer over its master port. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note that an ongoing LPDMA transfer can be a data transfer (a read-followed-by-write single transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to LPDMA_CxCR.SUSP.

The suspend and resume sequence is illustrated in the figure below.

Figure 42. LPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the LPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

14.4.4 LPDMA channel abort and restart

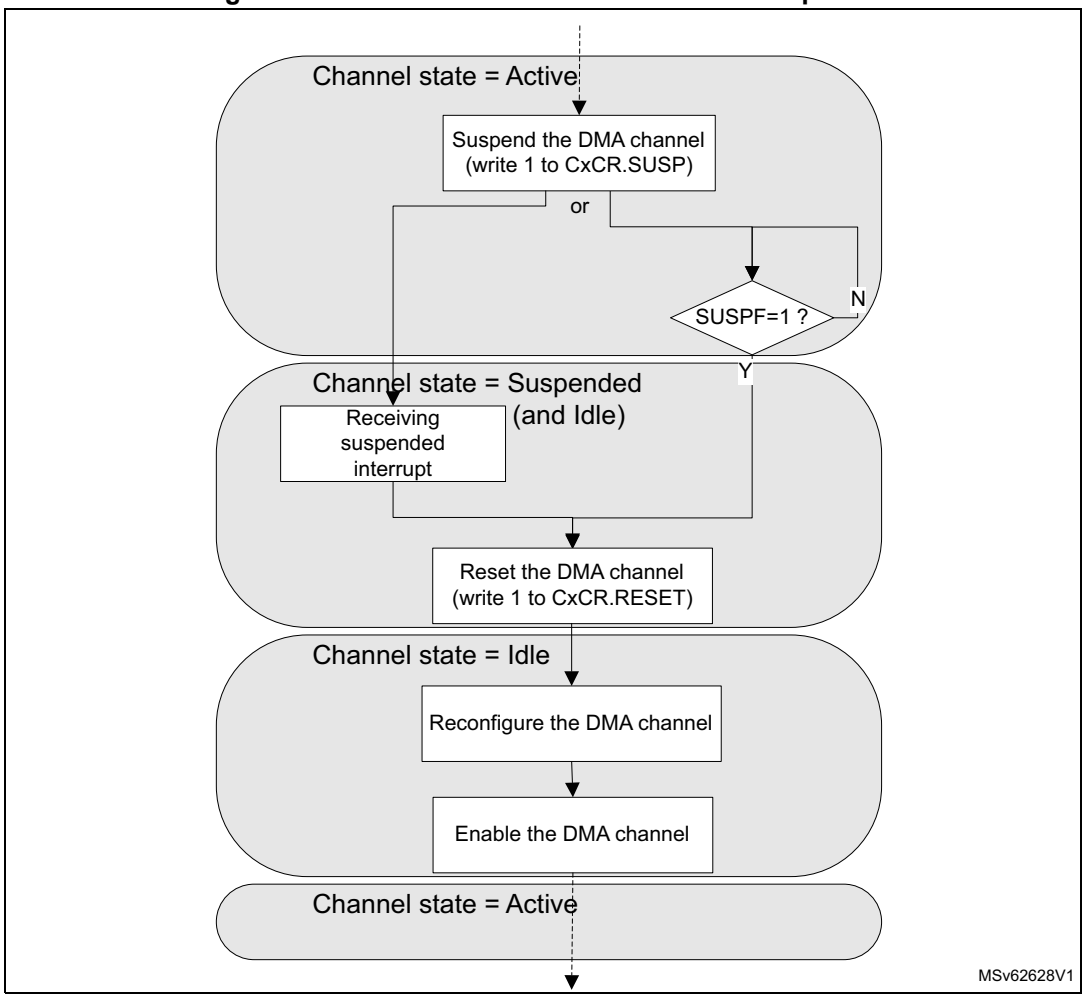
Alternatively, like for aborting a continuous LPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port.
3. The software resets the channel by writing 1 to LPDMA_CxCR.RESET. This causes the reset of the channel internal state, the reset of the LPDMA_CxCR.EN bit, and the reset of the LPDMA_CxCR.SUSP bit.

4. The software safely reconfigures the channel. The software must reprogram the hardware-modified LPDMA_CxBR1, LPDMA_CxSAR, and LPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the LPDMA_CxCR.EN bit.

The abort and restart sequence is illustrated in the figure below.

Figure 43. LPDMA channel abort and restart sequence



14.4.5 LPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in LPDMA_CxLBAR)
- the link address offset (LA[15:2] field in LPDMA_CxLLR)

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits of the LPDMA_CxLLR register.

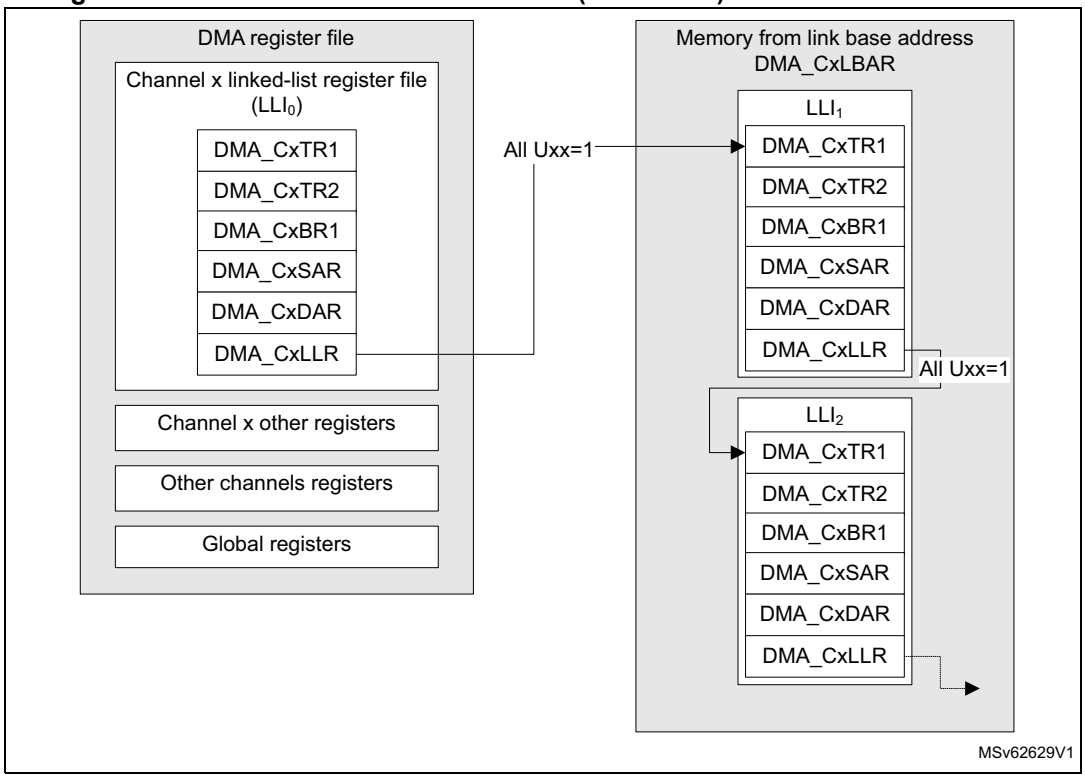
In linked-list mode, each LPDMA linked-list register (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the LPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Caution: The user must program the pointer to the next linked-list data structure (LPDMA_CxLLR[15:0]) not to exceed the 64-Kbyte addressable space defined by the link base address register (LPDMA_CxLBAR). The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL) of the LPDMA_CxLLR register are all asserted, the linked-list data structure in memory is maximal with six contiguous 32-bit locations, including LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR (see the figure below) and including the first linked-list register file (LLI_0) and the next LLIs (LLI_1, LLI_2,...) in the memory.

Figure 44. Static linked-list data structure (all Uxx = 1) of channel x



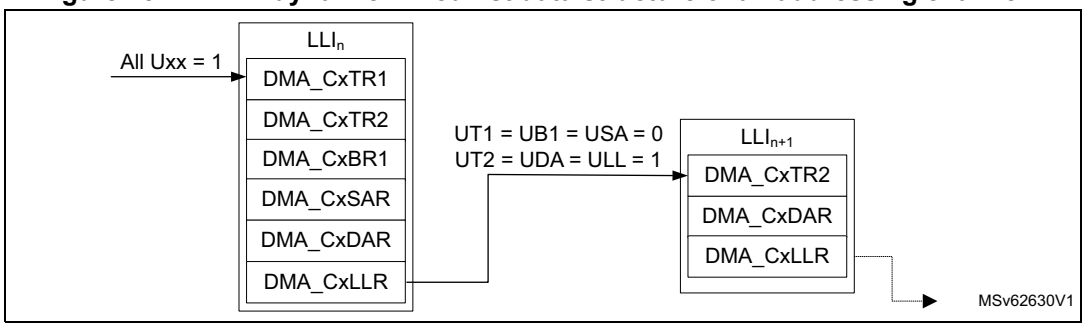
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register LPDMA_CxLLR is pointing to the updated value of the LPDMA_CxTR2 instead of the LPDMA_CxTR1 which is not to be modified.

Example: if UT1 = UB1 = USA = 0, and if UT2 = UDA = ULL = 1, the next LLI does not contain an updated value for LPDMA_CxTR1, nor LPDMA_CxBR1, nor LPDMA_CxSAR. The next LLI contains an updated value for LPDMA_CxTR2, LPDMA_CxDAR, and LPDMA_CxLLR, as shown in the figure below.

Figure 45. LPDMA dynamic linked-list data structure of an addressing channel x



14.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: LPDMA executes the data transfer as described by the LPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: LPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the LPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (LPDMA_CxBR1.BNDT[15:0] = 0 and LPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in LPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended LPDMA usage, a LPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, LPDMA_CxCR.LSM = 0) or a LPDMA channel x can be programmed for a single execution of a LLI (link step mode, LPDMA_CxCR.LSM = 1), as described in the next paragraphs.

14.4.7 LPDMA channel state and linked-list programming in run-to-completion mode

When LPDMA_CxCR.LSM = 0, a LPDMA channel x is initially programmed, started by writing 1 to LPDMA_CxCR.EN, and after (possibly) completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the LPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when LPDMA_CxLLR[31:0] = 0 and LPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

LPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits LPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits Uxx of LPDMA_CxLLR are null (UT1, UT2, UB1, USA, UDA, ULL).

The channel may never be completed when LPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated with the same value
  - or LPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI.

In the regular data transfer completion at a block level, LPDMA_CxBR1.BNDT[15:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 14.4.14* for more details).

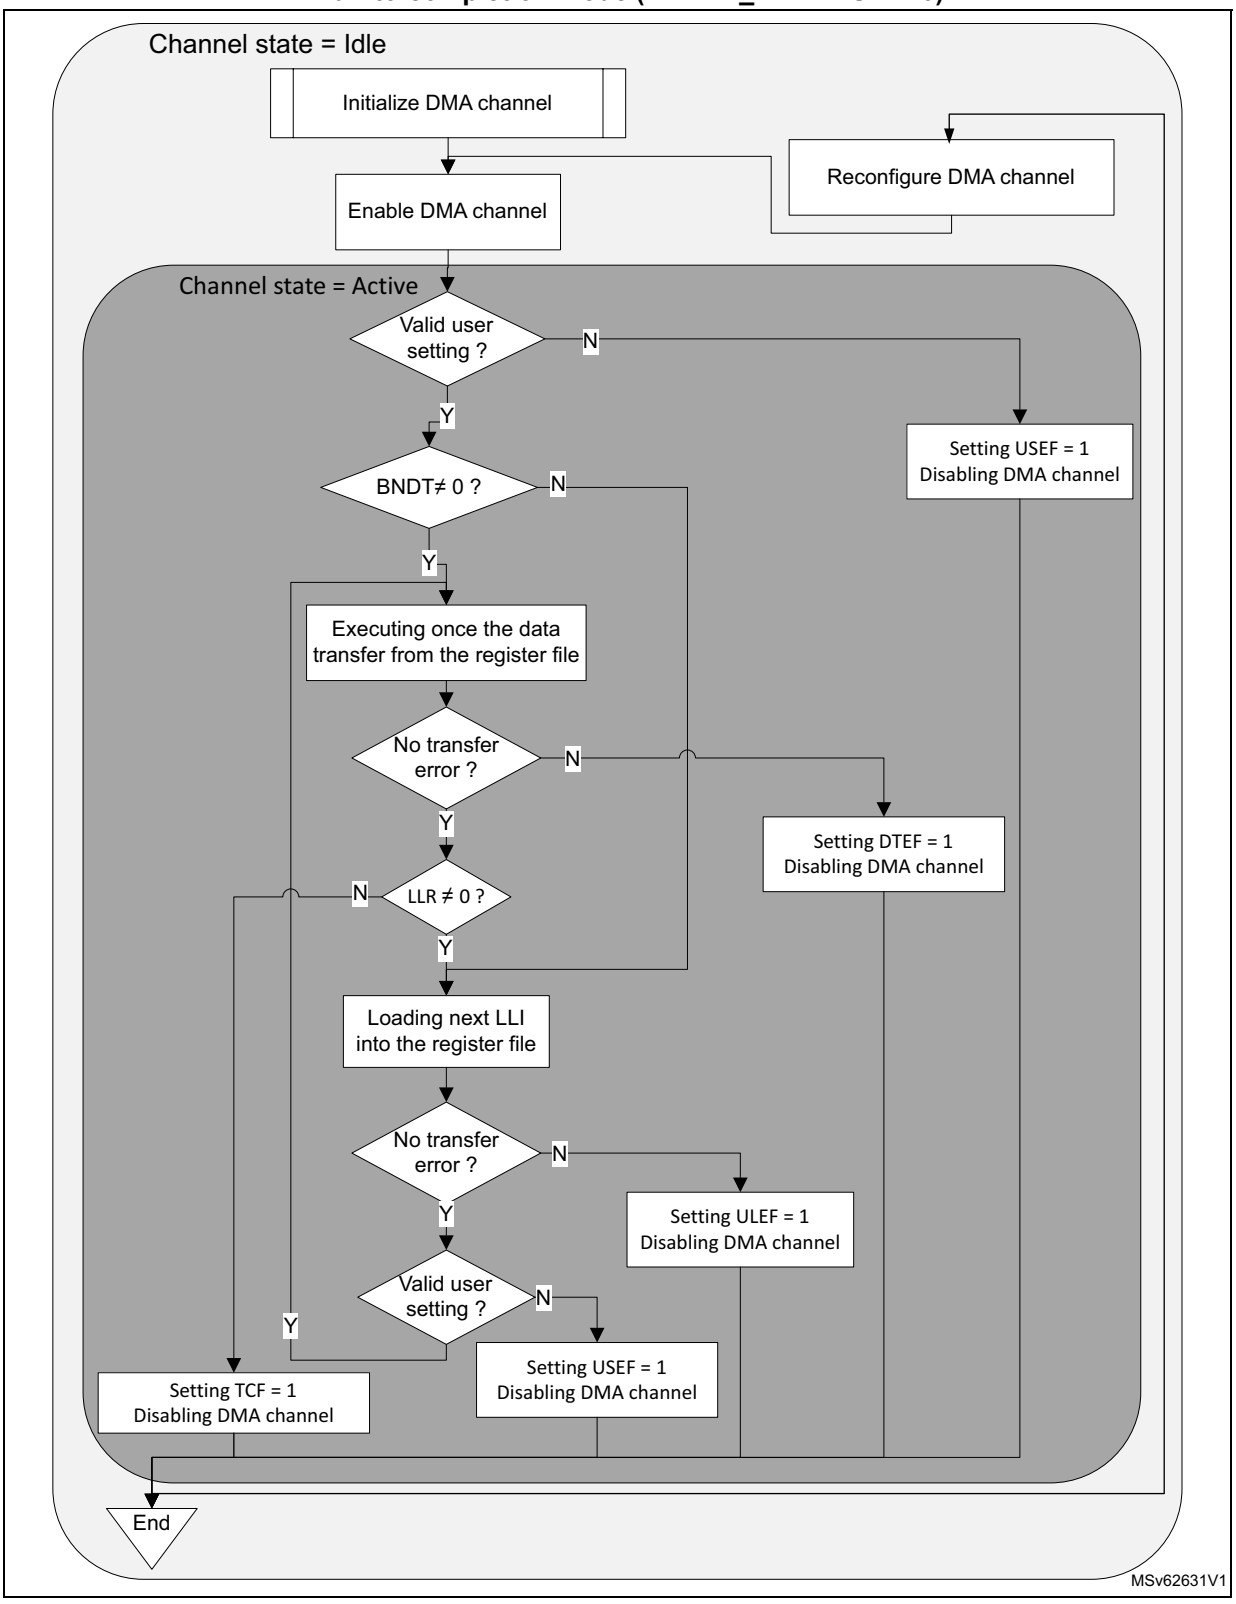
In the typical run-to-completion mode, the allocation of a LPDMA channel, including its fine programming, is done once during the LPDMA initialization. In order to have a reserved data communication link and LPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 46 depicts the LPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 46 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 46, BNDT ? 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ? 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 14.3.6).

Figure 46. LPDMA channel execution and linked-list programming in run-to-completion mode (LPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the LPDMA_CxTR2 in the data structure of the LLI_{n-1}:

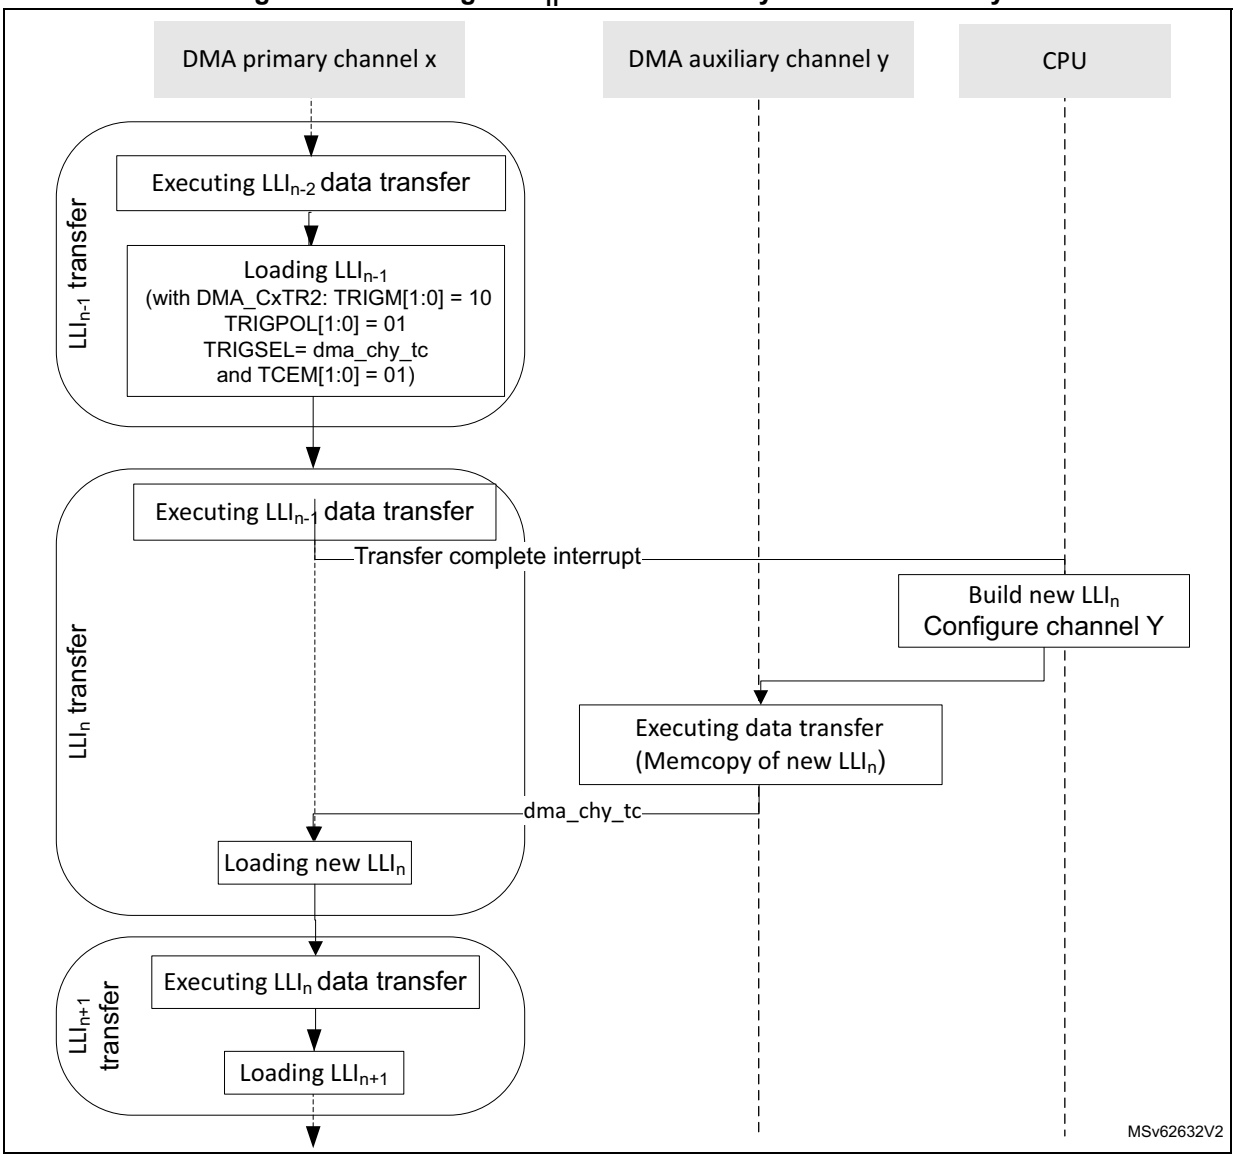
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 14.3.7* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event lpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 47 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 47. Inserting a LLI_n with an auxiliary LPDMA channel y



14.4.8 LPDMA channel state and linked-list programming in link step mode

When LPDMA_CxCR.LSM = 1, a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A LPDMA channel transfer can be programmed at LLI level, started by writing 1 into LPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - LPDMA_CxTR1 defines the source/destination elementary single transfers.
  - LPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]).
  - LPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - LPDMA_CxSAR/LPDMA_CxDAR defines the source/destination transfer start address.
  - LPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when LPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the LPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated with the same value, or LPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

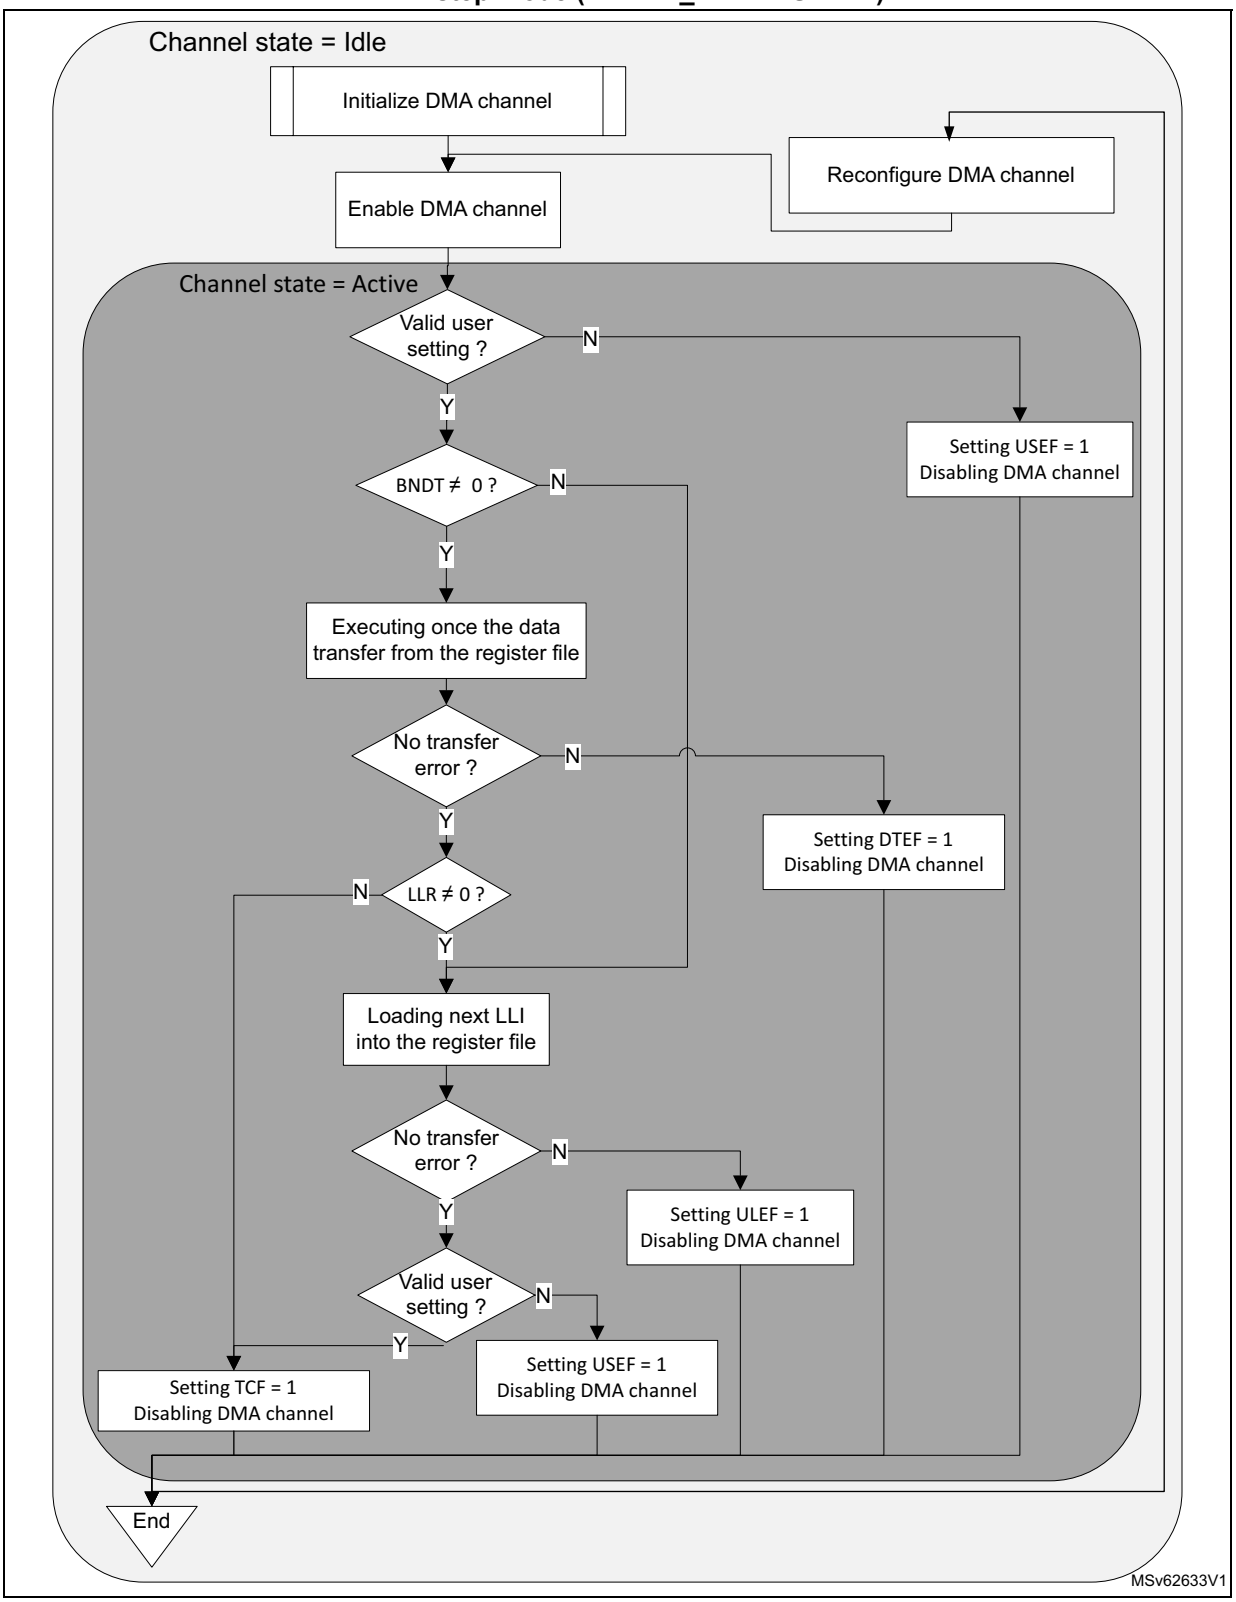
In the regular data transfer completion at a block level, LPDMA_CxBR1.BNDT[15:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 14.4.14* for more details).

Figure 48 depicts the LPDMA channel execution mode, and its programming in link step mode.

Note: Figure 48 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 48, BNDT ? 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ? 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 14.3.6).

Figure 48. LPDMA channel execution and linked-list programming in link step mode (LPDMA_CxCR.LSM = 1)

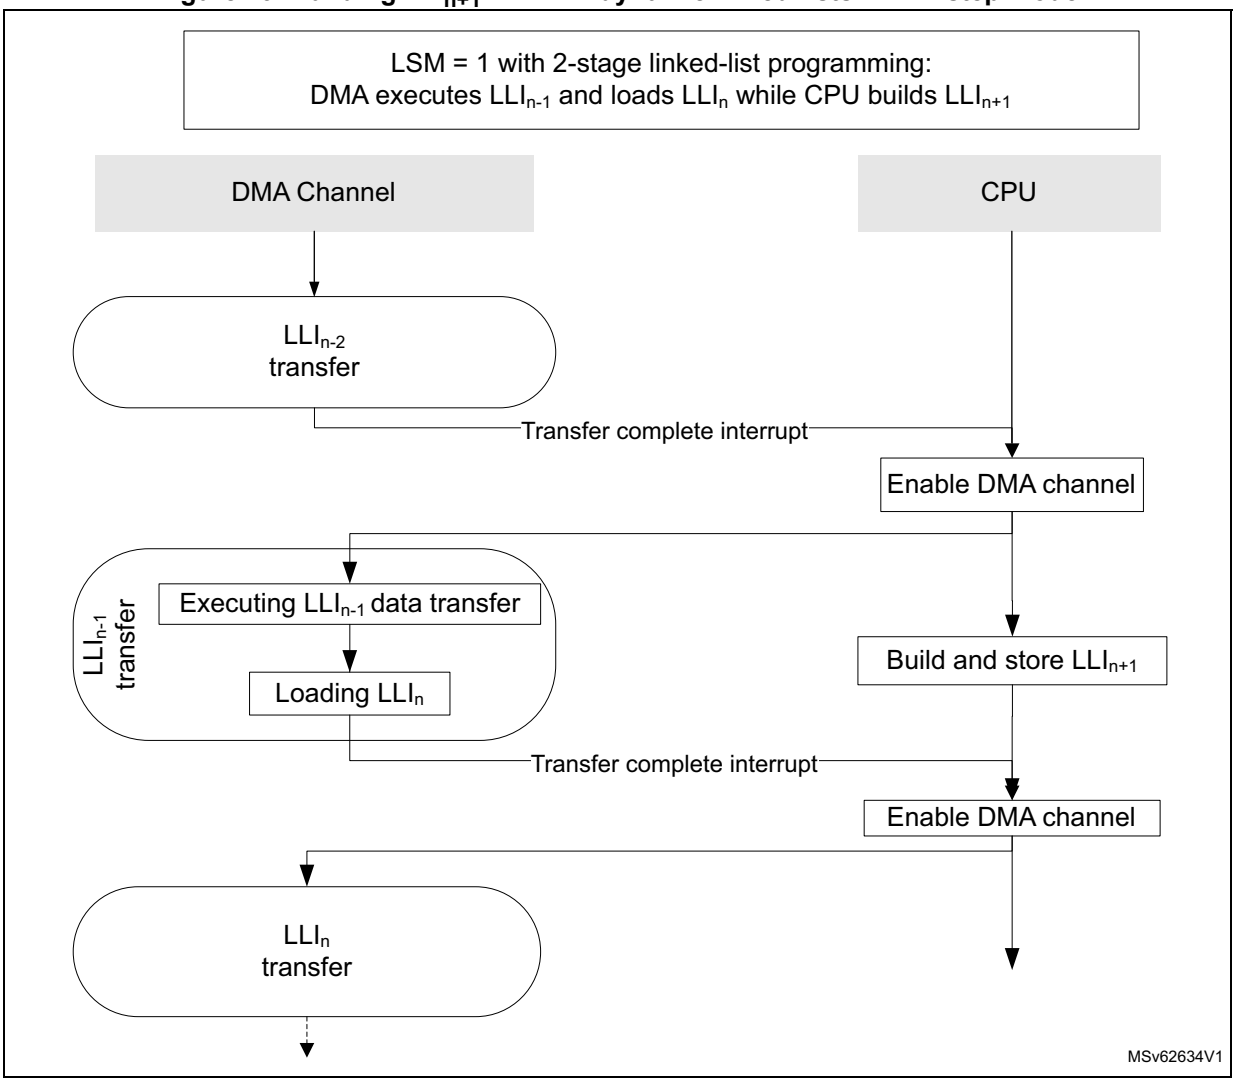


The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of LPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after LPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

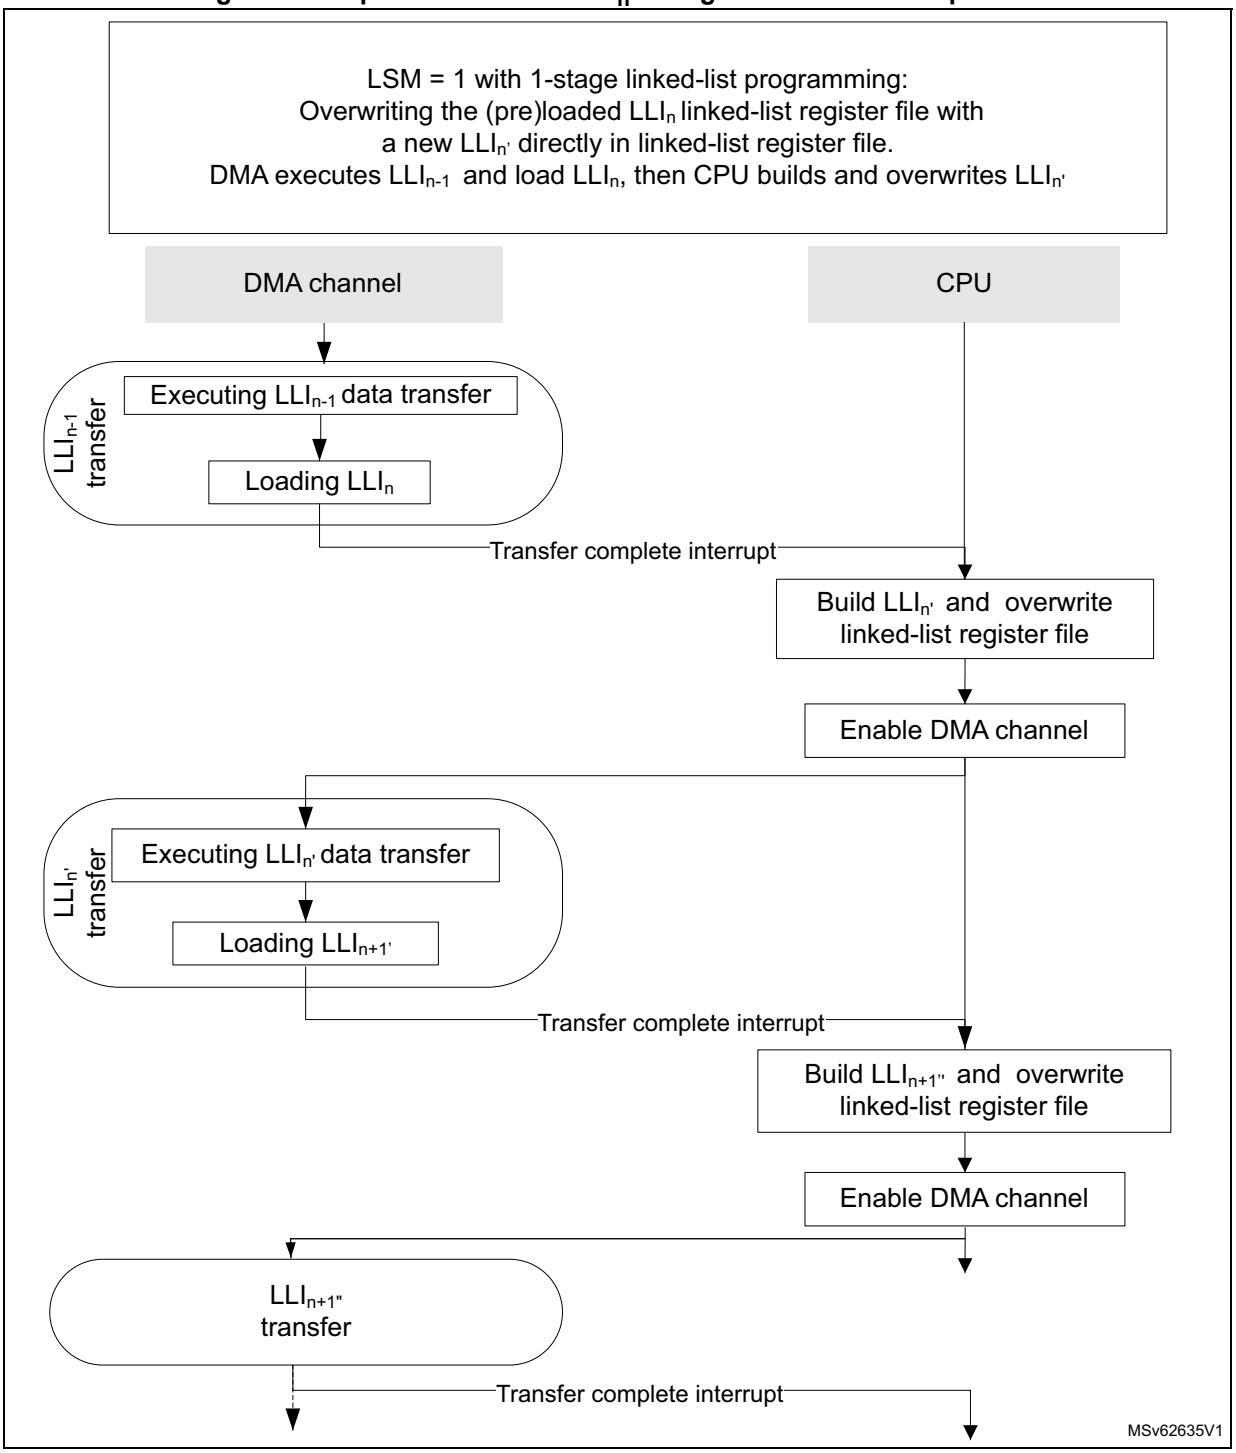
Figure 49. Building LLI_{n+1}: LPDMA dynamic linked-lists in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new $LLI_{n'}$, after LPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new $LLI_{n'}$, as shown in *Figure 50*.

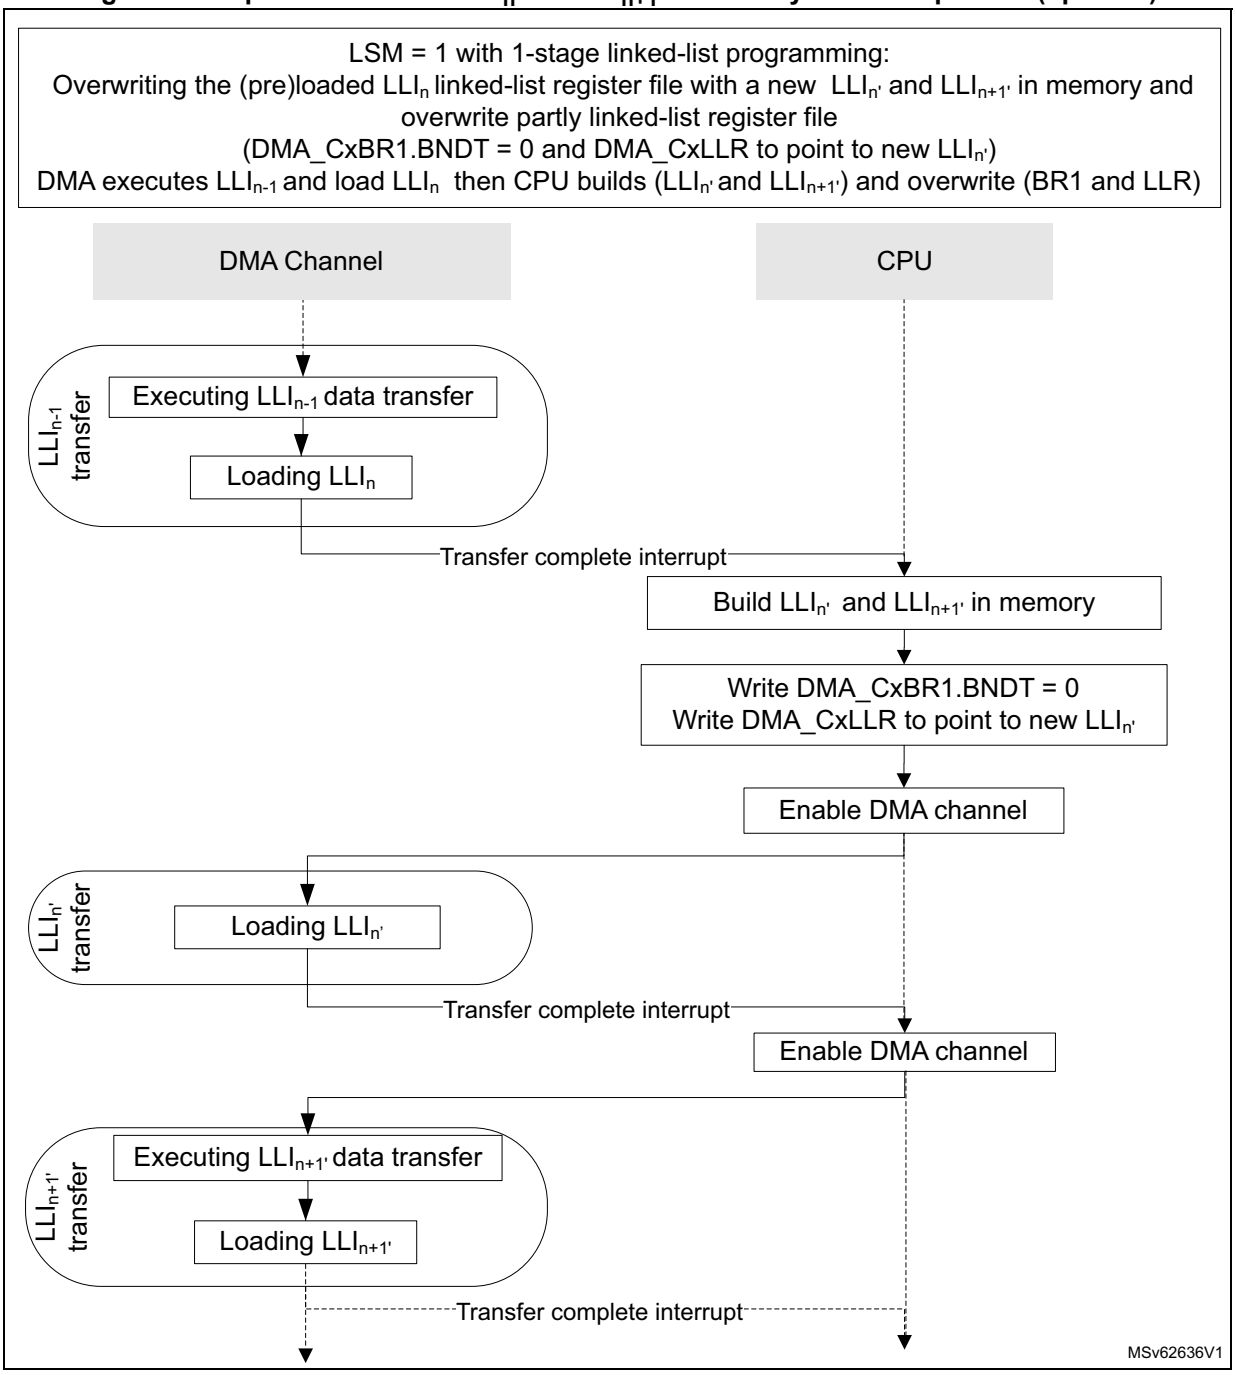
Figure 50. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after LPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new $LLI_{n'}$) as shown in *Figure 51*.

Figure 51. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



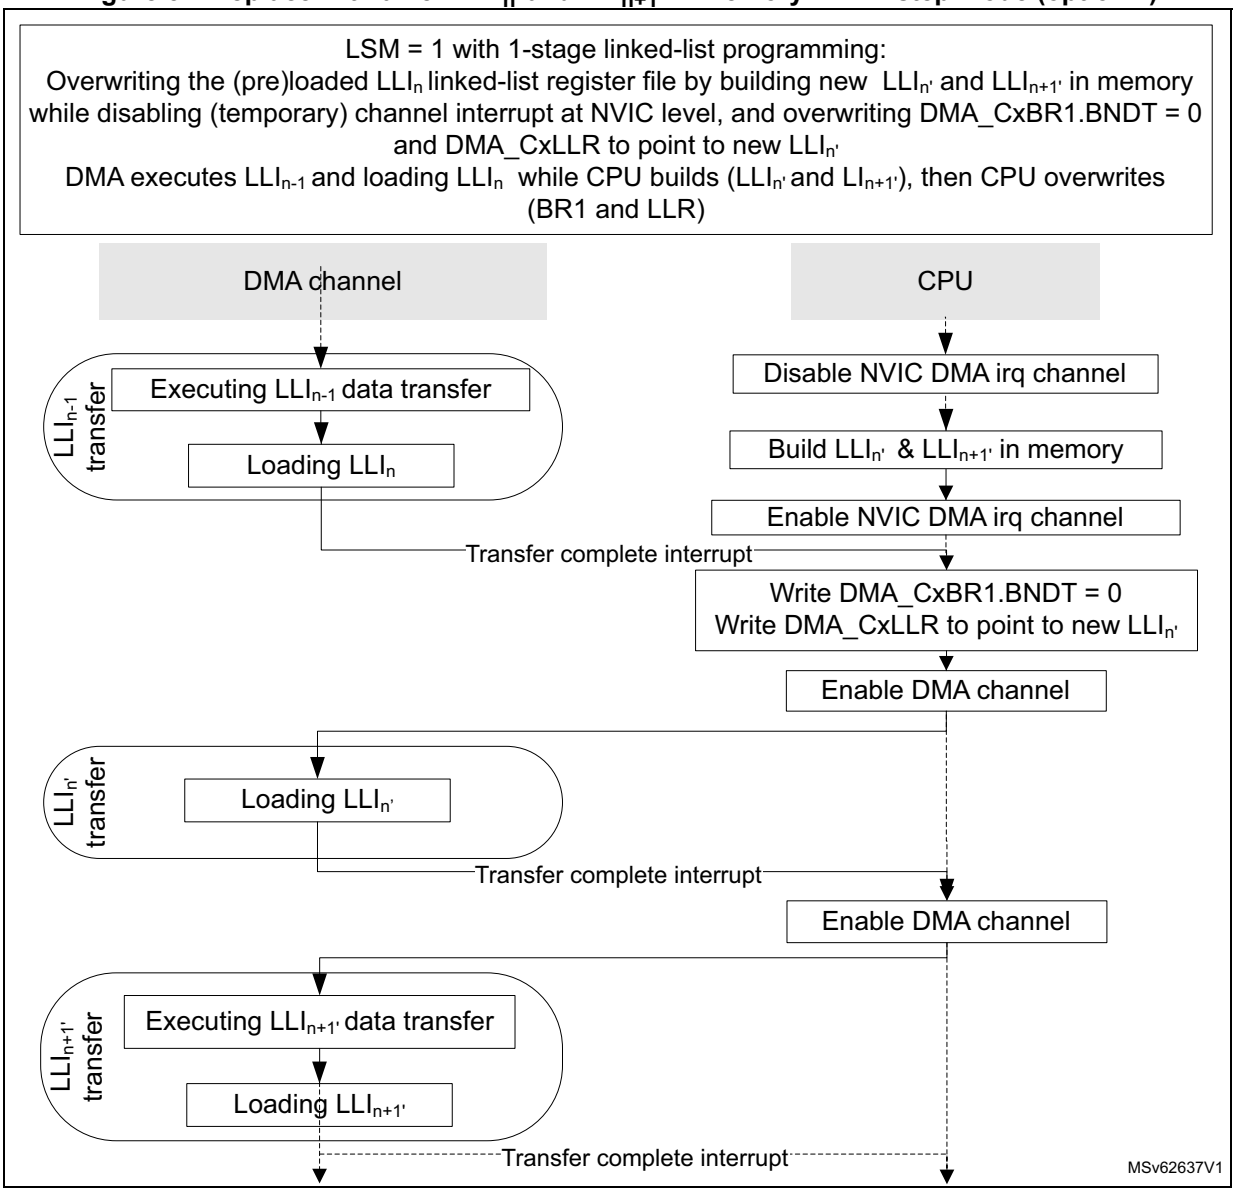
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile LPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 52*.

Figure 52. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



14.4.9 LPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (LPDMA_CxCR.EN = 0) and update the execution mode (LPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the LPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the LPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 14.4.4*)

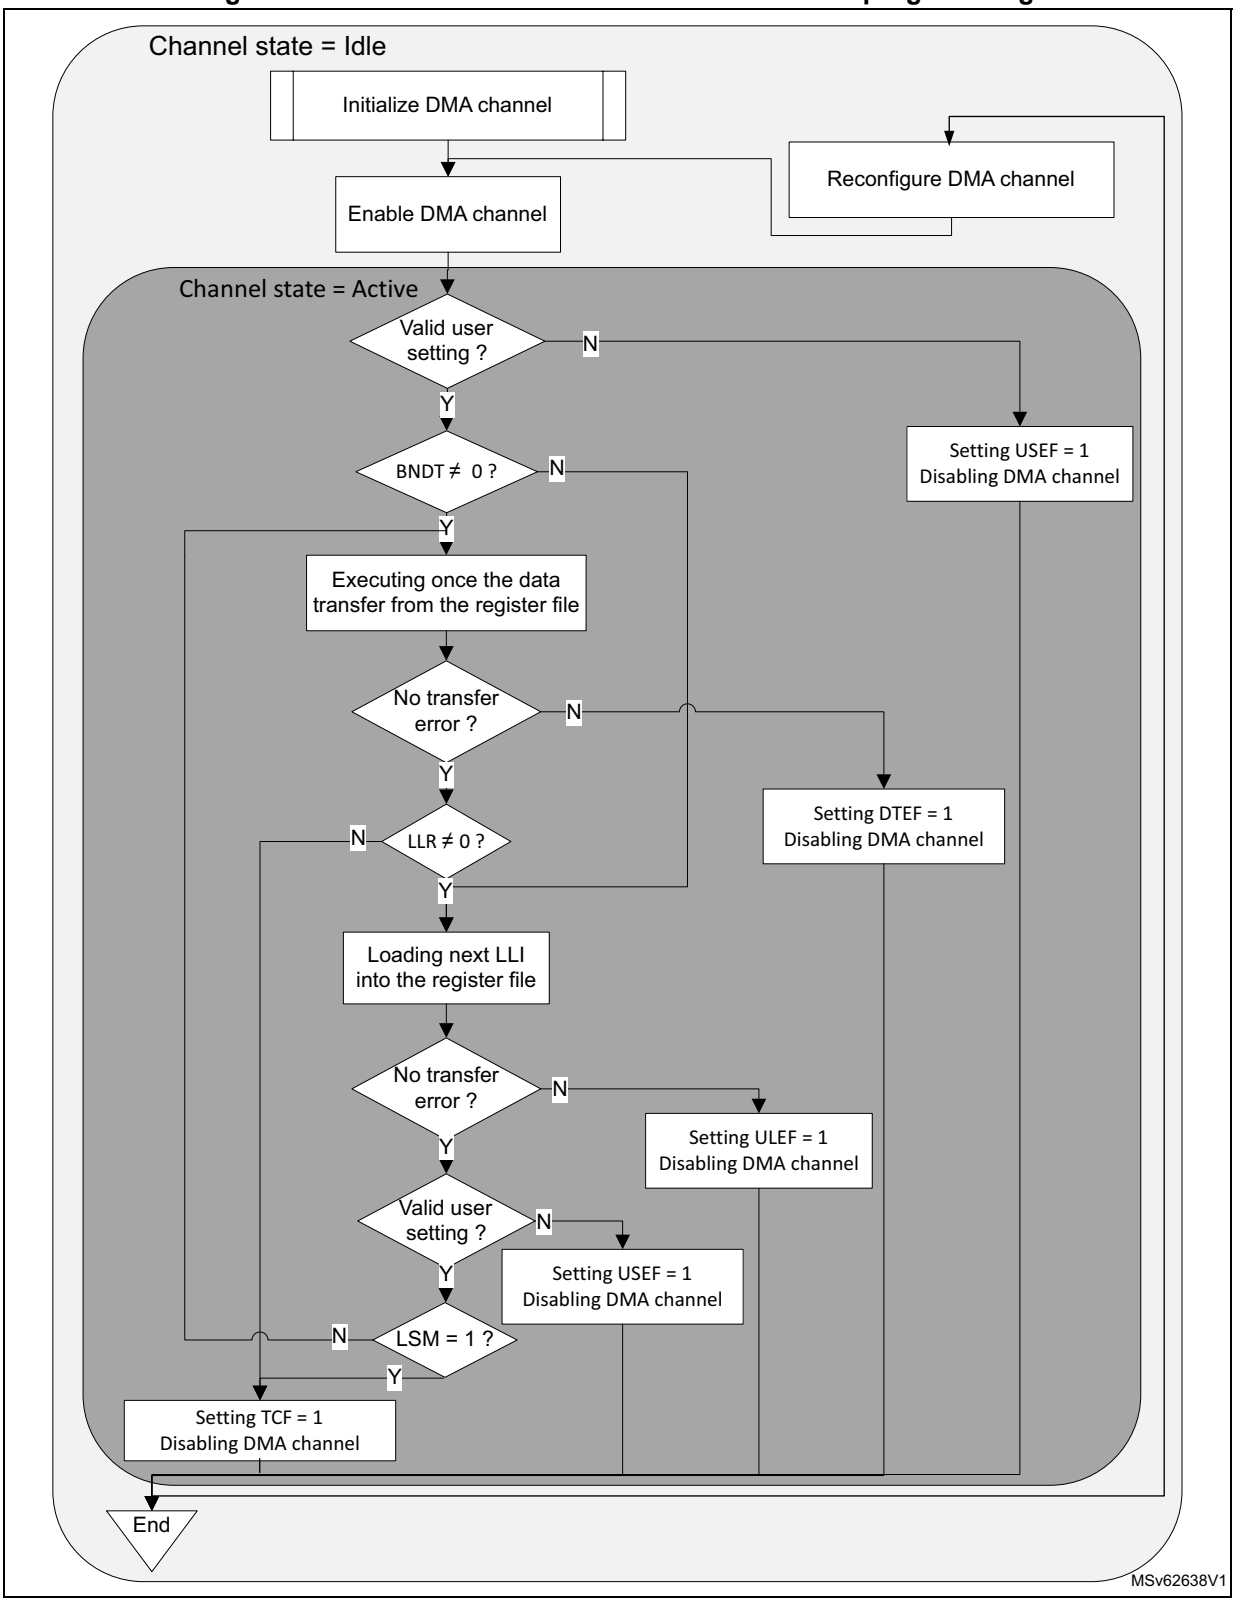
In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 53 shows the overall and unified LPDMA linked-list programming, whatever is the execution mode.

Note: Figure 53 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 53, BNDT ? 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ? 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 14.3.6).

Figure 53. LPDMA channel execution and linked-list programming



14.4.10 LPDMA direct transfers

There is a single transfer operation mode called the direct mode. Any LPDMA channel is used in direct mode. Any channel is implemented without any FIFO (for every channel x, dma_fifo_size[x] = 0).

LPDMA single

A programmed transfer at the lowest level is called a LPDMA single.

A LPDMA single data width is 1, 2 or 4 bytes, as defined by the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields of LPDMA_CxTR1(respectively for source and destination).

Note: The user must not assign a 8-byte data width (SDW_LOG2[1:0] = 0b11 or DDW_LOG2[1:0] = 0b11) else a user setting is reported and no transfer is issued.

The addressing mode after each data of a LPDMA single is defined by the SINC and DINC bits of LPDMA_CxTR1(respectively for source and destination): either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a LPDMA source/destination single (defined by LPDMA_CxSAR and LPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a LPDMA single.

The next single address in the table is the next source/destination address, pointed by LPDMA_CxSAR and LPDMA_CxDAR, once the programmed source/destination single is completed.

Table 95. Programmed LPDMA source/destination single

Programmed LPDMA source/destination single	SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/ DINC	Addressing mode	SAR/DAR next single address	Address alignment
Fixed byte single	00	1	0	Fixed	+0	1
Fixed half-word single	01	2				2
Fixed word single	10	4				4
Incremented byte single	00	1	1	Incremented	+1	1
Incremented half-word single	01	2			+2	2
Incremented word single	10	4			+4	4
Forbidden	11	Causes USEF generation and none single to be issued.				

In direct mode, a LPDMA single is an AHB single transfer.

LPDMA data handling: byte-based padding/truncation, sign extension and left/right alignment

The user can configure some data manipulation between a transferred data from the source and its transfer to the destination. Data handling is controlled by the LPDMA_CxTR1 register:

- If destination data width = source data width (DDW_LOG2[1:0] = SDW_LOG2[1:0]), the source data is copied as is and transferred to the destination.
- Else, depending on PAM:
  - If destination data width > source data width, the source data can be either right-aligned and padded with 0 s, or sign extended up to the destination data width.
  - If destination data width < source data width, the source data can be either right-aligned and left-truncated down to the destination data width, or left-aligned and right-truncated down to the destination data width.

There is no data manipulation between two distinct transferred data from the source, before the generation of the destination transfer.

The table below lists possible data handling from the source to the destination.

Table 96. Programmed data handling

SDW_ LOG2[1:0]	Source data	Source data stream(1)	DDW_ LOG2[1:0]	Destination data	PAM[0]	Destination data stream(1)

			10	Word	0 (RA, 0P)	$00B_3B_2,00B_1B_0$
					1 (RA, SE)	SSB_3B_2,SSB_1B_0
10	Word	$B_7B_6B_5B_4,B_3B_2B_1B_0$	00	Byte	0 (RA, LT)	B_{12},B_8,B_4,B_0
					1 (LA, RT)	B_{15},B_{11},B_7,B_3
			01	Half-word	0 (RA, LT)	B_5B_4,B_1B_0
				Word	1 (LA, RT)	B_7B_6,B_3B_2
			10		xx	$B_7B_6B_5B_4,B_3B_2B_1B_0$

1. Data stream is timely ordered starting from the byte with the lowest index a.k.a B_0.
2. RA = right aligned. LA = left aligned. RT= right truncated. LT = left truncated.
3. 0P = zero bit padding up to the destination data width.
4. SE = sign bit extended up to the destination data width.

14.4.11 LPDMA transfer request and arbitration

LPDMA transfer request

As defined by LPDMA_CxTR2, a programmed LPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the LPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see *Section 14.3.5*). The selected hardware request can be one of the following:
  - a hardware request from a peripheral configured in LPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - a hardware request from a peripheral for its control registers update from the memory
  - a hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral LPDMA request via LPDMA_CxTR.REQSEL[6:0] to two different channel if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

LPDMA transfer request for arbitration

For a given channel, a LPDMA requested data transfer from the source address to the destination address is arbitrated versus simultaneous requested LPDMA transfers from other channels, in order to be scheduled over the AHB master port. A LPDMA data transfer is atomic to the LPDMA arbitration: it consists of an AHB read single, immediately followed by an AHB write single. It is granted by the arbiter once for both AHB transfers, based on the channel priority defined by LPDMA_CxCR.PRIO[1:0].

An arbitrated LPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the master port.

The re arbitration occurs after each granted single transfer:

- whatever how the requested data transfer is programmed:
  - with a software request for a memory-to-memory transfer (LPDMA_CxTR2.SWREQ = 1)
  - with a hardware request (LPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer
- whatever the hardware request type

When the requested data transfer is programmed with a hardware request from a peripheral (LPDMA_CxTR2.SWREQ = 0), the first memory read of a block is gated by the occurrence of the corresponding and selected hardware request, whatever the peripheral is source or destination of the transfer. This first read request to the memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

LPDMA arbitration

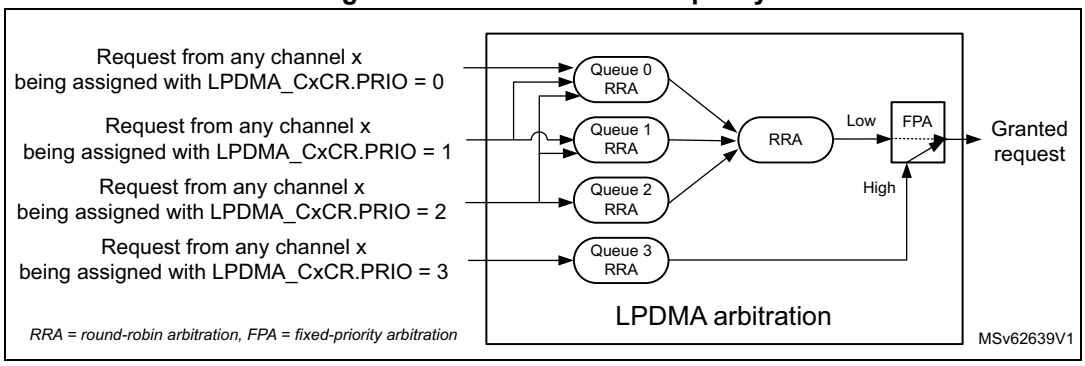
The LPDMA arbitration is directed from the 4-grade assigned channel priority (LPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 54*, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 54. LPDMA arbitration policy



1. RRA: round-robin arbitration
2. FPA: fixed-priority arbitration

LPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive LPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any LPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one LPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
- **Example 2**: application where the user distributes a same non-null N number of LPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is

    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is

    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is

    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is

    $B_{n, P0} = 1/N * 1/9 * (1 - B_{Q3})$

    $B_{n, P1} = 1/N * 5/18 * (1 - B_{Q3})$

    $B_{n, P2} = 1/N * 11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ? 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ? 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ? 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for J > 0 (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ (K>0 in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the LPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

14.4.12 LPDMA triggered transfer

A programmed LPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGSEL[5:0] (see *Section 14.3.7* for the trigger selection).

The triggered transfer, as defined by the trigger mode in LPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first single read of a block, or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The LPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

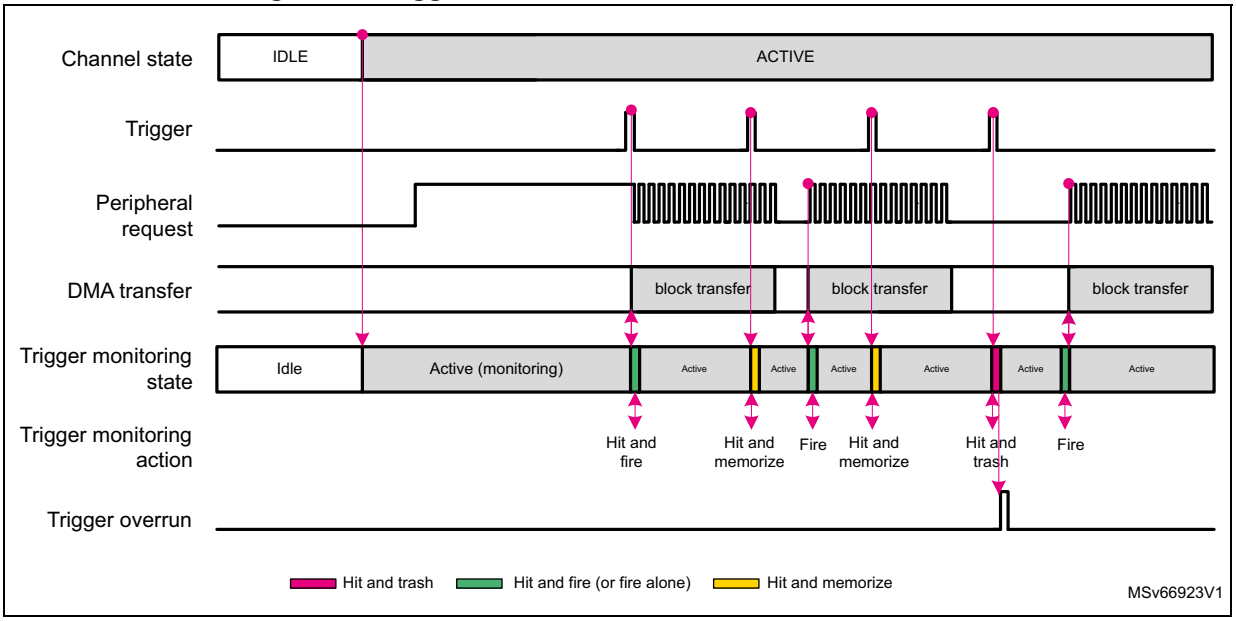
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next LLI_{n+1}, that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (LPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 55. Trigger hit, memorization and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

14.4.13 LPDMA circular buffering with linked-list programming

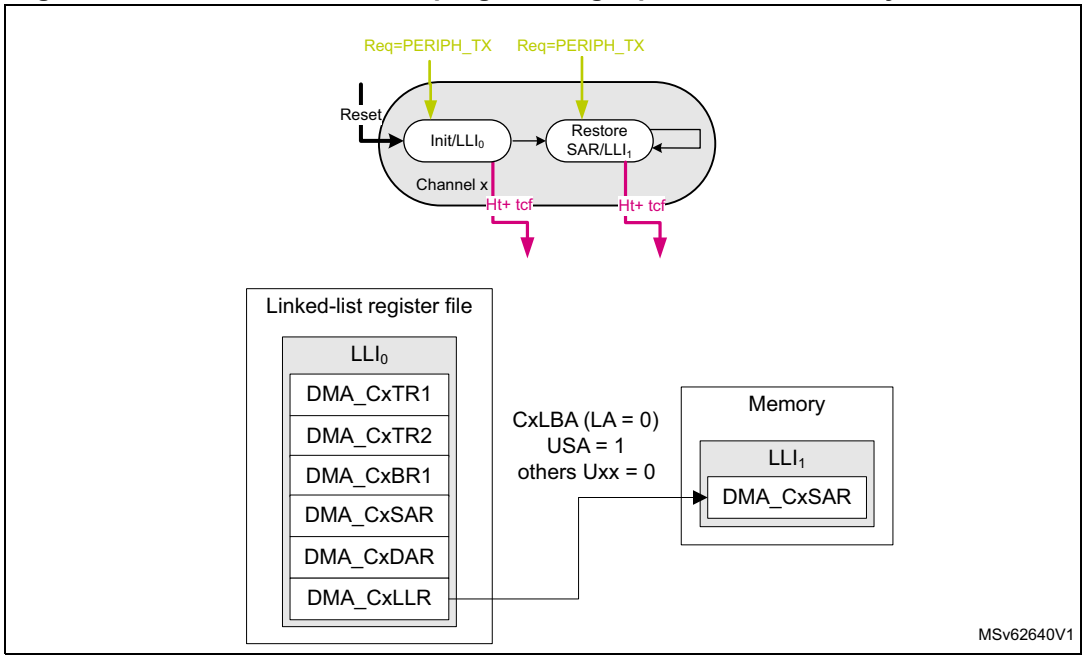
LPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete transfer events/interrupts generation (LPDMA_CxCR.HTIE = 1 and LPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). LPDMA automatically reloads the initially programmed LPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore LPDMA_CxBR1.

The figure below illustrates this programming with a LPDMA channel and a source circular buffer.

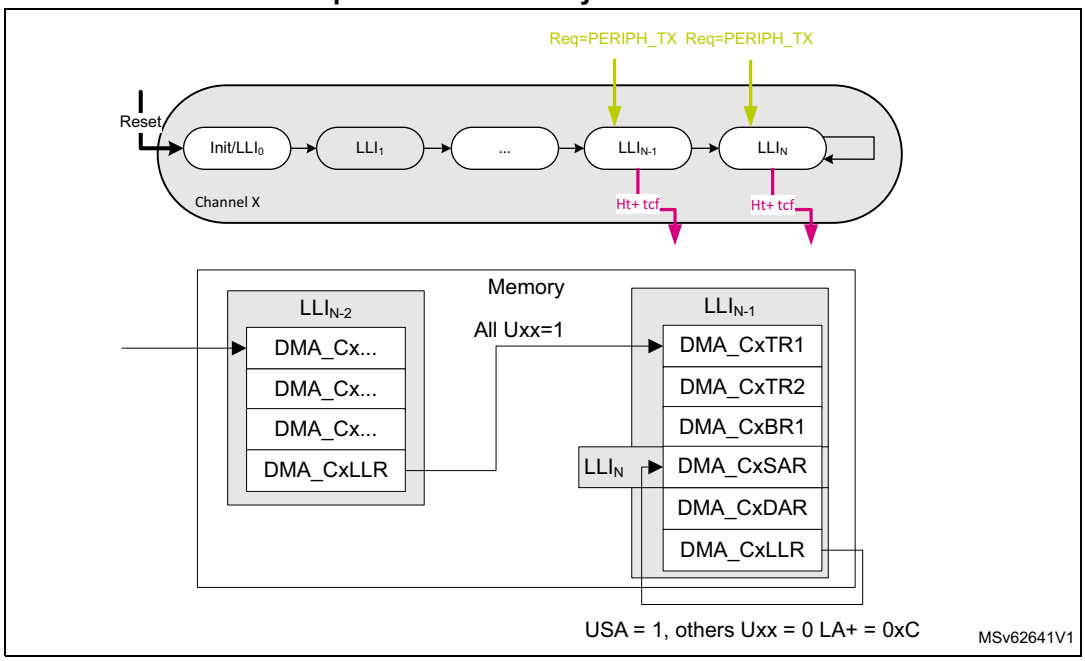
Figure 56. LPDMA circular buffer programming: update of the memory start address



If circular buffering must be executed after some other transfers over the shared LPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

The figure below illustrates this programming with a shared LPDMA channel, and a source circular buffer.

Figure 57. Shared LPDMA channel with circular buffering: update of the memory start address



14.4.14 LPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate an LPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 14.3.6*).

If the related LPDMA channel x is also programmed in peripheral flow-control mode (LPDMA_CxTR2.PFREQ = 1):

- The LPDMA block transfer starts as follows:
  - If LPDMA_CxBR1.BNDT[15:0] ? 0, the programmed value is internally taken into account by the LPDMA hardware.
  - If LPDMA_CxBR1.BNDT[15:0] = 0, the LPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The LPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when LPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on LPDMA_CxTR2 (see *LPDMA channel x transfer register 2 (LPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (LPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (LPDMA_CxSAR[31:0] or LPDMA_CxDAR[31:0]).

14.4.15 LPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via LPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for LPDMA_PRIVCFGR, LPDMA_SECCFGR, that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the master port.

LPDMA generates a DMA channel state versus privilege, reflecting LPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each DMA channel x.

Additionally, the LPDMA generates the privileged illegal access pulse signal on an illegal unprivileged access to a privileged LPDMA register. This signal may be used or not, depending on the product (see the system security section for more details).

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have LPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the LPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

14.4.16 LPDMA error management

LPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware). The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the data error (LPDMA_CxSR.DTEF = 1).
- After a LPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a LPDMA data transfer error, the user must issue a channel reset (set LPDMA_CxCR.RESET) to reset the hardware LPDMA channel data path before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a LPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware), the channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the link error (LPDMA_CxSR.ULEF = 1).
- After a LPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (LPDMA_CxLBAR and LPDMA_CxLLR), including the protection attributes.
- After a LPDMA link error, the user must explicitly write the linked-list register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a LPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (LPDMA_CxCR.EN forced and cleared by the LPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and a user setting error (LPDMA_CxSR.USEF = 1).
- After a LPDMA user setting error, the user must perform a debug session, taking care of the LPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (LPDMA_CxBR1.BNDT[15:0] = 0 and LPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source single transfer (LPDMA_CxBR1.BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source single transfer (LPDMA_CxSAR[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination single transfer (LPDMA_CxDAR[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed double-word source data width (LPDMA_CxTR1.SDW_LOG2[1:0] = 0b11)
  - a programmed double-word destination data width (LPDMA_CxTR1.DDW_LOG2[1:0] = 0b11
  - a programmed linked-list item LLI_{n+1} with a null data transfer (LPDMA_CxLLR.UB1 = 1 and LPDMA_CxBR1. BNDT = 0)

14.5 LPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, LPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, LPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

14.6 LPDMA in low-power modes

Table 97. Effect of low-power modes on LPDMA

Mode	Description
Sleep	No effect. LPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the LPDMA registers is kept when entering Stop mode.
Standby	The LPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 14.3.3* to know which Stop mode is supported.

14.7 LPDMA interrupts

There is one LPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 98. LPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
LPDMA_CHx	Transfer complete	LPDMA_CxCR.TCIE	LPDMA_CxSR.TCF	Write 1 to LPDMA_CxFCR.TCF
	Half transfer	LPDMA_CxCR.HTIE	LPDMA_CxSR.HTF	Write 1 to LPDMA_CxFCR.HTF
	Data transfer error	LPDMA_CxCR.DTEIE	LPDMA_CxSR.DTEF	Write 1 to LPDMA_CxFCR.DTEF
	Update link error	LPDMA_CxCR.ULEIE	LPDMA_CxSR.ULEF	Write 1 to LPDMA_CxFCR.ULEF
	User setting error	LPDMA_CxCR.USEIE	LPDMA_CxSR.USEF	Write 1 to LPDMA_CxFCR.USEF
	Suspended	LPDMA_CxCR.SUSPIE	LPDMA_CxSR.SUSPF	Write 1 to LPDMA_CxFCR.SUSPF
	Trigger overrun	LPDMA_CxCR.TOFIE	LPDMA_CxSR.TOF	Write 1 to LPDMA_CxFCR.TOF

A LPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal lpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (LPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (LPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into LPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by LPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is a half-block transfer. A half-block transfer occurs when half of the source block size bytes (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

See *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single data transfer from the source or to the destination (DTEF)
- during an update of a LPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a LPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the LPDMA channel programming versus the USEF root causes list (see *Section 14.4.16*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

14.8 LPDMA registers

The LPDMA registers must be accessed with an aligned 32-bit word data access.

14.8.1 LPDMA privileged configuration register (LPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (LPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (LPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV7	PRIV6	PRIV5	PRIV4	PRIV3	PRIV2	PRIV1	PRIV0
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PRIVx**: privileged state of channel x (x = 7 to 0)

0: unprivileged

1: privileged

14.8.2 LPDMA configuration lock register (LPDMA_RCFGLOCKR)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attribute in order to individually lock, for example at boot time, the privileged attributes of any DMA channel/resource (to lock the setting of LPDMA_PRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **LOCKx**: lock the configuration of LPDMA_PRIVCFGR.PRIVx until a global DMA reset (x = 7 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global DMA reset.

0: privilege configuration of the channel x is writable.

1: privilege configuration of the channel x is not writable.

14.8.3 LPDMA masked interrupt status register (LPDMA_MISR)

Address offset: 0x00C

Reset value: 0x0000 0000

This is a read register.

A masked interrupt status bit MISx is asserted by hardware for each channel x. It is a logical OR of all the LPDMA_CxSR flags, each source flag being enabled by the corresponding LPDMA_CxCR interrupt enable bit.

Every bit is de-asserted by hardware when writing 1 to the corresponding LPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bit fields returning zero.

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MISx**: masked interrupt status of channel x (x = 7 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

14.8.4 LPDMA channel x linked-list base address register (LPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x LPDMA_PRIVCFGR.PRIVx.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the LPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit LPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 **LBA[31:16]**: linked-list base address of LPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

14.8.5 LPDMA channel x flag clear register (LPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (LPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: clears the corresponding TOF flag

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half-transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

14.8.6 LPDMA channel x status register (LPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or unprivileged, depending on the privileged state of the channel (LPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	r	r	r	r	r	r	r								r

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: clears the corresponding TOF flag

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half-transfer flag
0: no half-transfer event
1: a half-transfer event occurred
A half-transfer event is a half-block transfer that occurs when half of the bytes of the source block size (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is de-asserted by hardware when the channel is enabled (LPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

14.8.7 LPDMA channel x control register (LPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (LPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	Res.	LSM

	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x LPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (LPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0). Then LPDMA_CxBR1.BNDT[15:0] = 0.
1: channel executed **once** for the current LLI
First the block transfer is executed as defined by the current internal register file until LPDMA_CxBR1.BNDT[15:0] = 0). Secondly the next linked-list data structure is conditionally uploaded from memory as defined by LPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half-transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:

Software must write 1 in order to suspend an active channel (with an ongoing DMA transfer over its master ports).

The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 42*.

0: write: resume channel, read: channel not suspended

1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (LPDMA_CxSR.SUSPF = 1 and LPDMA_CxSR.IDLEF = LPDMA_CxCR.EN = 1)
- channel in disabled state (LPDMA_CxSR.IDLEF = 1 and LPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (LPDMA_CxBR1, LPDMA_CxSAR and LPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 43*).

0: no channel reset

1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is de-asserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example: if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

14.8.8 LPDMA channel x transfer register 1 (LPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x in LPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DINC	Res.	DDW_LOG2[1:0]	
												rw		rw	rw

Res.	Res.	Res.	Res.	PAM	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SINC	Res.	SDW_LOG2[1:0]	
				rw								rw		rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:20 Reserved, must be kept at reset value.

Bit 19 **DINC**: destination incrementing single

0: fixed single

1: contiguously incremented single

The destination address, pointed by LPDMA_CxDAR, is kept constant after a single transfer, or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a single in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A destination single transfer must have an aligned address with its data width (start address LPDMA_CxDAR[2:0] versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and none transfer is issued.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PAM**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a single destination transfer is equal to the data width of a single source transfer, this bit is ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher that source data width, and the condition PAM_2 is when destination data width is higher than source data width.

Condition: PAM_1

0: source data is transferred as right aligned, padded with 0s up to the destination data width

1: source data is transferred as right aligned, sign extended up to the destination data width

Condition: PAM_2

0: source data is transferred as right aligned, left-truncated down to the destination data width

1: source data is transferred as left-aligned, right-truncated down to the destination data width

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **SINC**: source incrementing single

0: fixed single

1: contiguously incremented single

The source address, pointed by LPDMA_CxSAR, is kept constant after a single transfer or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a single in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

a source block size must be a multiple of the source data width (LPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source single transfer must have an aligned address with its data width (start address LPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

14.8.9 LPDMA channel x transfer register 2 (LPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory, if LPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	Res.	SWREQ	Res.	Res.	REQSEL[6:0]						
rw	rw		rw	rw		rw			rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half-transfer complete events generation.

00: at block level (when LPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

01: same as 00

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half-transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (i.e. directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then the half-transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half-transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address LPDMA_CxLLR.LA[15:2] to zero and clears all the LPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].
00: no trigger (masked trigger event)
01: trigger on the rising edge
10: trigger on the falling edge
11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the LPDMA transfer (as per *Section 14.3.7*), with an active trigger event if TRIGPOL[1:0] = 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.
If the channel x is enabled (LPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 0b00 or 0b11, these TRIGM[1:0] bits are ignored.
Else, a DMA transfer is conditioned by at least one trigger hit:
00: at block level: the first single read of each block transfer is conditioned by one hit trigger.
01: same as 00
10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.
11: at programmed single level: each programmed single read is conditioned by one hit trigger.
The LPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 0b01 or respectively TRIGPOL[1:0] = 0b10).
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.
Transferring a next LLI_{n+1} that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.
After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized, and a trigger overrun flag is reported (LPDMA_CxSR.TOF = 1), an interrupt is generated if enabled (LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 14.3.6 for the list of the implemented channels with this feature.
If the channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:
0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in LPDMA control mode. The LPDMA is programmed with LPDMA_CxCBR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.
1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The LPDMA block transfer can be early completed by the peripheral itself (see *Section 14.3.6* for more details).

Bit 11 **BREQ**: block hardware request

If the channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a single level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 14.3.5*).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when LPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: DMA hardware request selection

These bits are ignored if channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 14.3.4*.

Caution: The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active DMA channels (LPDMA_CxCR.EN = 1 and LPDMA_CxTR2.SWREQ = 0 for these channels). DMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

14.8.10 LPDMA channel x block register 1 (LPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if LPDMA_CxLLR.UB1 = 1, this register is automatically updated by DMA from the next LLI in memory.
- If LPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed values for the field BNDT[15:0].
- If all the update bits LPDMA_CxLLR.Uxx are null and if LPDMA_CxLLR.LA[15:0] # 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI

- If LPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if LPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if LPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all LPDMA_CxLLR.Uxx = 0 and if LPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if LPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

14.8.11 LPDMA channel x source address register (LPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (LPDMA_CxTR1.SINC), this field is either kept fixed or incremented by the data width (LPDMA_CxTR1.SDW_LOG2[1:0]) after each single source data, reflecting the next address from which data is read.

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by LPDMA from the memory, provided the LLI is set with LPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source single (SA[32:0] versus LPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

14.8.12 LPDMA channel x destination address register (LPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (LPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (LPDMA_CxTR1.DDW_LOG2[1:0]) after each single destination data, reflecting the next address from which data is written.

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by DMA from the memory, provided the LLI is set with LPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination single (DA[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

14.8.13 LPDMA channel x linked-list address register (LPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.ULL = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update LPDMA_CxTR1 from memory

This bit controls the update of the LPDMA_CxTR1 register from the memory during the link transfer.

0: no LPDMA_CxTR1 update

1: LPDMA_CxTR1 update

Bit 30 **UT2**: Update LPDMA_CxTR2 from memory

This bit controls the update of the LPDMA_CxTR2 register from the memory during the link transfer.

0: no LPDMA_CxTR2 update

1: LPDMA_CxTR2 update

Bit 29 **UB1**: Update LPDMA_CxBR1 from memory

This bit controls the update of the LPDMA_CxBR1 register from the memory during the link transfer.

0: no LPDMA_CxBR1 update from memory and internally restored to the previous programmed value

1: LPDMA_CxBR1 update

Bit 28 **USA**: update LPDMA_CxSAR from memory

This bit controls the update of the LPDMA_CxSAR register from the memory during the link transfer.

0: no LPDMA_CxSAR update

1: LPDMA_CxSAR update

Bit 27 **UDA**: Update LPDMA_CxDAR register from memory

This bit is used to control the update of the LPDMA_CxDAR register from the memory during the link transfer.

0: no LPDMA_CxDAR update

1: LPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update LPDMA_CxLLR register from memory

This bit is used to control the update of the LPDMA_CxLLR register from the memory during the link transfer.

0: no LPDMA_CxLLR update

1: LPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list DMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list DMA internal register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register LPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

15 Nested vectored interrupt controller (NVIC)

15.1 NVIC main features

- 98 maskable interrupt channels (not including the 16 Cortex®-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late-arriving interrupts.

The NVIC manages all interrupts including the core exceptions.

15.2 SysTick calibration value register

The Cortex-M33 embeds one SysTick timer. The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. To match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When the SysTick clock source is CPU clock HCLK
  the reload value = (HCLK x STCALIB) - 1
- When the SysTick clock source is an external clock (HCLK/8)
  the reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: The SysTick clock source is a CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

SysTick reload value = (100 x STCALIB) - 1 = 0x1869F

15.3 Interrupt and exception vectors

The gray rows in the table below describe the vectors without specific position.

For the actual availability of some peripherals, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved.

1. If multiple pending interrupts have the same programmed priority level, the pending interrupt with the lowest IRQ number takes precedence. For example, if both interrupt[n] and interrupt[n+1] are pending and have the same priority, then interrupt[n] is processed before interrupt[n+1]. For further information, refer to the Arm Cortex-M33 technical documentation.

16 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wake-up through configurable and direct event inputs. It provides wake-up requests to the power control, and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wake-up requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux I/O port selection.

16.1 EXTI main features

The EXTI main features are the following:

- 40 input events are supported.
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wake-up flag in the peripheral, have a flag in the EXTI, and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wake-up event.

The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), with the following features
  - Selectable active trigger edge
  - Interrupt pending status register bits independent for the rising and falling edge
  - Individual interrupt and event generation mask, used for conditioning the CPU wake-up, interrupt and event generation
  - Software trigger possibility
  - EXTI I/O port selection
- Direct events (interrupt and wake-up sources from peripherals having an associated flag which requires to be cleared in the peripheral), with the following features:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status flag is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask, used to condition the CPU wake-up and event generation
  - No software trigger possibility

16.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in *Figure 58*.

The register block contains all EXTI registers. The event input trigger block provides event input edge trigger logic. The masking block provides the event input distribution to the different wake-up, interrupt, and event outputs, and their masking.

The EXTI mux provides the I/O port selection on to the EXTI event signal.

Figure 58. EXTI block diagram

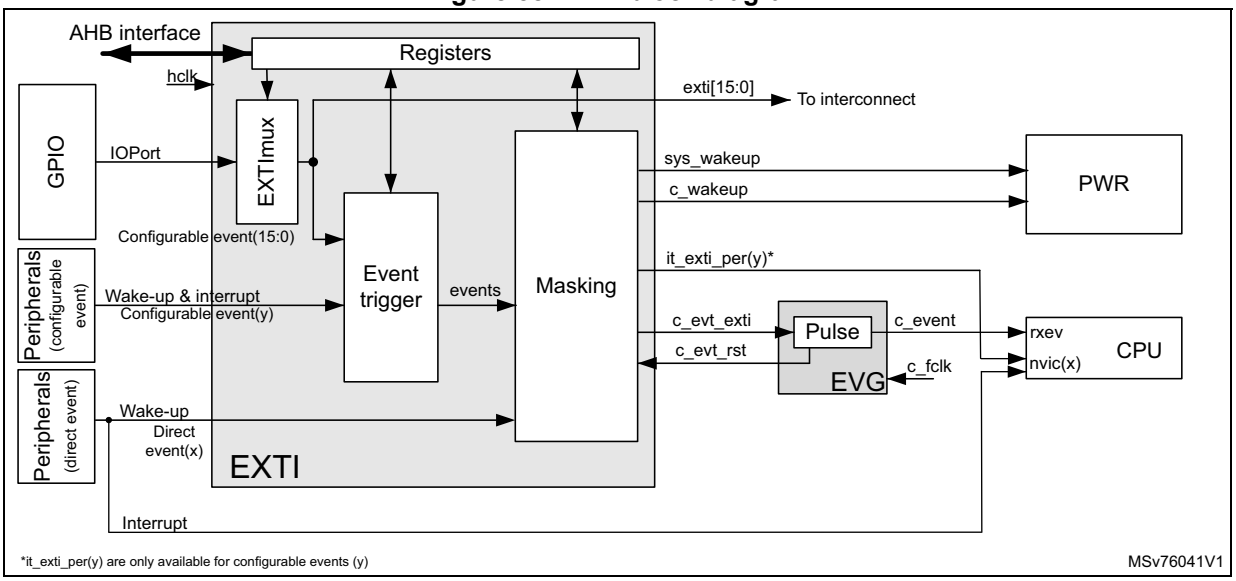

Table 101. EXTI signals

Pin name	I/O	Description
AHB interface	I/O	EXTI register bus interface.
hclk	I	AHB bus clock and EXTI system clock
Configurable event(y)	I	Asynchronous wake-up events from peripherals without an associated interrupt and flag
Direct event(x)	I	Synchronous and asynchronous wake-up events from peripherals with an associated interrupt and flag
IOPort(n)	I	GPIO block I/O ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_per (y)	O	Interrupts to the CPU associated with configurable event (y)
c_evt_exti	O	High-level sensitive event output for CPU, synchronous to hclk
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wake-up	O	Asynchronous system wake-up request to PWR for ck_sys and hclk
c_wake-up	O	Wake-up request to PWR for CPU, synchronous to hclk

Table 102. EVG signals

Pin name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

16.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wake-up or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wake-up signals that generate a pulse or do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- Peripheral interrupt and wake-up signals with a status bit in the peripheral to be cleared are connected to an EXTI direct event input. There is no status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral. It is the peripheral interrupt that interrupts the CPU directly.

All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wake-up signals are connected to the PWR and are used to wake up the system and the CPU subsystem bus clocks.

16.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the following table.

For the actual availability of some peripherals, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved.

Table 103. EXTI line connections

EXTI Line	Line source	Line type
0-15	GPIO	Configurable
16	PVD output	Configurable
17	RTC	-
18	TAMP	-
19	LSE CSS	-
20	I2C1 wake-up	-
21	I3C1 wake-up	-

16.3 EXTI functional description

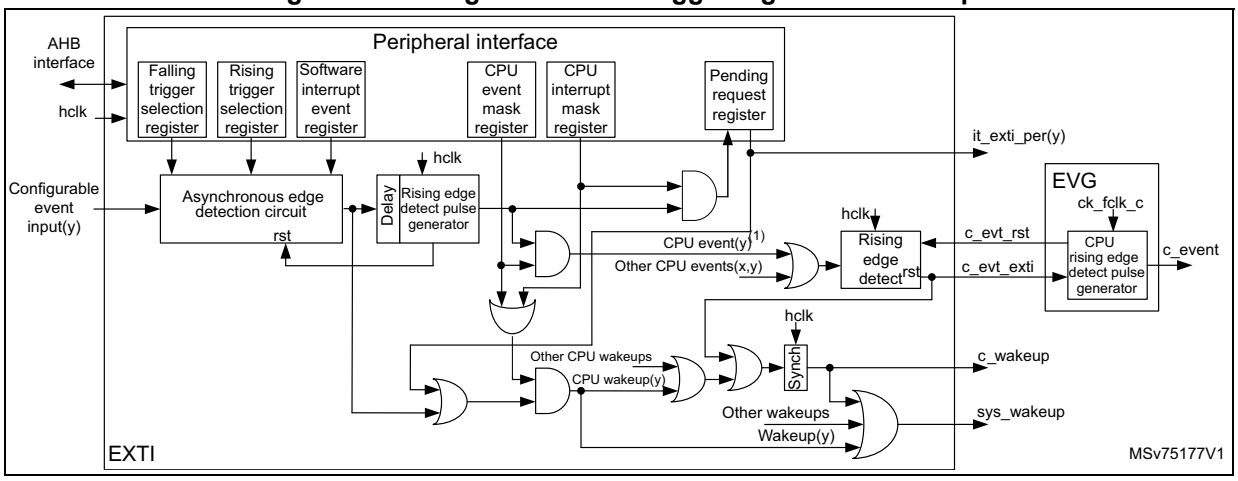
The events features are controlled from register bits as follows:

- Active trigger edge enable
  - by rising edge selection in EXTI_RTSRx
  - by falling edge selection in EXTI_FTSRx
- Software trigger in EXTI_SWIERx
- Interrupt pending flag in:
  - EXTI_RPRx
  - EXTI_FPRx
- CPU wake-up and interrupt enable in EXTI_IMR1 and EXTI_IMR2
- CPU wake-up and event enable in EXTI_EMRx

16.3.1 EXTI configurable event input wake-up

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU sub-system bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wake-up event.

Figure 59. Configurable event trigger logic CPU wake-up



1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wake-up (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wake-up (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

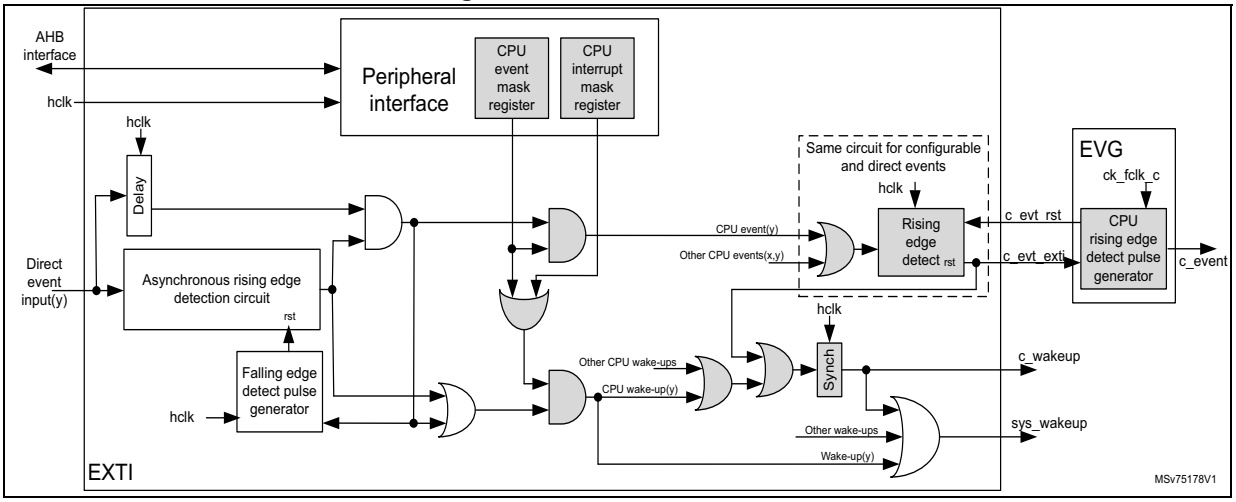
Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

16.3.2 EXTI direct event input wake-up

The direct events do not have an associated EXTI interrupt. The EXTI only wakes up the system and CPU subsystem clocks, and can generate a CPU wake-up event. The peripheral synchronous interrupt, associated with the direct wake-up event, wakes up the CPU.

The EXTI direct event is able to generate a CPU event that wakes up the CPU. The CPU event may occur before the associated peripheral interrupt flag is set.

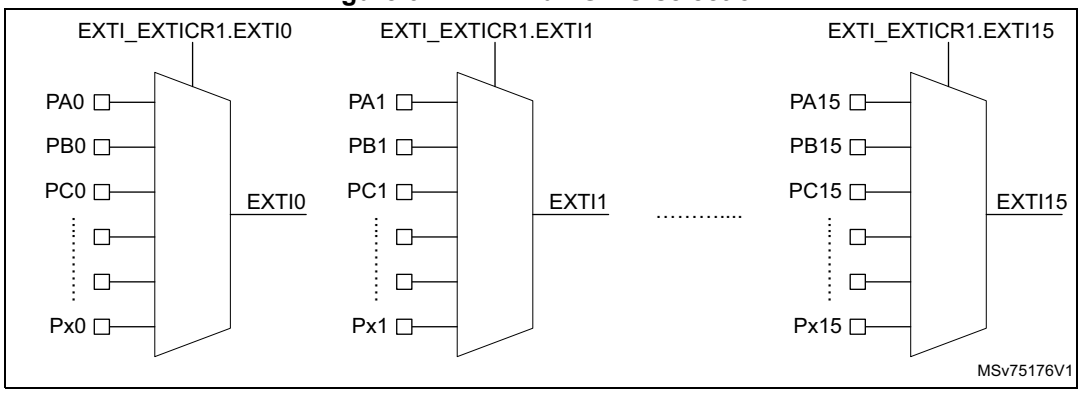
Figure 60. EXTI direct events



16.3.3 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wake-up. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The selection of a GPIO port as EXTI mux output is controlled in EXTI_EXTICRx (x = 1 to 4).

Figure 61. EXTI mux GPIO selection



The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

16.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wake-up generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 104. Masking functionality

CPU interrupt enable (in EXTI_IMR.IMn)	CPU event enable (in EXTI_EMR.EMn)	Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)	Exti(n) interrupt(1)	CPU event	CPU wake-up
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. Only if CPU event is enabled in EXTI_IMR.IMn.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set: the CPU sub-system is woken up and the CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn pending bits must be cleared by software writing it to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

16.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the privileged configurable events.
- Change the masking of the privileged input events.
- Clear pending status of the privileged input events.

Table 105. Register protection overview

Register name	Access type	Protection(1)
EXTI_RTSR	RW	Privilege can be bit-wise enabled in EXTI_PRIVCFGR
EXTI_FTSR	RW	
EXTI_SWIER	RW	
EXTI_RPR	RW	
EXTI_FPR	RW	
EXTI_PRIVCFGR	RW	Always privilege.
EXTI_EXTICRn	RW	Privilege can be bit-wise enabled in EXTI_PRIVCFGR.

Table 105. Register protection overview (continued)

Register name	Access type	Protection[1]
EXTI_IM	RW	Privilege can be bit-wise enabled in EXTI_PRIVCFGR.
EXTI_EMR	RW	

1. Privilege is enabled with the individual Input event (EXTI_PRIVCFGR register).

16.5.1 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

16.6 EXTI registers

The EXTI register map is divided in the following sections:

Table 106. EXTI register map sections

Address offset	Description
0x000 - 0x01C	General configurable event [31:0] configuration
0x020 - 0x03C	General configurable event [57:32] configuration
0x060 - 0x06C	EXTI IO port mux selection
0x070 - 0x0BC	CPU input event configuration

All registers can be accessed with word (32-bit), half-word (16-bit) and byte (8-bit) access.

For the actual availability of some peripherals, check the datasheet or *Table 3: Memory map and peripheral register boundary addresses*. If not present, consider them as reserved and keep them at reserved value.

16.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 16 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT16
															rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FTx:** Falling trigger event configuration bit of configurable event input x [(1)] (x = 16 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI16
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **SWIx:** Software interrupt on event x (x = 16 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

16.6.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RPIFx:** configurable event inputs x rising edge pending bit (x = 16 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

16.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FPIFx:** configurable event inputs x falling edge pending bit (x = 16 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

16.6.6 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **RT39:** Rising trigger event configuration bit of configurable event input 39[1]
When EXTI_PRIVCFGR.PRIV39 is disabled, RT39 can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV39 is enabled, RT39 can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RT36:** Rising trigger event configuration bit of configurable event input 36[1]
When EXTI_PRIVCFGR.PRIV36 is disabled, RT36 can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV36 is enabled, RT36 can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 3 Reserved, must be kept at reset value.

Bit 2 **RT34:** Rising trigger event configuration bit of configurable event input 34[1]
When EXTI_PRIVCFGR.PRIV34 is disabled, RT34 can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV34 is enabled, RT34 can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 1:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.8 EXTI falling trigger selection register 2 (EXTI_FTSR2)

Address offset: 0x024

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT39	Res.	Res.	FT36	Res.	FT34	Res.	Res.
								rw			rw		rw		

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FT39:** Falling trigger event configuration bit of configurable event input 39(1)
When EXTI_PRIVCFGR.PRIV39 is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV39 is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **FT36:** Falling trigger event configuration bit of configurable event input 36(1)
When EXTI_PRIVCFGR.PRIV36 is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV36 is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FT34:** Falling trigger event configuration bit of configurable event input 34(1)
When EXTI_PRIVCFGR.PRIV34 is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIV34 is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bits 1:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.9 EXTI software interrupt event register 2 (EXTI_SWIER2)

Address offset: 0x028

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI39	Res.	Res.	SWI36	Res.	SWI34	Res.	Res.
								rw			rw		rw		

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **SWI39:** Software interrupt on event 39

When EXTI_PRIVCFGR.PRIV39 is disabled, SWI39 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV39 is enabled, SWI39 can only be accessed with privileged access. Unprivileged write to this SWI39 is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event 39. This bit is auto cleared by hardware.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **SWI36:** Software interrupt on event 36

When EXTI_PRIVCFGR.PRIV36 is disabled, SWI36 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV36 is enabled, SWI36 can only be accessed with privileged access. Unprivileged write to this SWI36 is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event 36. This bit is auto cleared by hardware.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWI34:** Software interrupt on event 34

When EXTI_PRIVCFGR.PRIV34 is disabled, SWI34 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV34 is enabled, SWI34 can only be accessed with privileged access. Unprivileged write to this SWI34 is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event 34. This bit is auto cleared by hardware.

Bits 1:0 Reserved, must be kept at reset value.

16.6.10 EXTI rising edge pending register 2 (EXTI_RPR2)

Address offset: 0x02C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF39	Res.	Res.	RPIF36	Res.	RPIF34	Res.	Res.
								rw			rw		rw		

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **RPIF39:** configurable event inputs 39 rising edge pending bit

When EXTI_PRIVCFGR.PRIV39 is disabled, RPIF39 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV39 is enabled, RPIF39 can only be accessed with privileged access. Unprivileged write to this RPIF39 is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RPIF36:** configurable event inputs 36 rising edge pending bit

When EXTI_PRIVCFGR.PRIV36 is disabled, RPIF36 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV36 is enabled, RPIF36 can only be accessed with privileged access. Unprivileged write to this RPIF36 is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **RPIF34:** configurable event inputs 34 rising edge pending bit

When EXTI_PRIVCFGR.PRIV34 is disabled, RPIF34 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV34 is enabled, RPIF34 can only be accessed with privileged access. Unprivileged write to this RPIF34 is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 1:0 Reserved, must be kept at reset value.

16.6.11 EXTI falling edge pending register 2 (EXTI_FPR2)

Address offset: 0x030

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF39	Res.	Res.	FPIF36	Res.	FPIF34	Res.	Res.
								rw			rw		rw		

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FPIF39:** configurable event inputs x falling edge pending bit

When EXTI_PRIVCFGR.PRIV39 is disabled, FPIF39 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV39 is enabled, FPIF39 can only be accessed with privileged access. Unprivileged write to this FPIF39 is discarded, unprivileged read returns 0.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **FPIF36:** configurable event inputs x falling edge pending bit

When EXTI_PRIVCFGR.PRIV36 is disabled, FPIF36 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.FPIF36 is enabled, FPIF36 can only be accessed with privileged access. Unprivileged write to this FPIF36 is discarded, unprivileged read returns 0.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FPIF34:** configurable event inputs x falling edge pending bit

When EXTI_PRIVCFGR.PRIV34 is disabled, FPIF34 can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIV34 is enabled, FPIF34 can only be accessed with privileged access. Unprivileged write to this FPIF34 is discarded, unprivileged read returns 0.

0: No falling edge trigger request occurred

1: Falling edge trigger request occurred

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 1:0 Reserved, must be kept at reset value.

16.6.12 EXTI privilege configuration register 2 (EXTI_PRIVCFGR2)

Address offset: 0x038

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV39	PRIV38	PRIV37	PRIV36	PRIV35	PRIV34	PRIV33	PRIV32
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PRIVx:** Privilege enable on event input x (x = 39 to 32)
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

16.6.13 EXTI external interrupt selection register (EXTI_EXTICR1)

Address offset: 0x060

Reset value: 0x0000 0000

EXTI mux 0, 1, 2, 3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

17 Cyclic redundancy check calculation unit (CRC)

17.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

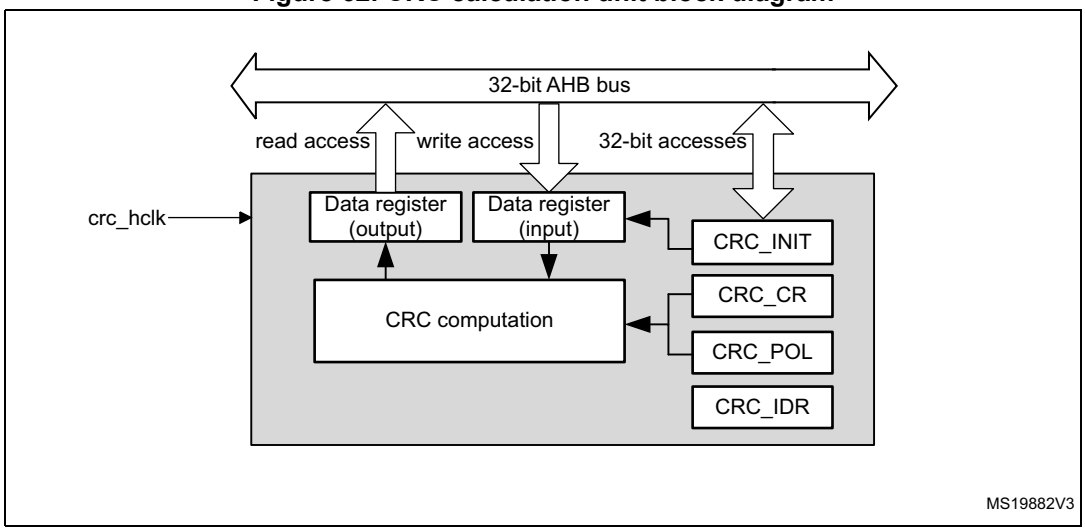
17.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility options on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

17.3 CRC functional description

17.3.1 CRC block diagram

Figure 62. CRC calculation unit block diagram



17.3.2 CRC internal signals

Table 108. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

17.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. When the RTYPE_IN bit is set in CRC_CR, non-word accesses to CRC_DR register are ignored. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on input data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register. If RTYPE_IN bit is set in this register, the input reversing operation can be performed with a byte or half-word granularity, but not with single bit granularity.

For example, with RTYPE_IN cleared, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte (REV_IN[1:0] = 01)
- 0xD458B23C with bit-reversal done by half-word (REV_IN[1:0] = 10)
- 0xB23CD458 with bit-reversal done on the full word (REV_IN[1:0] = 11)

With RTYPE_IN set, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x3C4D1A2B with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x4D3C2B1A with byte-reversal done by word (REV_IN[1:0] = 10)

The output data can also be reversed by setting the REV_OUT[1:0] bits in the CRC_CR register. If RTYPE_OUT is set in this register, the output reversing operation is performed with a byte or half-word granularity, but not with single bit granularity.

With RTYPE_OUT cleared, the operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

With RTYPE_OUT set, 0x11223344 output data are converted as:

- 0x33441122 with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x44332211 with byte-reversal done by word (REV_IN[1:0] = 10)

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC 7-, 8-, 16-, and 32-bit calculations. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7-, 8-, 16-, or 32-bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

17.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes when RTYPE bit is cleared in CRC_CR. When RTYPE is set, only word accesses are allowed. For the other registers only 32-bit accesses are allowed.

17.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

17.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

17.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **RTYPE_OUT**: Reverse type output
This bit controls the reversal granularity of the output data.
0: Bit level output
1: Byte or half-word level output

Bit 9 **RTYPE_IN**: Reverse type input
This bit controls the reversal granularity of the input data.
0: Bit level input
1: Byte or half-word level input

Bits 8:7 **REV_OUT[1:0]**: Reverse output data
This bitfield controls the reversal of the bit order of the output data.
00: Bit order not affected (RTYPE_OUT = 0 or 1)
01: Bit-reversed output format (RTYPE_OUT = 0) or half-word reversal done by word (RTYPE_OUT = 1)
10: Bit order not affected (RTYPE_OUT = 0) or byte reversal done by word (RTYPE_OUT = 1)
11: Bit order not affected (RTYPE_OUT = 0 or 1)

Bits 6:5 **REV_IN[1:0]**: Reverse input data
This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected (RTYPE_IN = 0 or 1)
01: Bit reversal done by byte (RTYPE_IN = 0) or half-word reversal done by word (RTYPE_IN = 1)
10: Bit reversal done by half-word (RTYPE_IN = 0) or byte reversal done by word (RTYPE_IN = 1)
11: Bit reversal done by word (RTYPE_IN = 0) or bit order is not affected (RTYPE_IN = 1)

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.

17.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]

18 CORDIC coprocessor (CORDIC)

18.1 CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

18.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

18.3 CORDIC functional description

18.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

18.3.2 CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register.

Table 110 lists the functions supported by the CORDIC coprocessor.

Table 110. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	$\tan^{-1} x$	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	$\tanh^{-1} x$	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2), and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, and cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 18.3.4*) can be applied to extend the range beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 111. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • cos θ	[-1, 1]

Table 111. Cosine parameters (continued)

Parameter	Description	Range
RES2	m • sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 112. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • sin θ	[-1, 1]
RES2	m • cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 113. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 113. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 114. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 115. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \tan^{-1} x$, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, $x = \tan \theta$. If $|x| > 1$, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is $\tan \theta = 128$, which corresponds to an angle $\theta = 89.55$ degrees. For $|x| > 128$, a software method must be used to find $\tan^{-1} x$.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle $\theta = \tan^{-1} x$. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 116. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 117. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions e^x = cosh x + sinh x, and e^{-x} = cosh x- sinh x.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 118. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \bullet 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \bullet$atanh x	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the -0.806 to +0.806 range are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 119. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x < 2^{-n} < 1-2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 120 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 120. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \leq x < 1$	$0.0535 \leq ARG1 < 0.5$
2	$1 \leq x < 3$	$0.25 \leq ARG1 < 0.75$
3	$3 \leq x < 7$	$0.375 \leq ARG1 < 0.875$
4	$7 \leq x \leq 9.35$	$0.4375 \leq ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 121. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 122 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 122. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	$0.027 \leq ARG1 < 0.75$
1	$0.75 \leq x < 1.75$	$0.375 \leq ARG1 < 0.875$
2	$1.75 \leq x \leq 2.341$	$0.4375 \leq ARG1 \leq 0.585$

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

18.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

18.3.4 Scaling factor

Several of the functions listed in *Section 18.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is

required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

18.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 63*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 64*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 65*).

Figure 63. CORDIC convergence for trigonometric functions

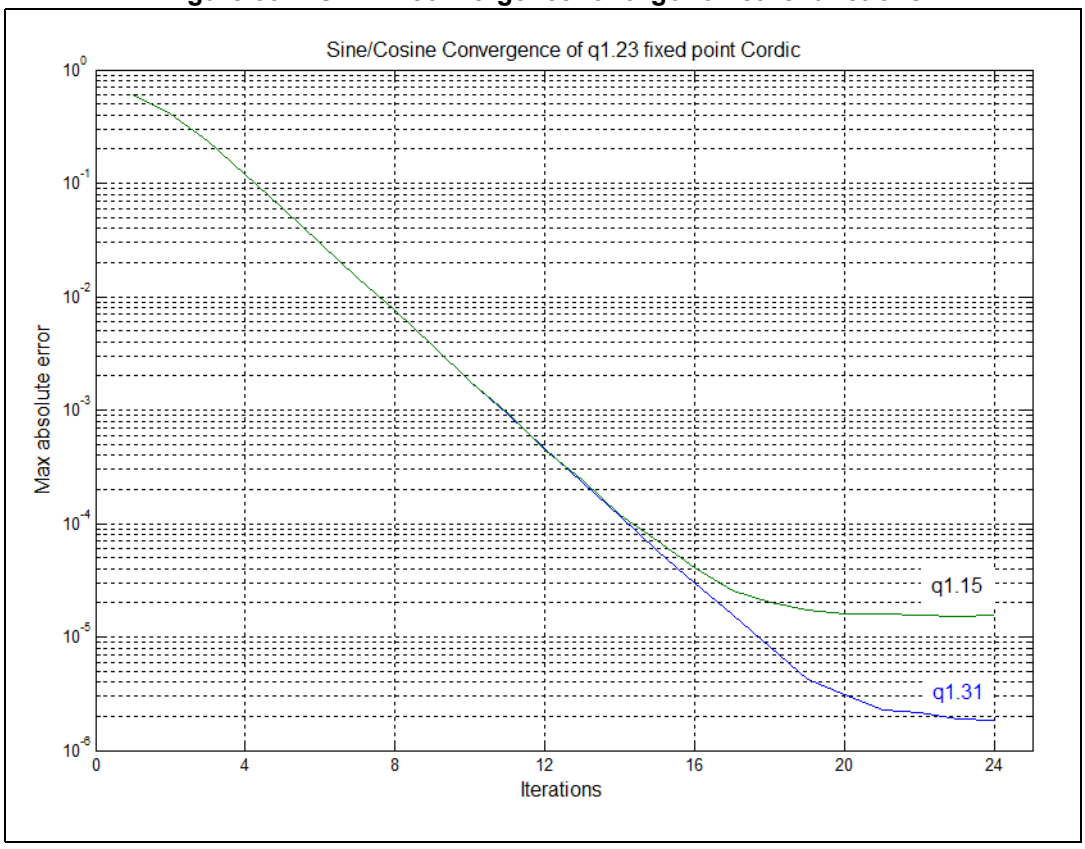

Figure 64. CORDIC convergence for hyperbolic functions

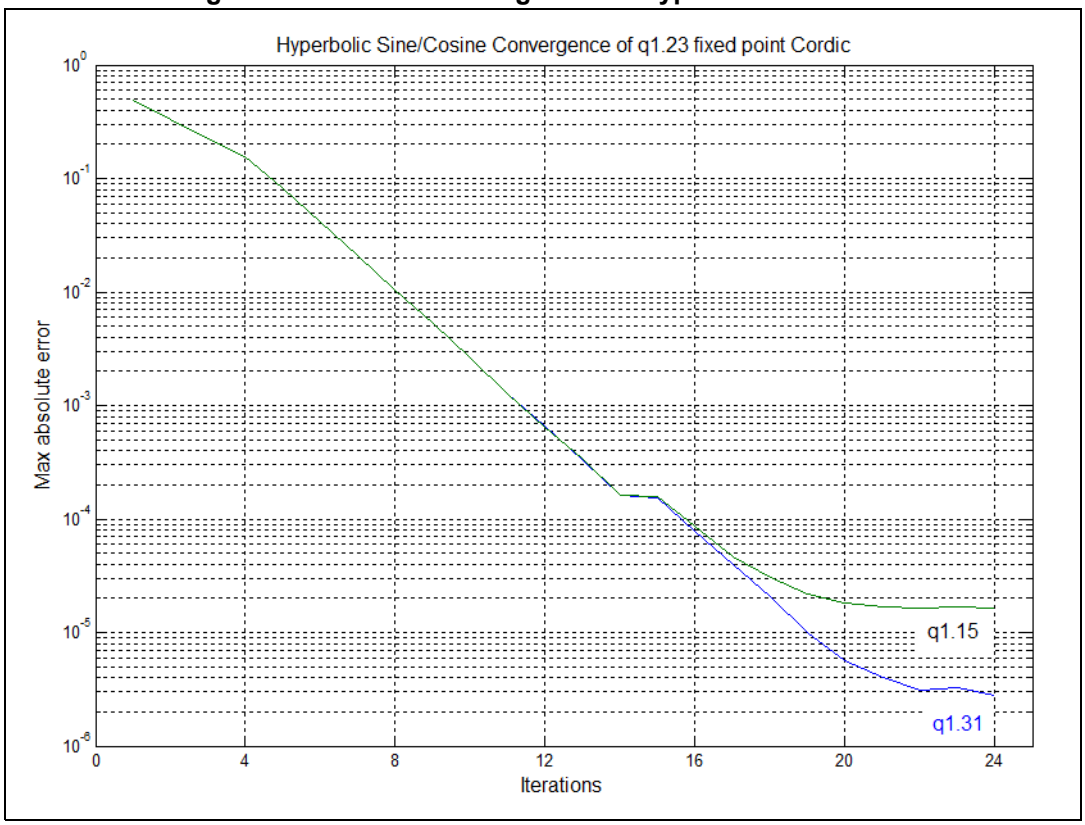

Figure 65. CORDIC convergence for square root

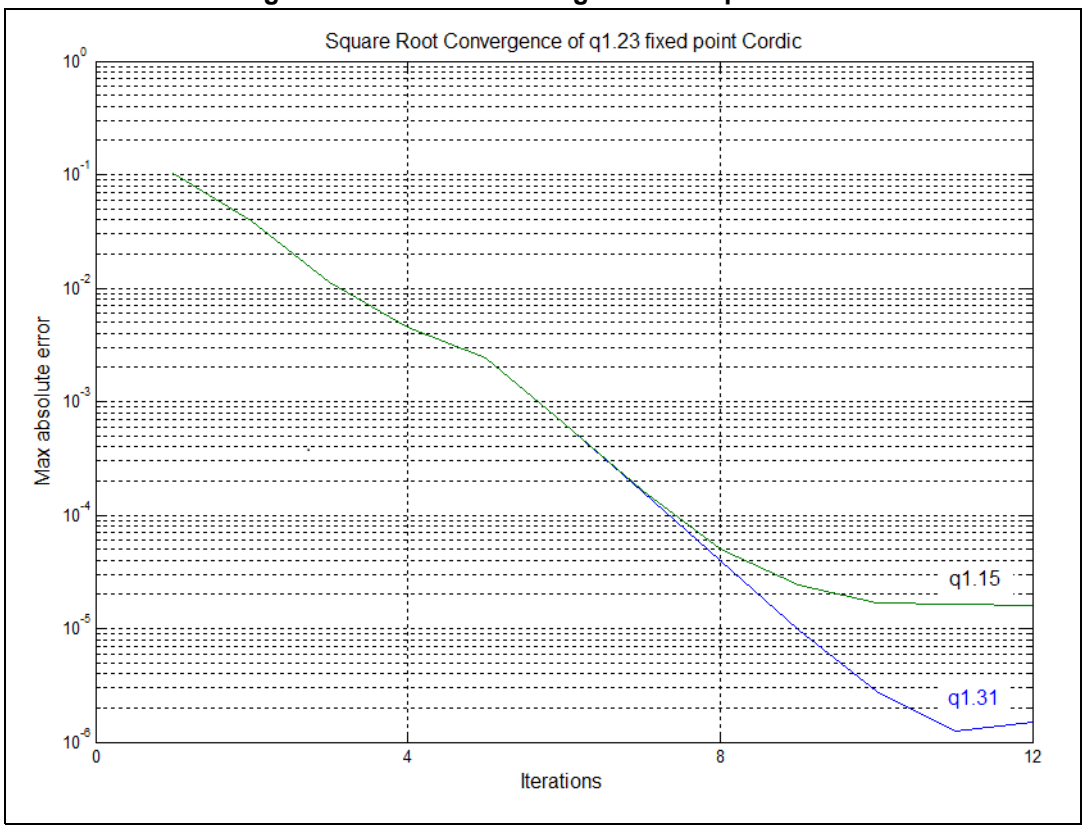

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 123*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

Table 123. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 123. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

18.3.6 Zero-overhead mode

The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait-states until the calculation is completed, before returning the result. It is then possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be reprogrammed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous ones have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be a calculation in progress, or waiting for the results to be read, and an operation pending. Any further access to CORDIC_WDATA while an operation is pending cancels it and overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

18.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice, depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. The processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (for example, if low latency interrupts must be serviced).

18.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

18.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

18.4 CORDIC registers

The CORDIC registers can be accessed only in 32-bit word format

18.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	N ARGS	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register
0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register
0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
0: Disabled. No DMA write requests are generated.
1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
0: Disabled. No DMA read requests are generated.
1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.
0: Disabled. No interrupt requests are generated.
1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor
The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 18.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to *Table 123*.
Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square root
10 to 15: Reserved

18.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 18.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

18.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

18.4.4 CORDIC register map

Table 124. CORDIC register map and reset value

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

19 Extended-SPI interface (XSPI)

This section applies only for STM32C59xx/C5Axx devices.

19.1 XSPI introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocol with associated frame format:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

19.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, octal communication
- Dual-memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- XSPI interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

- Dual chip select support (NCS1 and NCS2)
- Extended external memory support: if two same size external memories (extmem1 and extmem2) are connected to the same I/O port, contiguously in the memory map and driven by a single XSPI. This XSPI automatically switches CS to extmem1 or extmem2, according to the address on interconnect side.
- Possibility to disable the automatic prefetch

19.3 XSPI implementation

19.4 XSPI functional description

19.4.1 XSPI block diagram

Figure 66. XSPI block diagram for octal configuration

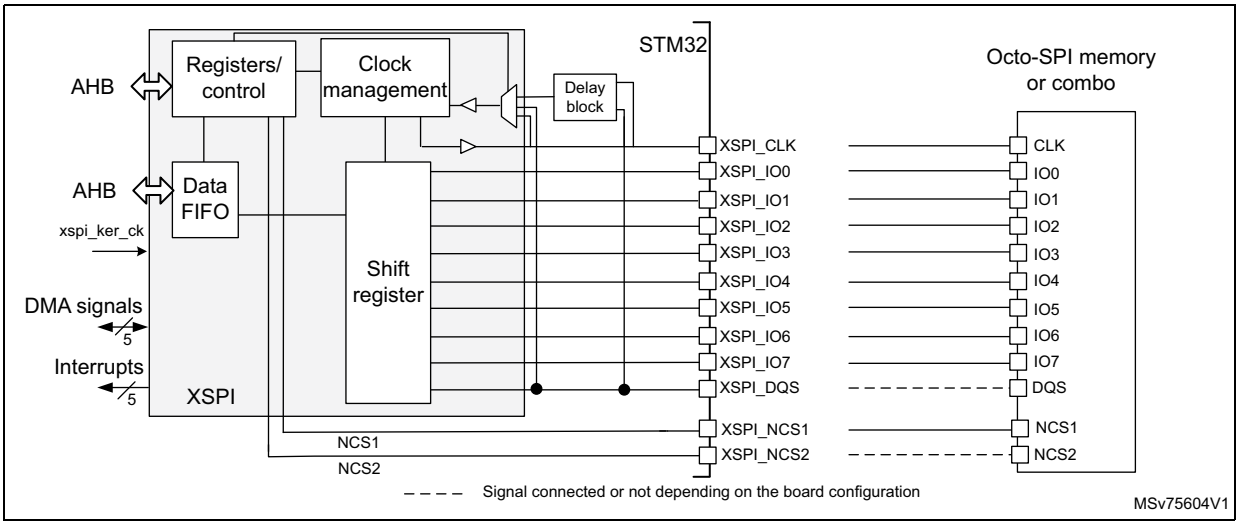

Figure 67. XSPI block diagram for quad configuration

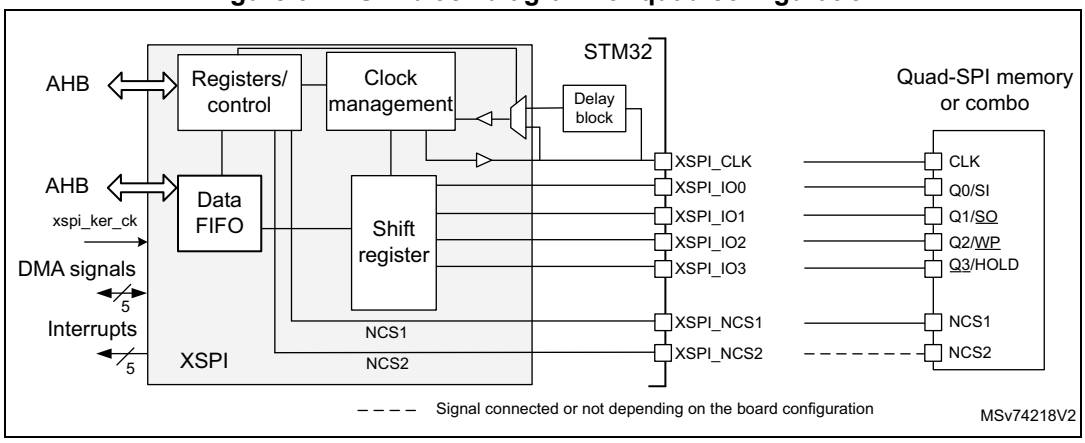

Figure 68. XSPI block diagram for dual-quad configuration

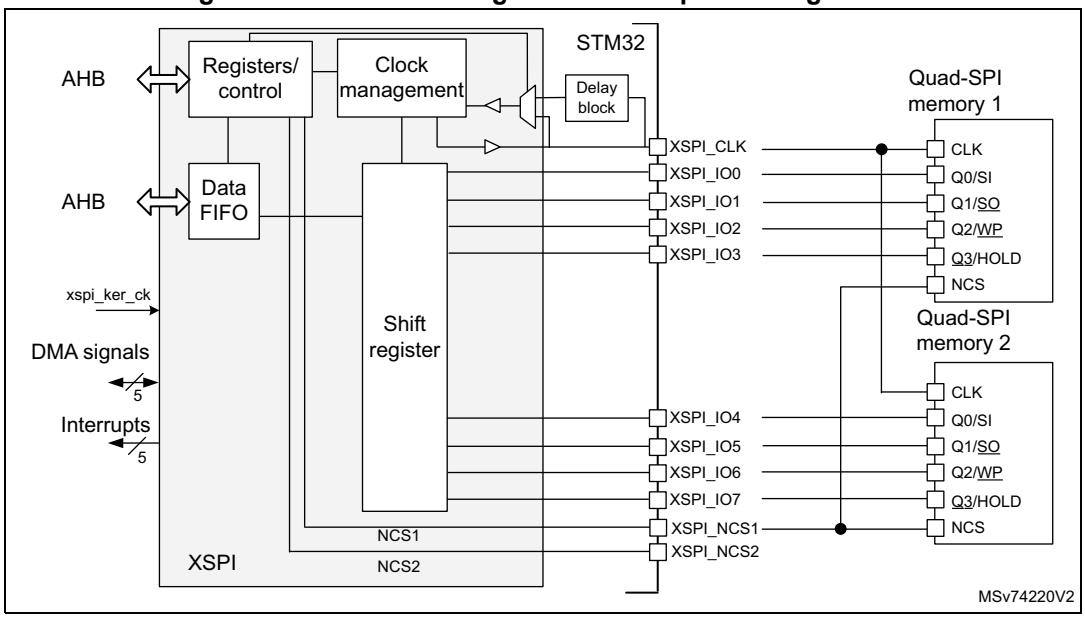


19.4.2 XSPI pins and internal signals

Table 126. XSPI input/output pins

Pin name	Type	Description
XSPI_CLK	Output	XSPI clock
XSPI_IOn (n = 0 to 7)	Input/output	XSPI data pins
XSPI_NCS1,2	Output	Chip select for the memory
XSPI_DQS	Input/output	Data strobe/write mask signal from/to the memory

Caution: Use the same configuration (output speed, HSLV[(a)]) for all XSPI input/output pins to avoid any data corruption.

Table 127. XSPI internal signals

Signal name	Type	Description
xspi_hclk	Input	XSPI AHB clock
xspi_ker_ck	Input	XSPI kernel clock
xspi_dma	N/A	DMA request signal
xspi_it	Output	Global interrupt line (see *Table 131* for the multiple sources of interrupt)

a. When applicable.

19.4.3 XSPI interface to memory modes

The XSPI supports the following protocol:

- regular-command protocol
- HyperBus protocol

The XSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time)
- CLK: communication clock
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

19.4.4 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:

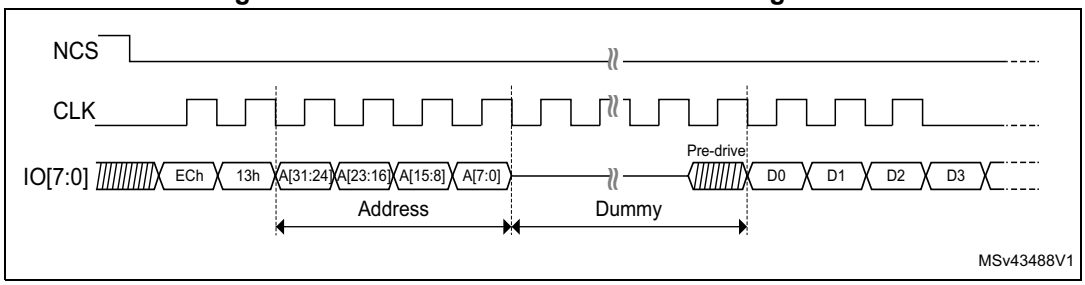
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 69. SDR read command in octal configuration



The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR, and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in XSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in XSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, the quad-, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in XSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

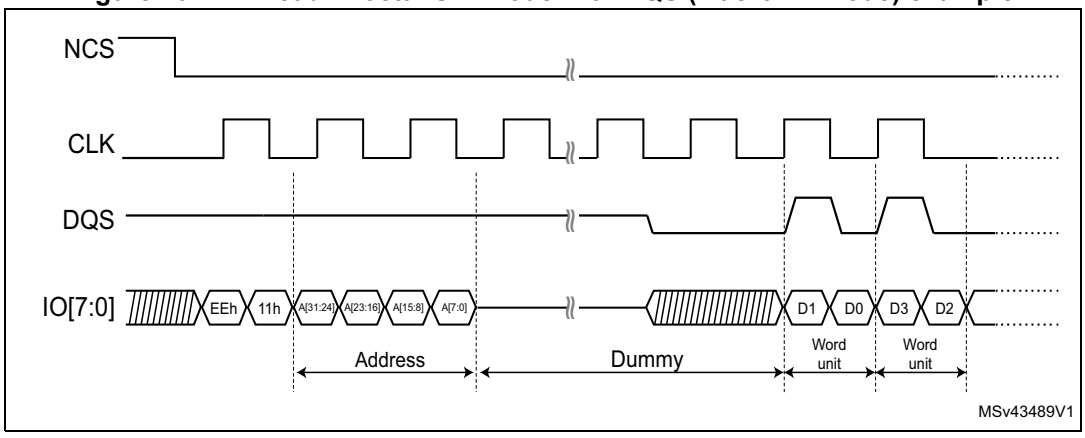
In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in XSPI_CCR.

Figure 70. DTR read in octal-SPI mode with DQS (Macronix mode) example



19.4.5 XSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 010, IO0 and IO1 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 011, IO0 to IO3 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase, when DMODE[2:0] = 100, IO[0:7] are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

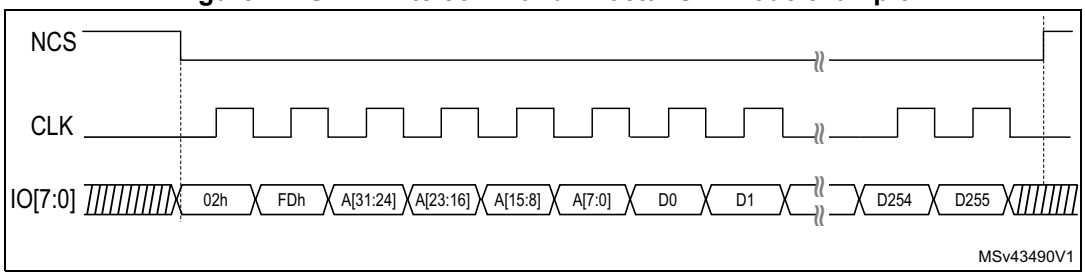
Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the XSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

Figure 71. SDR write command in octal-SPI mode example



Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

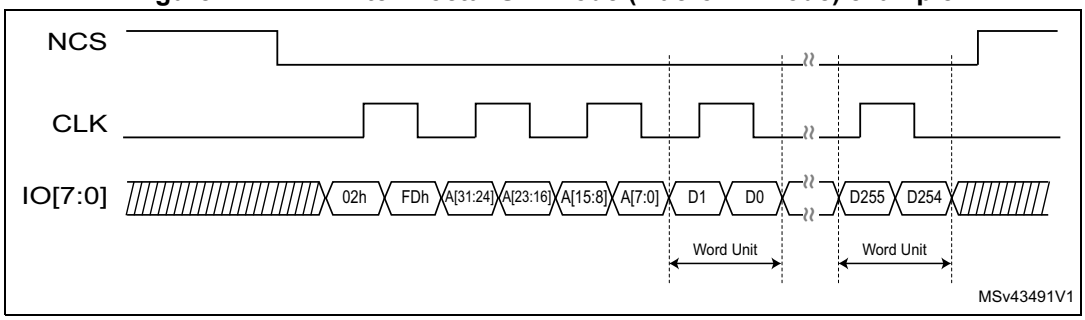
In DTR mode, when the XSPI drives the IO0 to IO7 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of XSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 72. DTR write in octal-SPI mode (Macronix mode) example



Dual-quad configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

19.4.6 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- DQS for read and write data strobe and latency insertion
- NCS
- CLK

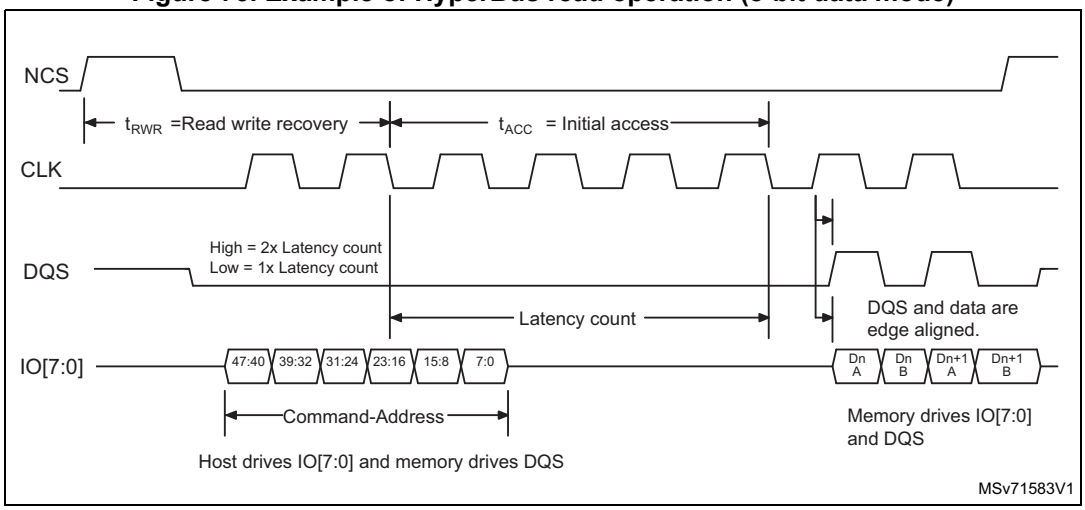
The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 73. Example of HyperBus read operation (8-bit data mode)



The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 128. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.

Table 128. Command/address phase description

CA bit	Bit name	Description
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

The address space is configured through the memory type MTYP[2:0] in XSPI_DCR1.

The total size of the device must be configured through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in XSPI_HLCR) according to the memory latency

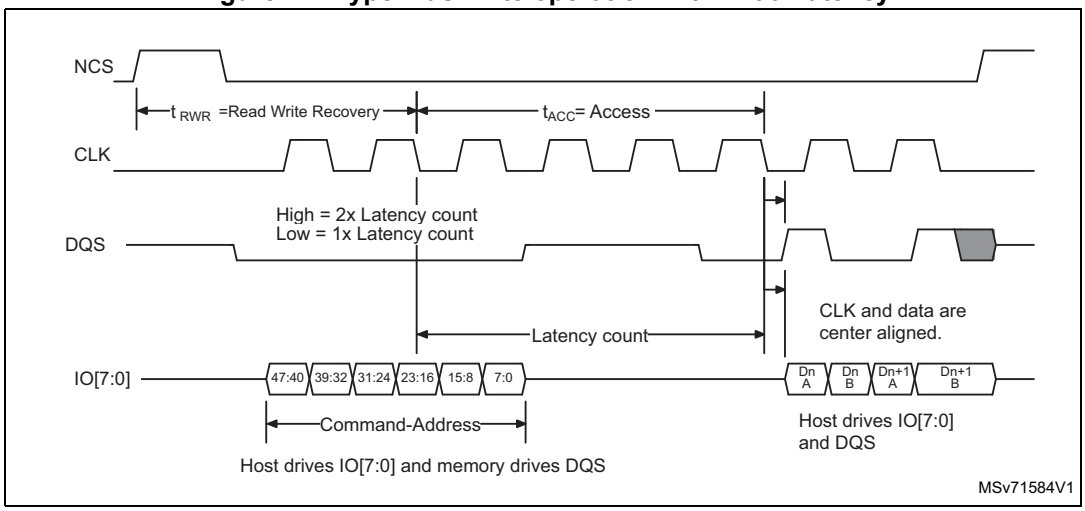
During the read operation, the DQS is used by the device, in two ways (see *Figure 73*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

Figure 74. HyperBus write operation with initial latency



Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the XSPI to meet the device request.

Figure 75. HyperBus read operation with additional latency

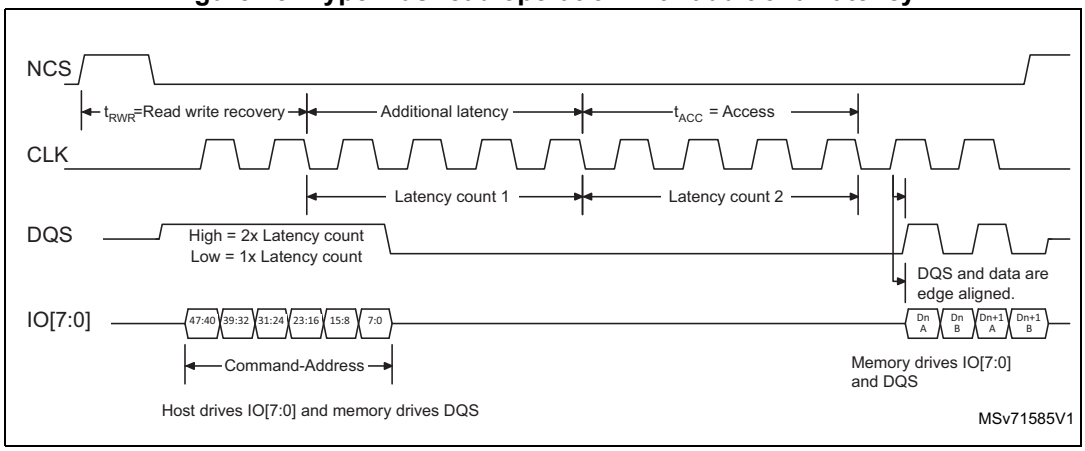


Figure 76. HyperBus write operation with additional latency

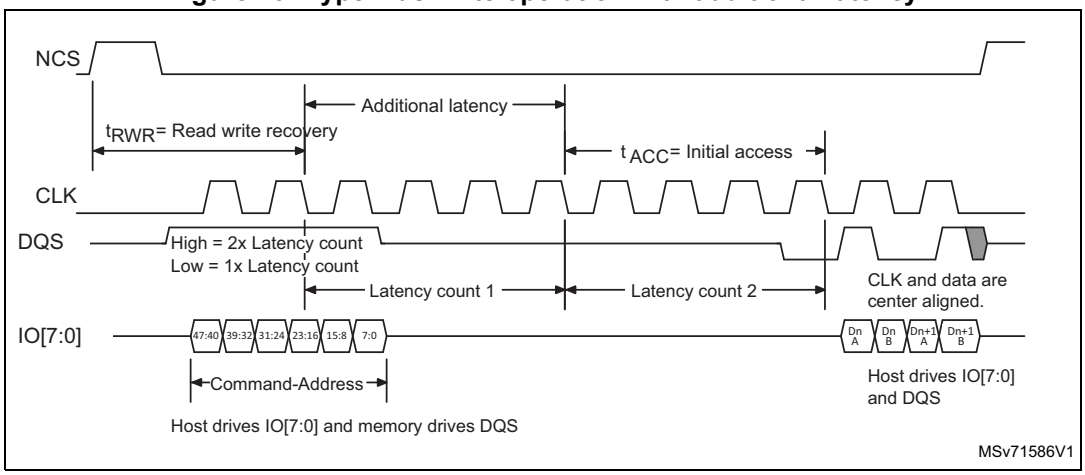


Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

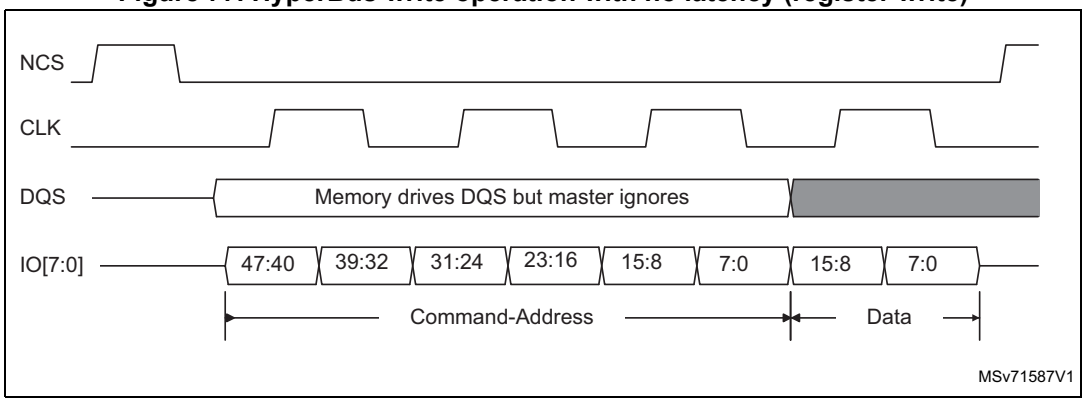
The latency can be forced to 2 x t_{ACC} by setting LM in XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.

Figure 77. HyperBus write operation with no latency (register write)

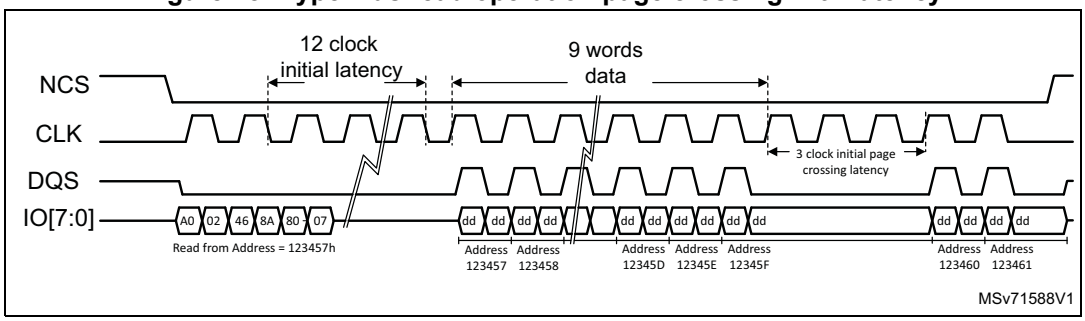


Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 78. HyperBus read operation page crossing with latency



19.4.7 Specific features

The XSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The XSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated XSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in XSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

19.4.8 XSPI operating mode introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

19.4.9 XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in XSPI_SR, and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication

in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode pass through a 32-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in XSPI_DR, and immediately transferred in the internal FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

19.4.10 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must then be configured in fixed latency.

19.4.11 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time. This prefetch feature can be disabled by setting the NOPREF bit in XSPI_DCR1. Disabling the prefetch can be beneficial for performance when the transfer requests are short and jumping frequently between non-consecutive addresses.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

The controller can apply an automatic address offset to simplify memory area code switching, such as during a firmware update (if the address offset feature is available in the product implementation table). To enable this feature, set the ADOFFEN bit in the XSPI_CR register and configure the offset value in the ADOFF[4:0] bitfield of the XSPI_DCR1 register. The offset is modulo 256 bytes.

19.4.12 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

19.4.13 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

19.4.14 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the associated delay block DLYB connected externally to the peripheral
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in XSPI_HLCR.

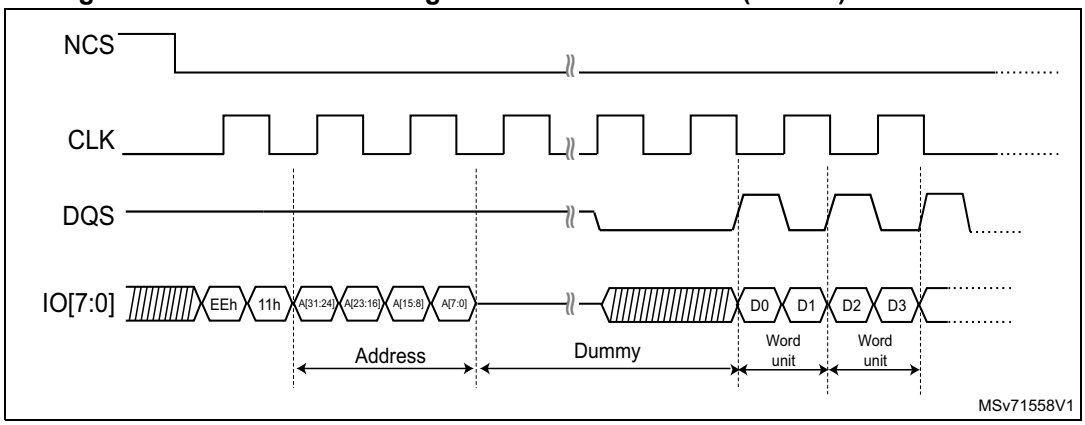
Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 79. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access



- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 70: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 129: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock one when reading data from the memory.

Figure 80. OctaRAM read operation with reverse data ordering D1/D0

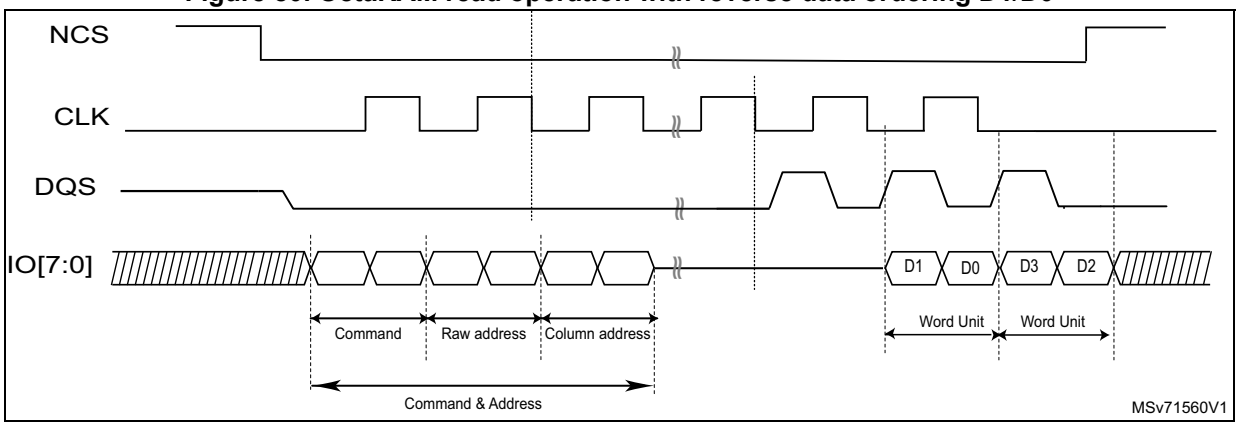


Table 129. OctaRAM command address bit assignment (based on 64 Mb(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64 Mb OctaRAM address assignment:
Row Address [RA12:RA0]: 8K. Column Address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.
- Standard mode. It is the mode to use whenever the targeted memory is not corresponding to any other configurations described in this section. MTYP[2:0] = 010 for this standard mode.

19.4.15 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.

8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as XSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000),
the communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in XSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.
3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

XSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

XSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

This shift is performed by an external delay block (DLYB) located outside the XSPI. This external delay block has to be calibrated (by enabling FRCK) before starting the first transfer, and recalibrated regularly. The control of this feature depends on the device implementation (see the delay block (DLYB) section in this document for more details about DLYB and calibration procedure, and the product datasheet for freq_min value).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in XSPI_DCR1.

19.4.16 XSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

19.4.17 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AHB slave error in the following situations, setting the BERRF flag in XSPI_SR and generating an interrupt if enabled (BERRIE = 1 in XSPI_CR) (if the Bus error bit feature is available in the product implementation table, otherwise the Slave bus error response is generated at system level as transaction response with no dedicated bit into the controller status register):

- The memory-mapped mode is disabled and an AHB read or write request occurs.
- A read or write (including the address offset if ADOFFEN bit is set) address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to *Section 19.4.18: XSPI BUSY and ABORT*.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in HyperBus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the AHB bus transfer size (HSIZE) is different from 4 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and octal mode is set.

19.4.18 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the SPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

19.4.19 XSPI reconfiguration or deactivation

Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:

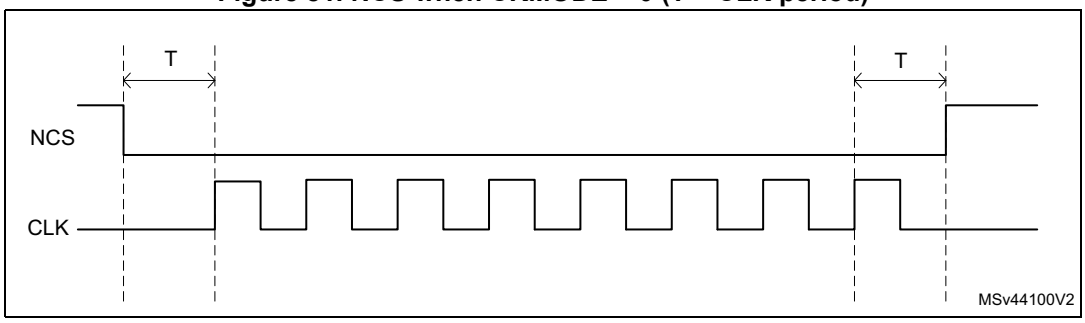
- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

19.4.20 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 81. NCS when CKMODE = 0 (T = CLK period)



Note: Clock mode 3 is not supported.

In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1.
The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.

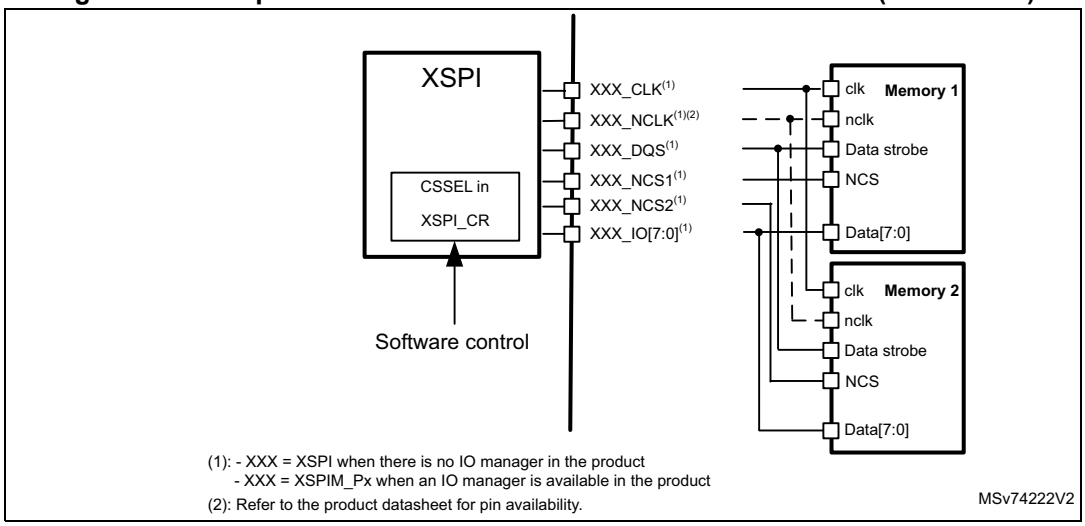
19.4.21 Software control of two external memories

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus.

From a memory-map point of view, these two memories are located in the same address range.

Figure 82. Example of software control of two external memories (octal mode)



19.4.22 Hardware-controlled extended memory support

One XSPI instance is able to control autonomously the generation of the two chip-select signals (NCS1 and NCS2). This feature is activated by setting EXTENDMEM in XSPI_DCR1 and allows two external memories to be connected to the same I/O port driven by the XSPI.

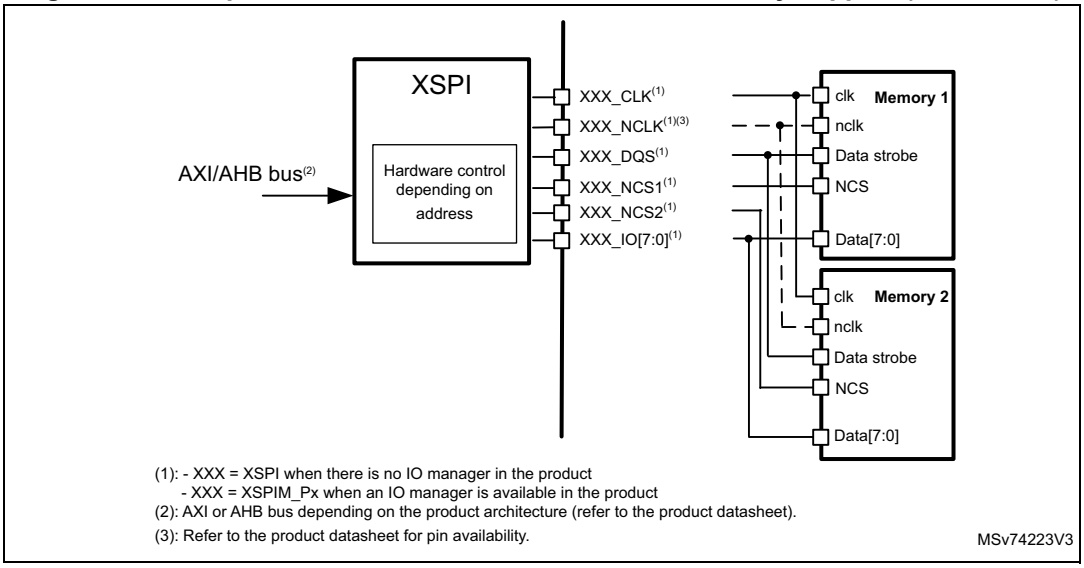
The aim is to extend by a factor two, the available external memory size. Both memories must be contiguous in the memory map. Both external memories must be of the same type and size. The size of one external memory must be set in DEVSIZE of XSPI_CR.

- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address: XSPI_base_address + $2^{DEVSIZE}$ - 1], NCS1 is generated.
- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address + $2^{DEVSIZE}$: XSPI_base_address + 2 × $2^{DEVSIZE}$ - 1], NCS2 is generated.

Note: If the access crosses the middle boundary of the external memory, CS changes automatically (no write into XSPI_AR in indirect mode, or new memory access in memory-mapped mode is needed).

The EXTENDMEM feature (set in bit 21 of XSPI_DCR1) and the Dual-memory mode (set in bit 6 of XSPI_CR) are exclusive: EXTENDMEM = 1 and DMM = 1 as this configuration is not supported.

Figure 83. Example of hardware-controller extended memory support (octal mode)



19.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 130. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				

Table 130. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Octal memory in DTR mode without WDM(6)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

19.6 XSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 131. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE

Table 131. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

19.7 XSPI registers

19.7.1 XSPI control register (XSPI_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MSEL	FMODE[1:0]		Res.	Res.	NOPREF	CSSEL	PMM	APMS	BERRIE	TOIE	SMIE	FTIE	TCIE	TEIE
	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					Res.	DMM	Res.	ADOFFEN	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw		rw		rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **MSEL**: External memory select

This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).

0: External memory 1 selected (data exchanged over IO[3:0])

1: External memory 2 selected (data exchanged over IO[7:4])

This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Note: This bitfield can be modified only when BUSY = 0.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the XSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **NOPREF**: No prefetch data

This bit disables the automatic prefetch in the external memory.

0: Automatic prefetch enabled

1: Automatic prefetch disabled

Bit 24 **CSSEL**: Chip-select selection
This bit indicates if it must copy NCS to NCS1 or NCS2.
0: NCS1 active
1: NCS2 active
Note: This bit can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.
Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.
1: Automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 **BERRIE**: Bus error interrupt enable
This bit enables the bus error interrupt (if Bus error bit feature is available in the product implementation table).
0: Interrupt disabled
1: Interrupt enabled

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable
This bit enables the status-match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.

00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.

00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.

...

11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.

Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **ADOFFEN**: Address offset enable

An offset may be applied on the memory address. The offset value is set into ADOFF[4:0].

0: Address offset disabled

1: Address offset enabled

Note: This bit can be modified only when BUSY = 0. This bit is present only if the address offset feature is available in the product implementation table.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via XSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the XSPI.

0: XSPI disabled

1: XSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

19.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADOFF[4:0]					MTYP[2:0]			Res.	Res.	EXTENDMEM	DEVSIZE[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLYBYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 **ADOFF[4:0]**: Address offset

This bitfield defines the memory address offset value added to the current address requested to be sent by the controller to hit the external memory using the following formula:
Offset value = $2^{[ADOFF+8]}$. (modulo 256 bytes)
Maximum allowed value is 19 since the memory-mapped mode is limited to 256 Mbytes address space. For greater value, the address offset will not be applied to the address sent by the controller.
This bitfield is relevant only if ADOFFEN is set and if FMODE[1:0] = 11 (memory-mapped mode) and if the address offset feature is available in the product implementation table.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect-read/write modes must be used.

Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **EXTENDMEM**: Extended memory support

This bit is only relevant when one XSPI drives two same size external memories located in contiguous places in the memory map. In this case, DEVSIZE[4:0] represents the size of each external memory. When this bit is set, the XSPI automatically controls which of NCS1 or NCS2 is active.

0: NCS1 and NCS2 values depend from CSSEL bit in XSPI_CR (software controlled).

1: NCS1 and NCS2 values depend from the address of transfer (hardware controlled).

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:

Number of bytes in device = $2^{[DEVSIZE+1]}$.

DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

In regular-command protocol, if DMM = 1 or EXTENDMEM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set. Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0

This bit is read-only and is read as zero.

19.7.3 XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the XSPI_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Other: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

19.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Other: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:0 Reserved, must be kept at reset value.

19.7.5 XSPI device configuration register 4 (XSPI_DCR4)

Address offset: 0x014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Other: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the memory clock period: if XSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

19.7.6 XSPI status register (XSPI_SR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	BERRF	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r		r	r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **BERRF**: Bus error flag

This bit is set when a bus error occurs. It is cleared by writing 1 to CBERRF. This bit has a meaning if Bus error bit feature is available in the product implementation table.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

19.7.7 XSPI flag clear register (XSPI_FCR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CBERRF	Res.	CTOF	CSMF	Res.	CTCF	CTEF
									w		w	w		w	w

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CBERRF**: Clear bus error flag

Writing 1 clears the BERRF flag in the XSPI_SR register (if Bus error bit feature is available in the product implementation table).

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the XSPI_SR register.

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the XSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the XSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the XSPI_SR register.

19.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

19.7.9 XSPI address register (XSPI_AR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In dual-memory configuration, AR[0] is forced to 0.

Caution: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiply the address by two when accessing the memory registers.

19.7.10 XSPI data register (XSPI_DR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

19.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

19.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match

19.7.13 XSPI polling interval register (XSPI_PIR)

Address offset: 0x090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval

Number of CLK cycles between a read during the automatic status-polling phases

19.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Other: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

19.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw		rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.

This bit allows the data to be sampled later in order to consider the external signal delays.

0: No shift

1: 1/2 cycle shift

The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

0: No delay hold

1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency. In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

19.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

19.7.17 XSPI alternate bytes register (XSPI_ABR)

Address offset: 0x120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

19.7.18 XSPI low-power timeout register (XSPI_LPTR)

Address offset: 0x130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period
After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.
This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

19.7.19 XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Other: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

19.7.20 XSPI wrap timing configuration register (XSPI_WPTCR)

Address offset: 0x148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.

This bit allows the data to be sampled later in order to consider the external signal delays.

0: No shift

1: 1/2 cycle shift

The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.

0: No quarter cycle delay

1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.

In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

19.7.21 XSPI wrap instruction register (XSPI_WPIR)

Address offset: 0x150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

19.7.22 XSPI wrap alternate bytes register (XSPI_WPABR)

Address offset: 0x160

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

19.7.23 XSPI write communication configuration register (XSPI_WCCR)

Address offset: 0x180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Other: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

19.7.24 XSPI write timing configuration register (XSPI_WTCR)

Address offset: 0x188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

19.7.25 XSPI write instruction register (XSPI_WIR)

Address offset: 0x190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TACC[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	WZL	LM
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.
0: Variable initial latency
1: Fixed latency

Note: This bit must be set when using the dual-octal HyperBus configuration.

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

20 Delay block (DLYB)

This section applies only to STM32C59xx/C5Axx devices.

20.1 DLYB introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an XSPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

20.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

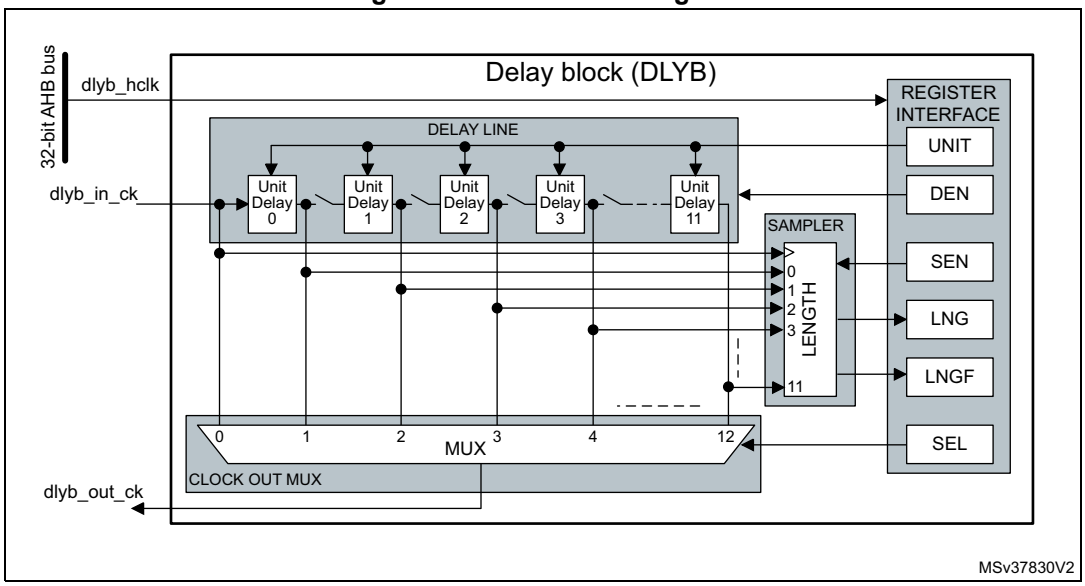
20.3 DLYB functional description

20.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 84. DLYB block diagram



20.3.2 DLYB pins and internal signals

Table 133 lists the DLYB internal signals.

Table 133. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

20.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 134. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don't care	Don't care	Don't care	Don't care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

20.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

20.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

XSPI use case:

The delay block is used in conjunction with XSPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small “Unit” gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

20.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

20.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

20.4.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

20.4.3 DLYB register map

Table 135. DLYB register map and reset values

21 Analog-to-digital converters (ADC)

21.1 ADC introduction

This section describes the implementation of up to 3 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 is controlled independently.

Each ADC consists of one 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 14 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned (default configuration) 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

21.2 ADC main features

- High-performance features
  - Up to 3 ADCs, out of which two of them can operate in dual mode:
    ADC1 is connected to 12 external channels + 2 internal channels
    ADC2 is connected to 14 external channels
    ADC3 is connected to 14 external channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - AHB slave bus interface to allow fast data handling
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Fixed latency for a trigger to start of sampling
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Four dedicated data registers for the injected channels
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance

  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (autodelayed mode)
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shifts
- Data preconditioning
  - Gain compensation
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC): up to 14 GPIO pads
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for the internal temperature sensor (V_{SENSE})
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timer events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 85 shows the block diagram of one ADC.

21.3 ADC implementation

Table 136. ADC features

ADC modes/features	ADC1, ADC2(1)	ADC3(2)
Resolution	12 bits	
Maximum sampling speed	2 Msps (12-bit resolution)

21.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 86: ADC clock scheme*). This selection is done in the RCC (refer to section *Reset and clock control (RCC)* for more information):

1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous from the AHB clock.
2. The ADC clock can be derived from AHB clock (selected in RCC).

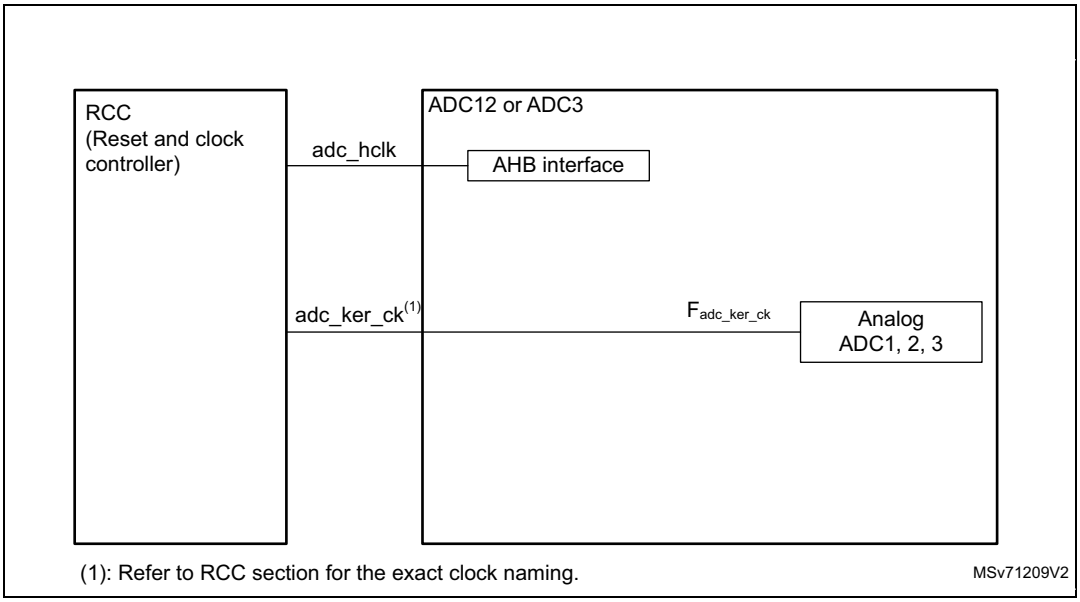
Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected.

Option **2** corresponds to a pseudosynchronous clock. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains). This accurate trigger is supported only by trgo or trgo2 timer triggers.

For further details on the synchronization between ADC and timers, refer to section *ADC synchronization* in each timer section, and to section *Peripheral clock distribution* in the RCC section.

The clock is configured through the RCC and must be compliant with the operating frequency specified in the device datasheet.

Figure 86. ADC clock scheme



Clock ratio constraint between ADC clock and AHB clock

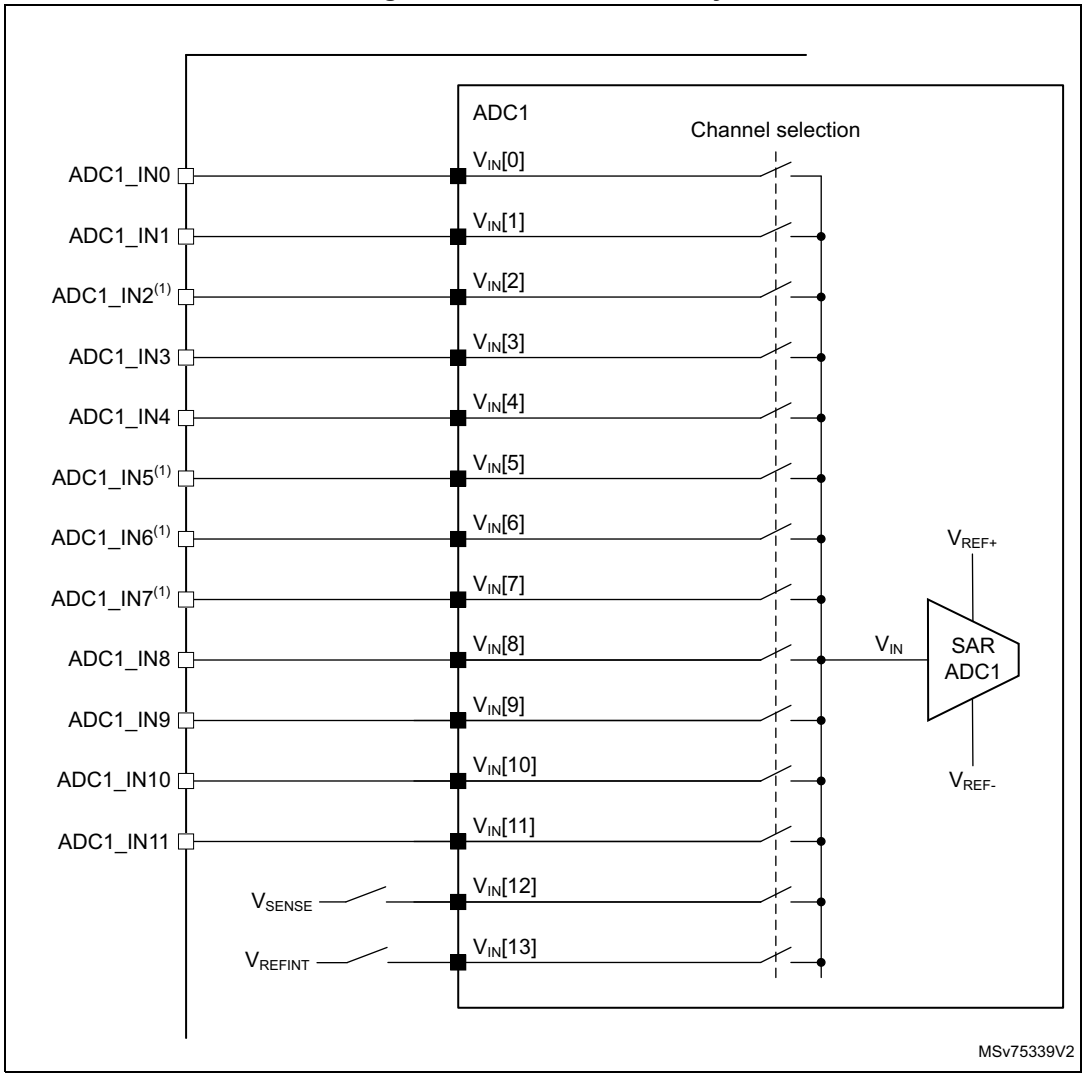
There are no constraints to respect for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

When adc_hclk operates at a higher frequency than adc_ker_ck, writing to the AHB register does not immediately update the ADC configuration due to clock domain crossing delays. To guarantee that the configuration is properly applied within the adc_ker_ck domain, it is necessary to wait for four adc_ker_ck clock cycles after the AHB register update.

21.4.4 ADC connectivity

ADC inputs are connected to external channels as well as internal sources as described below.

Figure 87. ADC1 connectivity



1. On the STM32C53x/542 devices, these external channels can be connected to two GPIOs selected through the SBS_PMCR register.

Figure 88. ADC2 connectivity

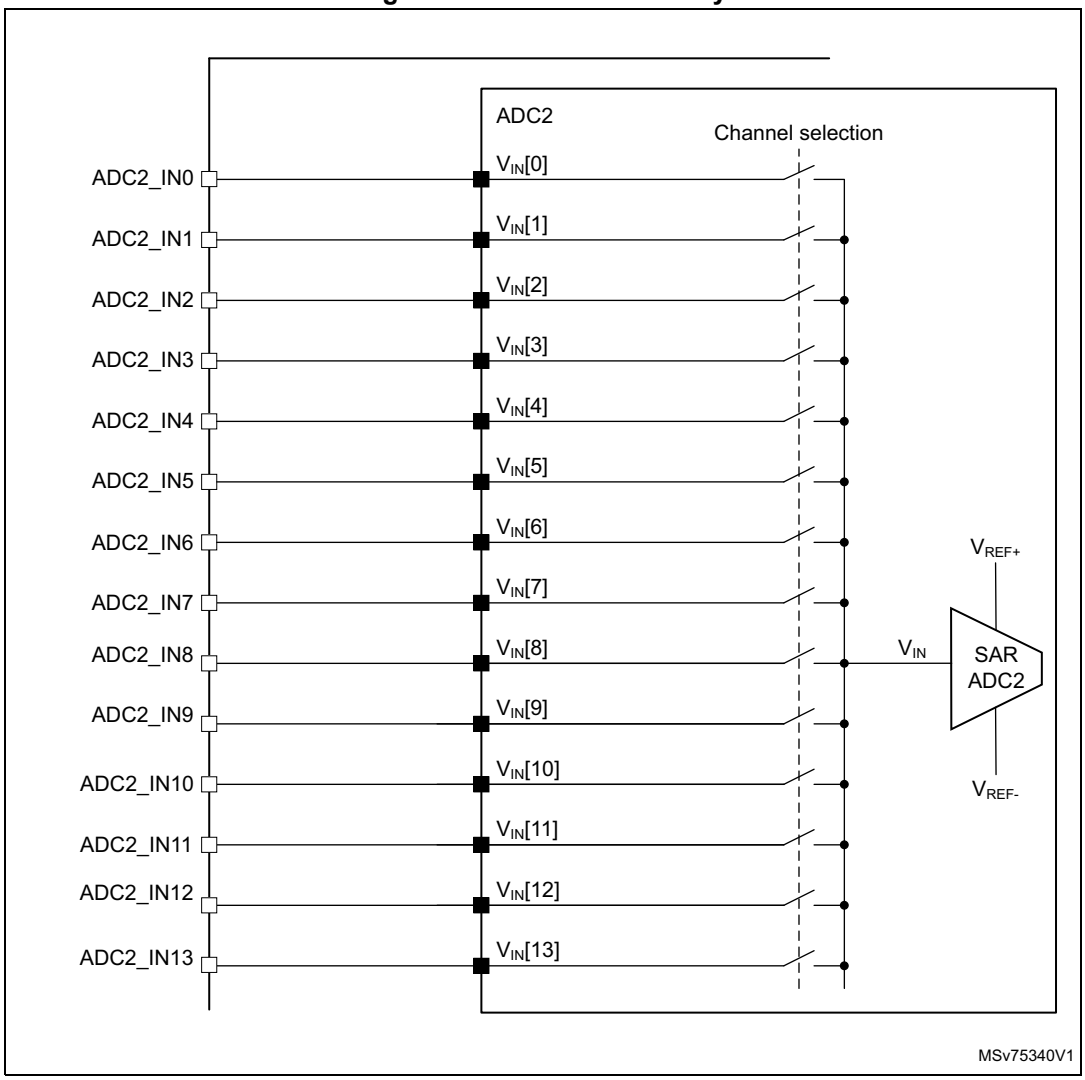


Figure 89. ADC3 connectivity

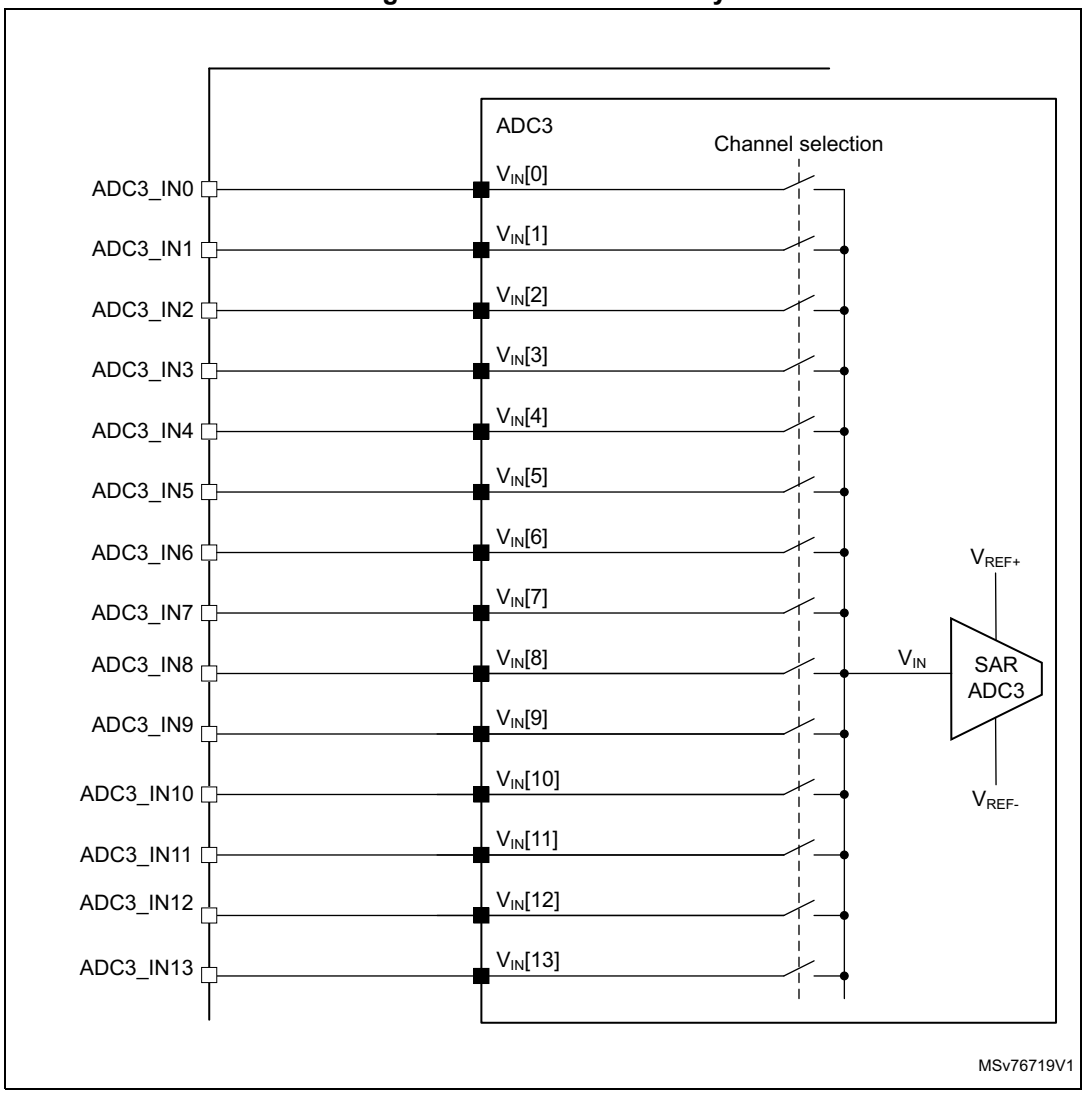


21.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and it can generate AHB error in case of wrong HSIZE.

21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of the DEEPPWD bit is 1 in the ADC_CR register).

To activate the ADC, first exit the Deep-power-down mode by clearing the DEEPPWD bit.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the ADVREGEN bit of the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software. For the startup time of the ADC voltage regulator, refer to the device datasheet for $T_{ADCVREG_STUP}$ parameter.

When ADC operations are complete, the ADC can be disabled by clearing the ADEN bit of the ADC_CR register. Power can then be saved by disabling the ADC voltage regulator (by clearing ADVREGEN).

Additional power can be saved by entering ADC Deep-power-down mode again (by setting DEEPPWD of ADC_CR register). This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and the ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN cleared), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or reapply the calibration factor, which was previously saved (refer to *Section Calibration*).

21.4.7 Calibration (ADCAL, ADC_CALFACT)

Each ADC provides an automatic calibration procedure that drives all the calibration sequences including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor, which is 7-bit wide and is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration is initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). The ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT[6:0] of the ADC_CALFACT register.

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before reenabling the ADC.

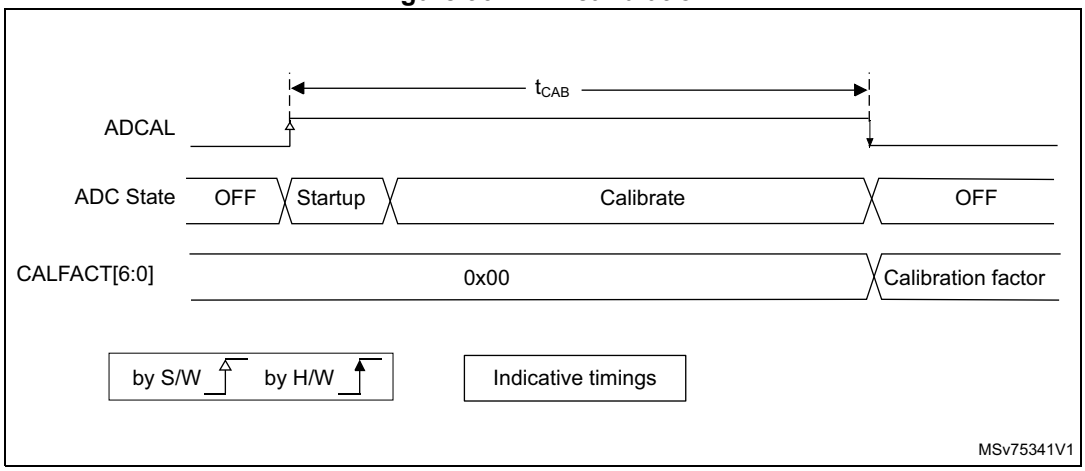
The internal analog calibration is lost each time the power of the ADC is removed (for example, when the product enters Standby). In this case, to avoid spending time recalibrating the ADC, it is possible to rewrite the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when the V_{REF+} voltage changed more than 10% (see *Section 21.4.31: Monitoring the internal voltage reference*).

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Set ADCAL.
4. Wait until ADCAL = 0.
5. The calibration factor can be read from the ADC_CALFACT register.

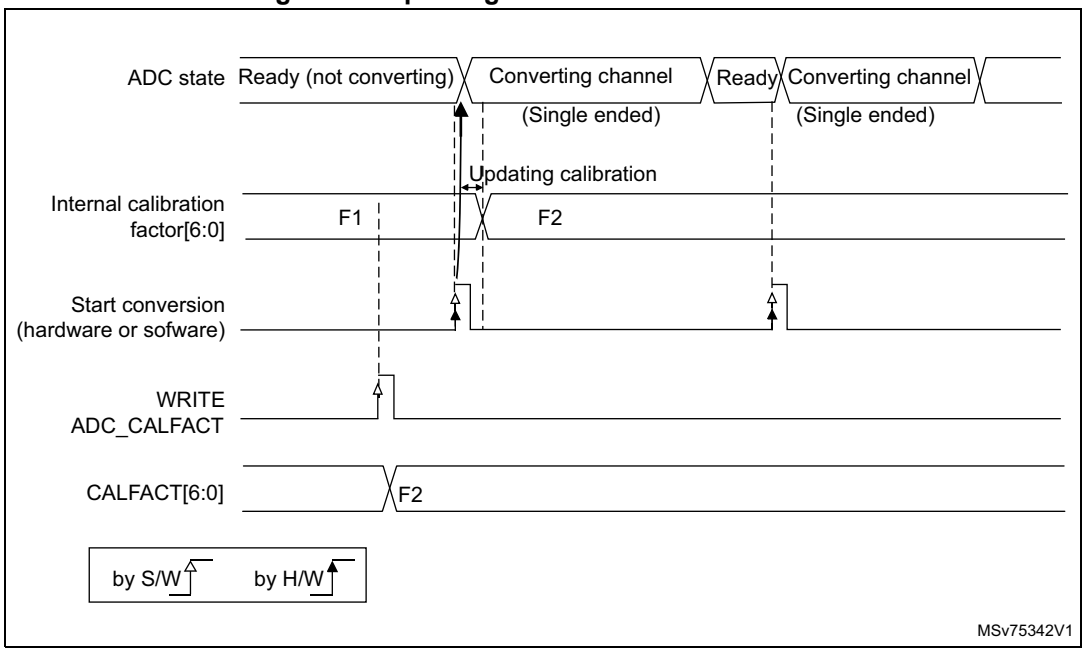
Figure 90. ADC calibration



Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT.

Figure 91. Updating the ADC calibration factor



21.4.8 ADC on-off control (ADEN, ADDIS, ADRDY)

First, follow the procedure described in *Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

Once DEEPPWD is cleared and ADVREGEN is set, the ADC can be enabled. It requires a t_{STAB} stabilization time before starting converting accurately (see *Figure 92*).

Two control bits enable or disable the ADC:

- Set ADEN to enable the ADC. The ADRDY flag is set once the ADC is ready for operation.
- Set ADDIS to disable the ADC. ADEN and ADDIS are automatically deasserted by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 21.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs if regular triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs, if injected triggers are enabled.

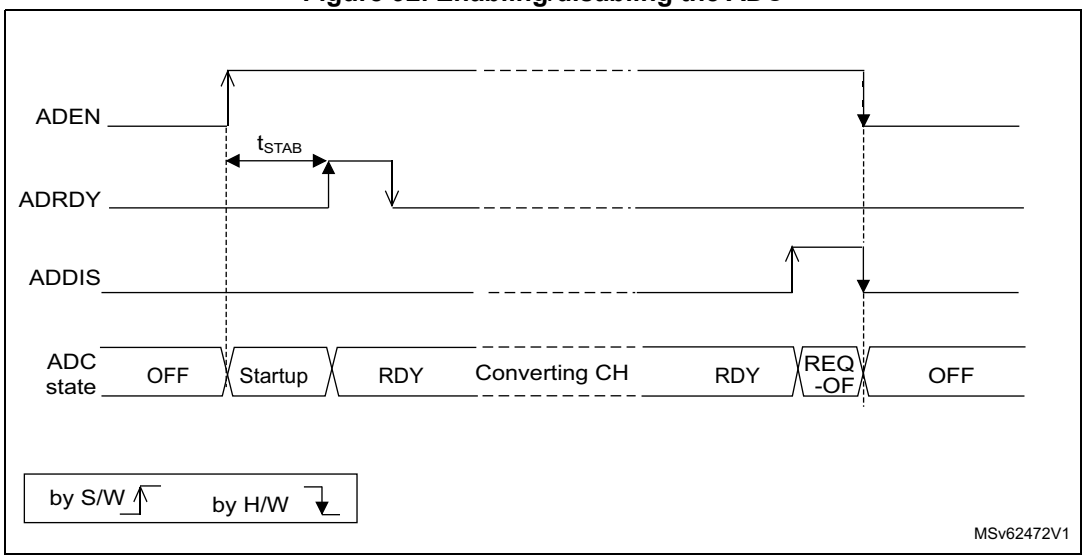
Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by programming it to 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE must be set).
4. Clear the ADRDY bit in the ADC_ISR register by programming it to 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop all regular and injected ongoing conversions by setting ADSTP and JADSTP. Then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait for ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 92. Enabling/disabling the ADC



21.4.9 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC section) and configure the ADEN bit in the ADC_CR register, only if the ADC is disabled (ADEN must be cleared).

The software can write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if no regular conversions are ongoing (ADSTART must be cleared).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if no injected conversions are ongoing (JADSTART must be cleared).
- ADC_TRy register thresholds can be modified when an analog-to-digital conversion is ongoing (refer to *Section 21.4.27: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for details).
- To modify the all above control bits when the software trigger function is used, an ADSTP or JADSTP must be issued to make sure all activities are stopped, even if ADSTART and JADSTART are cleared.

The software is allowed to write the ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and if there is no pending request to disable the ADC.

Note: Not all forbidden write accesses to ADC control bits are protected by hardware. In some cases, the ADC state may become unknown. To recover from this situation, the ADC must be disabled (ADEN = 0 as well as all the bits of the ADC_CR register).

21.4.10 Channel selection (ADC_SQRy, ADC_JSQR)

The ADC features up to 14 multiplexed channels per ADC, out of which:

- Up to 14 analog inputs coming from GPIO pads (ADCx_IN[i]). Depending on the device, not all of them are available on GPIO pads.
- The ADC is connected to up to 2 internal analog inputs:
  - internal reference voltage (V_{REFINT})
  - Internal temperature sensor (V_{SENSE})

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, TSEN in the ADCC_CCR registers.

Refer to *ADC interconnection* tables in *Section 21.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to ADC pins.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_IN3, ADCx_IN8, ADCx_IN2, ADCx_IN2, ADCx_IN0, ADCx_IN2, and ADCx_IN2.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the LEN[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the JLEN[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while a regular conversion is ongoing. ADC regular conversions must consequently be stopped by setting ADSTP (refer to *Section 21.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)*).

21.4.11 Channel preselection register (ADC_PCSEL)

The PCSEL bit of the ADC_PCSEL register controls the analog switch integrated in the I/O.

For each channel selected through SQRx or JSQRx bits, the corresponding PCSEL bit must be configured in advance in the ADC_PCSEL register. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed. The analog switch integrated in the I/O cannot react as fast as the ADC multiplexer. To avoid the delay due to the analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V_{IN} of each ADC input. For example, if the ADC converts ADCx_IN1, PCSEL1 bit must also be set in ADC_PCSEL register.

Note: Configuring the PCSEL bit is not necessary for the internal channels (such as V_{REFINT}).

21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be sufficient for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time, which is programmable through the SMP[2:0] bits of the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 3 ADC clock cycles
- SMP = 001: 5 ADC clock cycles
- SMP = 010: 8 ADC clock cycles
- SMP = 011: 13 ADC clock cycles
- SMP = 100: 25 ADC clock cycles
- SMP = 101: 48 ADC clock cycles
- SMP = 110: 139 ADC clock cycles
- SMP = 111: 289 ADC clock cycles

The total conversion time is calculated as follows (12-bit mode):

$$T_{CONV} = \text{Sampling time} + 13 \text{ ADC clock cycles}$$

Example

With $F_{adc_ker_ck}$ = 32 MHz and a sampling time of 3 ADC clock cycles:

$$T_{CONV} = (3 + 13) \times \text{ADC clock cycles} = 16 \text{ ADC clock cycles} = 500 \text{ ns}$$

The ADC notifies the end of the sampling phase by asserting the EOSMP flag (only for regular conversion).

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum and a maximum sampling times as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

The bulb sampling mode enables to obtain longer sampling time.

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPRx registers. The very first ADC conversion after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

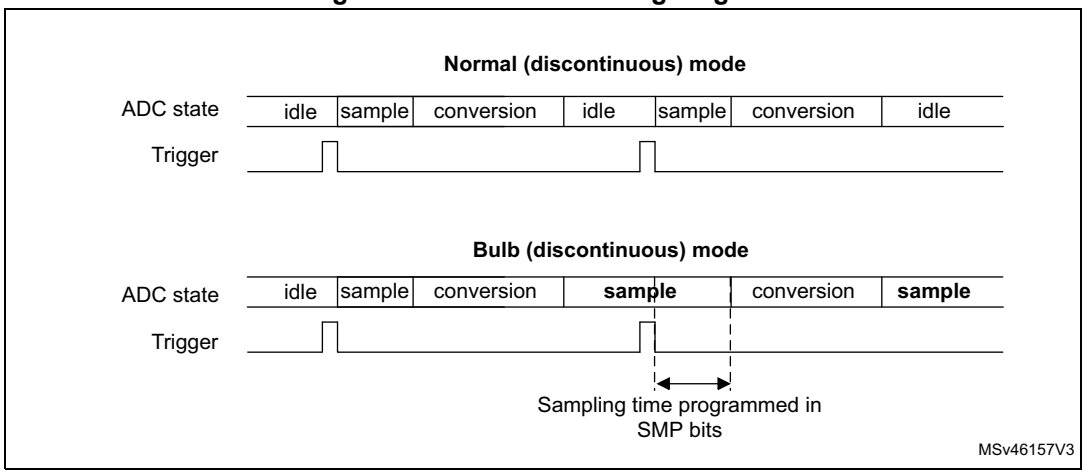
The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

Bulb mode is supported exclusively in regular conversion; dual mode is not supported.

The BULB bit can be modified only when the ADEN bit of the ADC_CR register is cleared.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

Figure 93. Bulb mode timing diagram



Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected (EXTEN[1:0] = 01), each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

Due to the synchronization mechanism, the minimum allowed pulse width is seven adc_ker_ck periods.

When a software trigger is selected (EXTEN[1:0] = 00), the software trigger is not the ADSTART bit of ADC_CR but the SWTRIG bit. The SWTRIG bit has to be set to start the sampling period, and it has to be cleared to end the sampling period and start the conversion. In this mode, the minimum sampling time is limited to seven ADC clock cycles.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is only compatible with the discontinuous mode. DISCNUM must be cleared for regular conversion mode. It is not supported for injected conversion mode and autoinjection mode.

When the SMPTRIG bit is set, setting the BULB bit is not allowed and only regular conversion is supported.

The sampling time control trigger mode is not compatible with the following dual modes: DUAL[4:0] = 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, and 0b01001.

21.4.13 Single conversion mode

To enable the single conversion mode for regular channels, clear both CONT and DISCEN bits in ADC_CFGR1 register. To enable it on injected channel, clear JDISCEN bit.

In single conversion mode, the ADC performs once all the regular conversions of the programmed channels. This mode is started by one of the following events:

- ADSTART bit set in the ADC_CR register (for a regular channel)
- JADSTART bit set in the ADC_CR register (for an injected channel)
- An external hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit 8-level FIFO accessible through the ADC_DR register,
- The EOC (end of regular conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers,
- The JEOC (end of injected conversion) flag is set, and
- An interrupt is generated if the JEOCIE bit is set.

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set, and
- An interrupt is generated if the JEOSIE bit is set.

The ADC then stops until a new external regular or injected trigger occurs or until the ADSTART or JADSTART bit is set again.

Note: To convert a single channel, program a sequence with a length of 1.

21.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts all the conversions of the sequence. This mode is started by setting the CONT bit of the ADC_CFGR1 register, either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the eight 32-bit word FIFO accessible through the ADC_DR register.
- The EOC (end of conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled, this means that it is forbidden to set both DISCEN and CONT bits.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit) (refer to Section : Autoinjection mode).

21.4.15 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN and CONT = 0 bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the LEN[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - First trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - Second trigger: channels converted are 6, 7, 8 (an EOC event is generated at the end of each conversion).
  - Third trigger: channels converted are 9, 10, 11 (an EOC event is generated at the end of each conversion) and an EOS event is generated after the conversion of channel 11.
  - Fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all devices.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels with DISCNUM = 0.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JLEN[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - First trigger: channel 1 converted (a JEOC event is generated)
  - Second trigger: channel 2 converted (a JEOC event is generated)
  - Third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all devices.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both autoinjection mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

21.4.16 Starting conversions (ADSTART, JADSTART)

ADC regular conversions can be started by setting ADSTART.

When ADSTART is set, the conversion starts:

- Immediately if EXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 00.

The application software starts ADC injected conversions by setting JADSTART.

When JADSTART is set, the conversion starts:

- Immediately if JEXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected injected hardware trigger, if JEXTEN[1:0] is not equal to 00.

Note: In autoinjection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by autoinjected conversions (JADSTART must be kept cleared).

When the hardware trigger is enabled, ADSTART and JADSTART also indicate whether an ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared, indicating that the ADC is idle.

In the case of software triggering, ADSTP and/or JADSTP must be set before ADC reconfiguration.

ADSTART is deasserted by hardware:

- In single mode with software regular trigger (CONT = 0, EXTEN = 0x0): at any end of regular conversion sequence (EOS assertion)
- In discontinuous mode (CONT = 0, DISCEN = 1, DISCNUM= x): at any of subgroup sequence
- In all cases (CONT and EXTEN don't care), after execution of the ADSTP procedure asserted by the software

Note: In continuous mode (CONT = 1), ADSTART is not deasserted by hardware when EOS is asserted because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN ≠ 0x00), ADSTART is not deasserted by hardware when EOS is asserted to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is deasserted by hardware:

- In single mode with software injected trigger (JEXTEN = 0x0): at the end of each injected conversion sequence (JEOS assertion)
- In discontinuous mode (JDISCEN = 1): at the end of any conversion
- In all cases (JEXTEN=x), after execution of the JADSTP procedure asserted by the software

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

In bulb mode (BULB = 1), the previous end-of-conversion automatically starts the sampling, then setting ADSTART starts the conversion including the programmed sampling time.

In sampling time control trigger mode (SMPTRIG = 1), SWTRIG bit must be set to start the conversion.

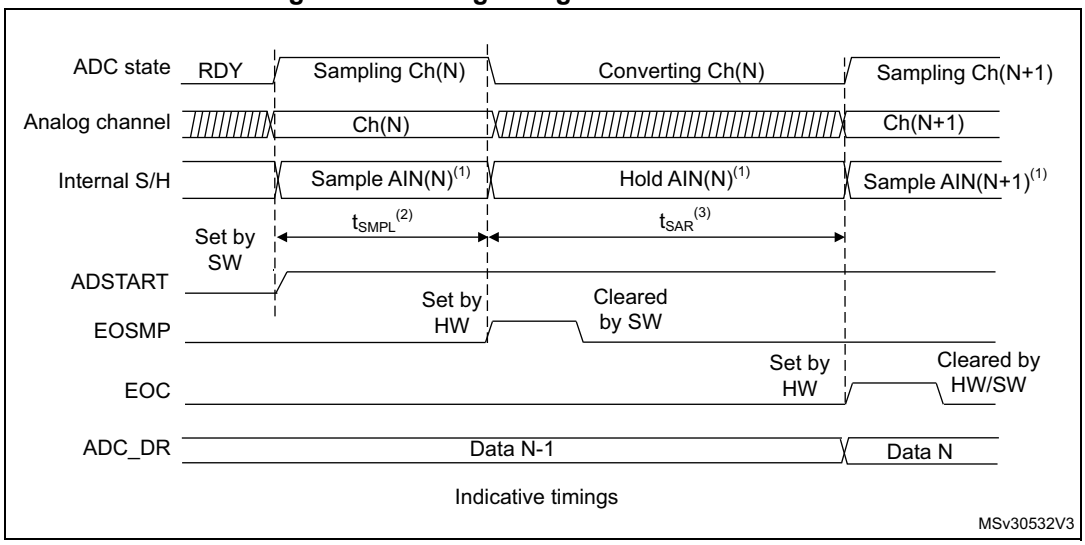
21.4.17 Timing

The elapsed time between the start of a conversion and the end of a conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [3\ _{|min} + 13\ _{|12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 93.75\ ns\ _{|min} + 406.25\ ns\ _{|12bit} = 500\ ns$ (for $F_{adc_ker_ck} = 32$ MHz)

Figure 94. Analog-to-digital conversion time



1. AIN represents the input voltage captured by the internal Sample and Hold (S/H) capacitor.
2. t_{SMPL} depends on SMP[2:0].
3. t_{SAR} depends on RES[2:0].

Note: The bulb and the sampling time control trigger modes are not described in Figure 94: Analog-to-digital conversion time.

21.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop ongoing regular conversions by setting ADSTP and ongoing injected conversions by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This allows, for instance, the reconfiguration of the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with the partial result discarded (the ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (the ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC restarts a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (for regular conversion), or JADSTP/JADSTART bits (for injected conversion) are deasserted by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In autoinjection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 95. Stopping ongoing regular conversions

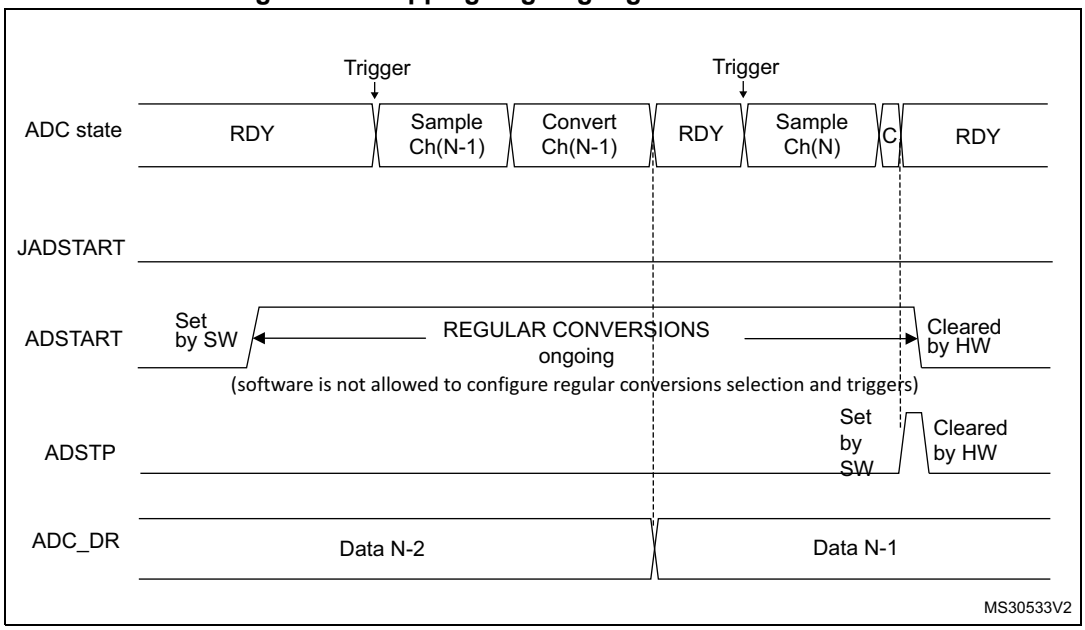


Figure 96. Stopping ongoing regular and injected conversions

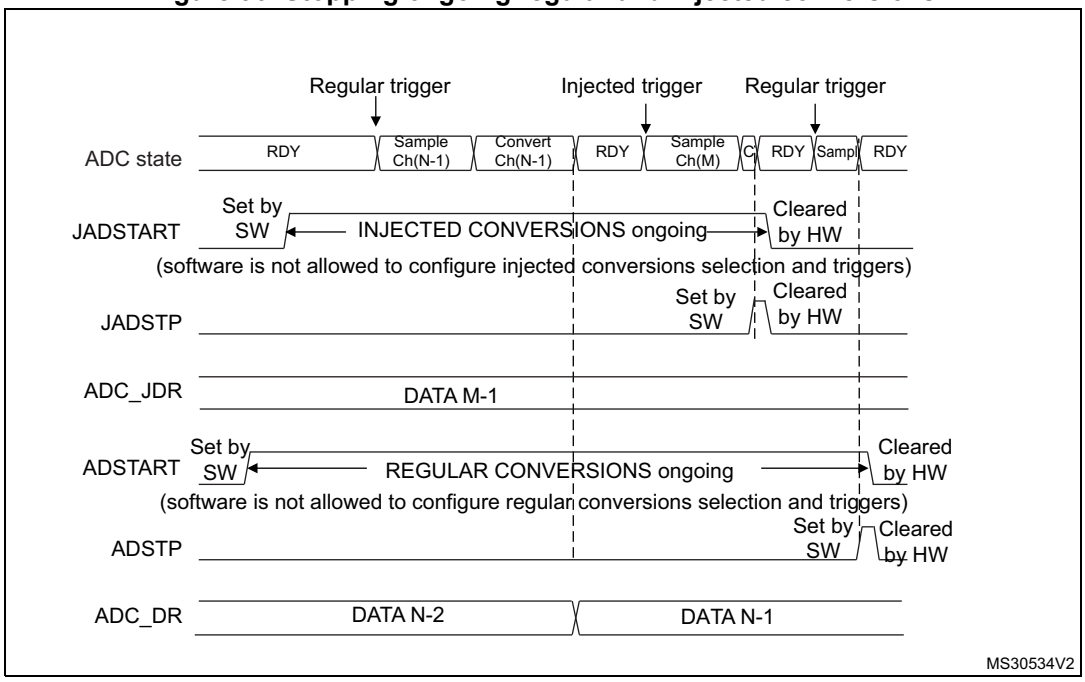


21.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once the software has set ADSTART while the injected trigger selection is effective once the software has set JADSTART bit.

All hardware triggers that occur while a conversion is ongoing are ignored:

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 140 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 140. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge (sampling time controlled in SMPTRIG mode)
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

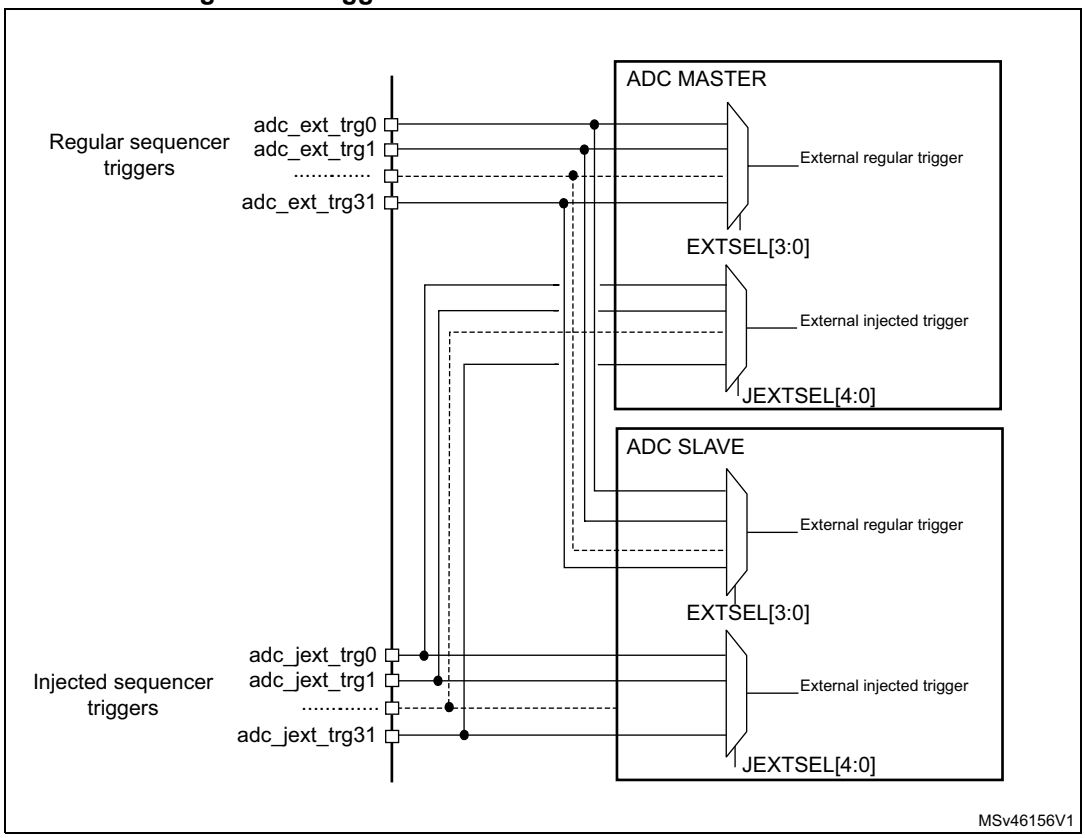
Table 141. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

The EXTSEL and JEXTSEL control bits select which, out of 32 possible events, can trigger the conversion of the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Figure 97. Triggers shared between ADC master and slave



Refer to *ADC interconnection* tables in *Section 21.4.2: ADC pins and internal signals* for the list of the external triggers.

21.4.20 Injected channel management

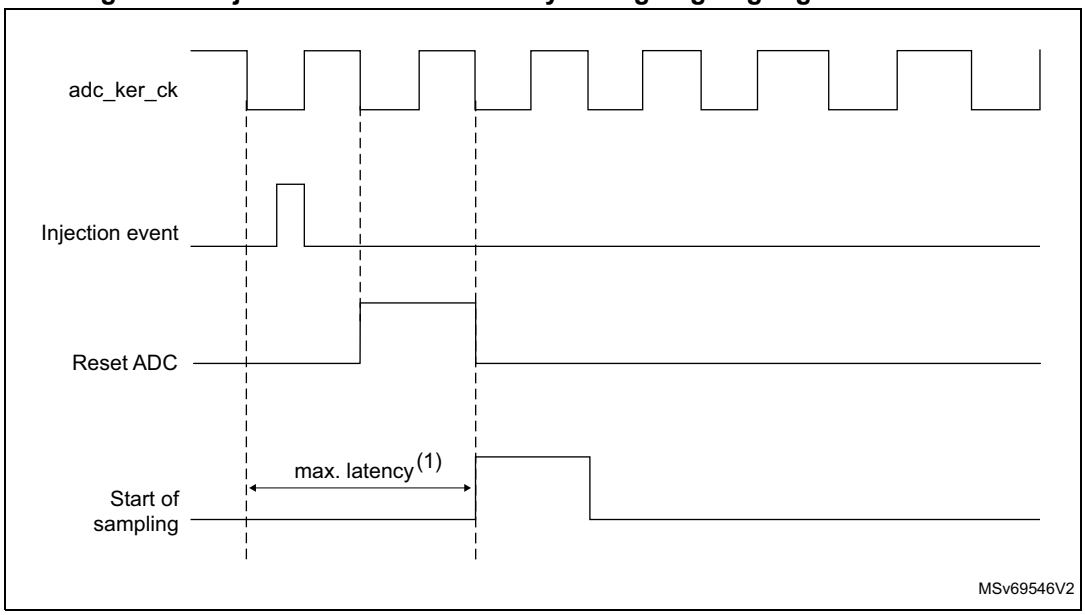
Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR1 register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once if JDISCEN = 0).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 98* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence.

Figure 98. Injected conversion latency during ongoing regular conversion



1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

Autoinjection mode

If the JAUTO bit in the ADC_CFGR1 register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

Note: Autoinjection mode is compatible with discontinuous mode.

21.4.21 Programmable resolution (RES) - fast conversion mode

Faster conversions can be performed by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] control bits. *Figure 103*, *Figure 104*, *Figure 105* and *Figure 106* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 142*.

Table 142. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 32 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 3 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 32 MHz
12	13 ADC clock cycles	406.25 ns	16 ADC clock cycles	500.0 ns
10	11 ADC clock cycles	343.75 ns	14 ADC clock cycles	437.5 ns
8	9 ADC clock cycles	281.25 ns	12 ADC clock cycles	375.3 ns
6	7 ADC clock cycles	218.75 ns	10 ADC clock cycles	312.5 ns

21.4.22 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application at the end of each regular conversion (EOC) event and injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set. The software can clear the EOC flag either by programming it to 1 or by reading ADC_DR. If ADC_DR FIFO is not emptied, the EOC flag is set again and an interrupt can be generated again.

The ADC sets the JEOC flag as soon as new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if the JEOCIE bit is set. The software can clear the JEOC flag either by programming it to 1 or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of the sampling phase by setting the EOSMP flag (for regular conversions only). The EOSMP flag is cleared by software by programming it to 1. An interrupt can be generated if the EOSMPIE bit is set.

21.4.23 End of conversion sequence (EOS, JEOS)

The ADC notifies the application at the end of each regular sequence (EOS) and injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the conversion of the last data of the regular sequence is complete. An interrupt can be generated if the EOSIE bit is set. The EOS flag is cleared by the software by programming it to 1.

The ADC sets the JEOS flag as soon as the conversion of the last data of the injected sequence is complete. An interrupt can be generated if the JEOSIE bit is set. The JEOS flag is cleared by the software by programming it to 1.

21.4.24 Timing diagram examples (single/continuous modes, hardware/software triggers)

21.4.25 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS[a], JLSHIFT[a], USAT, SSAT, POSOFF)

Data and alignment

At the end of each regular channel conversion (when an EOC event occurs), the result of the converted data is stored in the 32-bit wide ADC_DR data register with FIFO (when OVRMOD = 0). Since the data register has eight levels of FIFO, the EOC flag is raised again as far as the FIFO is not emptied.

At the end of each injected channel conversion (when a JEOC event occurs), the result of the converted data is stored in the 32-bit wide corresponding ADC_JDRy data register.

The OVSS[3:0], LSHIFT[3:0], JOVSS[3:0], and JLSHIFT[3:0] bitfields in the ADC_CFGR2 register select the alignment of the data stored after the conversion. By default, data are right-aligned. Refer to *Figure 103*, *Figure 104*, *Figure 105*, and *Figure 106* for examples of data alignment.

Note: The data can be aligned in normal and oversampling mode. The OVSS[3:0] bitfield is only effective in oversampling mode.

JOVSS[3:0] and JLSHIFT[3:0] is reserved for injected conversions. Their usage is the same as OVSS[3:0] and LSHIFT[3:0], unless otherwise specifically described.

Offset

An unsigned offset value y (y = 1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in the OFFSET[21:0] bitfield of the ADC_OFRy register. The channel to which the offset is applied is programmed to the OFFSETy_CH[4:0] bits of ADC_OFCFGRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSET[21:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example the maximum offset value is 0xFFF in 12-bit mode).

The offset can be used to convert unsigned data to signed data (for example the offset value is equal to 0x800 in 12-bit mode).

The offset correction is also supported in oversampling mode. In this mode, the offset is subtracted when all the oversampling operations are complete.

Note: If the OFFSET channel is selected but the offset value is 0x0000, this offset programming is ignored. If the same OFFSET channel is programmed in different registers multiple times, the first programmed register takes priority.

Table 148 describes how the computation is performed for all the possible ADC resolutions and offset settings.

a. Only for products that include this bit.

Table 143. Offset computation versus data resolution

Resolution (RES[1:0] bits)	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed or unsigned 24-bit data, right aligned to [11:0]	-
01: 10-bit	DATA[11:2],00	OFFSET[11:2]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	OFFSET[11:4]	Signed or unsigned 24 bit data right aligned to [7:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	OFFSET[11:6]	Signed or unsigned 24 bit data right aligned to [5:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 103, *Figure 104*, *Figure 105* and *Figure 106* show alignments for signed and unsigned data. JOVSS and JLSHIFT are not described here, but they behave the same as OVSS and LSHIFT.

Figure 103. Right alignment (offset disabled, unsigned value)

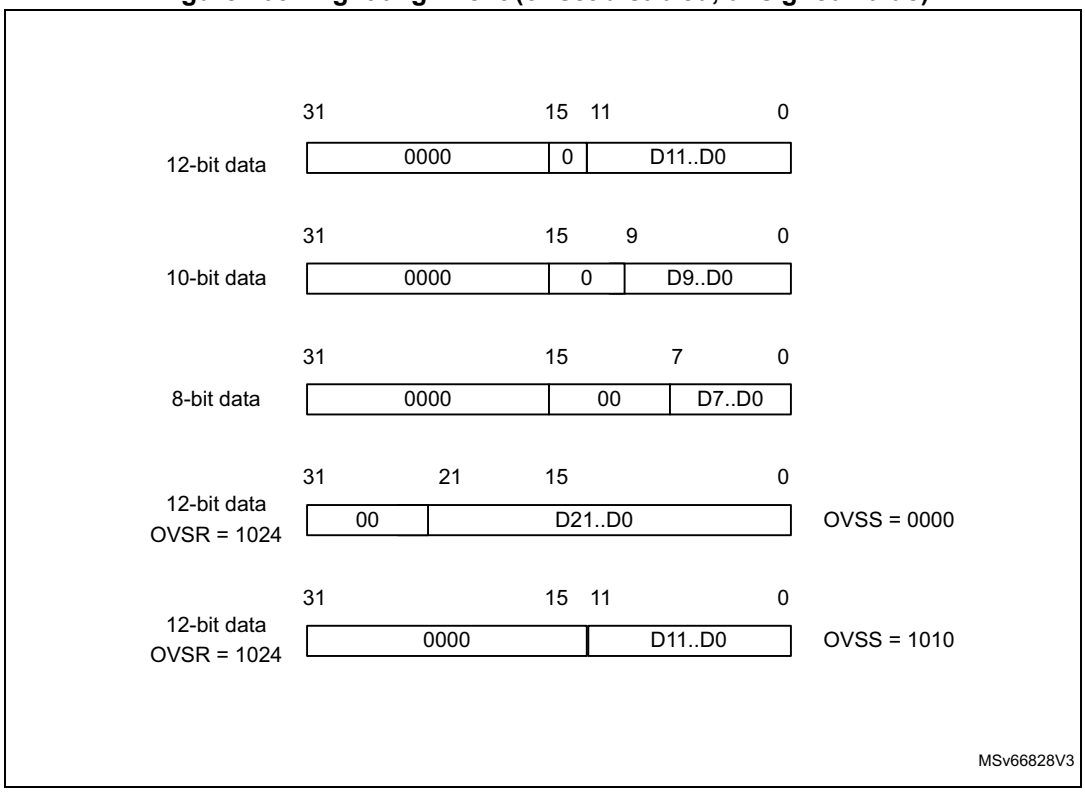

Figure 104. Right alignment (offset enabled, signed value)

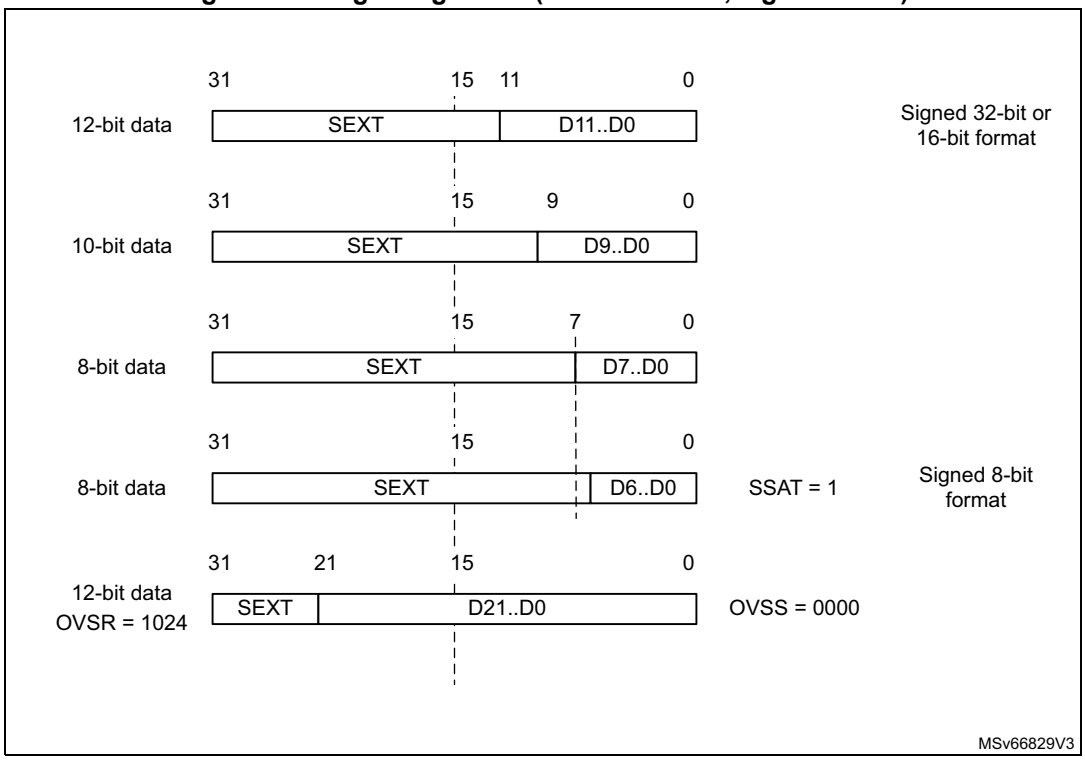

Figure 105. Left alignment (offset disabled, unsigned value)

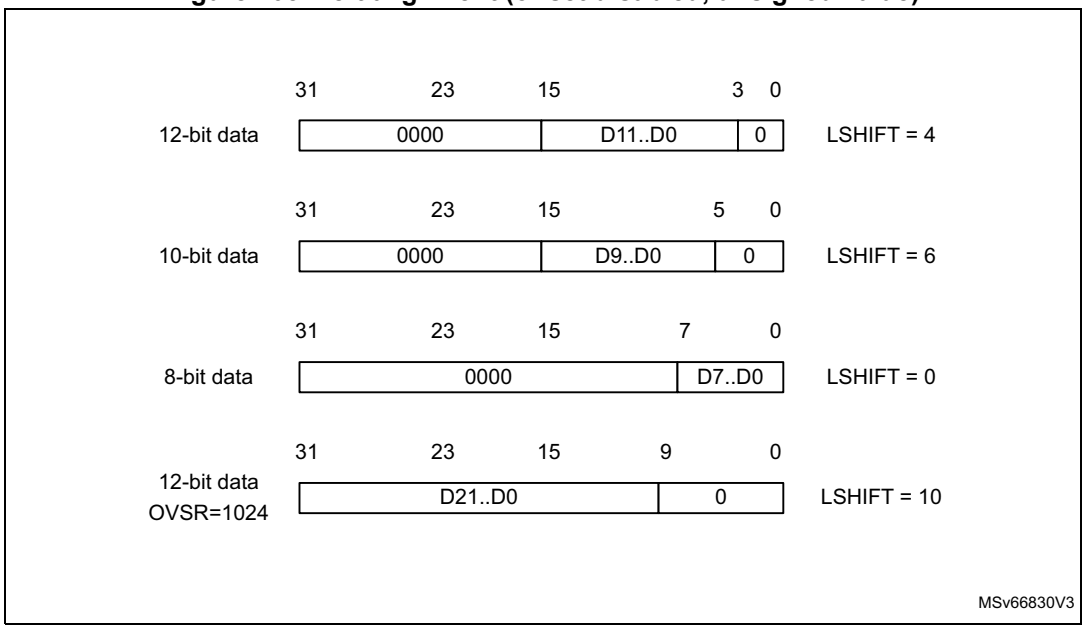

Figure 106. Left alignment (offset enabled, signed value)

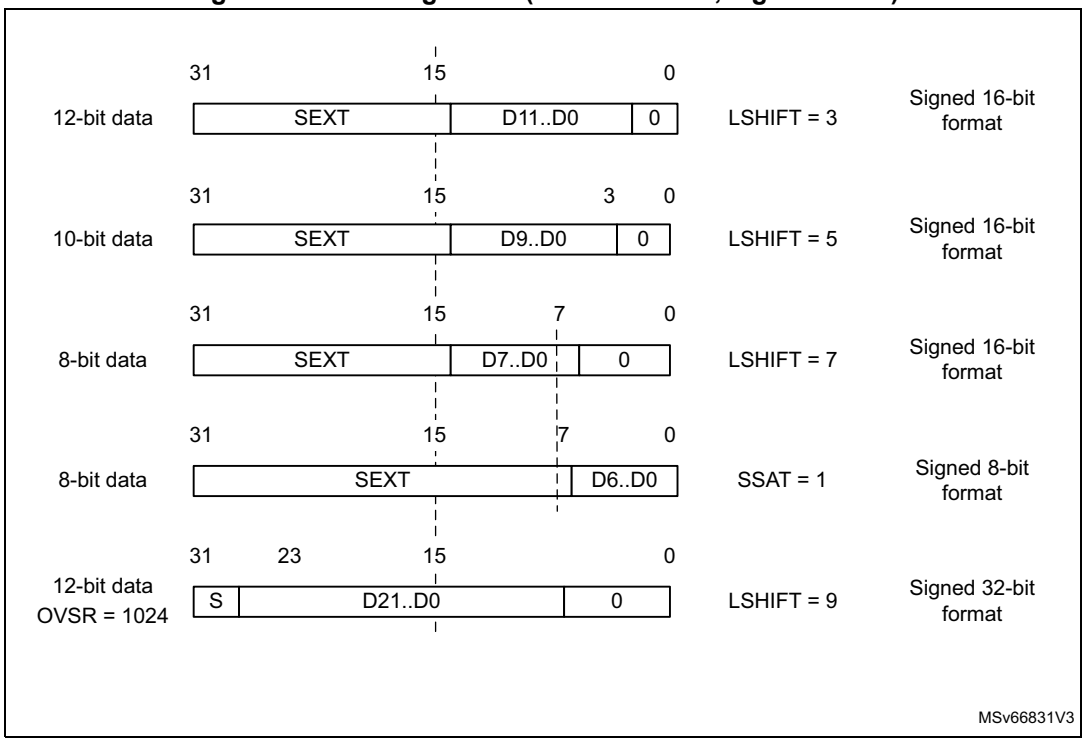

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original data width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFCFGRy register.

Unsigned 12-bit data can be extended to 13-bit signed data by using an offset value different from 0x800.

The original data width can be preserved by setting SSAT bit to limit the data width to 12 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

Table 144 shows the sign-extended data format corresponding to different resolutions.

Table 144.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	0	Sign-extended 13-bit significant data: SEXT[31:13] DATA[12:0]	0x0000 07FF - 0xFFFF F800
1	0	Sign-extended 12-bit significant data: SEXT[31:12] DATA[11:0]	0x7FF - 0x800

Table 144.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	1	Unsigned saturation 12-bit signification data: DATA[11:0]	0xFFF - 0x000
1	1	Reserved	-

Table 145 provides numerical examples for four different offset values.

Table 145. Numerical examples for 32-bit or 16-bit format (POSSPFF = 0)

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0xFFF	0x800	0x0000 07FF	0x07FF	0x07FF
0x800		0x0000 0000	0x0000	0x0000
0x000		0xFFFF F800	0x0000	0xF800
0xFFF	0x820	0x0000 07DF	0x07DF	0x07DF
0x800		0xFFFF FFE0	0x0000	0xFFE0
0x000		0xFFFF F7E0	0x0000	0xF7E0
0xFFF	0x7E0	0x0000 081F	0x081F	0x07FF
0x800		0x0000 0020	0x0020	0x0020
0x000		0xFFFF F820	0x0000	0xF820
0xFFF	0x020	0x0000 0FDF	0x0FDF	0x0FDF
0x800		0x0000 07E0	0x07E0	0x07E0
0x000		0xFFFF FFE0	0x0000	0xFFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this condition is respected.

Gain compensation

When the GCOMP bit is set in the ADC_GCOMP register, the gain compensation is activated on all the converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATAx or JDATAx bitfields, the LSB - 1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used in oversampling mode, the gain calculation is performed after the accumulation and

right-shift operations to minimize the power consumption (the gain calculation is done only once and not at each conversion).

The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode, the ROVSM bit of the ADC_CFGR2 register must be set to resume the pending conversion with the correct value.

When the gain compensation is activated, the ADC data latency is increased by one clock cycle. In continuous and scan conversion modes, the ADC conversion rate does not change.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) issues a notification that the regular converted data has not been read (by the CPU or the DMA) before the ADC_DR FIFO (eight stages) is overflowed, or adc_hclk clock is too slow to manage the data. If the CPU clears the EOC flag without reading the data register, the OVR flag may still be triggered.

The OVR flag is set when a new conversion completes while ADC_DR as single register or FIFO output is full. An interrupt is generated if the OVRIE bit is set.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP. The OVR flag is cleared by software by programming it to 1.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data are maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data is also discarded. The FIFO can be emptied through ADC_DR read access by the CPU while the OVR flag is set.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data. In this mode, DMA burst mode cannot be supported.

Figure 107. Example of overrun (OVRMOD = 0)

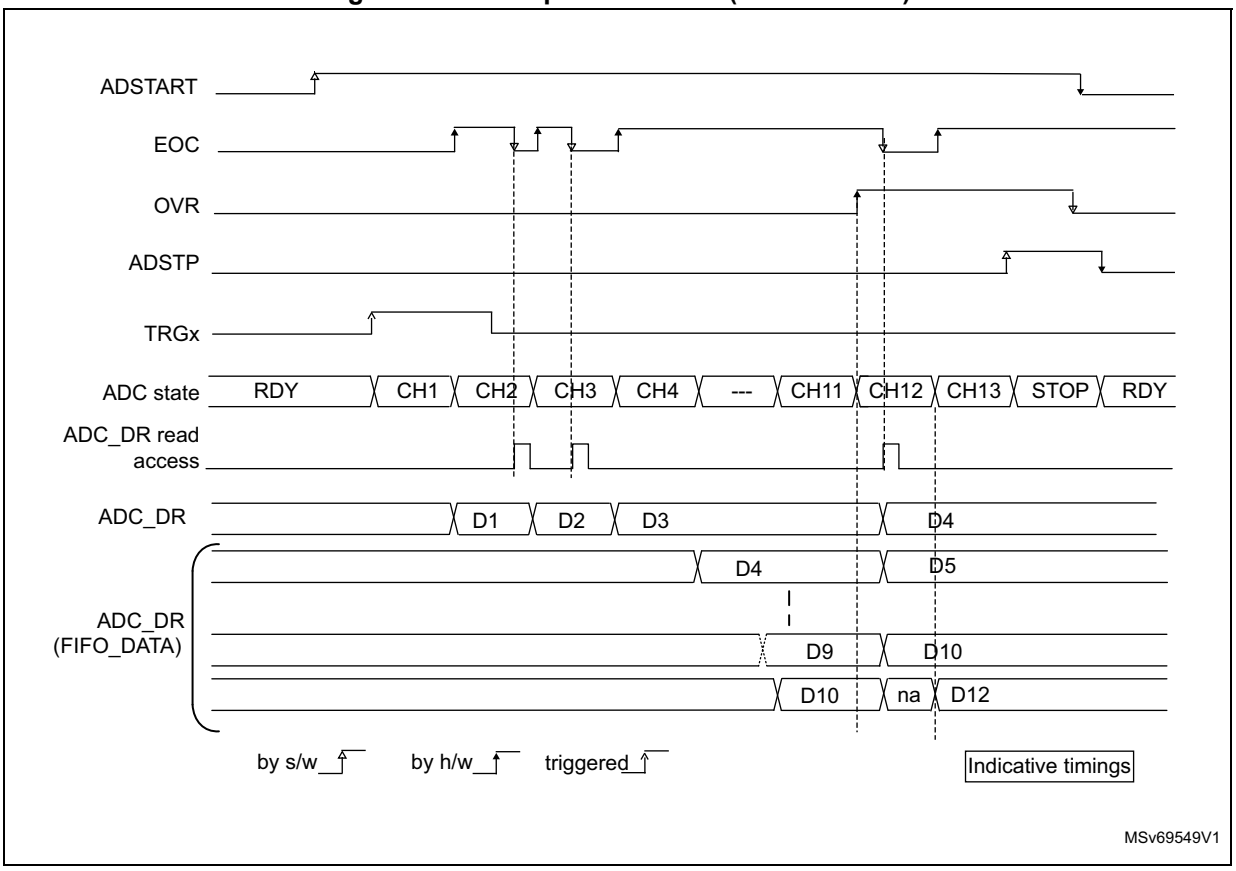

Figure 108. Example of overrun (OVRMOD = 1)

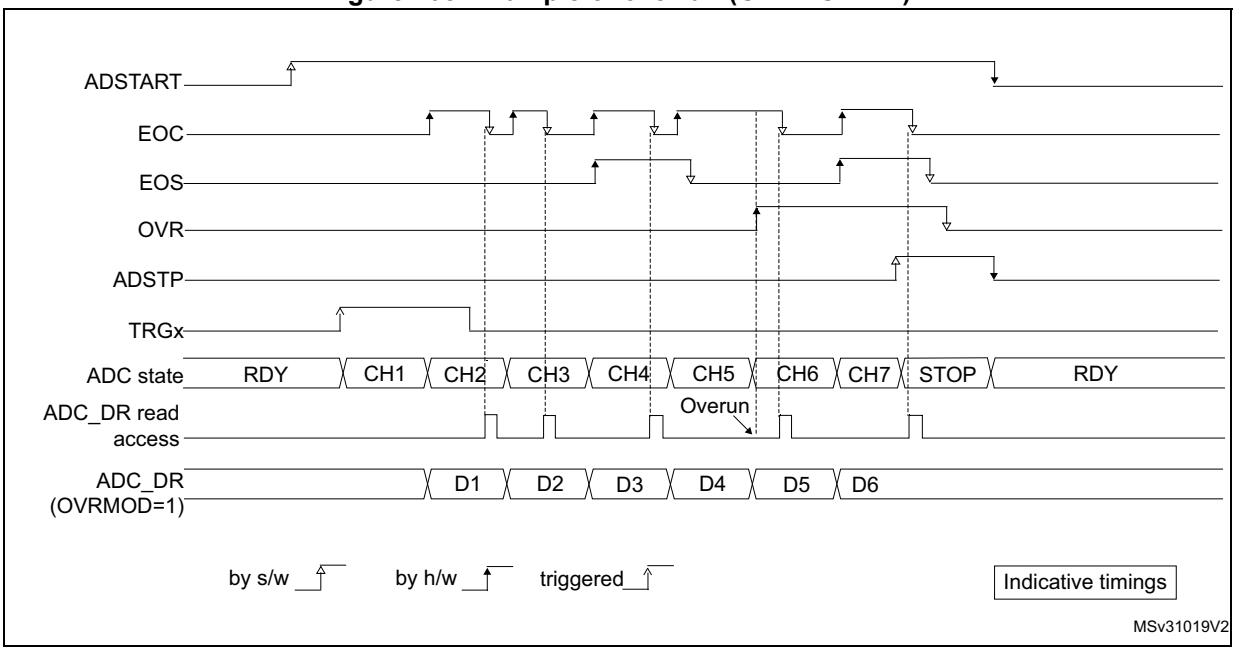

Note: Even if overrun may occur for injected channels, there is no overrun detection on these channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR1 register in single ADC mode), a DMA request is generated after each channel conversion. This allows the transfer of the converted data from the ADC_DR register to the destination location configured in the DMA.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA, which means that all the data transferred to the RAM can be considered as valid. (OVRMOD = 0).

When OVRMOD = 1, even if DMA does not transfer the data immediately, new data overwrite ADC_DR, causing DMA to potentially skip data. As a result, some conversion results may be missed in the data transferred to RAM.

Depending on the configuration of the OVRMOD bit, the data are either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*). If OVRMOD = 0 (data preserved), DMA transfer requests are blocked.

DMA can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register. Refer to *Section 21.4.29: Dual ADC modes* for information on DMA usage with dual ADC mode.

- DMA one-shot mode (DMNGT[1:0] = 01)

  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)

  This mode is suitable when programming the DMA when the number of transfers is unknown.

DMA one-shot mode (DMNGT[1:0] = 01)

In one-shot mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (that is when DMA_LACK interrupt occurs, see *Direct-memory controller* section) even if a new conversion has been started.

When DMA transfers are complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- All ongoing conversions are aborted with the partial result discarded.
- The scan sequence is stopped and reset.
- The DMA and ADC are stopped.

DMA circular mode (DMNGT[1:0] = 11)

In circular mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register. This allows the configuration of the DMA in circular mode to handle a continuous analog input data stream.

DMA single-transfer or burst mode with FIFO (OVRMOD = 0)

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. The DMA can be programmed either in single-transfer mode or in burst mode (four beats). The appropriate request line is selected by the DMA according to the mode selected. Refer to *Section Direct memory access controller* for further information.

Due to the existence of FIFO, DMA requests are generated until the FIFO is emptied. To stop DMA requests even when the FIFO is not emptied, set the ADSTP bit.

DMA for dual mode

Refer to *Section 21.4.29: Dual ADC modes*.

21.4.26 Dynamic low-power features

Autodelayed conversion mode (AUTDLY)

The ADC implements an autodelayed conversion mode controlled by the AUTDLY configuration bit in ADC_CFGR1. Autodelayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there must be risk of encountering an ADC overrun.

Regular conversion mode

When AUTDLY is set, a new conversion can start if the following conditions are met:

- The ADC_DR register is read or the EOC bit is cleared (see *Figure 109*).

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data and prevent overrun errors.

The delay is inserted after each regular conversion.

Injected conversion mode

When AUTDLY is set, a new conversion can start only if the JEOS bit has been cleared (see *Figure 110*). Since there are four ADC_JDRy registers, the autodelay is performed at the end on the injected conversion sequence.

There is no delay inserted between each conversion of the injected sequence, except after the last one.

A hardware trigger event occurring during this delay is ignored.

No delay is inserted between regular and injected conversions. The autodelay for regular and injected modes is managed separately.

Caution: The behavior is slightly different in autoinjection mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 113*).

In autoinjection mode, there is no delay between the last regular conversion and the first injected conversion. The user must clear the last EOC flag before clearing the JEOS flag, otherwise the next sequence might start before EOC flag is cleared.

In autodelay mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In autodelay mode with JAUTO = 0, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

Note: AUTDLY mode is not supported with SMPTRIG or BULB mode.

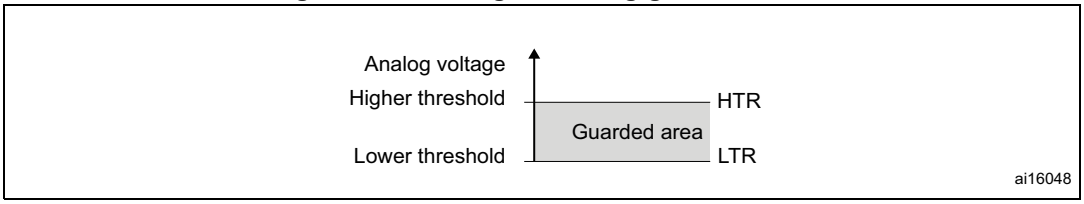
21.4.27 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)

Table 146. Analog window watchdog features

Feature	AWD1	AWD2	AWD3
Enable control	AWD1EN or JAWD1EN	ADC_AWD2CR	ADC_AWD3CR
Channel selection	AWD1CH[4:0]/AWD1SGL	ADC_AWD2CR	ADC_AWD3CR
Channel selection limitation	One or all channels	Any number of channels	
	Regular or injected	-	-
Threshold control	ADC_AWD1LTR / ADC_AWD1HTR	ADC_AWD2LTR / ADC_AWD2HTR	ADC_AWD3LTR / ADC_AWD3HTR
Filter configuration	AWDFILT[2:0] in ADC_AWDyHTR		
Interrupt	AWDy in ADC_ISR		

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 114. Analog watchdog guarded area



AWDy flag and interrupt

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it, or by setting ADDIS.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN or JAWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 147 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 147. Analog watchdog 1 channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog flag is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed through HTR[22:0] bits of the ADC_AWD1HTR register and LTR[22:0] bits of the ADC_AWD1LTR register for the analog watchdog 1.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024, offset and gain compensation)

When converting data with a resolution of less than 12 bits (defined by RES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data.

Table 148 describes how the comparison is performed for all the possible resolutions and for analog watchdog 1.

Table 148. Analog watchdog 1, 2, 3 comparison

Resolution (RES[1:0] bits)	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 12-bit	DATA[11:0]	LTR[22:0] and HTR[22:0]	-
01: 10-bit	DATA[11:2],00	LTR[22:0] and HTR[22:0]	The user must configure LTR[1:0] to 0b00 and HTR[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	LTR[22:0] and HTR[22:0]	The user must configure LTR[3:0] to 0b0000 and HTR[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	LTR[22:0] and HTR[22:0]	The user must configure LTR[5:0] to 0b000000 and HTR[5:0] to 0b000000.

1. Refer to *Section : Gain compensation* for additional details on analog watchdog comparison.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCH[13:0] (of ADC_AWD2CR and ADC_AWD3CR).

The corresponding watchdog is enabled when any bit of AWDCH[13:0] (of ADC_AWD2CR and ADC_AWD3CR) is set.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024 and offset compensation in signed format with gain compensation) and is programmed through the ADC_AWD2HTR, ADC_AWD2LTR, ADC_AWD3HTR and ADC_AWD3LTR registers.

When converting data with a resolution of less than 12 bits (defined by RES[1:0]) bits), the LSBs of the programmed threshold must be kept cleared, the internal comparison being performed on the full 12-bits converted data (left aligned).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADC_AWDy_OUT (*y* being the watchdog number), which is directly connected to the ETR input (external trigger) of some of the on-chip timers. Refer to the on-chip timers sections to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion that is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS). Note that stopping regular or injected conversions (by setting ADSTP or JADSTP) has no influence on the generation of ADCx_AWDy_OUT.

Note: The AWDy flag is set by hardware and reset by software: the AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADC_AWDy_OUT can toggle while the AWDy flag remains at 1 if the software did not clear the flag).

The AWDy flag is cleared by programming it to 1 or by set ADDIS bit. ADSTP and JADSTP bits do not reset the AWDy flag.

Figure 115. ADC_AWDy_OUT signal generation (on all regular channels)

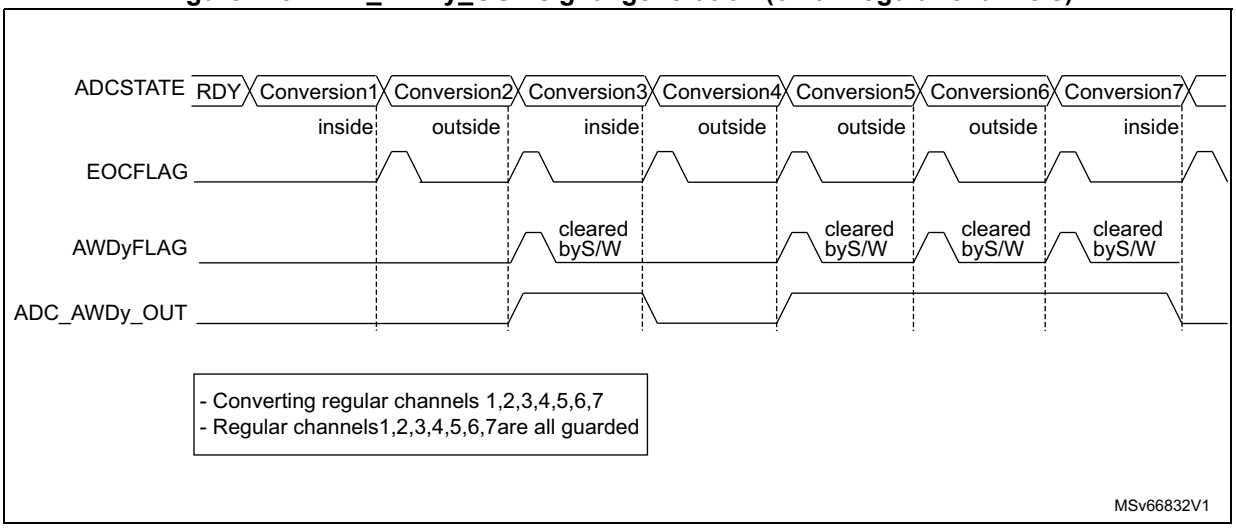


Figure 116. ADC_AWDy_OUT signal generation (AWDy flag not cleared by software)

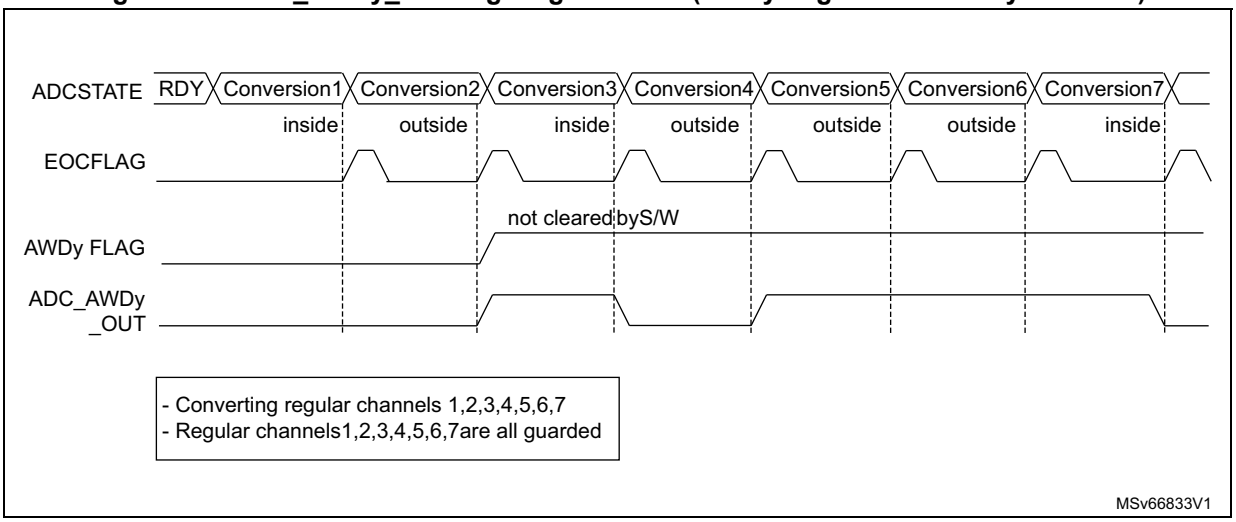

Figure 117. ADC_AWDy_OUT signal generation (on a single regular channel)

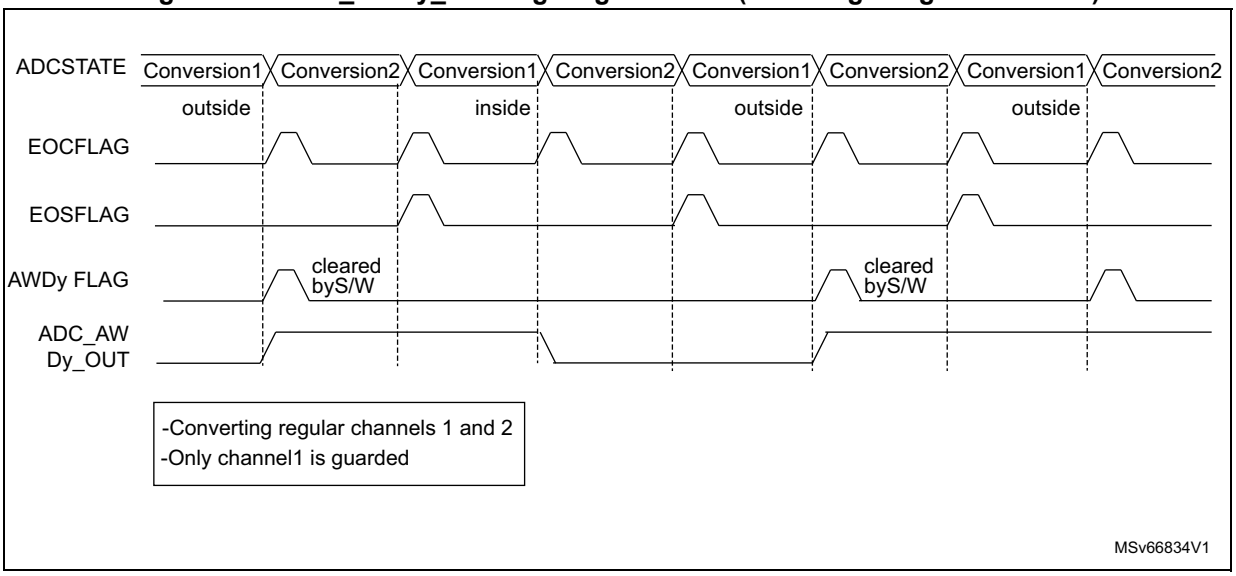

Figure 118. ADC_AWDy_OUT signal generation (on all injected channels)

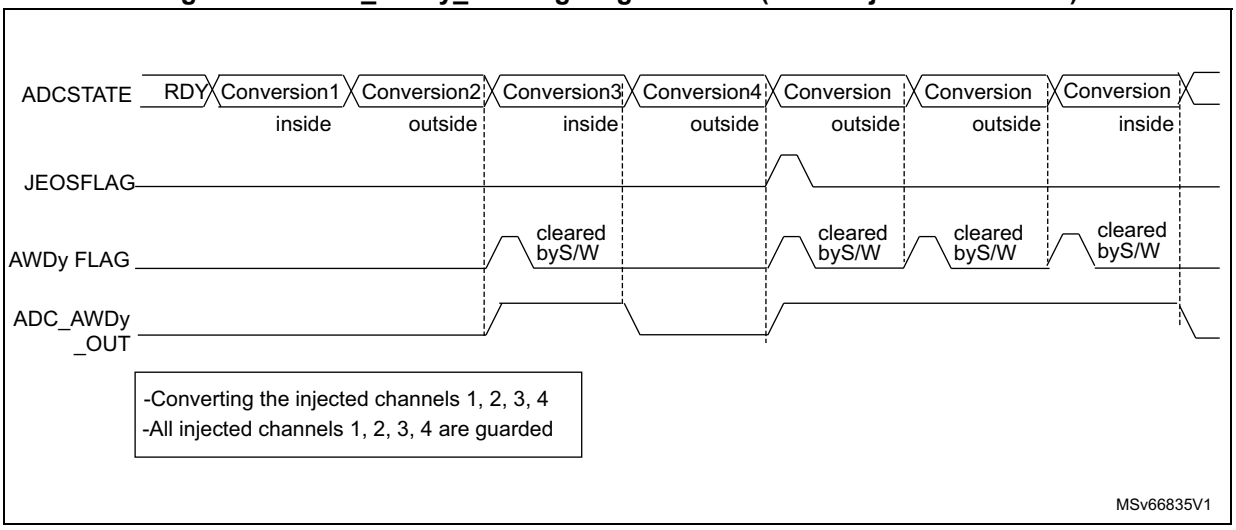

Analog watchdog threshold control on the fly

LTR[22:0] and HTR[22:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTR[22:0] and HTR[22:0] are updated during the ADC conversion of the ADC guarded channel, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new modified threshold, no interrupt and AWDy_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion that started after the threshold update. If AWDy_OUT is already asserted, programming the new thresholds does not deassert the AWDy_OUT signal. However, the watchdog threshold must not be changed twice during the four adc_ker_ck periods.

Analog watchdog filter for watchdog 1

With analog watchdog, a valid ADC conversion data range can be configured through the ADC_AWD1LTR and ADC_AWD1HTR registers. When the conversion results have consecutively passed the threshold for more than the watchdog filter value (AWDFILT[2:0] + 1), AWD1_OUT is generated as well as the AWD1 flag. Before this value is reached, AWD1 output is not activated.

Analog watchdog with gain and offset compensation

When the gain and offset compensation are enabled, the analog watchdog compares the data after the compensation.

21.4.28 Oversampler

The oversampling unit performs data preprocessing to offload the device. It is able to handle multiple conversions and average them into a single data with increased data width, up to 22 bits.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement and basic filtering.

The oversampling ratio N is defined by the OVSR[9:0] bits in the ADC_CFGR2 register, or by the JOVSS[3:0] bits in the ADC_CFGR3 register for parallel injected oversampling mode. They can range from 2x to 1024x. The division coefficient *M* consists of a right bit shift up to 10 bits. It is defined through the OVSS[3:0] bits of the ADC_CFGR2 register.

The summation unit can yield a result up to 22 bits, which can be left or right shifted at the end. When the right shift is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred to the ADC_DR data register.

Figure 119 gives a numerical example of the processing, from a raw 22-bit accumulated data to the final 12-bit result.

Figure 119. 12-bit result oversampling with 10-bit right shift and rounding

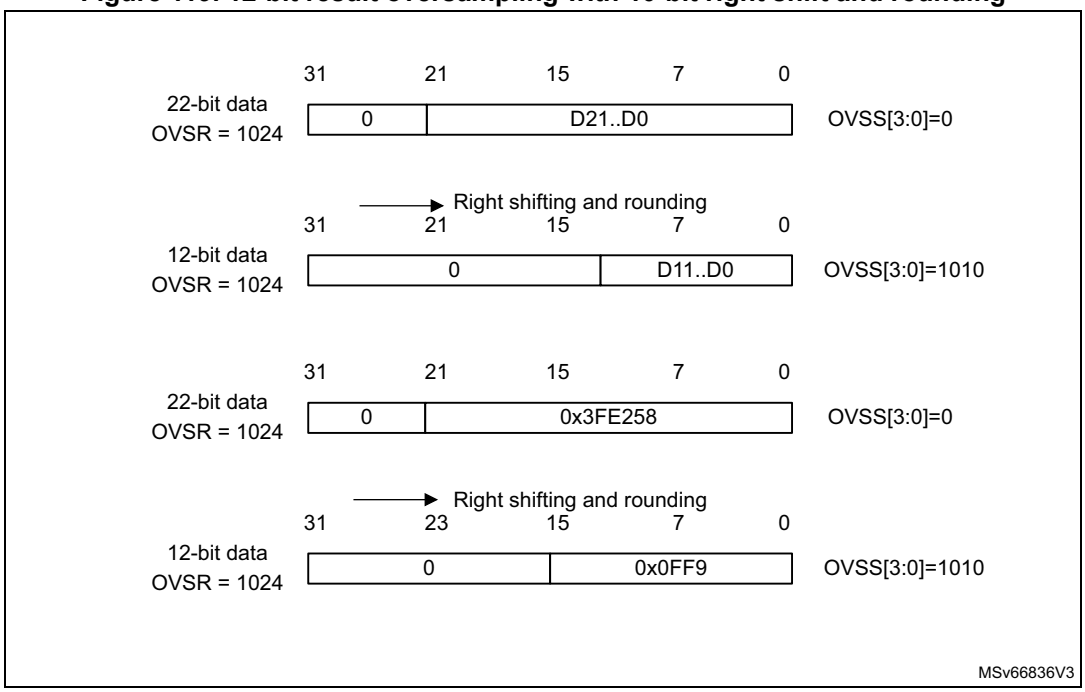

Table 107 gives data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 149. Maximum output results versus N and M

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS =0111	8-bit shift OVSS = 1000

The conversion timing rate does not change in oversampling mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversion, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase for regular conversion.
- The end of conversion (EOC) occurs once every N conversion, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after a total of N x sequence length conversions).

Unlike the conversion rate, the data latency changes in oversampling mode: each single conversion introduces an additional accumulation. As a result, an additional clock cycle is required when all the conversions are complete, after the accumulation and shift.
The EOC flag is set two additional clock cycles after the conversion is complete.

ADC operating modes supported in oversampling mode (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

- Single, discontinuous, or continuous conversion modes
- ADC conversions started either by software or triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits of the ADC_CFGR1 register) are accumulated, truncated, rounded, and shifted in the same way as 12-bit conversions are.
- Autoinjected mode (JAUTO) if JOVSPAR = 0 and oversampling ratio is the same for both regular and injected channels.

Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored and the comparison is always done using the full 23-bit values HTR[22:0] and LTR[22:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Triggered mode

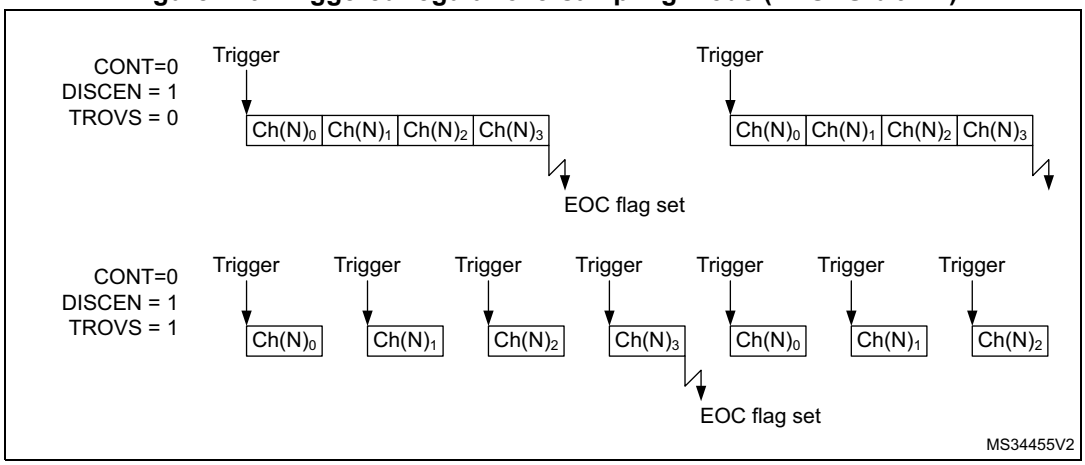
The oversampling can also be used for basic filtering purpose. Although it not a very powerful filter (slow roll-off and limited stop band attenuation), it can act as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched-mode power supply). For this purpose, a specific discontinuous mode can be enabled through the TROVS bit in ADC_CFGR2, to be able to achieve an oversampling frequency defined by the user and independent from the conversion time itself. The TROVS bit is supported with hardware trigger mode.

Figure 120 shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set and OVSR ≠ 0, the content of the DISCEN bit is ignored and considered as 1.

If the TROVS bit is set, neither software trigger nor JAUTO is supported.

Figure 120. Triggered regular oversampling mode (TROVS bit = 1)



Injected and regular sequencer management in oversampling mode

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode ROVSM bit defines how the regular oversampling sequence is resumed if it is interrupted by an injected conversion:

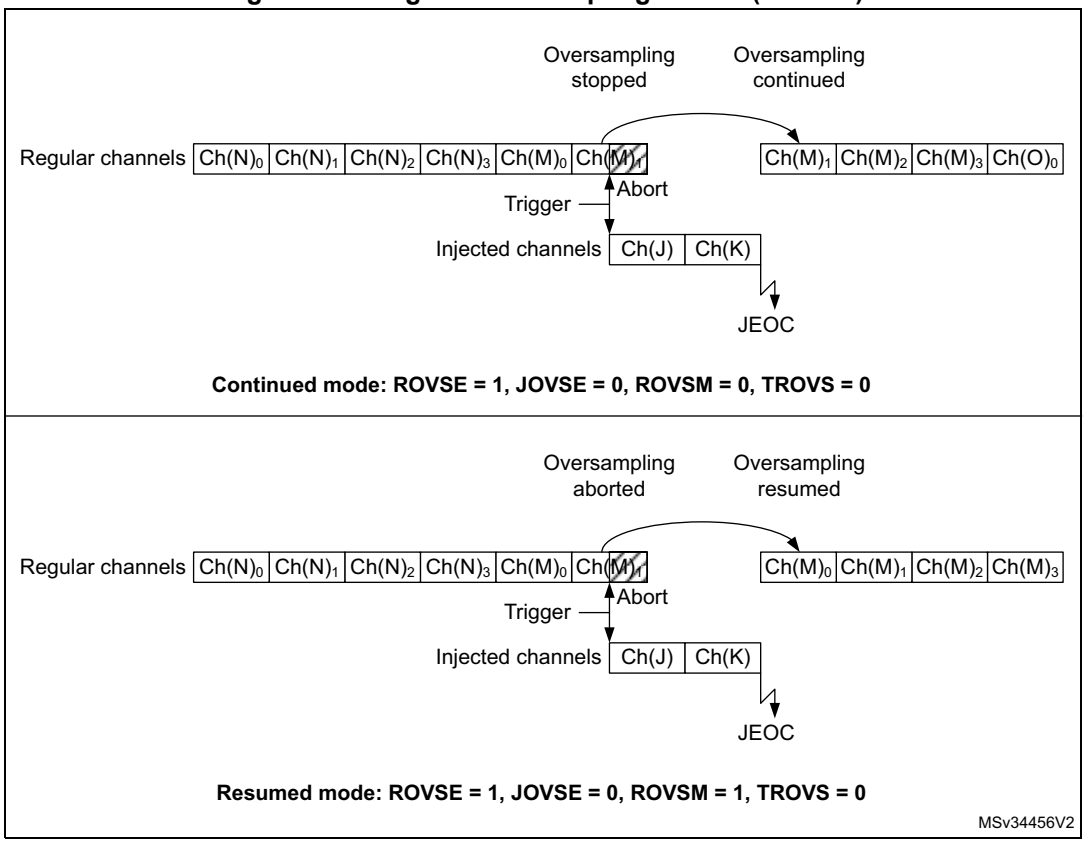
- In continuous mode (ROVSM = 0), the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that

oversampling is complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);

- In resumed mode (ROVSM = 1), the accumulation restarts from 0 (previous conversion results are ignored). This mode guarantees that all the data used for oversampling were converted back-to-back within a single time slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequence is blocked.

Figure 121 gives examples for a 4x oversampling ratio.

Figure 121. Regular oversampling modes (4x ratio)



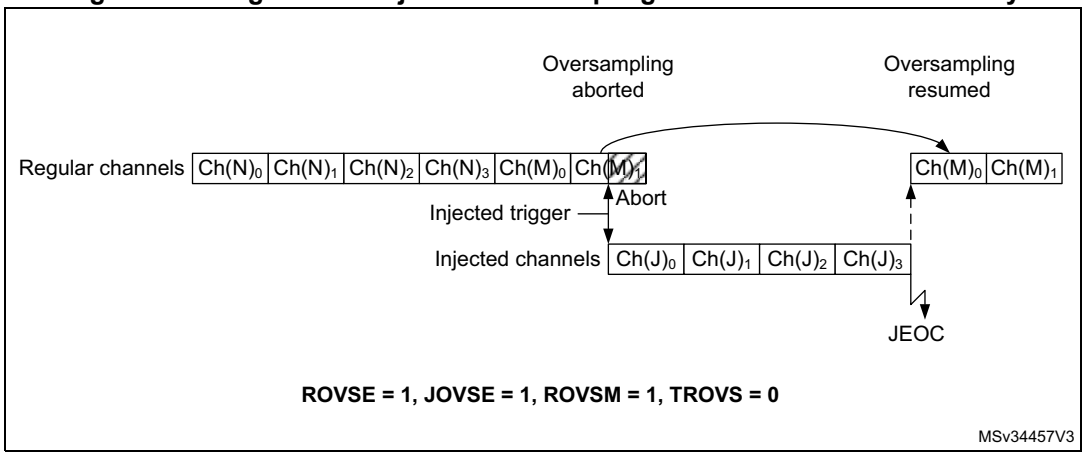
Oversampling injected channels only

The injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling must be resumed (ROVSM bit = 1), as shown in *Figure 122*. This limitation no longer applies in parallel injected oversampling mode.

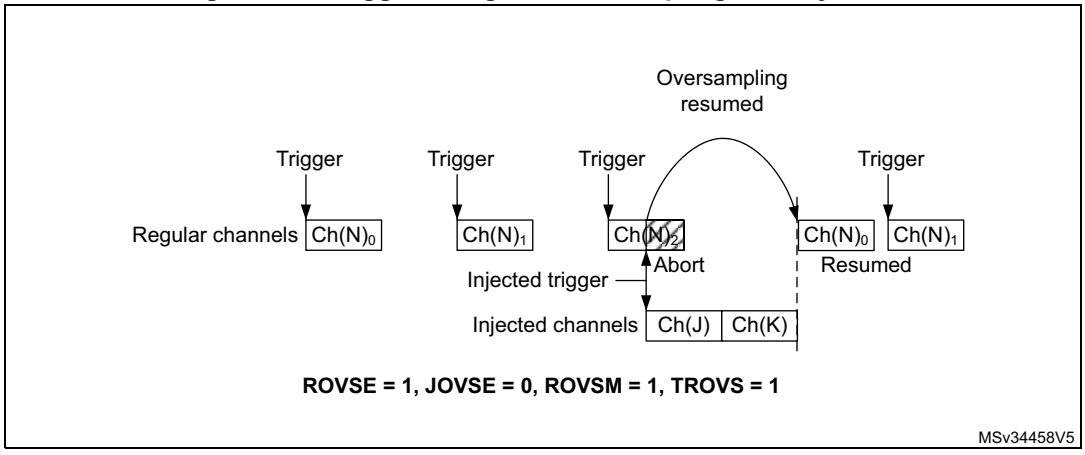
Figure 122. Regular and injected oversampling modes used simultaneously



Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected oversampling mode must be disabled and the ROVSM bit set (the resumed mode is forced). The JOVSE bit must be reset. The behavior is shown in *Figure 123*.

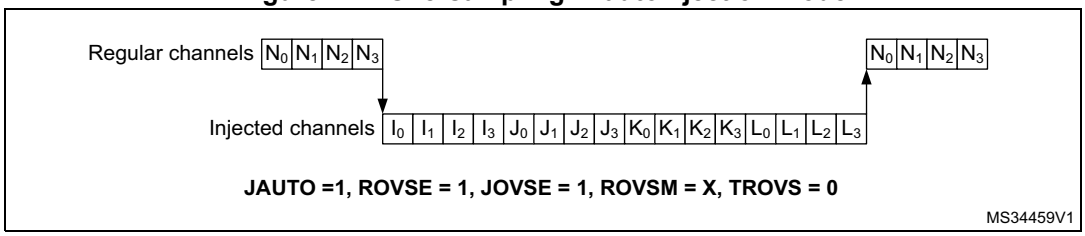
Figure 123. Triggered regular oversampling with injection



Autoinjection mode

It is possible to oversample autoinjected sequences and store all conversion results in registers. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in autoinjection mode. *Figure 124* shows how the conversions are sequenced.

Figure 124. Oversampling in autoinjection mode



Combined modes summary

Table 150 summarizes all combinations, including the modes that are not supported.

Table 150. Oversampler operating mode summary

Regular oversampling ROVSE	Injected oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

21.4.29 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 125*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADC master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when the DUAL[4:0] bits in the ADCC_CCR register are not equal to zero), the following bits are shared between the master and slave ADCs, with the slave ADC bits being ignored and always applying to the corresponding bits of the master ADC:

- ADC_CFGR1 register: DMNGT[2:0], RES[1:0], EXTEN[1:0], OVRMOD, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JAUTO, JDISCEN.
- ADC_CFGR2 register: ROVSE, JOVSE, TROVS, ROVSM, BULB, SWTRIG, SMPTRIG, OVSR[9:0].
- ADC_GCOMP register: GCOMP.
- ADC_CR register: ADSTART, ADSTP, JADSTART, JADSTP.
- ADC_CFGR1 register: CONT, DISCEN, DISCNUM[2:0].
- ADC_SQR1 register: LEN (for the regular conversion).
- ADC_JSQR register: JLEN[1:0], JEXTSEL[4:0], JEXTEN[1:0] (for the injected conversion).
- ADC_CFGR3 register: JOVSPAR, JOVSE, JOVSIVE, TJOVS, JOVSR[9:0] (for the injected conversion).

For dual mode usage, the sampling time of the master and slave channels must be equal.

To start a conversion in dual mode, the user must program the EXTEN[1:0], EXTSEL, JEXTEN[1:0] and JEXTSEL bits of the master ADC only to configure a software or hardware trigger and a regular or injected trigger. The EXTEN[1:0], JEXTEN[1:0], and JEXTSEL bits of the slave ADC are don’t care).

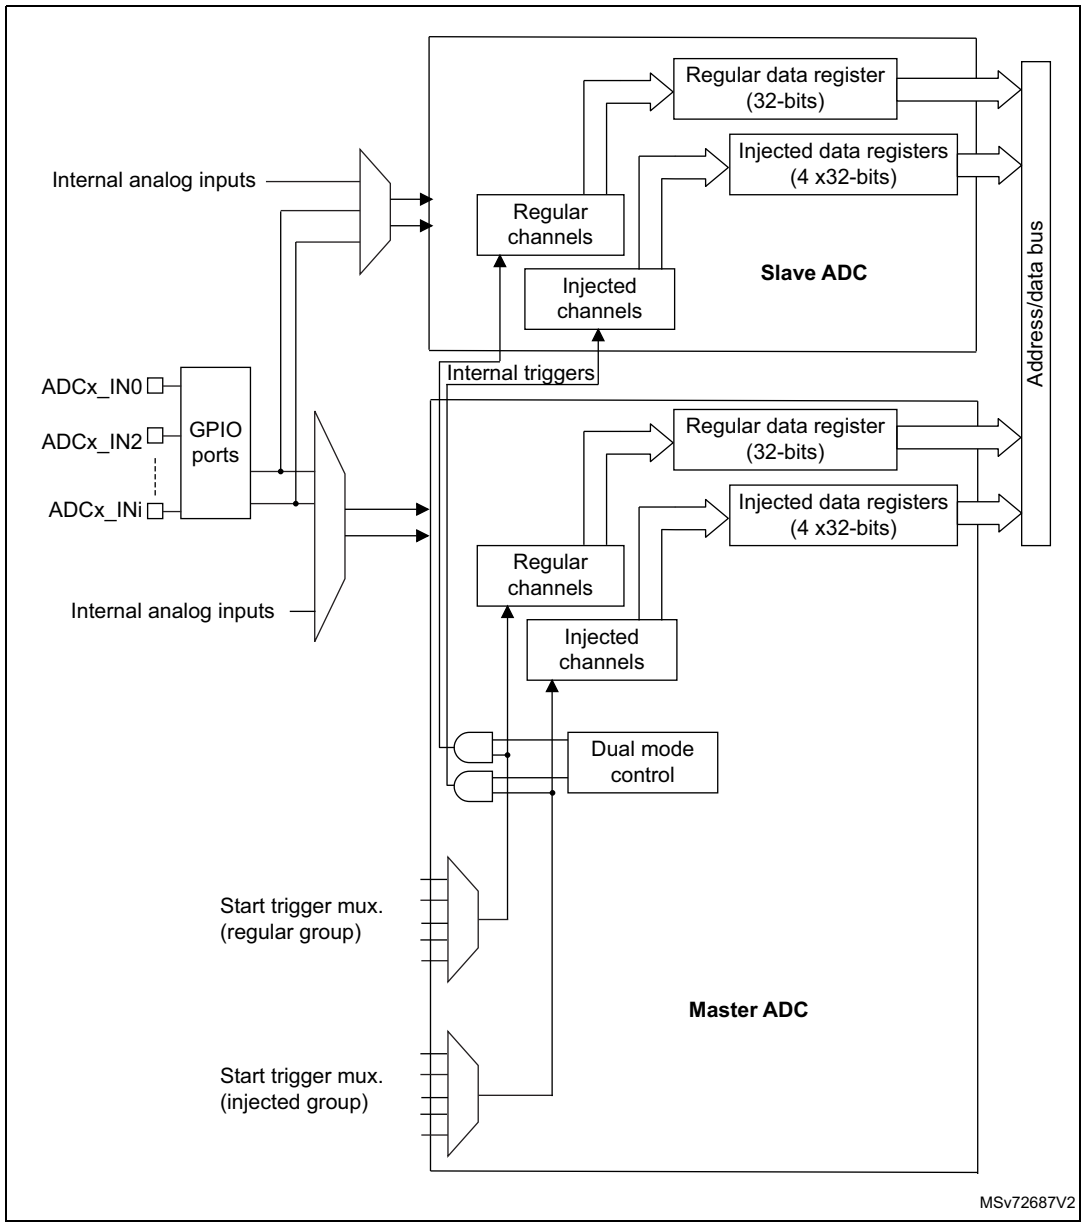
In regular simultaneous or interleaved modes, once the user sets the ADSTART or ADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, ADSTART or ADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes, once the user sets the JADSTART or JADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, JADSTART or JADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCC_CDR). The flags can also be read in parallel by reading the dual-mode status register (ADCC_CSR).

Note: In dual mode, BULB, JAUTO, SMPTRIG are not supported.

Figure 125. Dual ADC block diagram



1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode with independent regular conversion

The injected simultaneous mode is selected by programming DUAL[4:0] bits to 0b00101.

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

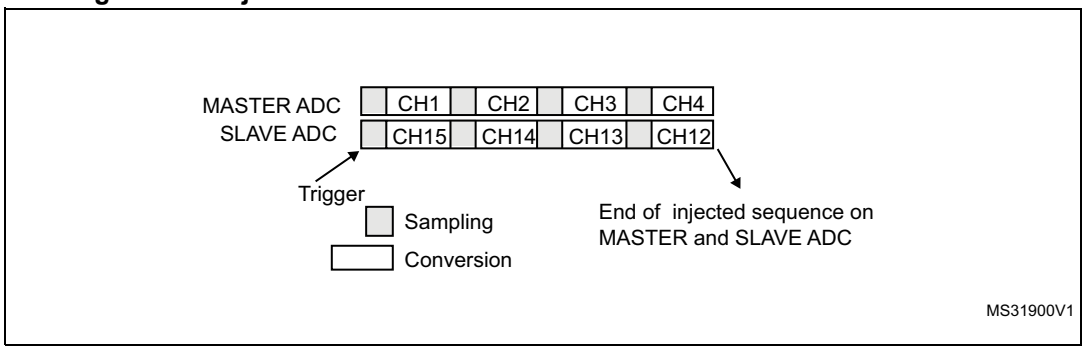
In simultaneous mode, the user software must convert sequences with the same length. Sampling times for channels with the same sequence number must be equal.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

The software is notified by interrupts when it can read the data:

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master-injected sequence is equal to the duration of the slave injected one (as shown in *Figure 126*), the software can enable only one of the two JEOS interrupts (for example the master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 126. Injected simultaneous mode on four channels: Dual ADC mode



If JDISCEN is set, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with the AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored.
  There is the same behavior for regular sequences occurring on the slave ADC.

In this mode, the following register bits are shared between the master and slave ADCs:

JADSTART, JADSTP, JDISCEN, JOVSE, JLEN, JEXTEN, JEXTSEL, GCOMPEN, JOVSECT, JOVSISE, JOVSE, and TJOVS.

Regular simultaneous mode with independent injected conversions

The regular simultaneous mode is selected by programming DUAL[4:0] bits to 0b00110.

This mode applies to a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR1 register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on the master or on the slave) aborts the current simultaneous conversions both for master and slave. They are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, the user software must convert sequences with the same length. Sampling times for channels with the same sequence number must be equal.

The software is notified by interrupts when it can read the data:

- As the duration of the master regular sequence is equal to the duration of the slave one (as shown in *Figure 127*), the software can enable only one of the two EOC interrupts (for example the master EOC) and read both converted data from the common data register (ADCC_CDR).
  The user can read data from either ADCC_CDR or ADCC_CDR2. Once software selects one of these registers, it must continue using the same register until the ADSTP procedure is executed.

The regular data can also be read using the DMA. Several methods are possible:

- Use two DMA channels (one for the master and one for the slave). In this case DAMDF[1:0] bits must be kept cleared:
  a) Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  b) Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configure the dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  a) Set DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
  b) A single DMA channel is used (the one corresponding to the master). Configure the DMA master ADC channel to read the common ADC data register (ADCC_CDR or ADCC_CDR2).
  c) A single DMA request is generated each time both the master and slave EOC events occur. At that moment:
  – The slave ADC converted data is available in the upper half-word of the 32-bit ADCC_CDR register
  – The master ADC converted data is available in the lower half-word of the ADCC_CDR register.

Alternatively, data can be read from ADCC_CDR2:

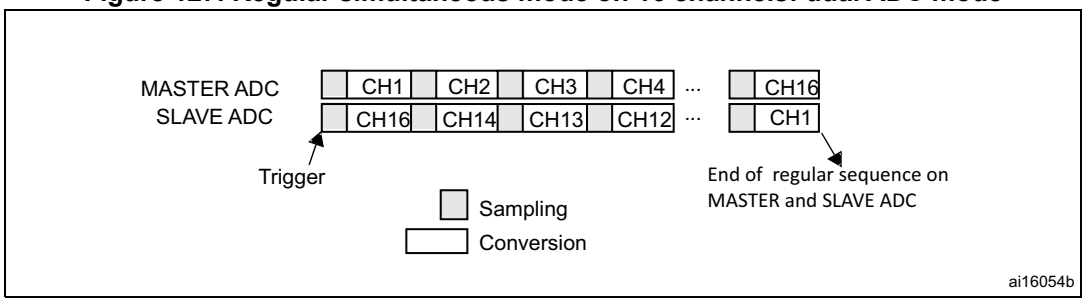
– The first read returns the master ADC data.

– The second read returns the slave ADC data.
After these reads, a DMA request is generated. The DMA transfers the slave data from the same data register and handles two transfers for dual mode operation.

d) Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Note: When DAMDF[1:0] = 0b10 or 0b11, the user must program the same number of conversions in the master and in the slave sequence. Otherwise, the remaining conversions do not generate a DMA request.

Figure 127. Regular simultaneous mode on 16 channels: dual ADC mode



If the DISCEN bit is set, each "*n*" simultaneous conversion of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with the AUTDLY mode:

- Once a simultaneous conversion of the sequence has completed, the next conversion in the sequence starts only after the EOC flag of both the master and the slave are cleared.
- Once a simultaneous regular sequence of conversions has completed, a new regular trigger event is accepted only after the EOC flag of both the master and the slave are cleared. Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

The DMA can be used to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

Interleaved mode with independent injected conversions

This mode is selected by programming DUAL[4:0] bits to 0b00111.

It can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately,
- The slave ADC starts after a delay of several ADC clock cycles after the sampling phase of the master ADC has completed (during the master ADC conversion period).

The minimum delay between two conversions in interleaved mode is configured in the DELAY bits in the ADCC_CCR register (see *Table DELAY bits versus ADC resolution*). This delay starts counting one half cycle after the end of the sampling phase of the master

conversion. This way, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

As the CONT bit is set on both the master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the master or slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Table 151. DELAY bits versus ADC resolution

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
0000	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$
0001	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$
0010	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$
0011	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$
0100	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$
0101	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
0110	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
0111	8 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1000	9 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1001	10 * $T_{adc_ker_ck}$	10 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1010	11 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1011	12 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1100	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
others	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$

Figure 128. Interleaved mode on 1 channel in continuous conversion mode: Dual ADC mode

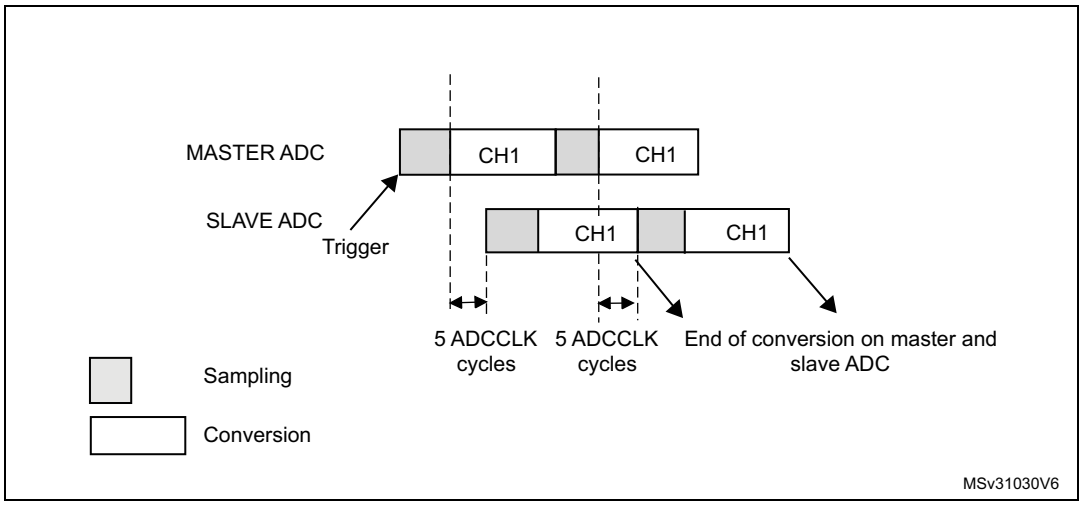


Figure 129. Interleaved mode on 1 channel in single conversion mode: Dual ADC mode

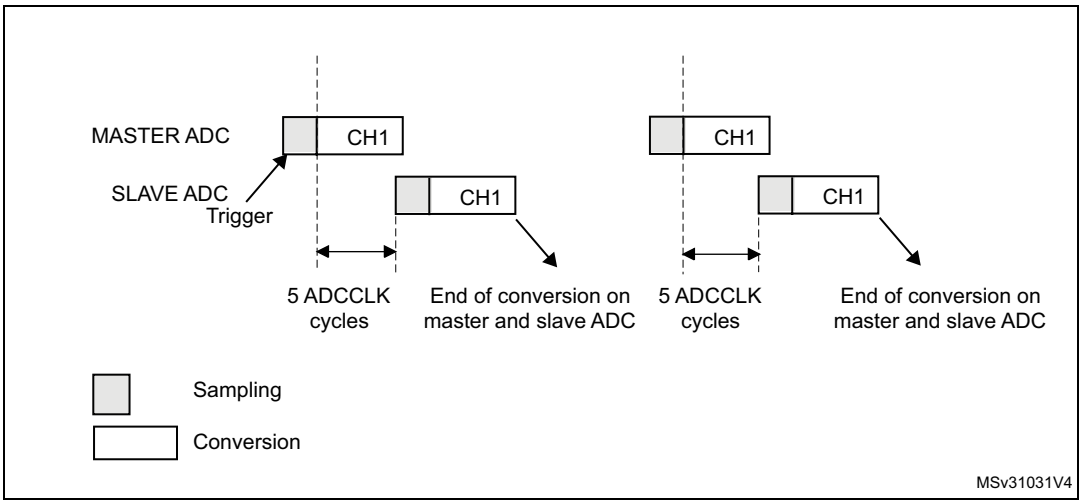


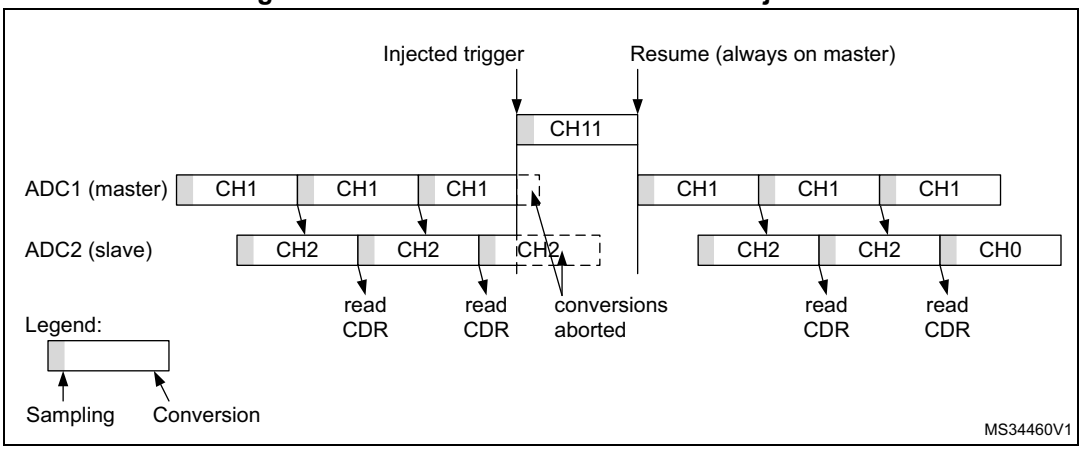
If the DISCEN bit is set, each "*n*" simultaneous conversion ("*n*" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In interleaved mode, injected conversions are supported. When injection is done (either on master or slave), both master and the slave regular conversions are aborted and the sequence is restarted from the master (see *Figure 130*).

Note: In interleaved mode, the ADCx_AWDy_OUT signal for the master ADC is synchronized with the EOC of the master ADC, but the interrupt flag is synchronized with the EOC/JEOC flag of the slave ADC.

In addition, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 130. Interleaved conversion with injection



Alternate trigger mode with independent regular conversions

The alternate trigger mode is selected by programming DUAL[4:0] bits to 0b01001.

This mode can only be started on an injected group. The source of the external trigger comes from the multiplexer injected group of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 0x0.

Injected discontinuous mode disabled (JDISCEN = 0)

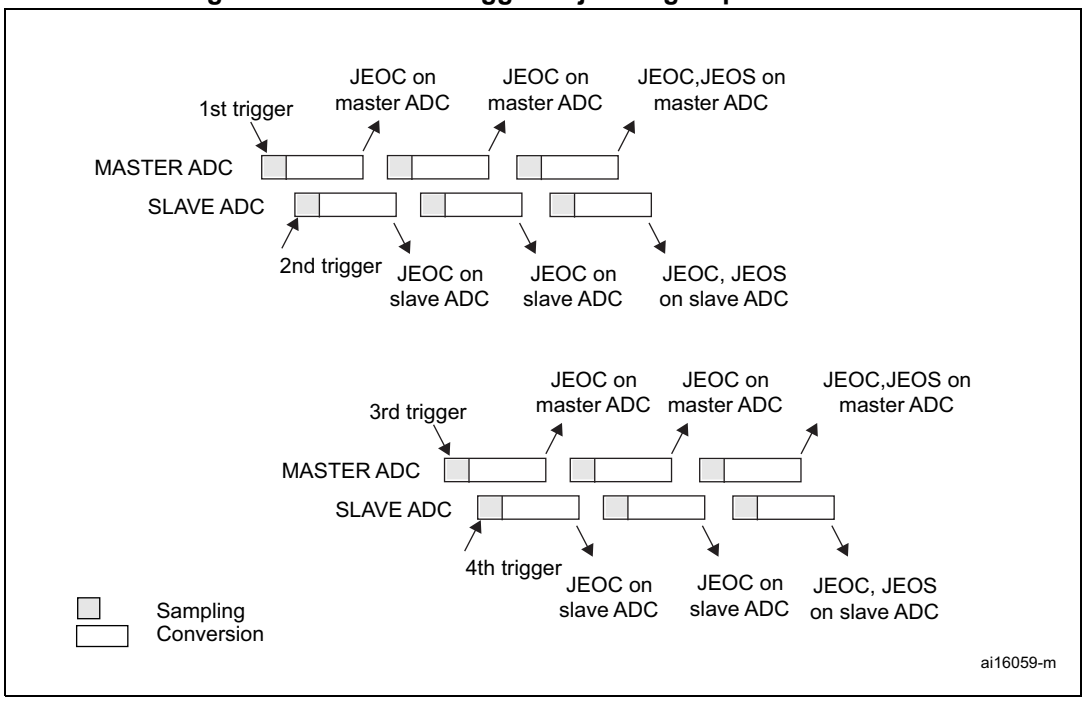
1. When the first trigger occurs, all injected master ADC channels in the group are converted.
2. When the second trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on...

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

Figure 131. Alternate trigger: injected group of each ADC



Note: Regular conversions can be enabled on one or all ADCs. In this case, the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between two trigger events must be greater than or equal to one ADC clock period. The minimum time interval between two trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1)

If the injected discontinuous mode is enabled for both master and slave ADCs:

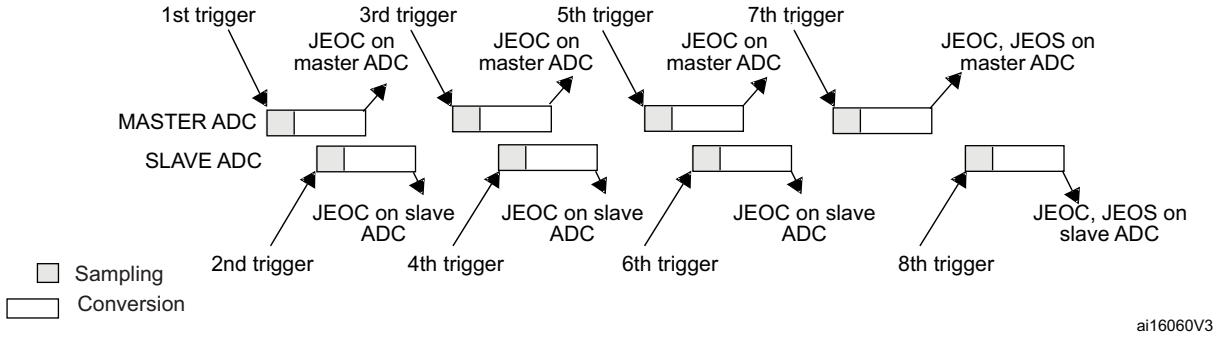
1. When the first trigger occurs, the first injected channel of the master ADC is converted.
2. When the second trigger occurs, the first injected channel of the slave ADC is converted.
3. And so on...

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

Figure 132. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode



Combined regular/injected simultaneous mode

This mode is selected by programming DUAL[4:0] bits to 0b00001.

The simultaneous conversion of a regular group can be interrupted to start the simultaneous conversion of an injected group.

Note: In combined regular/injected simultaneous mode, the user software must convert sequences with the same length.

Combined regular simultaneous and alternate trigger mode

This mode is selected by programming DUAL[4:0] bits to 0b00010.

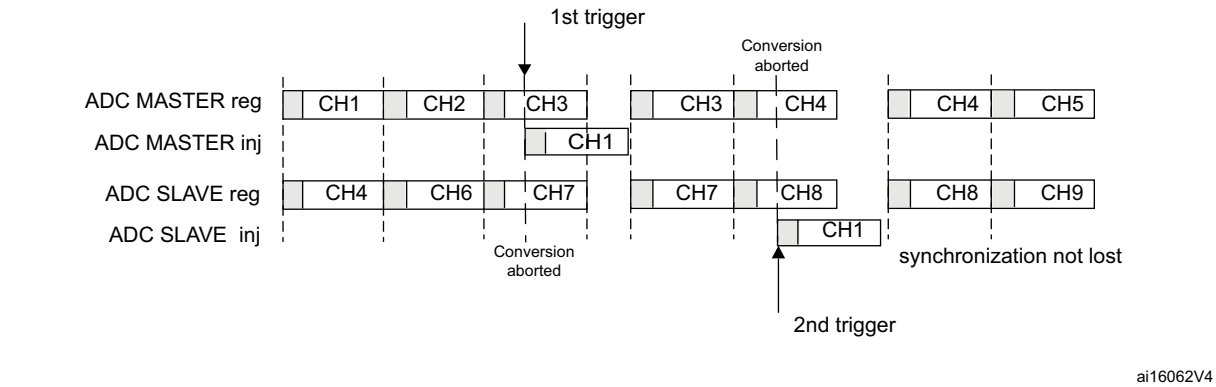
The simultaneous conversion of a regular group can be interrupted to start the alternate trigger conversion of an injected group. *Figure 133* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion immediately starts after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

Note: In combined regular simultaneous + alternate trigger mode, the user software must convert sequences with the same length.

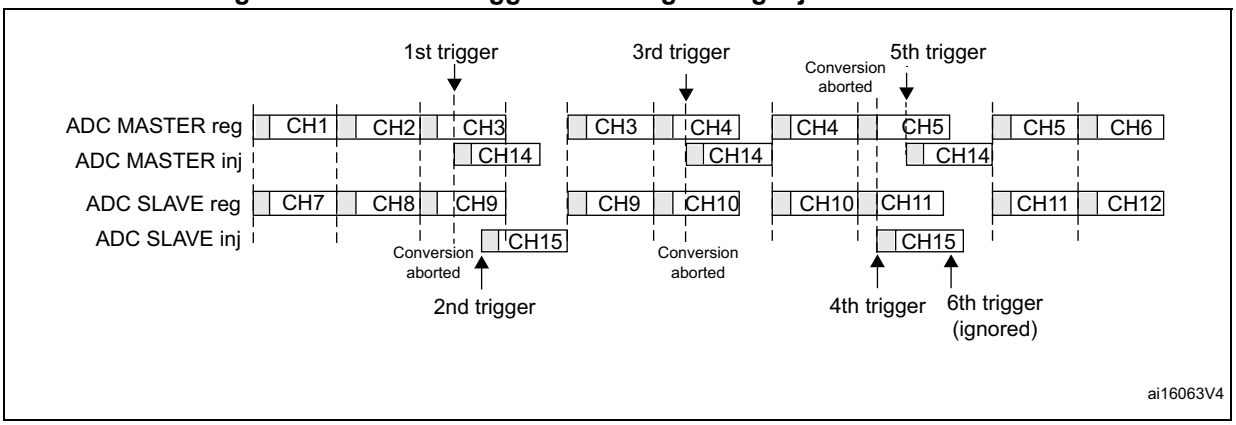
The software trigger is not supported for injected conversions.

Figure 133. Alternate + regular simultaneous



If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 134* shows the behavior in this case (note that the sixth trigger is ignored because the associated alternate conversion is not complete).

Figure 134. Case of trigger occurring during injected conversion



Combined injected simultaneous and interleaved mode

This mode is selected by programming DUAL[4:0] bits to 0b00011.

An interleaved conversion can be interrupted with a simultaneous injected event.

In this case, the interleaved conversion is immediately interrupted and the simultaneous injected conversion starts. At the end of the injected sequence, the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master's one. *Figure 135*, *Figure 136*, and *Figure 137* show examples of this behavior.

Note: In this mode, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 135. Interleaved single channel CH0 with injected sequence CH11, CH12

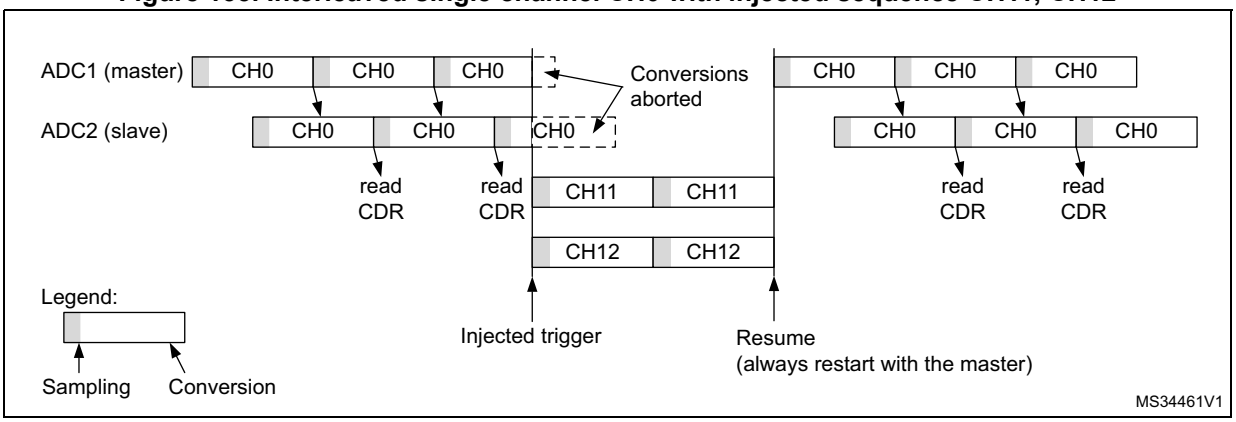


Figure 136. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first

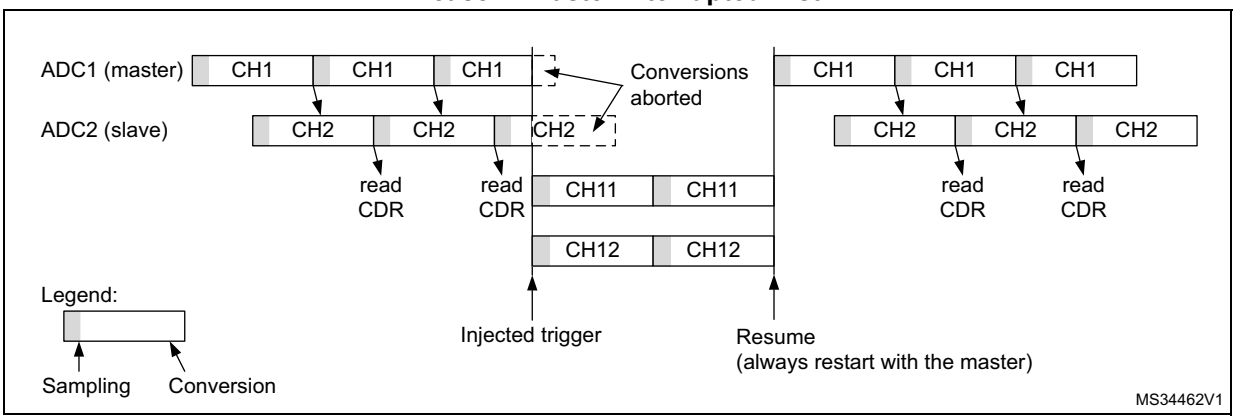

Figure 137. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first

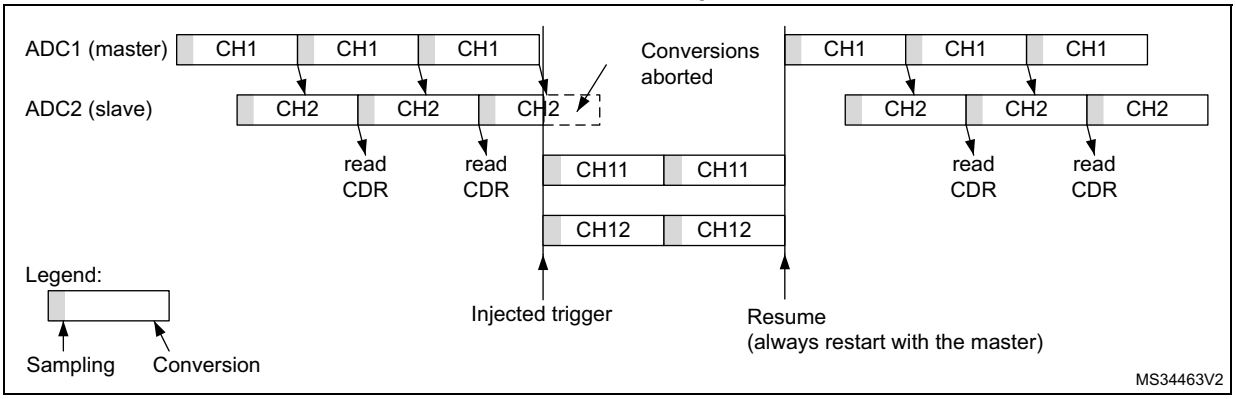
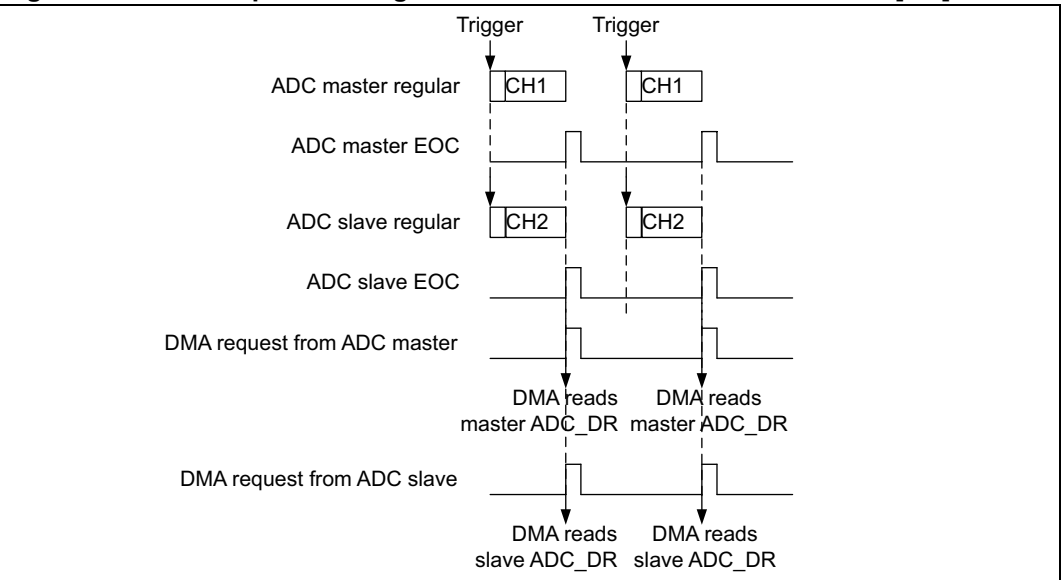


DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 138: DMA requests in regular simultaneous mode when DAMDF[1:0] = 0b00*).

Figure 138. DMA requests in regular simultaneous mode when DAMDF[1:0] = 0b00



Configuration where each sequence contains only one conversion. Master and slave timings are equal.

MSv31032V3

In interleaved mode or in simultaneous regular mode, it is also possible to save one DMA channel and transfer both data using a single DMA channel. To do this, the DAMDF[1:0] bits must be configured in the ADCC_CCR register:

- **DAMDF[1:0] = 0b10, 32-bit format:**

  A DMA request is generated alternatively after the master and slave EOC events have occurred. At that time, the data are alternatively available in the 32-bit register ADCC_CDR2 32-bit register.

  This mode is used when the data width is above 16 bits (conversion data width can exceed 16 bits when functions such as oversampling, compensation and left-bit shift, are used).

  Behavior: A DMA request is generated each time a new 32-bit data is available:

  – First DMA request: ADCC_CDR2[31:0] = MST_ADC_DR[31:0]

  – Second DMA request: ADCC_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF[1:0] = 0b10, 16-bit format**:

  A DMA request is generated alternatively after the master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCC_CDR contains the two half-words representing two ADC-converted data. The slave ADC data takes the upper half-word and the master ADC data takes the lower half-word. DMA transfers two data by one request.

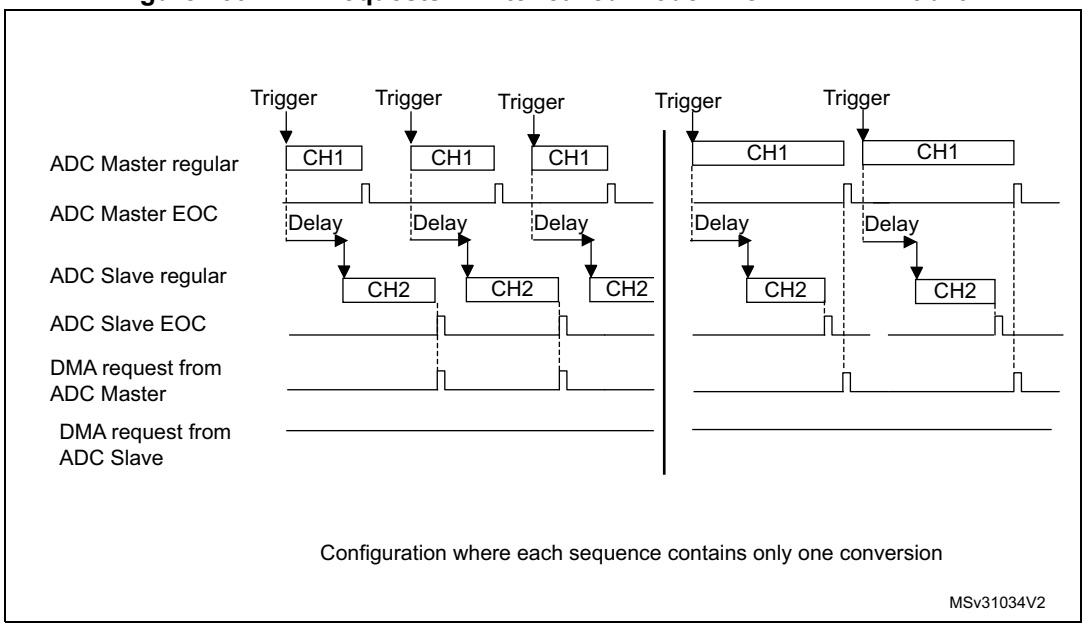
Any value above 16-bit in the master or the slave-converted data is truncated to the least 16 significant bits.

Behavior: A DMA request is generated each time a new 32-bit data is available:

– First DMA request:
ADCC_CDR[31:0] = (SLV_ADC_DR[15:0] << 16) | MST_ADC_DR[15:0]

– Second DMA request:
ADCC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 139. DMA requests in interleaved mode when DAMDF = 0b10



Note: When using dual ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion data is available.

- **DAMDF[1:0] = 0b11**:

  This mode is similar to the DAMDF[1:0] = 0b10 configuration. The only difference is that on each DMA request (two data are available), two bytes representing two ADC converted data are transferred as a half-word.

  This mode is used when the resolution is 6 bits or 8 bits and data are not signed.

  Behavior: A DMA request is generated each time two data items are available:

  – First DMA request:
  ADCC_CDR[15:0] = (SLV_ADC_DR[7:0] << 8)| MST_ADC_DR[7:0]

  – Second DMA request:
  ADCC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Note: DMA burst mode is not supported in ADC dual mode.

Overrun detection when OVRMOD = 0

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). The EOC bit

corresponding to one ADC might remains set because the data register of this ADC contains valid data.

Overrun detection when OVRMOD = 1

In dual ADC mode, if an overrun occurs on either ADC, the data register is overwritten, causing continuous DMA requests. This results in loss of data coherency.

DMA one-shot mode/ DMA circular mode when multi-ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), DMNGT[1:0] bits of the ADCC_CCR register must also be configured to select between DMA one-shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA*

Stopping the conversions in dual ADC modes

In dual ADC mode, the user software must set the ADSTP/JADSTP control bits in the master ADC to stop the conversions of both ADC. The other ADSTP control bit on the slave ADC has no effect in dual ADC mode.

Once both ADCs are effectively stopped, the ADSTART/JADSTART bits on the master and slave ADCs are both deasserted by hardware.

Analog watchdog in dual mode

The analog watchdog is supported in all dual modes.

Disabling the ADC in dual mode

During a dual-mode operation, the master ADC shares the ADC clock with the slave ADC. To disable the ADC correctly through the ADDIS bit of ADC_CR, set the ADSTP (or JADSP) bit on the master ADC. Once ADSTP (or JADSTP) becomes 0 both for the master and slave ADCs, set the ADDIS bit on the master ADC, then set the ADDIS bit on the slave ADC.

Autoinjection mode in dual mode

Autoinjection mode is not supported when DUAL[4:0] equals 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, or 0b01001.

Additionally, parallel injected oversampling mode is not supported in autoinjection mode.

Dual ADC modes supported in oversampling mode

It is possible to have oversampling enabled when working in dual ADC configuration. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

21.4.30 Temperature sensor

The temperature sensor can be used to measure the junction temperature (T_J) of the device.

The temperature sensor is internally connected to the ADC input channels, which are used to convert the sensor output voltage to a digital value (see *Table: ADC interconnection* in *Section 21.4.2: ADC pins and internal signals* for more details). When not in use, the sensor

can be put in power-down mode. It supports the temperature range specified in the product datasheet.

Figure 140 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

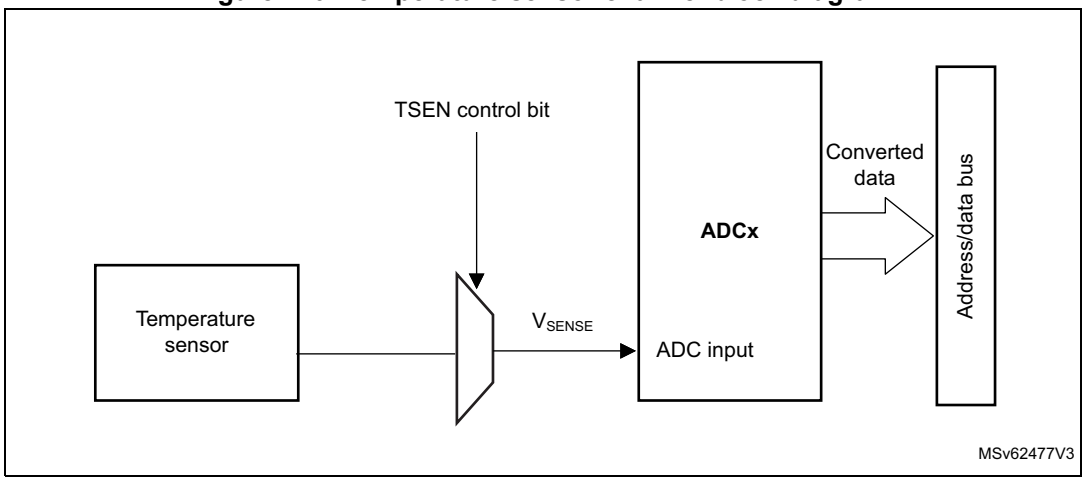
During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel, which is used to convert the sensor's output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

Figure 140 shows the block diagram of the temperature sensor.

Figure 140. Temperature sensor channel block diagram



Reading the temperature

To use the sensor:

1. Select the ADC input channel that is connected to V_{SENSE}.
2. Program with the appropriate sampling time (refer to the electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADCC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V_{SENSE} data in the ADC data register.

6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in °C)} = \frac{\text{TS_CAL2_TEMP} - \text{TS_CAL1_TEMP}}{\text{TS_CAL2} - \text{TS_CAL1}} \times (\text{TS_DATA} - \text{TS_CAL1}) + \text{TS_CAL1_TEMP}$$

Where:

- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

  Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Caution: The above formula is valid only if the V_{REF+} condition specified in the table *Temperature sensor calibration values* of the datasheet are respected.

Note: The sensor has a startup time after waking from power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN, and TSEN bits must be set simultaneously.

21.4.31 Monitoring the internal voltage reference

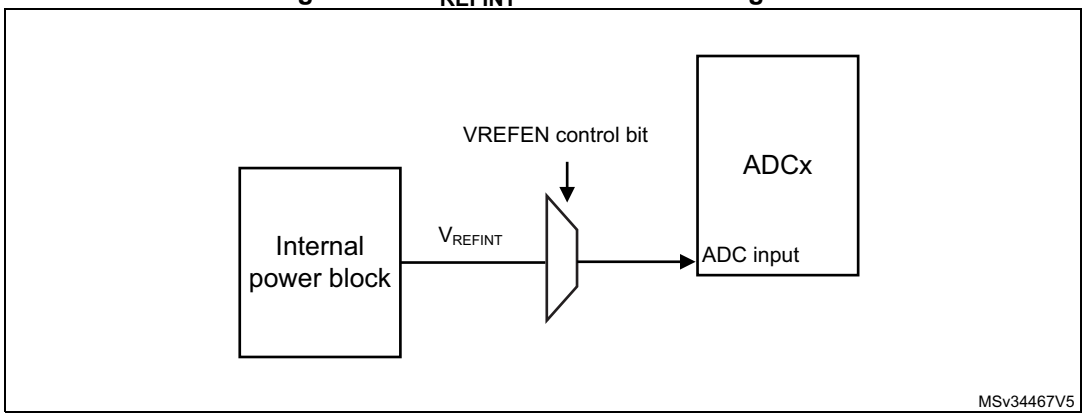
It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to the *ADC interconnection* table in *Section 21.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 141 shows the block diagram of the V_{REFINT} sensing feature.

Figure 141. V_{REFINT} channel block diagram



1. The VREFEN bit of the ADCC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+_Charac} \times VREFINT_CAL / VREFINT_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For some applications, the V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{REF+} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value.
- ADC_DATA is the value measured by the ADC on channel x (right-aligned).
- VREFINT_DATA is the actual VREFINT output value converted by the ADC.
- FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, we obtain $2^{12} - 1 = 4095$, or $2^8 - 1 = 255$ with 8-bit resolution.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

21.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (ADRDY flag)
- On the end of any conversion for regular groups (EOC flag)
- On the end of a sequence of conversion for regular groups (EOS flag)
- On the end of any conversion for injected groups (JEOC flag)
- On the end of a sequence of conversion for injected groups (JEOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2 and AWD3 flags)
- When the end of the sampling phase occurs (EOSMP flag)
- When the data overrun occurs (OVR flag)
- When the ADC internal voltage regulator output is ready (LDORDY flag)

Separate interrupt enable bits are available for flexibility.

Note: Interrupts are generated by the AHB clock domain. Since the ADC clock is adc_ker_ck, interrupt flags are delayed due to the synchronization between adc_ker_ck and AHB clock domains.

Table 152. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 flag is set	AWD1	AWD1IE			
	Analog watchdog 2 flag is set	AWD2	AWD2IE			
	Analog watchdog 3 flag is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			
	ADC internal voltage regulator ready	LDORDY	LDORDYIE			

21.6 ADC registers (for each ADC)

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

21.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDY	Res.	Res.	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
			rc_w1			rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: ADC internal voltage regulator output ready flag

This bit is set by hardware and cleared by software. It indicates that the ADC internal voltage regulator output is ready and that the ADC can be enabled or calibrated.

0: ADC LDO internal voltage regulator disabled

1: ADC LDO internal voltage regulator enabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD3LTR and ADC_AWD3HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD2LTR and ADC_AWD2HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD1LTR and ADC_AWD1HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it or when ADEN = 0.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it, when ADEN = 0, or by reading the corresponding ADC_JDRy register.

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel (a new conversion has completed while the EOC flag was already set) or when adc_hclk clock is too slow to manage the data.

It is cleared by software writing 1 to it or when ADEN = 0.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it or when ADEN = 0.

0: Regular conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it, when ADEN = 0, or by reading the ADC_DR register.

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase. It is cleared by software writing 1 or when ADEN = 0.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it or when ADEN = 0.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

21.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDYIE	Res.	Res.	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
			rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDYIE**: ADC internal voltage regulator interrupt enable

This bit is set and cleared by software to enable/disable the ADC internal voltage regulator interrupt.

0: Internal voltage regulator interrupt disabled

1: Internal voltage regulator interrupt enabled

Note: The software is allowed to write this bit only when ADEN = 0.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

21.6.3 ADC control register (ADC_CR)

Address offset: 0x008

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	Res.	DEEPPWD	ADVREGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs		rw	rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing)

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0 and ADEN =0).

Bit 28 **ADVREGEN**: ADC internal voltage regulator enable

This bits is set by software to enable the ADC internal voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC internal voltage regulator disabled

1: ADC internal voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.

The software can program this bit field only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be reconfigured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

When a software trigger is used, JADSTART bit is cleared by hardware, but JADSTP bit must be programmed to reconfigure the ADC.

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP command).

It is cleared by hardware when the conversion is effectively discarded. and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

When a software trigger is used, ADSTART bit is cleared by hardware. However it is necessary to write ADSTP bit to reconfigure the ADC.

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop ongoing regular conversions. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use ADSTP).

Note: In dual ADC regular simultaneous and interleaved modes, the ADSTP bit of the master ADC must be used to stop regular conversions on both ADCs. The other ADSTP bit is inactive.

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

- In single conversion mode when software trigger is selected (JEXTSEL = 0x0 and JDISEN = 1), this bit is cleared by hardware immediately after injected conversion starts.
- In all cases, after the execution of the JADSTP command, this bit and JADSTP are cleared by hardware simultaneously.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1, ADDIS = 0 and JAUTO = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

- In single conversion mode when software trigger is selected (EXTSEL = 0x0 and DISEN = 1), this bit is cleared by hardware immediately after regular conversion starts.
- In all cases, after the execution of the ADSTP command, this bit and ADSTP are cleared by hardware simultaneously.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and place it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1, ADDIS = 0 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all the bits of ADC_CR registers are cleared (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0), except for ADVREGEN bit which must be set. In addition, the software must wait for the startup time of the voltage regulator.

21.6.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x00C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	Res.	JDISCEN	DISCNUM[2:0]			DISCEN
	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1

00001: ADC analog input channel 1 monitored by AWD1

.....

01101: ADC analog input channel 13 monitored by AWD1

Others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADEN = 0.

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the JAUTO bit of the slave ADC is not valid and controlled by the JAUTO bit of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: When dual mode is enabled (DUAL bits of ADCC_CCR register are not equal to zero), the JDISCEN bit of the slave ADC is not valid and controlled by the JDISCEN bit of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCNUM[2:0] bits of the slave ADC are not valid and controlled by the DISCNUM[2:0] bits of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When regular dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bit of the slave ADC is not valid and controlled by the DISCEN bit of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the autodelayed conversion mode.

0: Autodelayed conversion mode off

1: Autodelayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the AUTDLY bit of the slave ADC is not valid and controlled by the AUTDLY bit of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When regular dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the CONT bit of the slave ADC is not valid and controlled by the CONT bit of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0

00001: adc_ext_trg1

00010: adc_ext_trg2

00011: adc_ext_trg3

00100: adc_ext_trg4

00101: adc_ext_trg5

00110: adc_ext_trg6

00111: adc_ext_trg7

...

11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit

01: 10-bit

10: 8-bit

11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

These bits are set and cleared by software to select how the ADC interface output data are managed.

00: Regular conversion data stored in DR only

01: DMA one-shot mode selected

10: Reserved

11: DMA circular mode selected

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

21.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSHIFT[3:0]				Res.	Res.	OVSR[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPTRIG	SWTRIG	BULB	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				Res.	Res.	Res.	Res.	ROVSE
rw	rw	rw			rw	rw	rw	rw	rw	rw					rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OVSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled
1: Sampling time control trigger mode enabled

If EXTEN[1:0] bits are set to 01, the sampling time starts on the trigger rising edge, and the conversion starts on the trigger falling edge.

The SMPTRIG bit must not be set when the BULB bit is set.

When EXTEN[1:0] bits are set to 00, set SWTRIG to start the sampling.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with sampling time control trigger mode*.*

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to trigger the conversion in sampling time control trigger mode.

0: Software trigger starts the conversion for sampling time control trigger mode
1: Software trigger starts the sampling for *sampling time control trigger mode*

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing), SMPTRIG = 1, and EXTEN[0:1] = 00.

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

BULB bit must not be set when the SWTRIG bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with bulb mode.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing). It is recommended to clear both JOVSE and GCOMP when ROVSM = 0.

Bit 9 **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift
0001: 1-bit shift
0010: 2-bit shift
0011: 3-bit shift
0100: 4-bit shift
0101: 5-bit shift
0110: 6-bit shift
0111: 7-bit shift
1000: 8-bit shift
1001: 9-bit shift
1010: 10-bit shift
Other: reserved, must not be used

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **ROVSE**: Regular oversampling enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled
1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing)

21.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 3 ADC clock cycles
001: 5 ADC clock cycles
010: 8 ADC clock cycles
011: 13 ADC clock cycles
100: 25 ADC clock cycles
101: 48 ADC clock cycles
110: 139 ADC clock cycles
111: 289 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

21.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	SMP13[2:0]			SMP12[2:0]			SMP11[2:0]			SMP10[2:0]		
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **SMPx[2:0]:** Channel x sampling time selection (x = 13 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 3 ADC clock cycles
001: 5 ADC clock cycles
010: 8 ADC clock cycles
011: 13 ADC clock cycles
100: 25 ADC clock cycles
101: 48 ADC clock cycles
110: 139 ADC clock cycles
111: 289 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

21.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	PCSEL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **PCSEL[13:0]**: Channel i ($V_{IN[i]}$) preselection

These bits are written by software to preselect the input channel I/O to be converted.

0: Input channel i ($V_{IN[i]}$) is not preselected for conversion, the result of the ADC conversion for this channel is wrong

1: Input channel i ($V_{IN[i]}$) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Configuring the PCSEL bit is not necessary for the internal channels (such as VREFINT).

21.6.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ2[3:0]				Res.	SQ1[4:0]					Res.	Res.	LEN[3:0]			
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **LEN[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.
0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

21.6.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ7[3:0]				Res.	SQ6[4:0]					Res.	SQ5[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 8th in the regular conversion sequence
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 7th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 6th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 5th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

21.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ14[4:0]					Res.	SQ13[4:0]					Res.	SQ12[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 14th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 13th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 12th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 11th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence
These bits are written by software with the channel number (0 to 13) assigned as the 10th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

21.6.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0 to 13) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

21.6.13 ADC regular data register (ADC_DR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 13) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 13) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 13) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 13) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JLEN[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

21.6.15 ADC offset y configuration register (ADC_OFCFGRy)

Address offset: 0x050 + 0x004 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POS OFF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed in bits OFFSET[21:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the data offset y.

Bit 26 **SSAT**: Signed saturation enable

This bit is set and cleared by software to enable the signed saturation feature.(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*).

0: Offset is subtracted maintaining the data integrity and extending converted data size (13-bit signed format)

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is set and cleared by software to enable the unsigned saturation feature.

0: Offset is subtracted maintaining the data integrity

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: Positive offset enable

This bit is set and cleared by software to enable the positive offset

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 Reserved, must be kept at reset value.

21.6.16 ADC offset y register (ADC_OFRy)

Address offset: 0x060 + 0x004 * (y -1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[21:16]					
										rw	rw	rw	rw	rw	rw

OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **OFFSET[21:0]:** Data offset y for the channel programmed in OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

21.6.17 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x070

Reset value: 0x0000 1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GCOMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP:** Gain compensation mode

This bit is set and cleared by software to enable the Gain compensation mode.

0: Regular ADC operation mode

1: Gain compensation enabled and applied on all channels.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing)

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]:** Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

00 1000 0000 0000: gain factor of 0.5

...

01 0000 0000 0000: gain factor of 1

10 0000 0000 0000: gain factor of 2

11 0000 0000 0000: gain factor of 3

...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.9999756

Note: This gain compensation is only applied when GCOMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing).

21.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x080 + 0x004 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **JDATA[31:0]:** Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left- or right-aligned as described in *Section 21.4.25: Data management*.

21.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	AWDCH[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **AWDCH[13:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWDCH[13:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

21.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	AWDCH[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **AWDCH[13:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWDCH[13:0] = 000..0, the analog Watchdog 3 is disabled.

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

21.6.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LTR[22:16]						
									rw	rw	rw	rw	rw	rw	rw

LTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **LTR[22:0]**: Analog watchdog 1 lower threshold

These bits are set and cleared by software to define the lower threshold for analog watchdog 1.

Refer to *Section 21.4.27: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)*.

21.6.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR)

Address offset: 0x0AC

Reset value: 0x003F FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AWDFILT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	HTR[22:16]

HTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.

000: No filtering, one detection generates an AWD1 flag or an interrupt

001: two consecutive detections generate an AWD1 flag or an interrupt

...

111: Eight consecutive detections generate an AWD1 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 1 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 1. Refer to *Analog windows watchdog* section.

21.6.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR)

Address offset: 0x0B0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 2 higher threshold
These bits are set and cleared by software to define the higher threshold for analog watchdog 2. Refer to *Analog windows watchdog* section.

21.6.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR)

Address offset: 0x0B8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **LTR[22:0]**: Analog watchdog 3 lower threshold
These bits are set and cleared by software to define the lower threshold for analog watchdog 3. Refer to *Analog windows watchdog* section.

21.6.26 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR)

Address offset: 0x0BC

Reset value: 0x003F FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HTR[22:16]

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 3 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 3. Refer to *Analog windows watchdog* section.

21.6.27 ADC calibration factors (ADC_CALFACT)

Address offset: 0x0C4

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT[6:0]**: Calibration factors

These bits can be written by hardware or by software.

Once the calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is applied once a new conversion is launched.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (ADC is enabled, no conversion is ongoing).

21.6.28 ADC option register (ADC_OR)

Address offset: 0x0D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:0 Reserved, must be kept at reset value.

21.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

21.7.1 ADC common status register (ADCC_CSR)

Address offset: 0x000

Reset value: 0x0000 0000

This register provides an image of the flags of the different ADCs. Nevertheless it is read-only and does not allow to clear the different flags. Instead each flag must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	LDORDY_SLV	Res.	Res.	AWD3_SLV	AWD2_SLV	AWD1_SLV	JEOS_SLV	JEOC_SLV	OVR_SLV	EOS_SLV	EOC_SLV	EOSMP_SLV	ADRDY_SLV
			r			r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

			r			r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **LDORDY_SLV:** ADC internal voltage regulator flag of the slave ADC
This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY_MST:** ADC internal voltage regulator flag of the master ADC
This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

21.7.2 ADC common control register (ADCC_CCR)

Address offset: 0x008

Reset value: 0x0000 0000

DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TSEN**: Temperature sensor voltage enable

This bit is set and cleared by software to control V_{SENSE} channel.

0: Temperature sensor channel disabled

1: Temperature sensor channel enabled

Note: The temperature sensor is not available on all ADC instances. Refer to Section 21.4.4: ADC connectivity for details.

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} channel.

0: V_{REFINT} channel disabled

1: V_{REFINT} channel enabled

Note: V_{REFINT} is not available on all ADC instances. Refer to Section 21.4.4: ADC connectivity for details.

Note: The software is allowed to write this bit only when ADEN = 0.

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:14 **DAMDF[1:0]:** Dual ADC mode data format

This bitfield are set and cleared by software. It specifies the data format in the common data register ADCC_CDR and ADCC_CDR2.

00: Dual ADC mode without data packing (ADCC_CDR and ADCC_CDR2 registers not used).

01: Reserved

10: Data formatting mode for any data width (ADCC_CDR data register is used when the data width is less than 16 bits, otherwise ADCC_CDR2 register is used)

11: Data formatting mode for data width lower that 8 bits (ADCC_CDR data register is used)

Note: The software is allowed to write these bits only when ADEN = 0 (ADC is disabled).

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between two sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode.
All the ADCs independent:
00000: Independent mode
The following settings apply to dual mode, master and slave ADCs working together
00001: Combined regular simultaneous + Injected simultaneous mode
00010: Combined regular simultaneous + Alternate trigger mode
00011: Combined interleaved mode + Injected simultaneous mode
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
Others: Reserved
All other combinations are reserved and must not be programmed

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

21.7.3 ADC common regular data register for dual mode (ADCC_CDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 21.4.29: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 21.4.29: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

21.7.4 ADC common regular data register for dual mode (ADCC_CDR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_ALT[31:16]

RDATA_ALT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs.

In dual mode, these bits contain the regular 32-bit data of the master and the slave ADC. Refer to *Section 21.4.29: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

21.8 ADC register map

ADC1 and ADC3 are master ADCs.

ADC2 operates as a slave from ADC1.

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

22 Digital-to-analog converter (DAC)

22.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the sample and hold mode.

22.2 DAC main features

The DAC main features are the following (see *Figure 142: Dual-channel DAC block diagram*):

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from VREF+ pin

Figure 142 shows the block diagram of a DAC channel and *Table 156* gives the pin description.

22.3 DAC implementation

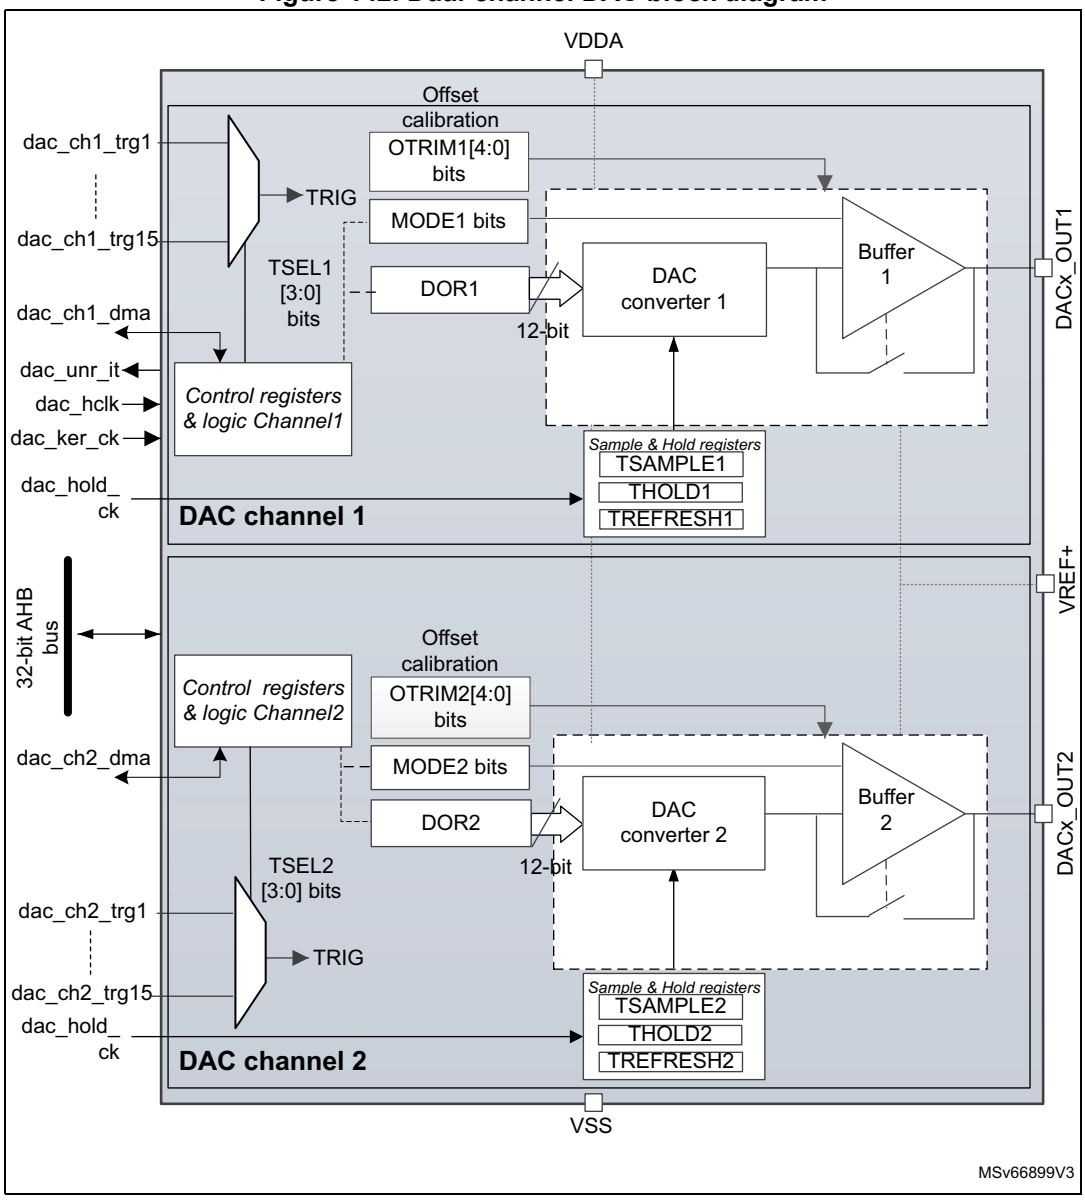
22.4 DAC functional description

22.4.1 DAC block diagram

Figure 142. Dual-channel DAC block diagram



1. MODEx bits in the DAC_MCR control the output mode and allow switching between the normal mode in buffer/unbuffered configuration and the sample and hold mode.
2. Refer to *Section 22.3: DAC implementation* for channel2 availability.

22.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator and operational amplifier.
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

Table 156. DAC input/output pins

Pin name	Signal type	Remarks
VREF+	Input, analog positive reference	The higher/positive reference voltage for the DAC, $V_{REF+} \leq V_{DDAmax}$ (refer to the product datasheet)
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUTy	Analog output signal	DACx channely analog output

Table 157. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch2_dma	Bidirectional	DAC channel2 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 15)	Inputs	DAC channel1 trigger inputs
dac_ch2_trgx (x = 1 to 15)	Inputs	DAC channel2 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_hclk	Input	DAC peripheral clock
dac_ker_ck	Input	DAC kernel clock
dac_hold_ck	Input	DAC low-power clock used in sample and hold mode
dac_out1	Analog output	DAC channel1 output for on-chip peripherals
dac_out2	Analog output	DAC channel2 output for on-chip peripherals

Table 158. DAC interconnection

Signal name	Source	Source type
dac_hold_ck	ck_lsi or ck_lse	LSI or LSE clock selected in the RCC
dac_chx_trg1 (x =1, 2)	tim1_trgo	Internal signal from on-chip timer
dac_chx_trg2 (x =1, 2)	tim2_trgo	Internal signal from on-chip timer
dac_chx_trg3 (x =1, 2)	Reserved	-
dac_chx_trg4 (x =1, 2)	Reserved	-
dac_chx_trg5 (x =1, 2)	tim5_trgo(1)	Internal signal from on-chip timer
dac_chx_trg6 (x =1, 2)	tim6_trgo	Internal signal from on-chip timer
dac_chx_trg7 (x =1, 2)	tim7_trgo	Internal signal from on-chip timer
dac_chx_trg8 (x =1, 2)	tim8_trgo	Internal signal from on-chip timer
dac_chx_trg9 (x =1, 2)	tim12_trgo	Internal signal from on-chip timer
dac_chx_trg10 (x =1, 2)	tim15_trgo	Internal signal from on-chip timer
dac_chx_trg11 (x =1, 2)	lptim1_ch1	Internal signal from on-chip timer
dac_chx_trg12 (x =1, 2)	exti9	External pin
dac_chx_trg13 (x =1, 2)	Reserved	-
dac_chx_trg14 (x =1, 2)	Reserved	-
dac_chx_trg15 (x =1, 2)	Reserved	-

1. Not available on STM32C53x/54x devices.

22.4.3 DAC clocks

Two clock sources can be used to update the DAC:

- dac_hclk: DAC peripheral clock (AHB clock)
- dac_ker_ck: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- dac_hold_ck: low-power clock used in sample and hold mode

The DAC clock is selected in the RCC.

22.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

22.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

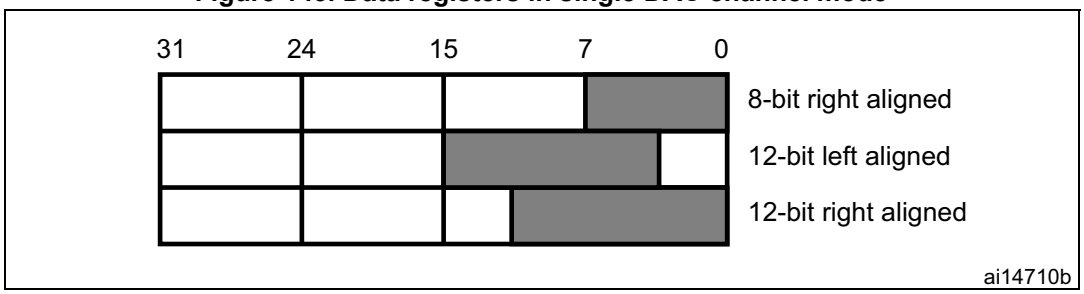
  – 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DAC_DHRx (data holding registerx, which are internal non-memory-mapped registers). The DAC_DHRx register is then loaded into the DAC_DORx register either automatically, by software trigger or by an external event trigger.

Figure 143. Data registers in single DAC channel mode



- Dual DAC channels (when available)

  There are three possibilities:

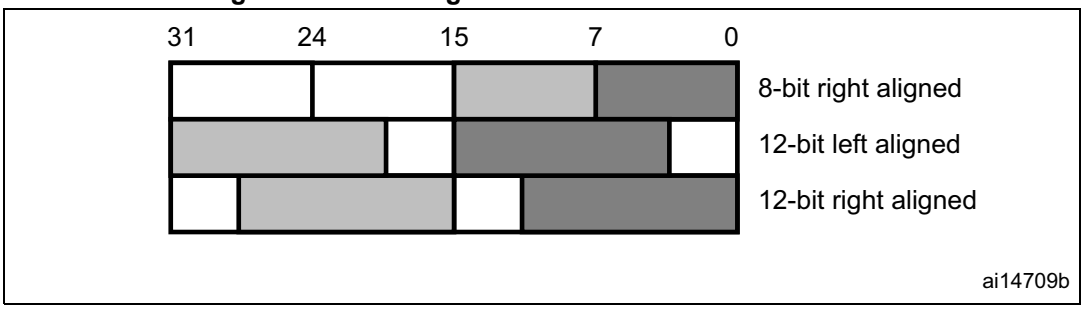
  – 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

  – 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

  – 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 144. Data registers in dual DAC channel mode



Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2's complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB of the data written to DAC_DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB is inverted. The four LSBs are simply ignored.

Table 159. Data format (case of 12-bit data)

SINFORMATx bit	DATA written to DAC_DHRx register	DATA transfered to DAC_DORx register
0	0x000	0x000
0	0xFFF	0xFFF
1	0x7FF	0xFFF
1	0x000	0x800
1	0xFFF	0x7FF
1	0x800	0x000

22.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_ker_ck clock speed is faster than 80 MHz.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk or dac_ker_ck clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

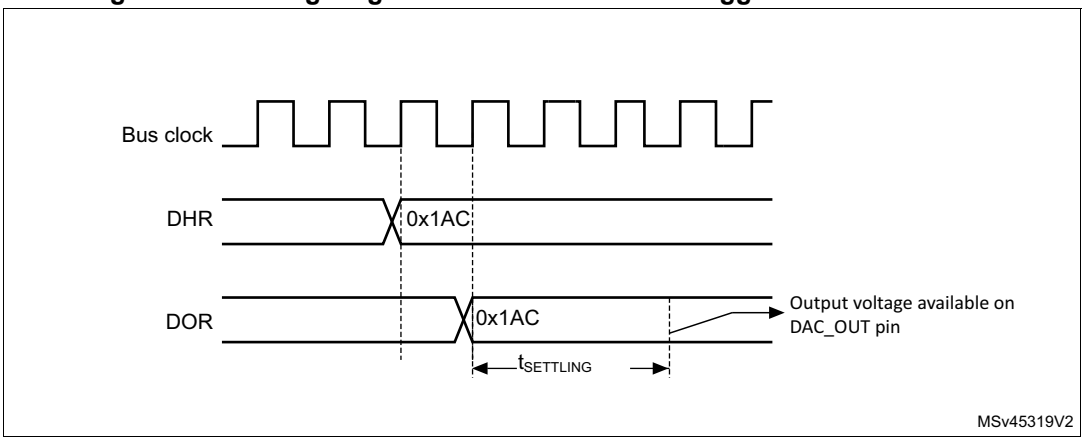
The above timing is only related to the limitation of the DAC interface. Refer also to the $t_{SETTLING}$ parameter value in the product datasheet.

Table 160. HFSEL description

HFSEL [2:0]	Clock frequency	Latency using AHB clock (dac_hclk)	Latency using dac_ker_ck clock	Function
000	< 80 MHz	3	4	DAC_DOR update rate up to 3 AHB clock cycles or 4 dac_ker_ck cycles.
001	≥ 80 MHz(1)	5	5	DAC_DOR update rate up to 5 AHB clock or dac_ker_ck cycles.
Others	Reserved	-	-	-

1. Refer to the device datasheet for the value of the maximum dac_hclk or dac_ker_ck frequency.

Figure 145. Timing diagram for conversion with trigger disabled TEN = 0



22.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and V_{REF+}.

The analog output voltage on the DAC channel pin is determined by the following equation:

$$\text{DAC output} = V_{REF} \times \frac{DOR}{4096}$$

where all voltages are expressed in Volt.

22.4.8 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

22.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

DMA double data mode

When the DMA controller is used in normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.
2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA double data mode.

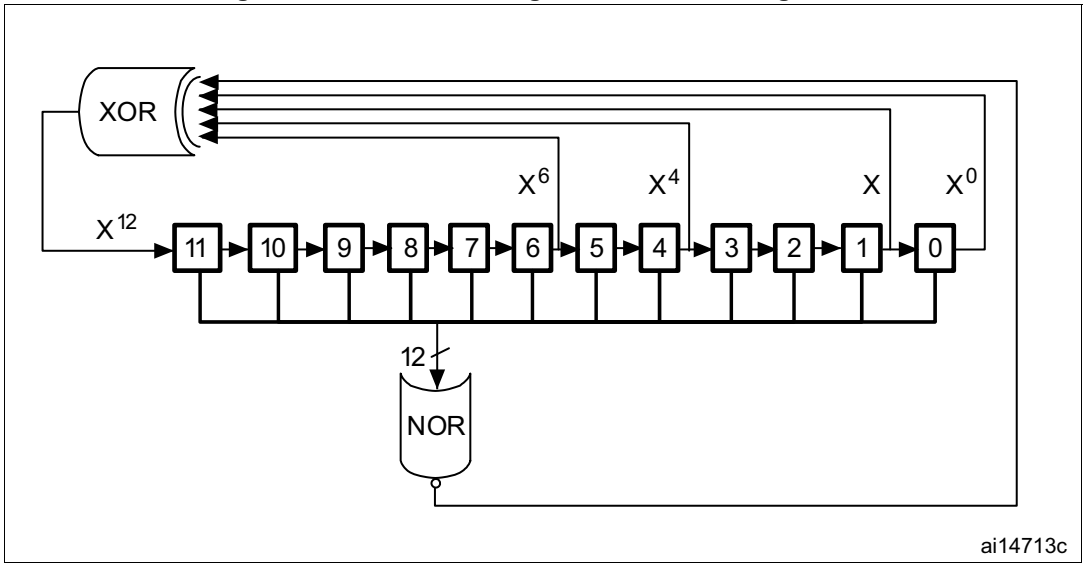
The following conditions must be met to change from double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

22.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 146. DAC LFSR register calculation algorithm

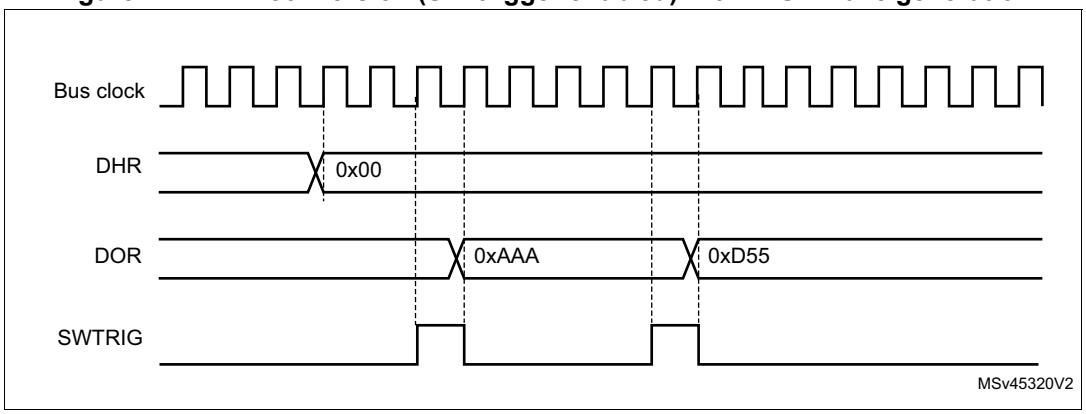


The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a 1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 147. DAC conversion (SW trigger enabled) with LFSR wave generation



Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

22.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 148. DAC triangle wave generation

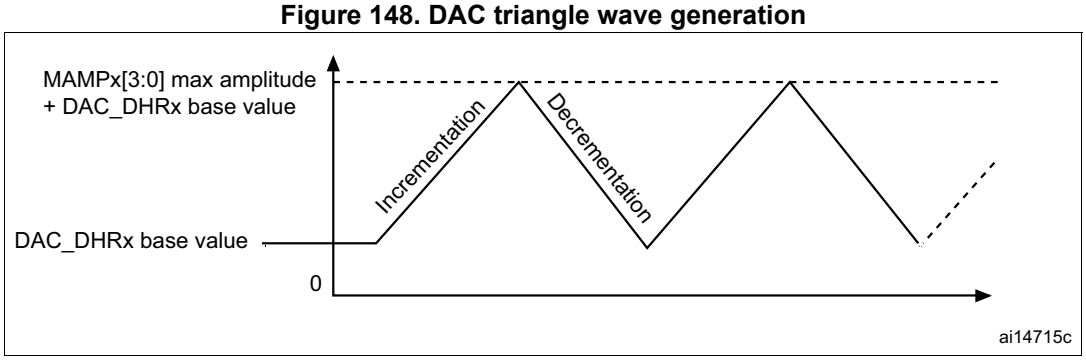


Figure 149. DAC conversion (SW trigger enabled) with triangle wave generation

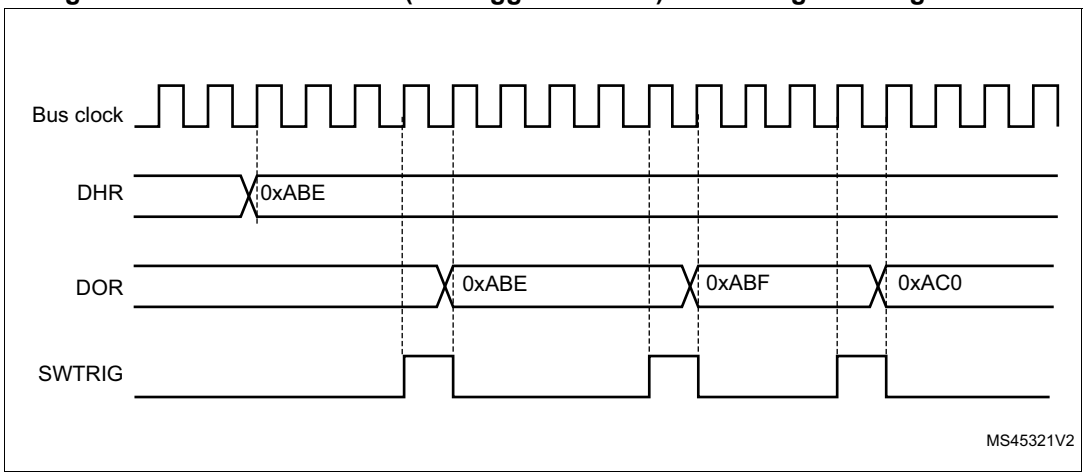


Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

22.4.12 DAC channel modes

Each DAC channel can be configured in normal mode or sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the sample and hold mode is enabled.

The sample/hold mode operations can be divided into three phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11.
- 62 cycles are required for hold phase: THOLDx[9:0] = 62.
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 161. Sample and refresh timings

Buffer State	t_{SAMP} (1)(2)	$t_{REFRESH}$ (2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula, the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8-bit resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only (refer to the datasheet for product data):

C_{SH} = 100 nF

V_{REF+} = 3.0 V

Sampling phase:

t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms

(where R_{BON} = 2 kΩ)

Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs

(where N_{LSB} = 10 (10 LSB drop during the hold phase)

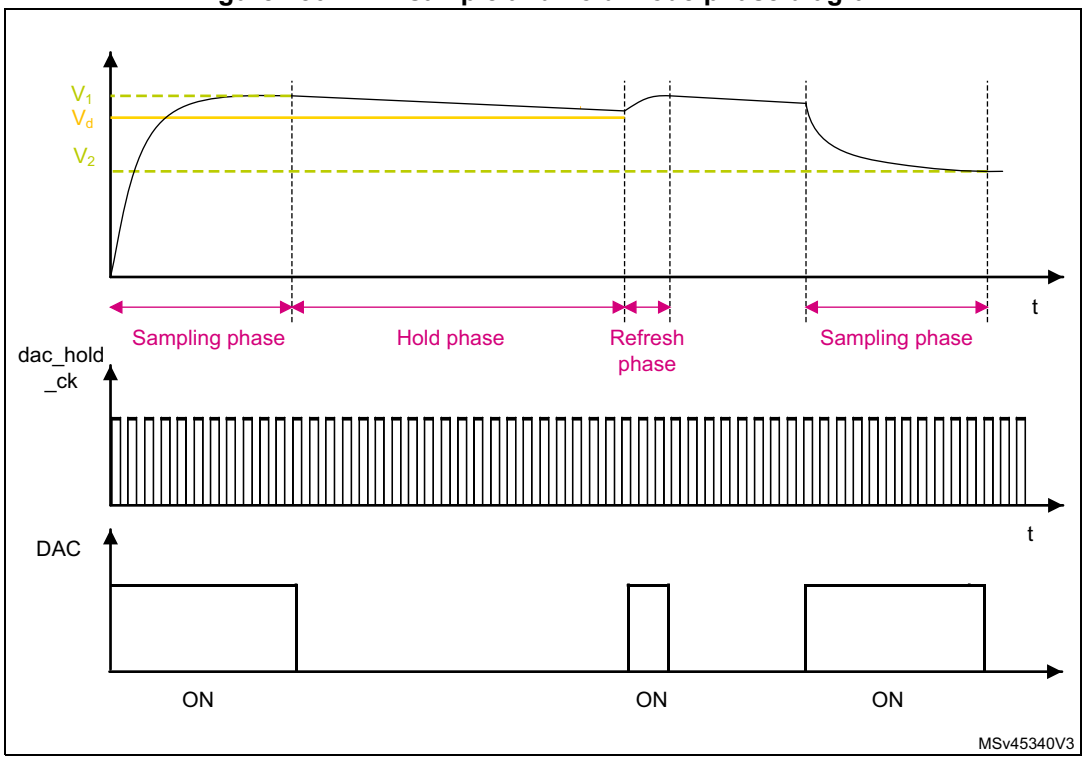
Hold phase:

$D_v = i_{leak} * t_{hold} / C_{SH}$ = 0.0073 V (10 LSB of 12bit at 3 V)

i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)

t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 150. DAC sample and hold mode phase diagram



Like in normal mode, the sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

  When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Table 162. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (such as comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (such as comparators)
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (such as comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)
1	1	1			Connected to on chip peripherals (such as comparators)

22.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = \left((D / 2^N) \times G \times V_{REF}\right) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{REF} is the nominal full-scale voltage, and V_{OS} is the offset voltage. For an ideal DAC channel, G = 1 and V_{OS} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{OS}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to V_{REF+}/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, V_{REF+} values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the nominal factory trimming conditions.

In addition, when V_{DD} is removed (example the device enters in Standby mode) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) Until the CAL_FLAGx is read as 1 or the maximum trimming code is reached, increment OTRIMx[4:0] and repeat substeps from (b) to (d).

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

Note: A t_{TRIM} delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, V_{REF+} and temperature conditions do not change during device operation while it enters more often in Standby mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

22.4.14 DAC channel conversion modes

Four conversion modes are possible.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Load the DAC channel data into the desired DHR registers (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DHRx register is transferred into DAC_DORx (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bits, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DAC channel triangle counter, with the same triangle amplitude, is added to the DHRx register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel triangle counter is then updated.

22.4.15 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DAC_DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.

2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

Simultaneous trigger with single LFSR generation

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated.
At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

22.5 DAC in low-power modes

Table 163. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC used with DMA.
Stop(1)	The DAC remains active with a static value. The sample and hold mode can be selected using LSE/LSI clock.
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 22.3: DAC implementation* for information on the Stop modes supported by the DAC peripheral.

22.6 DAC interrupts

Table 164. DAC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
DAC	DMA underrun	DMAUDRx	DMAUDRIEx	Write DMAUDRx = 1	Yes	No	No

22.7 DAC registers

Refer to *Section 1 on page 85* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

22.7.1 DAC control register (DAC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CEN2	DMAUDRIE2	DMAEN2	MAMP2[3:0]				WAVE2[1:0]		TSEL2[3]	TSEL2[2]	TSEL2[1]	TSEL2[0]	TEN2	EN2
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CEN1	DMAUDRIE1	DMAEN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1[3]	TSEL1[2]	TSEL1[1]	TSEL1[0]	TEN1	EN1
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in normal operating mode

1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled
01: Noise wave generation enabled
10: Triangle wave generation enabled
11: Reserved

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

For details on trigger configuration and mapping, refer to *Section 22.4.2: DAC pins and internal signals*.

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

Note: When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel1 in normal operating mode

1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled

01: Noise wave generation enabled

10: Triangle wave generation enabled

11: Reserved

Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bits 5:2 **TSEL1[3:0]**: DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
For details on trigger configuration and mapping, refer to *Section 22.4.2: DAC pins and internal signals*.

Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register

Note: When software trigger is selected, the transfer from the DAC_DHR1 *register to the DAC_DOR1 register takes only one dac_hclk clock cycle.*

Bit 0 **EN1**: DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

22.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWTRIG2	SWTRIG1
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

22.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC1DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DHRB[11:0]**: DAC channel1 12-bit right-aligned data B

These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software. They specify 12-bit data for DAC channel1.

22.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC1DHRB[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1.

22.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2)

This register is available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Address offset: 0x14

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DHRB[11:0]**: DAC channel2 12-bit right-aligned data
These bits are written by software. They specify 12-bit data for DAC channel2 when the DAC operates in DMA double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data
These bits are written by software. They specify 12-bit data for DAC channel2.

22.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2)

This register is available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC2DHRB[11:0]**: DAC channel2 12-bit left-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel2 when the DAC operates in double data mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data
These bits are written by software which specify 12-bit data for DAC channel2.

Bits 3:0 Reserved, must be kept at reset value.

22.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2)

This register is available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Address offset: 0x1C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHRB[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel2 when the DAC operates in double data mode.

Bits 7:0 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.

22.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC1DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.

22.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

22.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel1.

22.7.12 DAC channel1 data output register (DAC_DOR1)

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC1DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DORB[11:0]**: DAC channel1 data output
These bits are read-only. They contain data output for DAC channel1 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.

22.7.13 DAC channel2 data output register (DAC_DOR2)

This register is available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC2DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DORB[11:0]**: DAC channel2 data output
These bits are read-only. They contain data output for DAC channel2 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DOR[11:0]**: DAC channel2 data output
These bits are read-only, they contain data output for DAC channel2.

22.7.14 DAC status register (DAC_SR)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWST2	CAL_FLAG2	DMAUDR2	DORSTAT2	DAC2RDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1	r	r											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	rc_w1	r	r											

Bit 31 **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2, It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written

1:There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2

1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 28 **DORSTAT2**: DAC channel2 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 27 **DAC2RDY**: DAC channel2 ready status bit

This bit is set and cleared by hardware.

0: DAC channel2 is not yet ready to accept the trigger nor output data

1: DAC channel2 is ready to accept the trigger or output data

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after sample and hold mode enable and is set each time the software writes the register DAC_SHSR1, It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written

1:There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 **DORSTAT1**: DAC channel1 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Bit 11 **DAC1RDY**: DAC channel1 ready status bit

This bit is set and cleared by hardware.

0: DAC channel1 is not yet ready to accept the trigger nor output data

1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0 Reserved, must be kept at reset value.

22.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38

Reset value: 0x00XX 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM2[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM1[4:0]				
											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **OTRIM2[4:0]**: DAC channel2 offset trimming value

These bits are available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **OTRIM1[4:0]**: DAC channel1 offset trimming value

22.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SINFORMAT2	DMADOUBLE2	Res.	Res.	Res.	Res.	Res.	MODE2[2:0]		
						rw	rw						rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HFSEL[2:0]			Res.	Res.	Res.	SINFORMAT1	DMADOUBLE1	Res.	Res.	Res.	Res.	Res.	MODE1[2:0]		
rw	rw	rw				rw	rw						rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SINFORMAT2**: Enable signed format for DAC channel2

This bit is set and cleared by software.

0: Input data is in unsigned format

1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 24 **DMADOUBLE2**: DAC channel2 DMA double data mode

This bit is set and cleared by software.

0: DMA normal mode selected

1: DMA double data mode selected

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE2[2:0]:** DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

– DAC channel2 in normal mode

000: DAC channel2 is connected to external pin with Buffer enabled

001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled

010: DAC channel2 is connected to external pin with buffer disabled

011: DAC channel2 is connected to on chip peripherals with Buffer disabled

– DAC channel2 in sample and hold mode

100: DAC channel2 is connected to external pin with Buffer enabled

101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled

110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled

111: DAC channel2 is connected to on chip peripherals with Buffer disabled

Note: This register can be modified only when EN2 = 0.

Refer to Section 22.3: DAC implementation for the availability of DAC channel2.

Bits 15:13 **HFSEL[2:0]**: High frequency interface mode selection
000: High frequency interface mode disabled
001: High frequency interface mode enabled for 80 MHz ≤ dac_ker_ck ≤ 160 MHz
Others: Reserved, must not be used.

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1**: Enable signed format for DAC channel1
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Bit 8 **DMADOUBLE1**: DAC channel1 DMA double data mode
This bit is set and cleared by software.
0: DMA normal mode selected
1: DMA double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]:** DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
They can be set and cleared by software to select the DAC channel1 mode:
– DAC channel1 in normal mode
000: DAC channel1 is connected to external pin with Buffer enabled
001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
010: DAC channel1 is connected to external pin with Buffer disabled
011: DAC channel1 is connected to on chip peripherals with Buffer disabled
– DAC channel1 in sample & hold mode
100: DAC channel1 is connected to external pin with Buffer enabled
101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
111: DAC channel1 is connected to on chip peripherals with Buffer disabled
Note: This register can be modified only when EN1 = 0.

22.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]:** DAC channel1 sample time (only valid in sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWST1 of DAC_SR register is low, If BWST1 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

22.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	THOLD1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **THOLD2[9:0]:** DAC channel2 hold time (only valid in sample and hold mode).
Hold time = (THOLD[9:0]) x LSI/LSE clock period
These bits are available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.
Note: This register can be modified only when EN2 = 0.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **THOLD1[9:0]:** DAC channel1 hold time (only valid in sample and hold mode)
Hold time = (THOLD[9:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

22.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH2[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TREFRESH2[7:0]:** DAC channel2 refresh time (only valid in sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
These bits are available only on dual-channel DACs. Refer to *Section 22.3: DAC implementation*.
Note: This register can be modified only when EN2 = 0.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **TREFRESH1[7:0]:** DAC channel1 refresh time (only valid in sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

22.7.21 DAC register map

Table 165 summarizes the DAC registers.

Table 165. DAC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23 Comparator (COMP)

23.1 Introduction

The comparator can be used for a variety of functions including:

- Wake-up from a low-power mode triggered by an analog signal
- Analog signal conditioning
- Cycle-by-cycle current control loop when combined with a PWM output from a timer

23.2 COMP main features

- Selectable inverting analog inputs:
  - I/O pins
  - DAC channel outputs
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by the scaler (buffered voltage divider)
- I/O pins selectable as noninverting analog inputs
- Programmable hysteresis
- Programmable speed/consumption
- Mapping of outputs to I/Os
- Redirection of outputs to timer inputs for triggering:
  - Capture events
  - OCREF_CLR events (for cycle-by-cycle current control)
  - Break events for fast PWM shutdowns
- Blanking of comparator outputs
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)
- Interrupt output through the EXTI controller
- Direct interrupt output to the CPU
- Window mode

23.3 COMP implementation

23.3.1 COMP implementation for STM32C55x/562 and STM32C59x/5A3 devices

Table 166. COMP implementation for STM32C55x/562 and STM32C59x/5A3 (1)

COMP features	COMP1
Window mode	-
Programmable power and speed	X
Programmable hysteresis	X

1. X = supported, - = not supported

The following table lists the paired comparators required for window mode.

Table 170. Window paired comparators

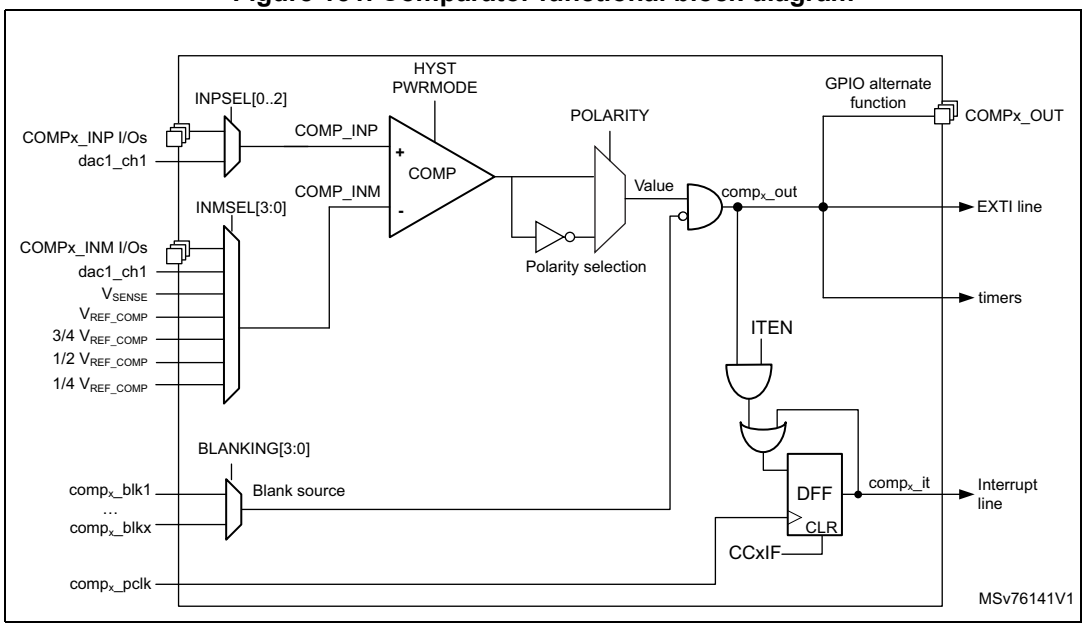
Window comparator	#1	#2
Upper threshold comparator	COMP1	COMP2
Lower threshold comparator	COMP2	COMP1

23.4 COMP functional description

23.4.1 COMP block diagram

The block diagram of the comparators is shown in the figure below.

Figure 151. Comparator functional block diagram



Note: The V_{SENSE} buffer is controlled by the ADC peripheral. To activate the buffer, set the TSEN bit in the ADCC_CCR register.

23.4.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet for more information.

The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- Emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- Cycle-by-cycle current control, using ETR inputs of timers
- Input capture for timing measurements

The comparator output can be simultaneously addressed internally and to the I/O pins.

Table 171. COMP input/output internal signals

Signal name	Signal type	Description
dac1_out1	Analog input	Analog signal from DAC peripheral
compx_blkx	Digital output	See *Table 173: COMP blanking source assignment*
compx_out	Digital output	COMPx output
compx_it	Digital output	COMPx interrupt out

Note: For the COMP non-inverting input, refer to Table 167: COMP implementation non-inverting input assignment for STM32C55x/562 and STM32C59x/5A3 and Table 169: COMP implementation non-inverting input assignment for STM32C53x/542.

Table 172. COMP inverting input assignment

INMSEL [3:0]	COMP1	COMP2
0000	¼ V_{REFINT}	¼ V_{REFINT}
0001	½ V_{REFINT}	½ V_{REFINT}
0010	¾ V_{REFINT}	¾ V_{REFINT}
0011	V_{REFINT}	V_{REFINT}
0100	dac1_ch1	dac1_ch2
0101	COMP1_INM1	COMP2_INM1
0110	COMP1_INM2	COMP2_INM2
0111	COMP1_INM3	COMP2_INM3
0100	VENSE	opamp1_out

Note: Other combinations are reserved.

0110	tim15_oc2	lptim1_ch1
0111	-	lptim1_ch2

1. Not available for STM32C53x and STM32C542.

23.4.3 COMP reset and clocks

The clock comp_pclk, provided by the clock controller, synchronous with the APB clock.

Note: ***Important:*** *The polarity selection logic and the output redirection to the port work independently of the APB clock. This allows the comparator to operate even in Stop mode. The interrupt line, connected to the NVIC of the CPU, requires the APB clock (comp_pclk) to work. In absence of the APB clock, the interrupt signal comp_it cannot be generated.*

23.4.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as overcurrent or thermal protection. For applications with specific functional safety requirements, the comparator configuration can be protected against undesired alteration that could happen, for example, at program counter corruption.

For this purpose, the comparator configuration registers can be write-protected (read-only).

Upon configuring a comparator channel, its LOCK bit is set to 1. This causes the entire register set of the comparator channel to become read-only, including the LOCK bit.

The write protection can only be removed through the MCU reset.

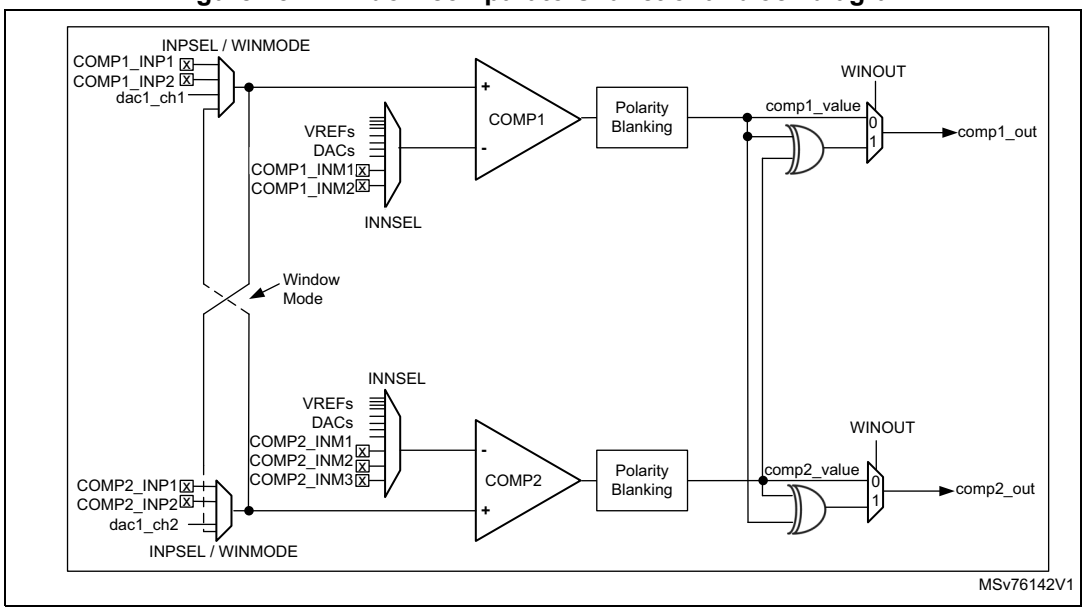
23.4.5 Window comparator (optional feature)

The purpose of the window comparator is to monitor the analog voltage to ensure it is within the voltage range defined by the lower and upper thresholds.

The two embedded comparators, COMP1 and COMP2, can be used to create a window comparator. The monitored analog voltage is connected to the noninverting (plus) inputs of comparators connected together (COMP1 or COMP2). The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

The output of the window comparator (COMP1 or COMP2) is selected with the control bit WINOUT.

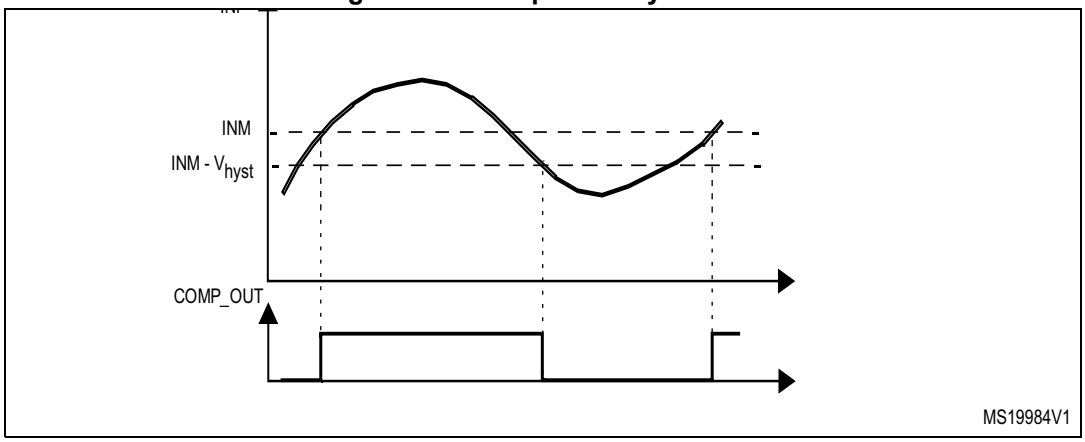
Figure 152. Window comparators functional block diagram



23.4.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.

Figure 153. Comparator hysteresis

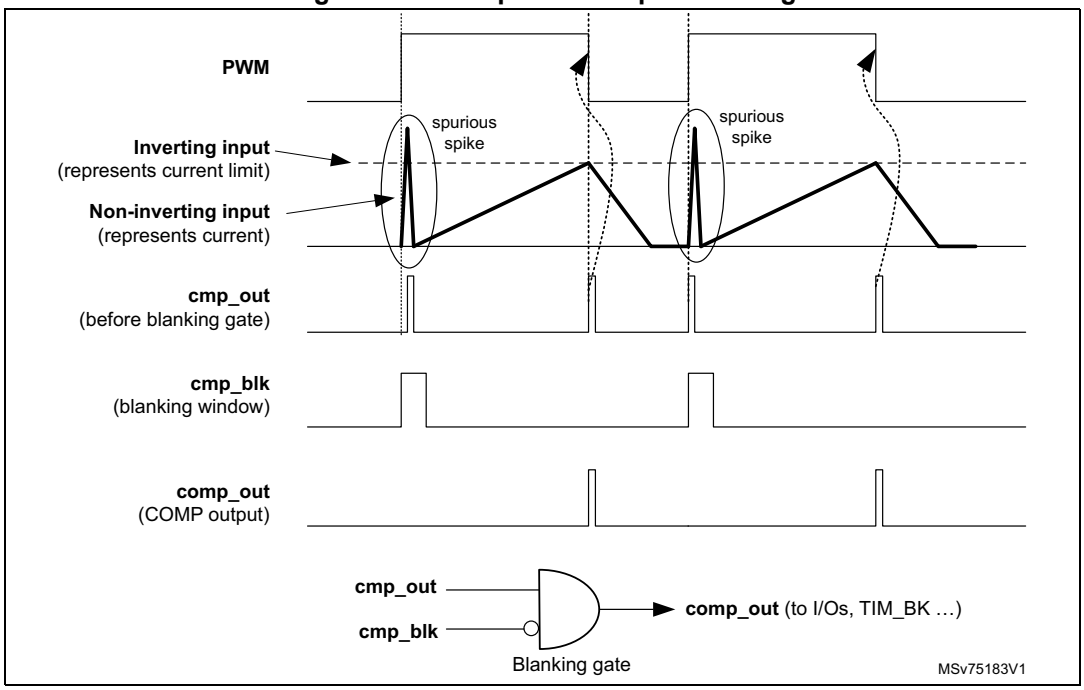


23.4.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals.

The blanking signal gates the internal comparator output such as to clean the comp_out from spurious pulses due to current spikes, as depicted in the following figure (the COMP channel number is not represented).

Figure 154. Comparator output blanking



23.4.8 COMP startup stabilization time

The comparator parameters and its output is undefined after the COMP is enabled (power-on) for a period defined as startup stabilization time. See the product datasheet for more details. If the comparator output is driving any critical stage of the design, it is recommended to redirect the comparator output to the device I/O through the GPIO alternate function or through IP configuration (such as timers) after the stabilization time elapses.

23.4.9 COMP power and speed modes

The power consumption of the COMP channels versus propagation delay can be programmed with PWRMODE[1:0] bit field in COMP_CFGRx registers.

23.5 COMP low-power modes

Table 174. Comparator behavior in low-power modes

Mode	Description
Sleep	No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.
Stop	No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.

Note: The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

23.6 COMP interrupts

There are two ways to use the comparator as interrupt source.

The comparator outputs are internally connected to the extended interrupt and event controller (EXTI). Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

The comparator also provides an interrupt line to the NVIC of the CPU. This functionality is used when the CPU is active to handle low-latency interrupt. It requires APB clock running.

23.6.1 COMP wake-up interrupt through EXTI

Refer to the *Section 16: Extended interrupts and event controller (EXTI)* for more details.

Sequence to enable the COMPx interrupt through EXTI block:

1. Enable the COMPx and wait for stabilization.
2. Configure the EXTI line, receiving the compx_wkup signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
3. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.

Table 175. COMP wake-up interrupt through EXTI control bits

Interrupt event	Event flag	Enable control bit	Exit Sleep mode	Exit Stop modes	Exit Standby mode
compx_wkup	Through EXTI	Through EXTI	Yes	Yes	N/A

23.6.2 COMP NVIC interrupt through EXTI

Refer to the *Section 16: Extended interrupts and event controller (EXTI)* and *Section 15: Nested vectored interrupt controller (NVIC)* for more details.

Sequence to enable the COMPx interrupt through the EXTI block:

1. Enable the COMP and wait for stabilization.
2. Configure the EXTI line, receiving the comp_out signal, in interrupt mode, select the rising, falling, or either-edge sensitivity and enable the EXTI line.
3. Configure and enable the IMx in EXTI_IMRx.

Table 176. COMP NVIC interrupt through EXTI control bits

Interrupt event	Interrupt flag	Enable control bit	Interrupt clear bit	Exit Sleep mode	Exit Stop modes
compx_it	RPIFx or FPIFx in EXTI_RPRx or EXTI.FPRx	RTx or FTx in EXTI.RTSRx or EXTI.FTSRx and IMx in EXTI.IMRx	RPIFx or FPIFx in EXTI_RPRx or EXTI.FPRx	Yes (with APB clock)	Yes

Note: It is mandatory to enable the APB clock to use this interrupt. If the clock is not enabled, an interrupt is not generated.

23.6.3 COMP interrupt through NVIC of the CPU

Refer to the *Section 15: Nested vectored interrupt controller (NVIC)* for more details.

Sequence to enable the COMP interrupt through NVIC of the CPU:

1. Enable the COMP and wait for stabilization.
2. Configure and enable the NVIC IRQ channel mapped to the comp_it line.
3. Configure and enable the ITEN in COMP_CFGRx.

Table 177. COMP interrupt through NVIC of the CPU control bits

Interrupt event	Interrupt flag	Enable control bit	Interrupt clear bit	Exit Sleep mode	Exit Stop modes
comp_it	C1IF in	ITEN in COMP_CFGR1	CC1IF	Yes (with APB clock)	No
	C2IF in	ITEN in COMP_CFGR2	CC2IF	Yes (with APB clock)	No

Note: It is mandatory to enable APB clock to use this interrupt. If clock is not enabled, interrupt is not generated.
The interrupt is active on level and not automatically clear by hardware. It must be cleared in the comparator interrupt handler by firmware with ITEN = 0 (COMP_CFGR1 register).
The interrupt signal comp_it is generated on comparator level, for this reason: upon interruption occurrence, the comp_it signal must be set to low as soon as possible to avoid comparator interrupt handler re-entrance. This can be done by setting ITEN = 0 or changing the comparator POLARITY bit.

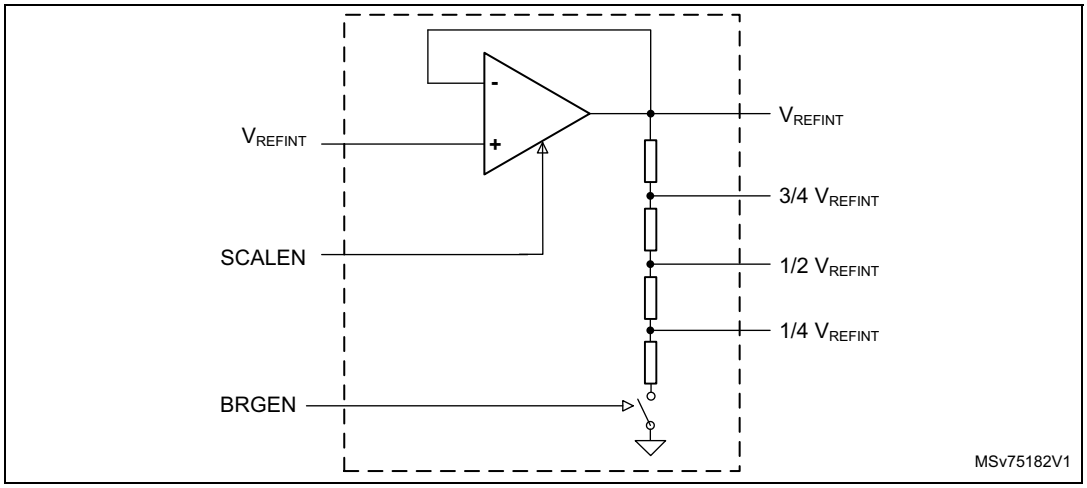
23.7 SCALER function

The scaler block is available to provide the different voltage reference levels to the comparator inputs. It is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference V_{REFINT}.

The amplifier and the resistor bridge can be enabled separately. The amplifier is enabled by the SCALEN bits of the COMP_CFGRx registers. The resistor bridge is enabled by the BRGEN bits of the COMP_CFGRx registers.

When the resistor-divided voltage is not used, the resistor bridge disconnect to reduce the consumption.

Figure 155. Scaler block diagram



23.8 COMP registers

23.8.1 Comparator status register (COMP_SR)

The COMP_SR is the comparator status register.

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **C2IF**: COMP2 channel interrupt flag
This bit is set by hardware when the COMP2 channel output is set.
This bit is cleared by software by writing CC12F = 1 in the COMP_ICFR register.

Bit 16 **C1IF**: COMP1 channel interrupt flag
This bit is set by hardware when the COMP1 channel output is set.
This bit is cleared by software by writing CC1IF = 1 in the COMP_ICFR register.

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **C2VAL:** COMP2 channel output status bit
This bit is read-only. It reflects the current COMP1 channel output taking into account POLARITY and BLANKING bits effect.

Bit 0 **C1VAL:** COMP1 channel output status bit
This bit is read-only. It reflects the current COMP1 channel output taking into account POLARITY and BLANKING bits effect.

23.8.2 Comparator interrupt clear flag register (COMP_ICFR)

The COMP_ICFR is the comparator interrupt clear flag register.

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **CC2IF**: Clear COMP2 channel interrupt flag
Writing 1 clears the C2IF flag in the COMP_SR register.

Bit 16 **CC1IF**: Clear COMP1 channel interrupt flag
Writing 1 clears the C1IF flag in the COMP_SR register.

Bits 15:0 Reserved, must be kept at reset value.

23.8.3 Comparator configuration register 1 (COMP_CFGR1)

The COMP_CFGR1 is the COMP1 configuration register.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw			rw	rw		rw		rw	rw	rw	rw	rw

Bit 31 **LOCK:** Lock
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel configuration register COMP_CFGR1[31:0]
0: COMP_CFGR1[31:0] register is read/write
1: COMP_CFGR1[31:0] is read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]:** COMP1 channel blanking source selection
Bits of this field are set and cleared by software (only if LOCK not set).
The field selects the input source for COMP1 channel output blanking.
Note: See Table 173: COMP blanking source assignment for more details.

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **INPSEL[2:0]**: COMP1 non-inverting input selection
These bits are set and cleared by software (only if LOCK not set).
They select which input is connected to the non-inverting input of COMP1 channel.
Note: See Table 167: COMP implementation non-inverting input assignment for STM32C55x/562 and STM32C59x/5A3 and Table 169: COMP implementation non-inverting input assignment for STM32C53x/542 for more details.

Bits 19:16 **INMSEL[3:0]**: COMP1 channel inverting input selection
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the inverting input of COMP1 channel.
Note: See Table 172: COMP inverting input assignment for more details.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WINOUT**: COMP1 output selector
This bit is controlled by software (if not locked). It selects the COMP1 output.
0: COMP1_VALUE
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see *Figure 152: Window comparators functional block diagram*

Bits 13:12 **PWRMODE[1:0]:** Power mode of the COMP1 channel
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel.
00: High speed/high power
01: Medium speed/medium power
All others values: Reserved

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **HYST[1:0]:** COMP channel hysteresis selection
These bits are set and cleared by software (only if LOCK not set). They select the hysteresis voltage of the COMP channel.
00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN:** COMP channel interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel.
0: Interrupt generation disabled for COMP channel
1: Interrupt generation enabled for COMP channel

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WINMODE**: COMP1 non-inverting input selector for window mode
This bit is controlled by software (if not locked). It selects the COMP1_INP input of COMP1.
0: Signal selected with INPSEL[1:0]
1: COMP2_INP signal of COMP2 (required for window mode, see *Figure 152: Window comparators functional block diagram*

Bit 3 **POLARITY:** COMP channel polarity selection
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel polarity.
0: COMP channel output is not inverted
1: COMP channel output is inverted

Bit 2 **SCALEN**: Voltage scaler enable

This bit is set and cleared by software (only if LOCK not set). This bit enables the V_{REFINT} scaler for the COMP channels.

0: V_{REFINT} scaler disabled

1: V_{REFINT} scaler enabled

Bit 1 **BRGEN:** Scaler bridge enable

This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.

0: Scaler resistor bridge disabled

1: Scaler resistor bridge enabled

Bit 0 **EN:** COMP channel enable

This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel.

0: Disable

1: Enable

23.8.4 Comparator configuration register 2 (COMP_CFGR2)

The COMP_CFGR2 is the COMP2 configuration register.

Address offset: 0x10

Reset value: 0x0000 0000

	rw	rw	rw			rw	rw		rw		rw	rw	rw	rw	rw

Bit 31 **LOCK:** Lock

This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel configuration register COMP_CFGR1[31:0]

0: COMP_CFGR2[31:0] register is read/write

1: COMP_CFGR2[31:0] is read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]:** COMP2 channel blanking source selection

Bits of this field are set and cleared by software (only if LOCK not set).

The field selects the input source for COMP1 channel output blanking.

Note: See Table 173: COMP blanking source assignment for more details.

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **INPSEL[2:0]**: COMP2 non-inverting input selection

These bit are set and cleared by software (only if LOCK not set).

They select which input is connected to the non-inverting input of COMP2 channel.

Note: See Table 169: COMP implementation non-inverting input assignment for STM32C53x/542 for more details.

Bits 19:16 **INMSEL[3:0]**: COMP2 channel inverting input selection
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the inverting input of COMP1 channel.
Note: See Table 172: COMP inverting input assignment for more details.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WINOUT**: COMP2 output selector
This bit is controlled by software (if not locked). It selects the COMP1 output.
0: COMP2_VALUE
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see *Figure 152: Window comparators functional block diagram*

Bits 13:12 **PWRMODE[1:0]:** Power mode of the COMP2 channel
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel.
00: High speed/high power
01: Medium speed/medium power
All others values: Reserved

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **HYST[1:0]:** COMP channel hysteresis selection
These bits are set and cleared by software (only if LOCK not set). They select the hysteresis voltage of the COMP channel.
00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN:** COMP channel interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel.
0: Interrupt generation disabled for COMP channel
1: Interrupt generation enabled for COMP channel

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WINMODE**: COMP2 non-inverting input selector for window mode
This bit is controlled by software (if not locked). It selects the COMP2_INP input of COMP2.
0: Signal selected with INPSEL[1:0]
1: COMP2_INP signal of COMP2 (required for window mode, see *Figure 152: Window comparators functional block diagram*

Bit 3 **POLARITY:** COMP channel polarity selection
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel polarity.
0: COMP channel output is not inverted
1: COMP channel output is inverted

Bit 2 **SCALEN**: Voltage scaler enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the V_{REFINT} scaler for the COMP channels.
0: V_{REFINT} scaler disabled
1: V_{REFINT} scaler enabled

Bit 1 **BRGEN:** Scaler bridge enable

This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.

0: Scaler resistor bridge disabled

1: Scaler resistor bridge enabled

Bit 0 **EN:** COMP channel enable

This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel.

0: Disable

1: Enable

23.8.5 COMP register map

Table 178. COMP register map and reset values

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

24 Operational amplifier (OPAMP)

This section applies only to STM32C53x/54x devices.

24.1 Introduction

The devices embed one operational amplifier instance, OPAMP1.

OPAMP contains an operational amplifier, an internal resistor divider, and multiplexers to set the OPAMP peripheral into a specific operating mode. In one of these, the operational amplifier inputs (INP and INM) and the output (OUT) are connected to external pins, which allows the use of OPAMP as a standalone operational amplifier device. The other OPAMP configurations allow the operation as a follower and as noninverting or inverting operational amplifier with programmable gain (with or without external filtering and/or biasing).

The programmable gain and the operating mode can be controlled through primary and secondary control register sets that can be activated in a time multiplex by the timer.

The operational amplifier output can be connected, through a multiplexer, to the OPAMP_VOUT pin or internally to a COMP input channel.

The INP input of OPAMP1 can be connected to an output of the internal DAC.

The operational amplifier operates at normal and high speed (slew rate). Its input offset is compensated through factory trimming, which can be modified by the user if needed.

As long as OPAMP is not required, it can be disabled to save power.

24.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current
- Low input offset voltage (factory compensated for)
- High frequency bandwidth
- Normal and high speed (slew rate)
- Timer-controlled operation

Note: Refer to the product datasheet for detailed OPAMP characteristics.

24.3 OPAMP implementation

The device has one OPAMP instance, OPAMP1. *Table 179* shows the pin and internal signal specific naming, and provides the assignment to I/Os and the possible connection of the internal signals:

- *Generic name* provides the pin and internal signal names as per *Figure 156*.
- *Instance-specific name* provides pin and internal signal names pertaining to each instance.
- *Assignment or possible connection* provides the assignment to I/O pins for signals on pins (in upper-case letters), and the possible connections of internal signals (in lower-case letters).

Table 179. OPAMP pin and signal assignment per instance

	Generic name	Instance-specific name	Assignment or possible connection	Comment
OPAMP1	OPAMP_VINM0	OPAMP1_VINM0	PA2	Selected as additional I/O function
	OPAMP_VINM1	OPAMP1_VINM1	PB1	
	OPAMP_VINP0	OPAMP1_VINP0	PA1	
	OPAMP_VINP1	OPAMP1_VINP1	PB0	
	OPAMP_VINP2	OPAMP1_VINP2	PB15	
	opamp_dac_in	opamp1_dac_in	dac2_int	-
	OPAMP_VOUT	OPAMP1_VOUT	PA6	Selected as additional I/O function
	opamp_out	opamp1_out	comp2_inn8	Selected in the COMP
	opamp_pclk	opamp1_pclk1	-	Enabled/disabled through RCC

24.4 OPAMP functional description

Each OPAMP instance can individually be enabled. When disabled, its output is in a high-impedance state. When enabled, it can operate in functional or in calibration mode.

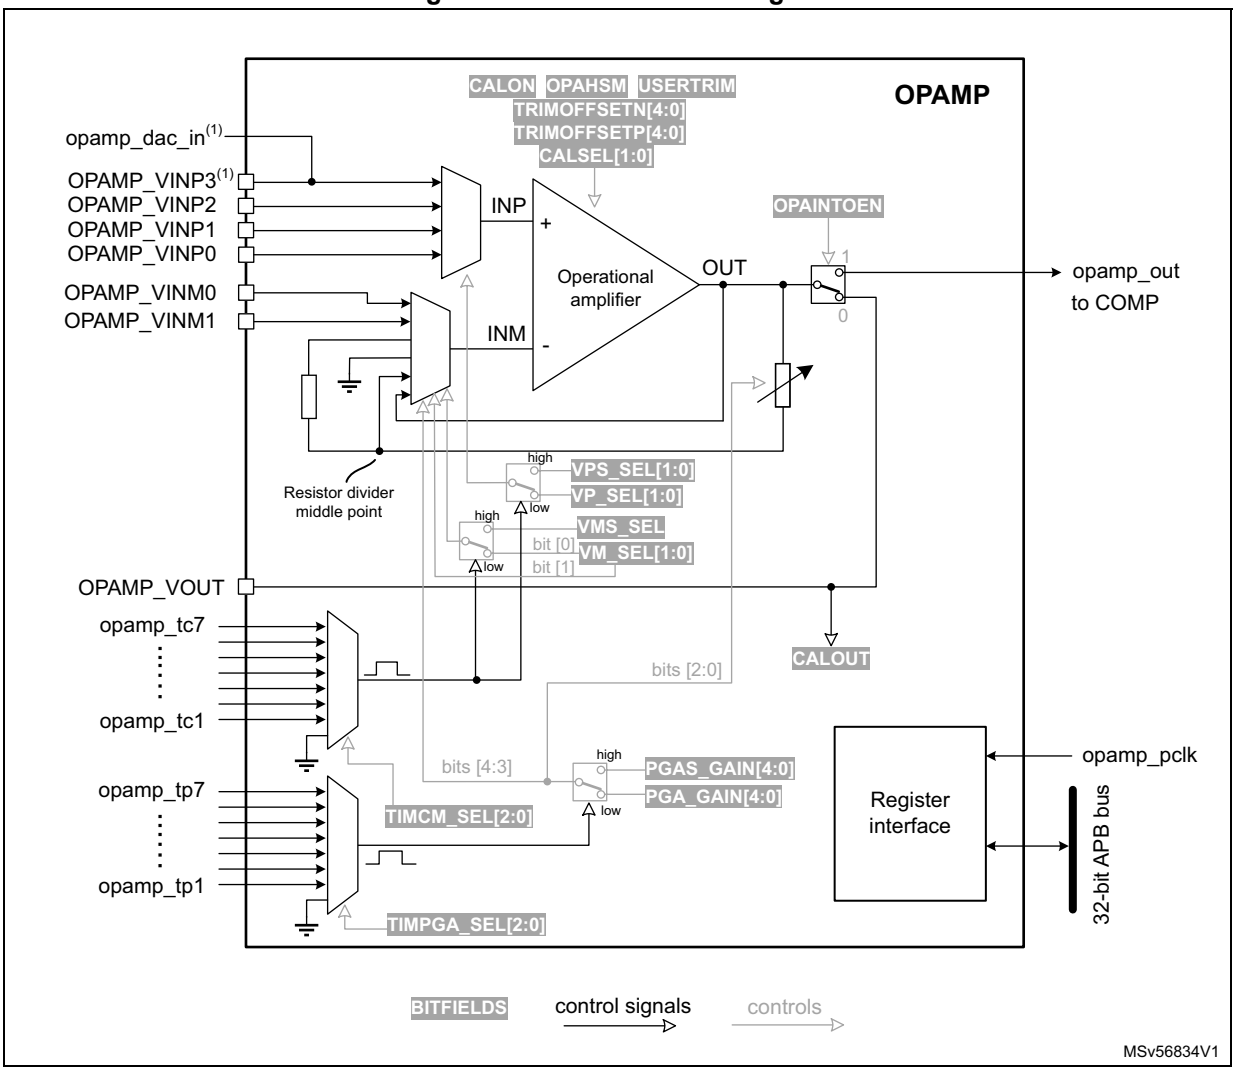
In functional mode, the inputs and the output of the operational amplifier are connected as described in *Section 24.4.8*. In calibration mode, they are all disconnected.

Caution: The GPIOs connected to the operational amplifier terminals through the OPAMP multiplexers must be configured in analog mode (default state), through the corresponding GPIOx_MODER register.

24.4.1 OPAMP block diagram

Figure 156 shows the block diagram of the OPAMP peripheral. The calibration multiplexers and some control bitfields are not shown.

Figure 156. OPAMP block diagram



1. Either OPAMP_VINP3 pin or DAC output, depending on the OPAMP instance. Refer to *Section 24.3*.

24.4.2 OPAMP pins and internal signals

Table 180 shows the pins used by the OPAMP peripheral. Their names correspond to the configuration for use as inputs or outputs. Refer to *Section 24.3* for the assignment of each to an I/O.

Table 180. OPAMP pins

Name	Type	Description
OPAMP_VINP0 OPAMP_VINP1 OPAMP_VINP2 OPAMP_VINP3	I	Selectable as INP noninverting input of the operational amplifier.
OPAMP_VINM0 OPAMP_VINM1	I	Selectable as INM inverting input of the operational amplifier.

Table 180. OPAMP pins (continued)

Name	Type	Description
OPAMP_VOUT	O	Operational amplifier output. Usable for other purposes when output OUT is redirected to an internal COMP channel.

Caution: The input and output pins connected, through the OPAMP multiplexers, to the operational amplifier terminals INP, INM, and OUT must be configured in analog mode (default state), through the corresponding GPIOx_MODER register.

Table 181 lists the OPAMP internal signals. Refer to *Section 24.3* for pthe ossible connection of each to internal resources and for specialization of the signal name.

Table 181. OPAMP internal input/output signals

Name	Type	Description
opamp_tc1 opamp_tc2 opamp_tc3 opamp_tc4 opamp_tc5 opamp_tc6 opamp_tc7	I	Signal from a timer channel, selectable as control signal switching between primary and secondary controls for the input multiplexers.
opamp_tp1 opamp_tp2 opamp_tp3 opamp_tp4 opamp_tp5 opamp_tp6 opamp_tp7	I	Signal from a timer channel, selectable as control signal switching between primary and secondary controls for the programmable gain and for setting the PGA flavor.
opamp_dac_in	I	Output of a DAC channel, selectable as noninverting operational amplifier input. Exclusive with the OPAMP_VINP3 pin.
opamp_pclk	I	Clock for OPAMP registers.
opamp_out	O	Operational amplifier output to an internal COMP channel, when redirected through the OPAINTOEN bit.

24.4.3 OPAMP reset and clocks

The OPAMP clock opamp_pclk provided by the clock controller is generated from the PCLK1 (APB1 clock). To access the OPAMP control registers, it is necessary to set the corresponding OPAMPxEN bit of the RCC_APB1ENR register.

The OPAMP registers can be reset through the corresponding OPAMPxRST bit of the RCC_APB1RSTR register.

24.4.4 OPAMP output redirection to an internal COMP channel

The operational amplifier output OUT can be redirected internally to a COMP channel, by setting the OPAINTOEN bit of the OPAMP_CSR register. In this case, the I/O pin OPAMP_VOUT on which the operation amplifier output OUT is mapped can be used for another purpose. See *Table 179* for possible COMP input channel assignment to OPAMP instances.

When OUT is connected to a COMP input channel, it is not connected to the OPAMP_VOUT pin.

24.4.5 OPAMP initial configuration

By default (upon reset):

- The operational amplifier inputs INP/INM and output OUT are connected to I/O pins.
- The registers for offset compensation contain factory trimming values and are in read-only access mode.
- The speed (slew rate) is set to normal.
- The timer-controlled operation of multiplexers is disabled.
- OPAMP is disabled.

24.4.6 OPAMP operational amplifier speed

The initial operational amplifier speed (slew rate, response) is normal. Setting the OPAHSM bit of the OPAMP_CSR register increases the speed. Both normal and high-speed mode characteristics are defined in the datasheet.

24.4.7 OPAMP enable

When disabled (default upon reset), the OPAMP control and calibration registers can still be modified. The operational amplifier output OUT is in high-Z state.

It is recommended to update the OPAMP registers while the OPAMP peripheral is disabled, to avoid spurious effects on the output.

OPAMP is enabled by setting the OPAEN bit of the OPAMP_CSR register. The INP and INM inputs and the OUT output are connected through the embedded multiplexers according to the control register settings and the timer control signals.

24.4.8 OPAMP operating modes

OPAMP can be configured to different operating modes or use cases, through:

- OPAMP control registers
- GPIOx_MODER registers, configuring the I/Os selected as OPAMP inputs and output
- COMP registers, selecting a COMP input channel when the operational amplifier output is redirected to the COMP
- External components, defining the gain, bias, or filtering parameters

The principal operating modes are:

- Stand-alone operational amplifier
- Follower
- Programmable-gain amplifier (PGA)

Refer to the following subsections for details and for different PGA flavors.

Through the OPAINTOEN bit of the *OPAMP control/status register (OPAMP_CSR)*, the operational amplifier output OUT can be connected to the I/O pin selected as OPAMP output (default) or to an internal COMP input channel. However, the latter option cannot be used when the operational amplifier output on the pin is required.

The OPAHSM bit (0 by default) allows increasing the operational amplifier speed (slew rate).

The USERTRIM bit can enable writing to the input offset trimming register, to allow modifying the by-default factory trimming values by the user.

The impedance of the input signal must be low enough to prevent the OPAMP input current from creating a voltage drop in the source, thus altering the input voltage. Refer to the electrical characteristics section in the datasheet for further details.

Standalone operational amplifier

For this use, ensure the following settings.

- Select a pin for the INP input (as opposed to a DAC output), with VP_SEL[2:0] and VPS_SEL[2:0] bitfields.
- Set the VM_SEL[1:0] bitfield to 0X, to ensure that a pin is selected for the INM input.
- Clear OPAINTOEN bit, to direct the operational amplifier output to the OPAMP_VOUT pin.

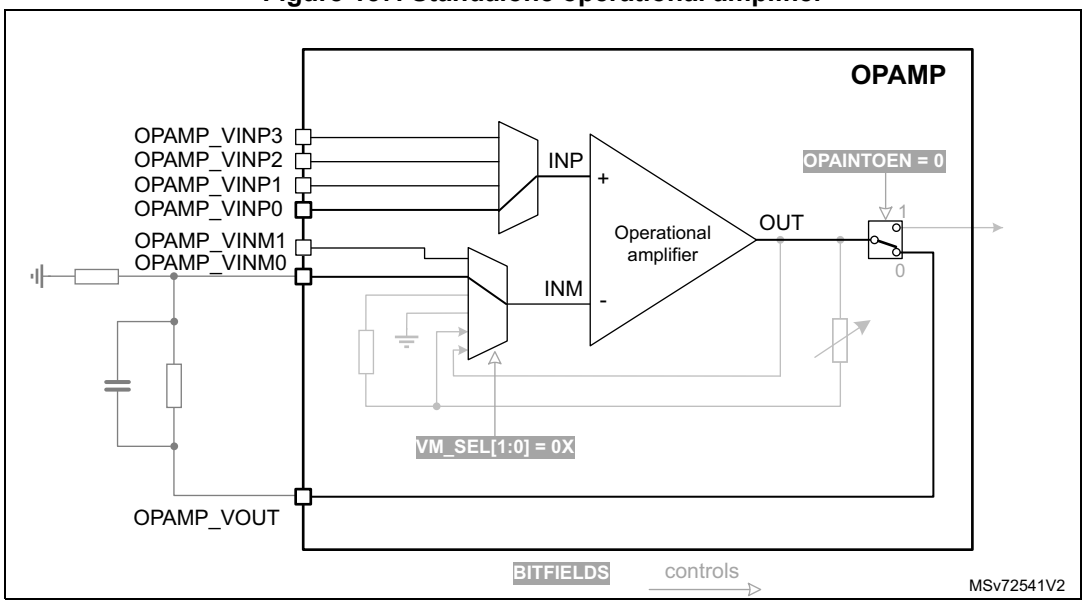
With these settings, the INP, INM inputs, and the OUT output of the operational amplifier are connected to pins and to no other internal structure.

Note: The OPAMP_CSR, OPAMP_TCMR, and GPIOx_MODER registers in their default state configure OPAMP as standalone operational amplifier, with normal speed, factory offset trimming values, and with OPAMP_VINP0 and OPAMP_VINM0 selected for INP and INM, respectively. The OPAMP is disabled so the OUT and OPAMP_OUT are in high-Z state.

Once enabled, OPAMP operates as a standalone operational amplifier, with the gain, filtering, and biasing determined by external routing and components.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin, and not to the internal COMP channel.

Figure 157. Standalone operational amplifier



Follower

To use OPAMP as a follower with an internal feedback, set the following bitfields as indicated:

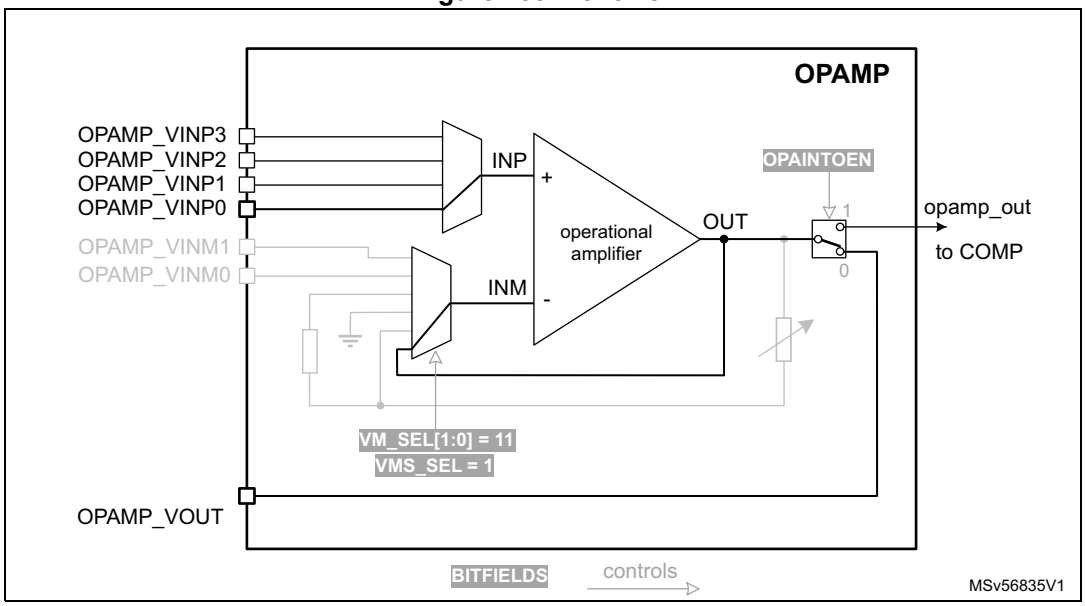
- VM_SEL[1:0] to 11 and VMS_SEL to 1, to loop the operational amplifier output back to its inverting input INM
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select for the noninverting input INP

Once enabled, the operational amplifier buffers the voltage selected on its noninverting input INP.

Note: The GPIOs corresponding to OPAMP_VINMy are free for another use.

In this mode, OPAMP takes two pins if a pin is selected for INP noninverting input. It takes a single pin if an internal DAC output is selected for INP noninverting input (on instances supporting this). Refer to Section 24.3.

Figure 158. Follower



Programmable-gain amplifier

When OPAMP is configured as a programmable-gain amplifier (PGA), the internal resistor divider with a programmable resistor value determines the amplifier gain. Refer to the datasheet for the values of the internal resistors.

The following sections describe different PGA flavors.

Noninverting PGA

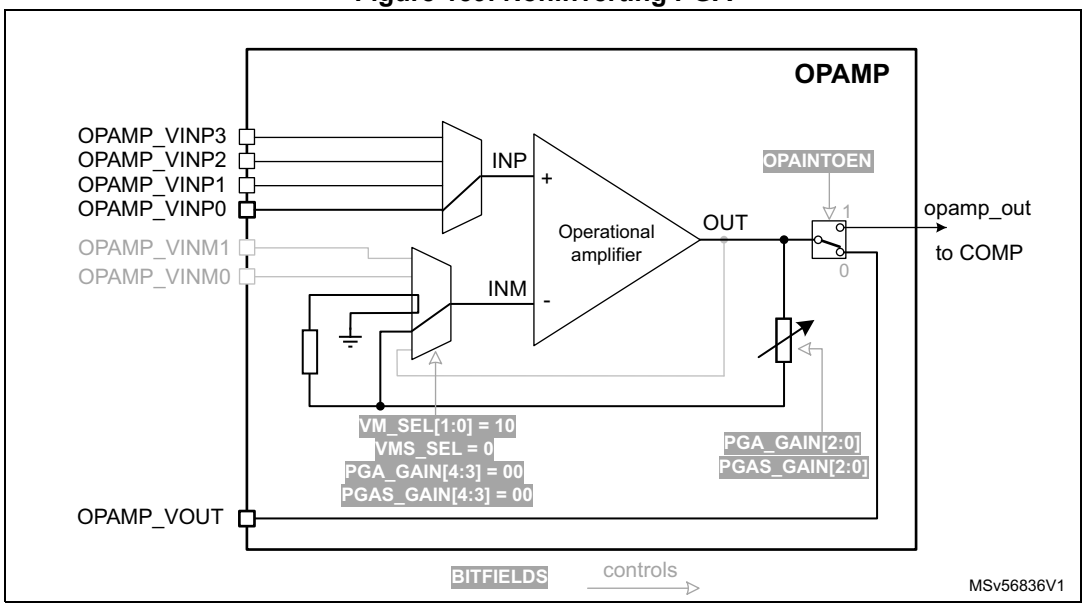
To use OPAMP as a noninverting PGA without filtering, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 00XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

Once enabled, OPAMP outputs a voltage that corresponds to the selected input pin voltage multiplied by the selected gain value.

Note: To avoid saturation, keep the product of the input voltage and the selected gain value below V_{DDA}.

Figure 159. Noninverting PGA



Noninverting PGA with filtering

To use OPAMP as a noninverting PGA with filtering, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 10XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

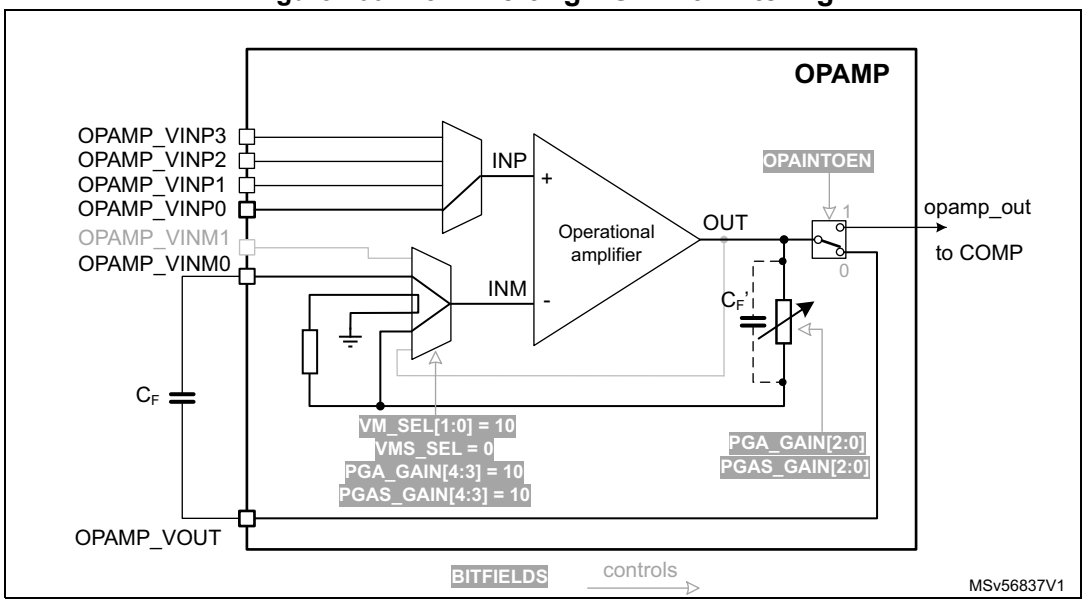
Once enabled, OPAMP outputs a voltage that corresponds to the selected input pin voltage multiplied with the selected gain (for static signals).

External components connected between the OPAMP_VOUT pin and the OPAMP_VINM0 pin are put in parallel with the internal programmable resistor. For example, connecting a capacitor C_F as shown in *Figure 160* has a filtering effect equivalent to C_F' of the same

capacitance. The gain for dynamic signals then also depends on the signal frequency and the cutoff frequency of the filter.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal COMP channel.

Figure 160. Noninverting PGA with filtering



Noninverting PGA with external bias, or inverting PGA

To use OPAMP as a noninverting PGA with external bias or as an inverting PGA, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 01XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

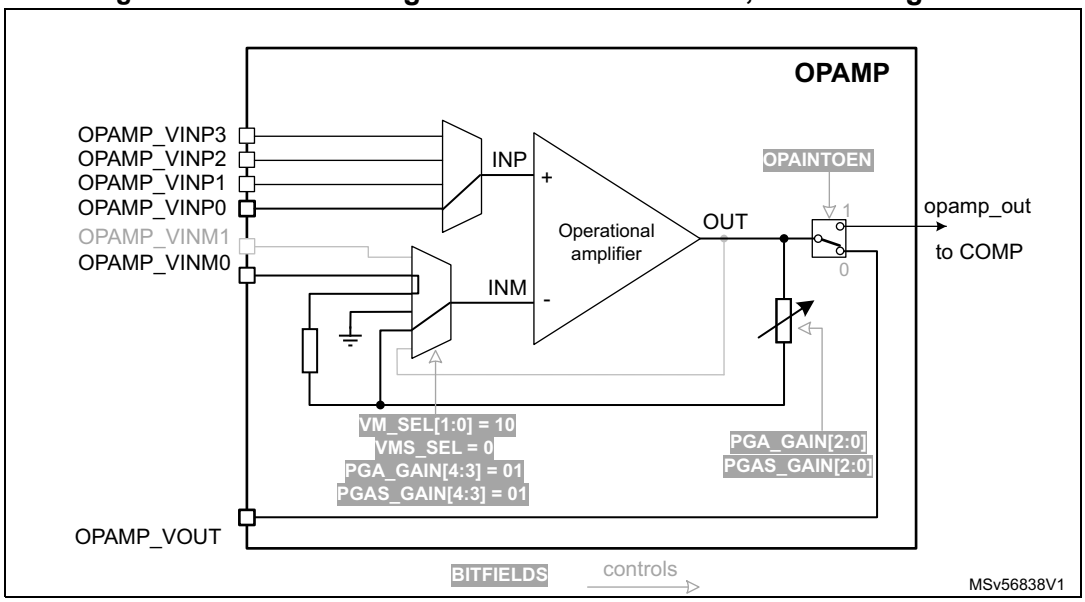
For the signal on the selected OPAMP_VINPy pin, OPAMP operates as a noninverting amplifier with the selected positive gain. The OPAMP_VINM0 pin is used as a reference (bias).

For the signal on the OPAMP_VINM0 pin, OPAMP operates as an inverting amplifier with the selected negative gain. The selected OPAMP_VINPy pin is used as a reference.

Note: The final gain depends upon the output impedance of the source connected to the OPAMP_VINM0 pin.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin, and not to the internal COMP channel.

Figure 161. Noninverting PGA with external bias, or inverting PGA



Inverting or noninverting PGA with external bias or/and filtering

To use OPAMP as a noninverting PGA with external bias, or as an inverting PGA with filtering, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 11XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

For the signal on the selected OPAMP_VINPy pin, OPAMP operates as a noninverting amplifier with the selected positive gain. The voltage on the OPAMP_VINM0 pin is used as a reference (bias).

For the signal on the OPAMP_VINM0 pin, OPAMP operates as an inverting amplifier with the selected negative gain. The voltage on the selected OPAMP_VINPy pin is used as a reference (bias). The output impedance of the biasing voltage source impacts the total gain.

In both cases, any external components connected between the OPAMP_VOUT pin and the OPAMP_VINM1 pin are put in parallel with the internal programmable resistor. For example, connecting a capacitor C_F as shown in the following figure has a filtering effect equivalent to C_F' of the same capacitance. The gain for dynamic signals then also depends on the signal frequency and the cutoff frequency of the filter.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal COMP channel.

Figure 162. Inverting or noninverting PGA with external bias or/and filtering

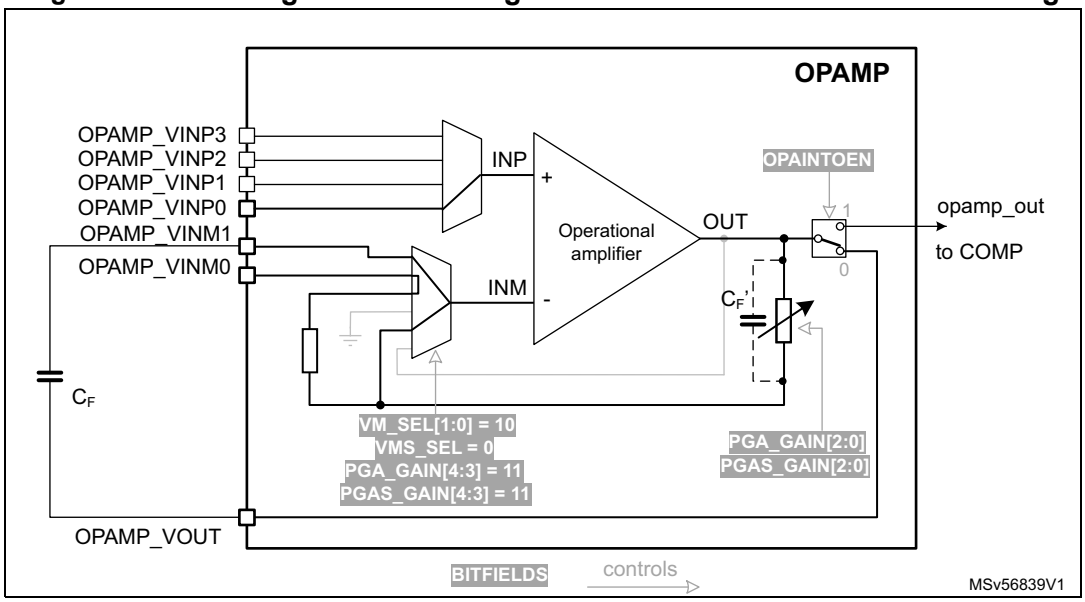


Figure 163. Simplified view

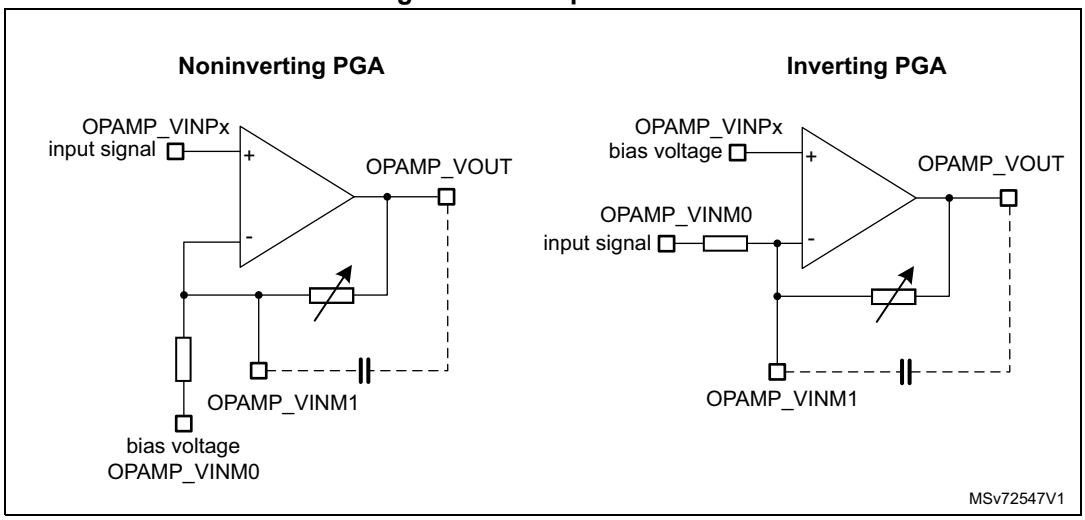


24.4.9 OPAMP programmable gain

In PGA mode, OPAMP allows selecting one of discrete positive (noninverting configuration) or negative (inverting configuration) gain values. The selection is done through the bits [2:0] of the PGA_GAIN[4:0] bitfield of the OPAMP_CSR register or through the bits [2:0] of the PGAS_GAIN[4:0] bitfield of the OPAMP_TCMR register. The control bitfield is selected with the control signal at the output of the opamp_tpX selector.

In noninverting mode, the programmable gain depends only upon the internal resistive divider. In inverting mode, depends upon the internal resistors, and upon the output impedance of the signal source. The higher it is, the greater impact it has on the final gain.

24.4.10 OPAMP operational amplifier offset compensation

The peripheral incorporates a trimming circuitry that impacts the operational amplifier input offset. The trimming circuitry is controlled through the TRIMOFFSETN[4:0] (for the N differential pair) and TRIMOFFSETP[4:0] (for the P differential pair) bitfields of the *OPAMP control/status register (OPAMP_CSR)*.

The TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields keep the trimming value for the N differential pair and P differential pair, respectively.

Upon reset, these registers are loaded with factory trimming values stored in the nonvolatile memory. As the USERTRIM bit is low, the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] control bitfields are read-only.

Note: The factory trimming values result from a calibration procedure run on the production line in specific production conditions.

When the offset compensation obtained with the factory trimming values is not acceptable for a specific use case (supply voltage, operating temperature), the user software can apply different trimming values.

To modify the trimming values, the user software has first to set the USERTRIM bit to allow writing into the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] control bitfields.

To retain the user trimming values, the user software has to write them into a nonvolatile memory. It typically retrieves them from the nonvolatile memory and writes into TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] at the startup, before the first use of OPAMP.

The resolution of the offset trimming allows reducing the input offset voltage to a value defined in the datasheet, at a defined supply voltage and die temperature.

24.4.11 OPAMP calibration

The calibration allows finding the trimming values that minimize the operational amplifier offset.

Setting the CALON bit isolates the operational amplifier INP and INM inputs and connects them to the internal reference voltage level selected through the CALSEL[1:0] bitfield. The operational amplifier is in a comparator (high gain, open loop) mode in which its output transits from one rail to another when the voltage level on one input crosses the voltage level on the other input.

The CALOUT flag reflects this digital value (lower rail or upper rail) of the OPAMP_VOUT pin.

The CALSEL[1:0] bitfield values 01 (low reference voltage) and 11 (high reference voltage) are intended for use in the calibration procedure. The value 01 is for trimming the PMOS through the TRIMOFFSETP[4:0] bitfield, the value 11 for trimming the NMOS through the TRIMOFFSETN[4:0] bitfield.

The calibration is carried out by software. Starting from the trimming bitfield at 0 and the CALOUT flag at one, the procedure consists in incrementing the trimming value until the CALOUT flag toggles to 0. The last trimming value is the one that compensates for the operational amplifier offset of the given OPAMP instance, and for the given supply voltage, die temperature, and differential pair stage (PMOS or NMOS). Upon each trimming value incrementation, the software must wait for at least the $t_{OFFTRIM}$max period defined in the product datasheet, before reading the CALOUT flag and potentially proceeding to the next incrementation step.

Note: The closer is the trimming value to the offset compensation point, the longer the output voltage takes to respond (without ever exceeding $t_{OFFTRIM}max$).

The full calibration consists of four calibration loops, as listed in *Table 182*. They can be executed in any order. The CALON bit must be set for executing any calibration loop. The calibration loops for the operational amplifier speed (slew rate) not required in the application can be omitted.

Table 182. Calibration loops

Calibration loop	Control bitfield		
	CALSEL[1:0]	TRIMOFFSETN[4:0]	TRIMOFFSETP[4:0]
NMOS	11	Increment	Keep as is
PMOS	01	Keep as is	Increment

Different OPAMP instances can be calibrated at any time, even at the same time.

Calibration initialization

To initialize the offset trimming value calibration:

- Enable OPAMP, by setting OPAEN.
- Make the trimming bitfields writable, by setting USERTRIM.
- Write TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields with 0b00000.

Calibration loop sequence

To execute a calibration loop, go through the following steps:

1. Select the calibration loop, with the CALSEL[1:0] bitfield. That is, the speed (slew rate) and the differential pair end (NMOS or PMOS) to calibrate.
2. Increment the appropriate trimming bitfield (TRIMOFFSETN[4:0] for NMOS, TRIMOFFSETP[4:0] for PMOS), keeping the other trimming bitfield as is.
3. Wait for at least the $t_{OFFTRIMmax}$ period.
4. Check the CALOUT flag (OPAINTOEN = 0). If high, go to step *2* (loop back).
5. The trimming bitfield is calibrated. Store the calibrated trimming value if required.

For a given speed (slew rate), execute both the NMOS and the PMOS calibration loops.

Note: During the calibration loop execution, the external connection of the operational amplifier output must not pull up or down currents exceeding 500 µA.

Calibrating when operational amplifier output goes to a COMP input

With the operational amplifier output redirected to an internal COMP input channel (OPAINTOEN bit set), the CALOUT flag does not reflect the operational amplifier output. To address this, it is advised to clear the OPAINTOEN bit for the time of calibration to make the CALOUT flag operate. When the calibration is completed, set OPAINTOEN to redirect the operational amplifier output back to a COMP input channel. As during the calibration the internal signal sent to the OPAMP_VOUT pin toggles, take care to prevent any conflict on the pin. For example, use the pin in the application as an input.

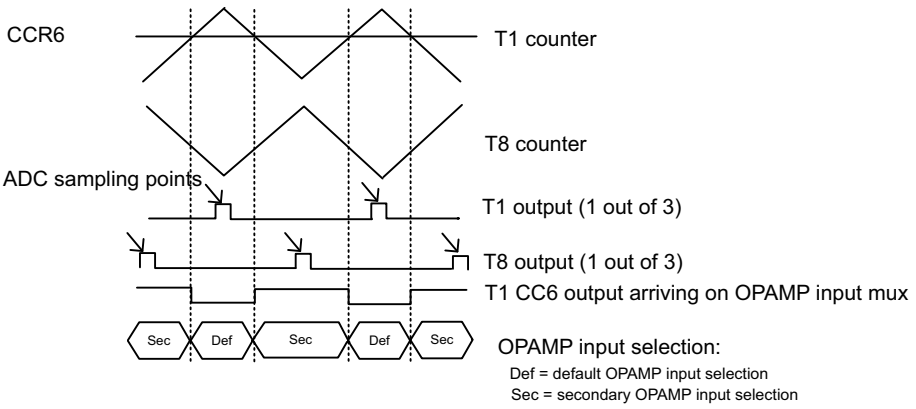
24.4.12 Timer-controlled operation

Certain timer channels (see *Table 183*) can toggle the control of the operational amplifier multiplexers between the primary configuration defined through the OPAMP_CSR register and the secondary configuration defined through the OPAMP_TCMR register.

Once configured, the mechanism operates even when the OPAMP clock is disabled.

As an example, this can be used for dual motor control. *Figure 164* illustrates the use of a timer compare output toggling the OPAMP primary (default) and secondary configurations, to measure alternatively the currents of the three phases of a motor, then of the other motor.

Figure 164. Timer-controlled operation for a dual motor application



Timer-controlled input selection

This operation is activated by writing a value other than 0 to the TIMCM_SEL[2:0] bitfield of the OPAMP_TCMR register, thus selecting one of the opamp_tcX signals. As long as the selected signal is low, the input selectors are controlled with the VP_SEL[1:0] and VM_SEL[1:0] bitfields of the OPAMP_CSR register. As long as it is high, the input selectors are controlled with the VPS_SEL[1:0] and VMS_SEL bitfields of the OPAMP_TCMR register. Writing 0 to TIMCM_SEL[2:0] (default upon reset) makes the input selectors steadily controlled with VP_SEL[1:0] and VM_SEL[1:0].

Table 183 gives the correspondence between the opamp_tcX and the timer signals.

Table 183. Timer-controlled input selection

TIMCM_SEL[2:0]	Signal name	Timer connection
000	-	None
001	opamp_tc1	tim1_oc6
010	opamp_tc2	tim2_oc4
011	opamp_tc3	tim12_oc1
100	opamp_tc4	tim15_oc2
101	opamp_tc5	Reserved
110	opamp_tc6	Reserved
111	opamp_tc7	Reserved

Timer-controlled programmable gain and PGA flavor

This operation is activated by writing a value other than 0 to the TIMPGA_SEL[2:0] bitfield of the OPAMP_TCMR register, thus selecting one of opamp_tpX signals. As long as the selected signal is low, the programmable gain and PGA flavor selectors are controlled with the PGA_GAIN[4:0] bitfield of the OPAMP_CSR register. As long as it is high, the input selectors are controlled with the PGAS_GAIN[4:0] bitfield of the OPAMP_TCMR register. Writing 0 to TIMPGA_SEL[2:0] (default upon reset) makes the programmable gain and PGA flavor selectors steadily controlled with PGA_GAIN[4:0].

The following table gives the correspondence of the opamp_tpX signals to timer signals.

Table 184. Timer-controlled programmable gain selection

TIMPGA_SEL[2:0]	Signal name	Timer connection
000	-	None
001	opamp_tp1	tim1_oc6
010	opamp_tp2	tim2_oc4
011	opamp_tp3	tim12_oc2
100	opamp_tp4	tim15_oc2
101	opamp_tp5	Reserved
110	opamp_tp6	Reserved
111	opamp_tp7	Reserved

24.5 OPAMP in low-power modes

Table 185. Effect of low-power modes on OPAMP

Mode	Description
Sleep	No effect.
Stop	No effect, OPAMP register contents are kept.
Standby	The OPAMP registers are powered down and must be re-initialized after exiting Standby mode.

24.6 OPAMP registers

24.6.1 OPAMP control/status register (OPAMP_CSR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	CAL OUT	TSTREF	TRIMOFFSETN[4:0]					TRIMOFFSETP[4:0]					PGA_GAIN[4:2]		
rw	r	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PGA_GAIN[1:0]		CALSEL[1:0]		CALON	Res.	Res.	OPAINTOEN	OPAHSM	VM_SEL[1:0]		USERTRIM	VP_SEL[1:0]		FORCE_VP	OPAEN
rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: OPAMP_CSR register lock

This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit is used to configure the OPAMP_CSR register as read-only.
0: OPAMP_CSR is read-write
1: OPAMP_CSR is read-only

Bit 30 **CALOUT:** Operational amplifier calibration output

This bit reflects the digital value of OPAMP output when OPAINTOEN bit is low. During the input offset calibration procedure, it provides the indication that the target trimming value is reached, by transiting from 1 to 0.
The bit cannot be used as long as the OPAINTOEN bit is high.

Bit 29 **TSTREF:** OPAMP calibration reference voltage output control

This bit is reserved for test. When set, OPAMP outputs the calibration reference voltage.
0: Does not output calibration reference voltage
1: Outputs calibration reference voltage

Bits 28:24 **TRIMOFFSETN[4:0]**: Trim for NMOS differential pairs

Upon reset, this bitfield is loaded with the factory trimming value. It can only be modified when the USERTRIM bit is set.

Bits 23:19 **TRIMOFFSETP[4:0]**: Trim for PMOS differential pairs

Upon reset, this bitfield is loaded with the factory trimming value. It can only be modified when the USERTRIM bit is set.

Bits 18:14 **PGA_GAIN[4:0]:** Operational amplifier programmable gain and PGA flavor primary control
This bitfield selects the programmable gain (bits [2:1]) and the PGA flavor ([bits 4:3]). Positive numbers represent positive gain (noninverting PGA), negative numbers negative gain (inverting PGA).
00000: gain 2
00001: gain 4
00010: gain 8
00011: gain 16
01000: gain -1 / gain 2 with bias on OPAMP_VINM0
01001: gain -3 / gain 4 with bias on OPAMP_VINM0
01010: gain -7 / gain 8 with bias on OPAMP_VINM0
01011: gain -15 / gain 16 with bias on OPAMP_VINM0
10000: gain 2 with filtering on OPAMP_VINM0
10001: gain 4 with filtering on OPAMP_VINM0
10010: gain 8 with filtering on OPAMP_VINM0
10011: gain 16 with filtering on OPAMP_VINM0
11000: gain -1 / gain 2 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11001: gain -3 / gain 4 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11010: gain -7 / gain 8 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11011: gain -15 / gain 16 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
Other: Not used

Bits 13:12 **CALSEL[1:0]:** Calibration selection
This bitfield selects the offset calibration reference voltage applied on the operational amplifier inputs when CALON and FORCE_VP bits are set.
00: $0.033*V_{DDA}$
01: $0.1*V_{DDA}$ (for PMOS calibration)
10: $0.5*V_{DDA}$
11: $0.9*V_{DDA}$ (for NMOS calibration)

Bit 11 **CALON:** Calibration mode enable
This bitfield disables or enables the calibration mode.
0: Calibration mode disabled
1: Calibration mode enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAINTOEN:** Operational amplifier internal output enable
This bit determines where the operational amplifier output is connected, either to the OPAMP_VOUT pin or internally to a COMP channel.
0: OPAMP_VOUT pin
1: COMP channel

Bit 7 **OPAHSM:** Operational amplifier high-speed mode
This bit determines the speed (slew rate) of the operational amplifier.
0: Normal speed
1: High speed
Only change this configuration when OPAMP is disabled.

Bits 6:5 **VM_SEL[1:0]:** Inverting input primary selection
This bitfield determines where the operational amplifier inverting input is connected to.
00: OPAMP_VINM0 pin
01: OPAMP_VINM1 pin
10: Internal resistor divider middle point
11: Operational amplifier output
The setting 10 is for the PGA use cases. With this setting, the connection of the OPAMP_VINM0 and OPAMP_VINM1 pins is determined by the PGA_GAIN[4:0] bitfield.
The setting 11 sets OPAMP in follower mode. With the other two settings, OPAMP is configured as a stand-alone operational amplifier.

Bit 4 **USERTRIM**: User trimming enable
This bit enables the user trimming of the operational amplifier input offset. When set, the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields, loaded with factory trimming values upon reset, become writable. This allows modifying the input offset trimming values by the user.
0: Disable (trimming by user not possible)
1: Enable (trimming by user possible)

Bits 3:2 **VP_SEL[1:0]:** Noninverting input primary selection
This bitfield determines where the operational amplifier noninverting input is connected to.
00: OPAMP_VINP0 pin
01: OPAMP_VINP1 pin
10: OPAMP_VINP2 pin
11: OPAMP_VINP3 pin or DAC output channel
Refer to *Section 24.3: OPAMP implementation* for OPAMP instance-dependent information.

Bit 1 **FORCE_VP:** Force internal reference on noninverting input
This bit is reserved for test. It allows forcing the calibration reference voltage selected through the CALSEL[1:0] bitfield on the operational amplifier noninverting input.
0: Do not force (normal operation)
1: Force

Bit 0 **OPAEN:** Operational amplifier enable
This bit enables and disables the operational amplifier.
0: Disable
1: Enable

24.6.2 OPAMP timer-controlled mode register (OPAMP_TCMR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMPGA_SEL[2:0]			PGAS_GAIN[4:0]					Res.	Res.	TIMCM_SEL[2:0]			VPS_SEL[1:0]		VMS_SEL
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: OPAMP_TCMR register lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit determines whether the OPAMP_TCMR register is read-write or read-only.
0: Read-write
1: Read-only (OPAMP_TCMR locked)

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:13 **TIMPGA_SEL[2:0]**: Timer toggle signal selection for programmable gain control
This bitfield is set and cleared by software. It selects the signal (coming from timer to OPAMP multiplexers) that toggles the programmable gain control bitfields between the primary (PGA_GAIN[4:0], signal at low level) and secondary (PGAS_GAIN[4:0], signal at high level).
000: None (gain permanently controlled through PGA_GAIN[4:0] and VM_SEL[1:0])
001: opamp_tp1
010: opamp_tp2
011: opamp_tp3
100: opamp_tp4
101: opamp_tp5
110: opamp_tp6
111: opamp_tp7

Bits 12:8 **PGAS_GAIN[4:0]**: Operational amplifier programmable gain and PGA flavor secondary control
This bitfield selects the programmable gain (bits [2:1]) and the PGA flavor ([bits 4:3]) when the timer signal selected through TIMPGA_SEL[2:0] is high. Positive numbers represent positive gain (noninverting PGA), negative numbers negative gain (inverting PGA).
00000: gain 2
00001: gain 4
00010: gain 8
00011: gain 16
01000: gain -1 / gain 2 with bias on OPAMP_VINM0
01001: gain -3 / gain 4 with bias on OPAMP_VINM0
01010: gain -7 / gain 8 with bias on OPAMP_VINM0
01011: gain -15 / gain 16 with bias on OPAMP_VINM0
10000: gain 2 with filtering on OPAMP_VINM0
10001: gain 4 with filtering on OPAMP_VINM0
10010: gain 8 with filtering on OPAMP_VINM0
10011: gain 16 with filtering on OPAMP_VINM0
11000: gain -1 / gain 2 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11001: gain -3 / gain 4 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11010: gain -7 / gain 8 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11011: gain -15 / gain of 16 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
Other: Not used

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:3 **TIMCM_SEL[2:0]**: Timer toggle signal selection for operational amplifier input control
This bitfield is set and cleared by software. It selects the signal (coming from timer to OPAMP multiplexers) that toggles the operational amplifier input configuration control bitfields between the primary (VP_SEL[1:0] / VM_SEL, signal at low level) and secondary (VPS_SEL[1:0] / VMS_SEL, signal at high level).
000: None (input configuration permanently controlled through VP_SEL[1:0] and VM_SEL)
001: opamp_tc1
010: opamp_tc2
011: opamp_tc3
100: opamp_tc4
101: opamp_tc5
110: opamp_tc6
111: opamp_tc7

Bits 2:1 **VPS_SEL[1:0]**: OPAMP noninverting input secondary selection.
This bitfield is set and cleared by software. It selects the signal to connect to the operational amplifier noninverting input as long as the level of the timer signal selected through the TIMCM_SEL[2:0] bitfield is high.
00: OPAMP_VINP0
01: OPAMP_VINP1
10: OPAMP_VINP2
11: OPAMP_VINP3 pin or DAC output channel
Refer to *Section 24.3: OPAMP implementation* for OPAMP instance-dependent information.

Bit 0 **VMS_SEL**: OPAMP inverting input secondary selection
This bitfield is set and cleared by software. It selects the signal to connect to the operational amplifier inverting input as long as the level of the timer signal selected through the TIMCM_SEL[2:0] bitfield is high. The effect also depends on the VM_SEL[1:0] bitfield.
Condition: VM_SEL[1:0] = 00 or 01
0: OPAMP_VINM0 (operation as stand-alone operational amplifier)
1: OPAMP_VINM1 (operation as stand-alone operational amplifier)
Condition: VM_SEL[1:0] = 10 or 11
0: Internal resistor divider middle point (operation as PGA)
1: Operational amplifier output (operation as follower)

24.6.3 OPAMP register map

Table 186. OPAMP register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.2 on page 90* for the register boundary addresses.

25 Coupling and chaining bridge (CCB)

This section only applies to STM32C59x/5A3 products.

25.1 CCB introduction

The coupling and chaining bridge (CCB) is a sophisticated security mechanism designed to ensure that private keys are protected, even against CPU access, and are wrapped with unique device keys, and stored securely in a secure storage.

The CCB can be programmed to implement special coupling and chaining operations required to protect private keys used in PKA protected operations.

These coupling and chaining operations involve the PKA, the SAES, and sometimes the RNG peripherals.

25.2 CCB main features

The principal features of the CCB are listed below:

- AHB system slave port, mapping multiple peripherals (see *Section 25.3*)
- AHB configuration slave port (CCB peripheral), accessible in write through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored). There is no limitation for reads.
- Optional coupling of PKA RAM writes to SAES input data register
- Support for multiple optional chaining options:
  - Read and write chaining between PKA RAM and SAES
  - SAES to CCB read chaining, with comparison to a 128-bit reference tag
  - RNG output chaining with either PKA RAM or SAES_IVR registers
- Dedicated sequences to support three PKA protected operations (modular exponentiation, scalar multiplication, ECDSA signature)
  - One-time sequence to prepare a PKA protected operation (blob creation)
  - Many-time sequence to execute PKA protected operation (blob usage)
- Optional private key generation for ECDSA signature, and for ECC private key cryptography (key never accessible to the application in clear-text)
- Possibility to encrypt, with AES-256, any PKA blob encryption key using the device unique secret key DHUK (in the SAES), which makes the PKA encrypted blob usable only on this device
- Software-reset capability
- Repository for cryptographic subsystem tamper event flags

25.3 CCB implementation

The CCB connects the peripherals listed in *Table 187*.

Table 187. Peripherals connected by CCB interconnect

Peripheral	Coupling and chaining feature(1)	Tamper status flag in CCB_SR
RNG	Yes	TAMP_EVT0
SAES	Yes	TAMP_EVT1
PKA	Yes	TAMP_EVT2 (registers + PKA RAM)
		TAMP_EVT3 (PKA operations)
CCB	Yes	TAMP_EVT4
AES	No	TAMP_EVT5
HASH	No	-

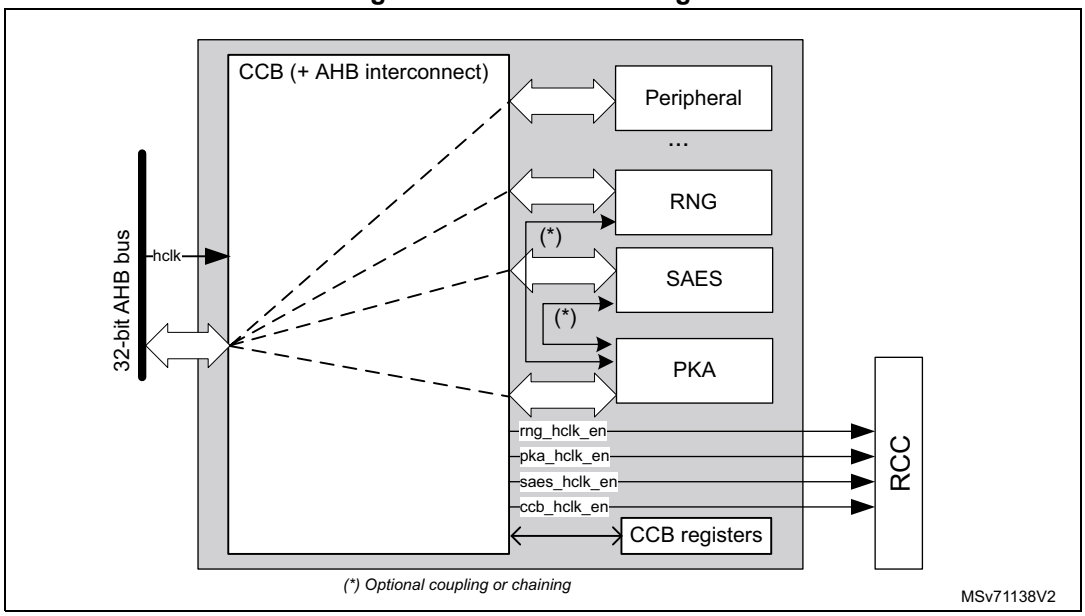
1. See *Section 25.4.4* for details.

25.4 CCB functional description

25.4.1 CCB block diagram

Figure 165 shows the CCB block diagram. Peripherals connected to the CCB interconnect, with optional coupling/chaining features, are defined in *Section 25.3*.

Figure 165. CCB block diagram



25.4.2 CCB internal signals

Table 188 describes the relevant internal signals interfacing the CCB peripheral. Signals targeting peripherals connected to the CCB are not listed.

Table 188. CCB internal input/output signals

Signal name	Signal type	Description
hclk	Digital input	Interconnect system clock input
ccb_hclk_en	Digital output	CCB clock request to the RCC
x_hclk_en	Digital output	Peripheral x clock request to the RCC (x = SAES, PKA, or RNG)

25.4.3 CCB reset and clocks

The CCB shares the same clock used by the AHB bus. Once the CCB clock is activated in the RCC, and coupling and chaining activity is activated by setting CCOP ≠ 0 in CCB_CR, the CCB automatically requests the RCC to enable RNG, SAES, and PKA clocks . These clocks remain enabled until the application gates them in the RCC, with CCOP cleared in the CCB_CR register.

The CCB has a dedicated reset bit in the RCC, and a system reset input. Locally to the CCB it is also possible to trigger a reset of the peripheral based on IPRST (do not use it when the application does not use CCB)in the CCB_CR register (refer to the bitfield description for details). Status register CCB_SR has a specific reset behavior (see *Section 25.7.2*).

When at least a cryptographic peripheral raises a tamper event, the CCB requests its clock to the RCC. The tamper status TAMP_EVTi of these peripherals can be found in the CCB_SR register, as defined in *Section 25.3*.

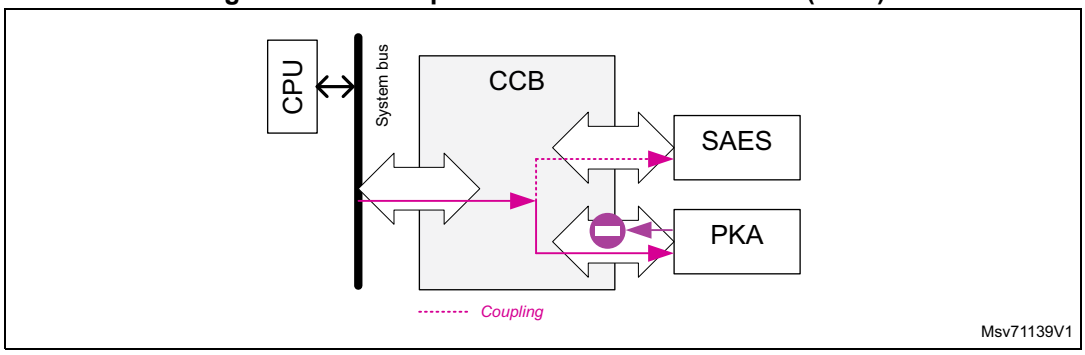
25.4.4 CCB coupling and chaining

Note: The selection of these chaining modes is defined in Section 25.5. In most of these operations, a read of the PKA RAM returns 0 (shown with a purple circle in the following figures).

Coupling CPU → PKA + SAES (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and sends them to SAES_DINR, as shown in *Figure 166*. Write to SAES_DINR is not coupled to the PKA. The CCB sends both data and address to SAES_DINR.

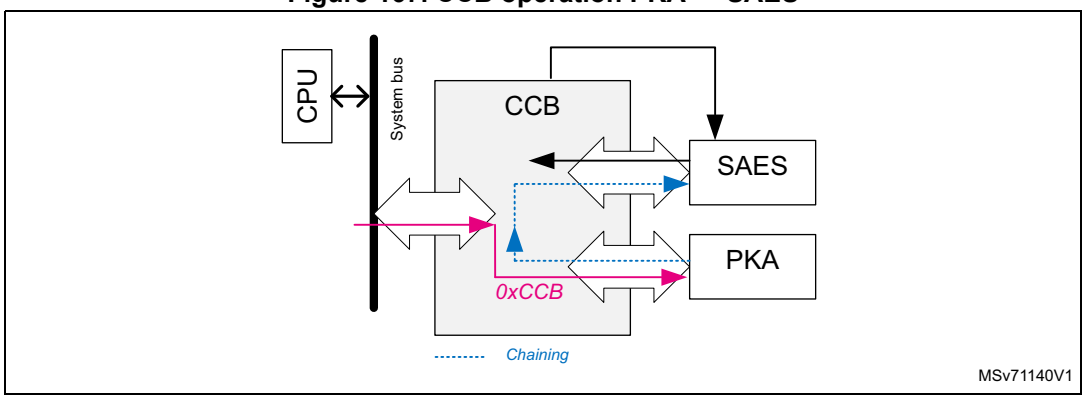
Figure 166. CCB operation CPU → PKA + SAES (write)



Chaining PKA → SAES

When the corresponding OPSTEP is selected, for each 32-bit write request to the PKA RAM of magic number 0xCCB, the CCB generates a read request from the write target (in the PKA RAM) to SAES_DINR.

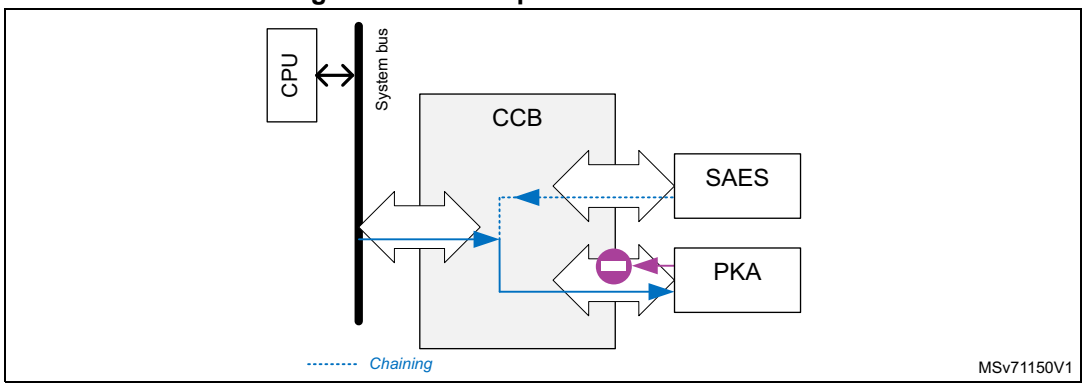
Figure 167. CCB operation PKA → SAES



Chaining SAES → PKA

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and substitutes these data by a 32-bit word coming from SAES_DOUTR. When available, this chaining is activated when the application writes 0xCCB to PKA RAM.

Figure 168. CCB operation SAES → PKA

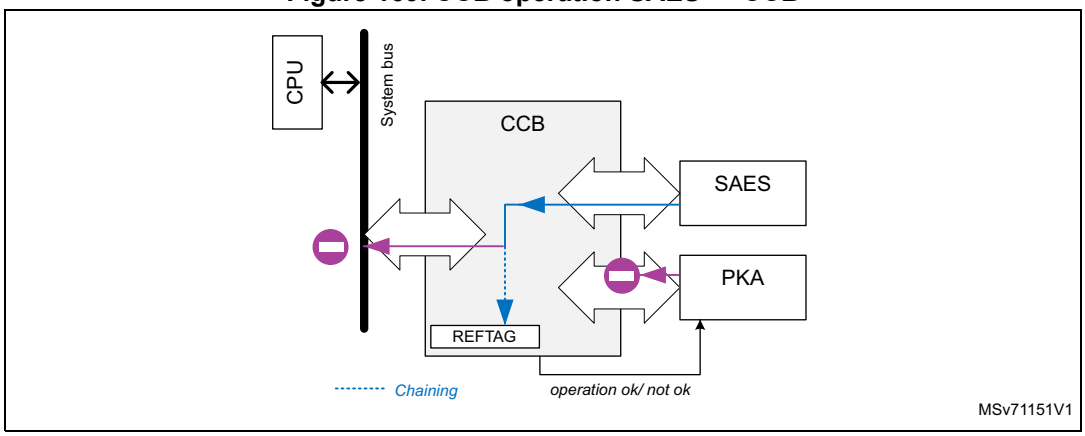


Chaining SAES → CCB

When the corresponding OPSTEP is selected, the CCB takes the read requests to SAES_DOUTR, and sends them to the system interconnect and to CCB_REFTAGRx holding the reference TAG information. For confidentiality reason, read data toward system bus are zeroed by the CCB.

If the CCB finds that the transfered value matches its reference information, it signals to the PKA that it can proceed with the protected PKA operation (START bit can be set).

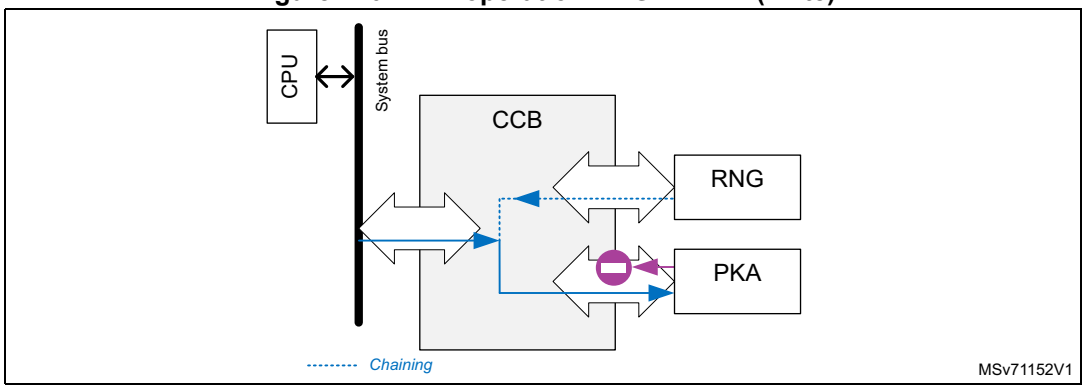
Figure 169. CCB operation SAES → CCB



Chaining RNG → PKA (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and substitutes these data with random numbers coming from RNG_DR. For consistency, the application can write 0xCCB to activate this chaining.

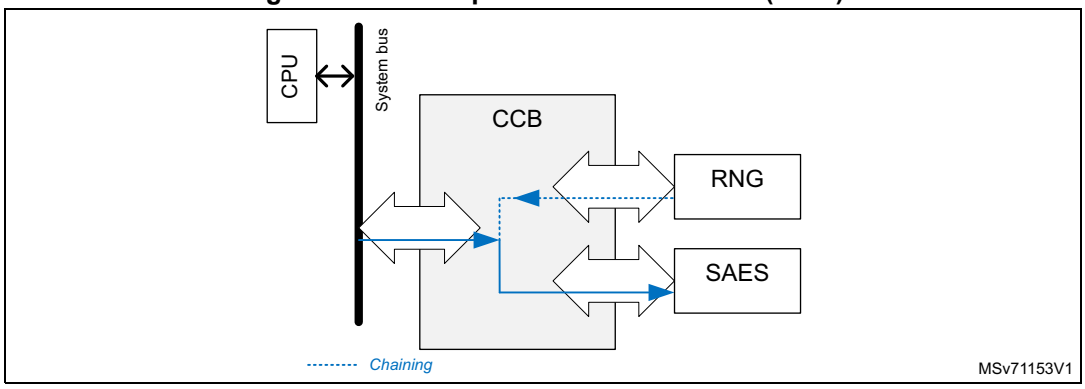
Figure 170. CCB operation RNG → PKA (write)



Chaining RNG → SAES (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to SAES_IVR1 to IVR3, and substitutes these data with random numbers coming from RNG_DR. For consistency, the application can write 0xCCB to activate this chaining.

Figure 171. CCB operation RNG → SAES (write)



25.4.5 CCB error management

When the CCB detects an error during a coupling and chaining operation (see *Section 25.5*), it sets accordingly OPERR[5:0] in CCB_SR (see *Section 25.7.2* for the possible errors).

When OPERR[5:0] ≠ 0 in CCB_SR, the CCB raises IPRST in CCB_CR, sets OPSTEP[4:0] to 0x1F, and sets CCB_BUSY bit to 1. The application must clear IPRST to be able to use again the CCB and the peripheral(s) used by the coupling and chaining operation.

25.5 CCB coupling and chaining operations

When an application must enforce private key confidentiality by wrapping them with a 256-bit hardware unique key, the following steps are needed:

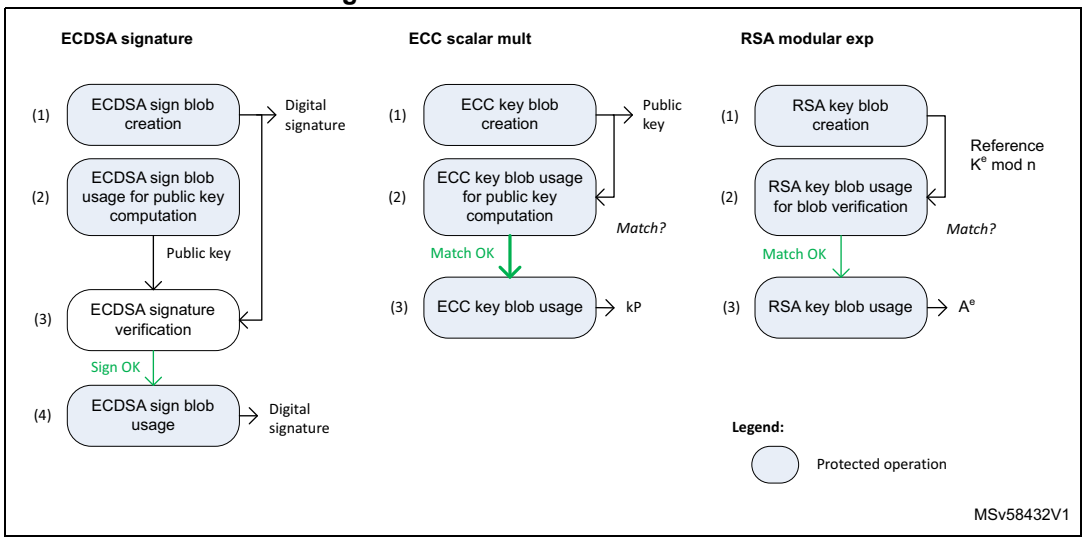
1. Select the protected operation in the PKA that uses this private key (ECDSA signature, scalar multiplication, modular exponentiation). Then, choose the CCOP value in the CCB that corresponds to the selected operation, as defined in this section. Then, as multiple cryptographic peripherals are used, make sure to follow the guidelines described in *Section 25.5.1*
2. When CCB is active (OPSTEP=0x1), select in the SAES the DHUK (with optional XOR with BHK), or unwrap in the SAES an existing blob encryption key that has been encrypted (in wrapped-key mo.de) using the DHUK. A 256-bit KEYSIZE must be selected.
   As the DHUK value is different when CCB is active or inactive, the operation of wrapping or unwrapping blob encryption key in SAES (with KMOD[1:0]=0x1) must be done when OPSTEP=0x1. Refer to operation with wrapped keys in *Section 28: Secure AES coprocessor (SAES)* for details.
3. When the application uses this protected operation in the PKA, it must load the related blob information in the PKA RAM and in SAES_DINR.
   – If the information exactly matches the conditions of the blob generation (choice and order of the writes of protected parameters in the PKA RAM, selection of blob

encryption key, use of original encrypted secrets), the CCB allows the application to set START bit in PKA_CR.

– If the blob information does not match the conditions of the blob generation, the application can only reset the sequence by setting IPRST bit in CCB_CR. CCB, PKA, and SAES become available when CCB_BUSY is cleared in CCB_SR.

4. At any time, the application can abort the executing protected operation by using the IPRST bit in CCB_CR.
5. When creating a blob, always use it once before trusting it to be stored in non-volatile memory or given to a less trusted code (see *Figure 172*). More specifically, each time a blob is created:
   – For ECDSA signature blob: use it to compute the public key, and use this key to verify the signature computed during the blob creation.
   – For ECC key blob: use it to compute the public key, and verify key coordinates match those of the key computed during the blob creation.
   – For RSA key blob: use it to compute a reference modular exponentiation and verify it matches the one computed during the blob creation.

Figure 172. Blob creation scenarios



This section describes how to do the above steps, for all available protected operations in the PKA. Note that:

- **Bold** elements in the following tables are key inputs that the application must save in non-volatile memory after the newly created blob has been confirmed by its first usage.
- The CCB automatically goes to the next step, updating the OPSTEP value, when the application clears or performs the end-step event described in tables of *Section 25.5.2* to *Section 25.5.4*.
- When an incremental read or write is mentioned, the application must write four bytes in the PKA memory, with an incremental memory address (modulo 0x8). Otherwise, the CMF error flag is triggered, and the process must be restarted.
- When writing to SAES_CR register the application must write the configuration expected by the CCB, otherwise an OPERR might be raised. Refer to the OPSTEP “CPU action” instructions in the application tables (*Table 189* through *Table 195*).
- When the CCB uses the RNG, the application must check in RNG_SR that no error occurred (SEIS = CEIS = 0), and that a random number is ready (DRDY = 1). In case of issue, RNGOKF is not set, and the application must ensure that the RNG is functional before running again the OPSTEP sequence that uses the RNG.
- For each OPSTEP>0, the application must manage the error flags that could occur in the RNG, SAES or PKA blocks. During a normal protected operation, no error flags are expected. Refer to *Section 25.4.5: CCB error management* for details on CCB error management.
- When CCB draws random number to compute ECC private keys, it implements the testing candidates method defined by NIST in FIPS PUB 186-4 section B.4.

Note: It is not possible to generate RSA key pairs with the CCB, they must be generated outside the device.

25.5.1 Preliminary steps before any protected operation

The following steps are required before running any operation described in this section:

1. Initialize the GTZC using the same security/privilege configuration protections for the SAES, PKA, RNG and CCB peripherals *Section 5: Global TrustZone® controller (GTZC)*. Otherwise OPERR=0x1A occurs (see *Section 25.7.2*).
2. Activate both RNG clocks, then initialize the peripheral to be fully functional, without pending errors.
3. Activate the PKA clock, then release the PKA reset. The PKA is functional once its RAM is automatically erased, and it has fetched the necessary random numbers. For further details refer to enabling/disabling PKA in *Section 30: Public key accelerator (PKA)*.
4. Activate the SAES clock, then release the SAES reset. The SAES is functional once it has fetched necessary random numbers.
5. Activate the CCB clock, set IPRST bit in CCB_CR, then clear it when CCB_BUSY=0x0 in CCB_SR.

Note: Step 4 can be done before step 3, as CCOP = 0x0.

25.5.2 ECDSA signature

This PKA operation is protected against side-channel attacks. When CCOP = 0x0, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0xC3, the private key d can be manipulated by the application only if encrypted, using a special blob called “ECDSA signature blob”.

ECDSA signature blob creation

The ECDSA signing operation is prepared by generating and then encrypting the private key d, and computing the reference GCM tag. This process is summarized *Table 189*, with coupling and chaining operations described in *Section 25.4.4*. This sequence starts by setting CCOP to 0xC0 or 0xC2 in CCB_CR.

Table 189. Blob creation steps for ECDSA signature (CCOP = 0b110000<i>0)

OP STEP	MODE in PKA	GCMPH in SAES	Coupling or chaining	End-step event(1)	CPU action in the step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x24 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt the blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set AES-GCM up in 256-bit encryption mode, with the DHUK or the decrypted key in register (if applicable). – Write hash z in the PKA RAM.
0x2		0x0	RNG -> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. SAES_IVR1 to SAES_IVR3 are loaded with randoms. – Read back **blob IV** in SAES_IVR registers.
0x3	0x24	0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in the SAES triggered after each 2x32-bit write.
0x6 (<i>=1)	0x24	0x2	RNG -> PKA	RNGOKF set	Write incrementally d in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if sanity check fails).
0x4 (<i>=0)			n/a	DATAOKF set	Write incrementally d in the PKA.
0x8	0x24		PKA -> SAES	DATAOKF set	– Read incrementally d from the PKA (writing 0xCCB magic numbers), and run AES encryption rounds. Special rule must be used for the last 64-bit word (see step 7 after the table). – Read **encrypted d** in SAES_DOUTR. – Repeat for each 16 bytes block of data.
0x9			RNG -> PKA	RNGOKF set, GCMPH = 0x3	– Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0xA(2)		0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR For the first two steps keep the SAES enabled (EN bit set).

Table 189. Blob creation steps for ECDSA signature (CCOP = 0b110000<i>0) (continued)

OP STEP	MODE in PKA	GCMPH in SAES	Coupling or chaining	End-step event(1)	CPU action in the step
0x19(3)	0x24	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM reads as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read signature (r,s) in PKA RAM, and save it in SRAM. It is used (at least once) for blob creation verification. – Set IPRST in CCB
0x0	N/A	N/A	N/A	N/A	– Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR. – Verify the newly created blob, running the *ECDSA signature blob use for public-key computation* with it.

1. The application must clear and/or perform the described event for the CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

The sequence described in *Table 189* is detailed below. Refer to the table for OPSTEP values and related coupling/chaining modes.

1. Write CCOP = 0xC0 or 0xC2 in CCB_CR.
2. Enable the PKA in the correct mode, writing in PKA_CR MODE=0x24 and EN=1 (repeat if the EN bit stays clear). Wait for INITOK=1 in PKA_SR.
3. Write the hash of the message in the PKA RAM
4. Initialize the ECC signature blob key in the SAES. This key can be the DHUK (KEYSEL = 0x1 or 0x4), or a key decrypted in 256-bit wrapped key mode by the DHUK (KEYSEL = 0x1 or 0x4, KMOD = 0x1, MODE = 0x1 or 0x2). See *Section 28: Secure AES coprocessor (SAES)* for details.
5. In the SAES, set the GCM chaining mode in encryption mode (CHMOD = 0x3, GCMPH = 0x0, MODE = 0x0, DATATYPE = 0x0). Then:
   a) Configure the 256-bit key size using KEYSIZE.
   b) Write SAES_IVRx, with any value (except SAES_IVR0 that must be equal to 0x2). For SAES_IV1 to IV3, random values are loaded into the SAES by the CCB. If an error occurs, RNGERRF is set in CCB_SR.
   c) Read back SAES_IVR1 to SAES_IVR3, and **save the value** in non-volatile memory after blob verification.
   d) Set EN in SAES_CR, and wait until CCF = 1 in SAES_ISR (end of GCM init).
   e) Clear CCF flag in SAES_ICR.
6. Select the header phase of the running GCM chaining mode (GCMPH = 0x1). Write the protected operation (ECDSA signature) mandatory parameters in the PKA RAM, as described in *Section 30: Public key accelerator (PKA)*. Do the following when writing data in the PKA:
   a) Write two 32-bit word in the PKA RAM, then wait until CCF is set in SAES_ISR. An SAES interrupt can be triggered when this flag is set.
   b) Clear CCF in SAES_ICR.

7. Select the payload phase of the running GCM chaining mode (GCMPH = 0x2). Write the private key *d* in the PKA RAM using the following sequence:
   a) If CCOP = 0xC0, write the private key d value in the PKA RAM. If CCOP = 0xC2, write the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The CCB then draws the value of *d* from the RNG, with PKA running a special sanity check to verify random compliance with NIST standard.
   b) Complete parameter information with the mandatory two 32-bit zeroed words. At the end of this process, the private key d of size *d_size* is written in the PKA RAM. Clear the error flag, then restart step 6 if the PKA sets RNGERRF when BUSY is cleared.
8. When the PKA sets its completion flag (RNGOKF if CCOP = 0xC2, DATAOKF if CCOP = 0xC0), clear it, then read the private key d in the PKA RAM using the sequence below (starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8):
   a) For each 64-bit word in the PKA RAM, write twice the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The target content of the PKA memory is transfered to SAES_DINR by the CCB. Wait until CCF is set in SAES_ISR (end of AES encryption). An SAES interrupt can be triggered when this flag is set.
   b) Clear CCF flag in SAES_ICR. Then read the encrypted private key d in SAES_DOUT, **to save it** in the non-volatile memory after blob verification.
   c) For the final 64-bit word (mandatory zeroed word): if the *d_size* is proportional to 16 bytes (for example, for 192- and 521-bit curves), the final 64 bits must be written to with two 32-bit magic numbers 0xCCB. If the *d_size* is not proportional to 16 bytes (for example, for 256- and 512-bit curves), the final 64 bits must be written with 0s.
9. When DATAOKF = 1 in PKA_SR (private key d ok), clear this flag. Then write to the integer k parameter addresses in the PKA memory, starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8. The CCB draws the value of k from the RNG. The PKA then runs a special sanity check to verify random compliance with NIST standard. Clear the error flag then restart this step if the PKA sets RNGERRF when BUSY is cleared.
10. When RNGOKF = 1 in PKA_SR (random k OK), clear this flag. Then select the final phase of the running GCM chaining mode (GCMPH = 0x3). Write the last GCM block in SAES_DINR. Then wait until CCF is set in SAES_ISR (end of GCM final).
11. Read SAES_DOUTR four times to retrieve the ECDSA signature blob reference tag. Save it in the non-volatile memory after blob verification. Do not disable SAES by clearing the EN bit.
12. Set START bit in PKA_CR to run the ECDSA signature operation.
13. When the PROCENDF completion flag is set save the ECDSA signature (r,s) of the hash z in SRAM to use it after using the new blob for public-key computation.
14. Clear CCOP by setting IPRST bit in CCB_CR. After CCB_BUSY is cleared in CCB_SR, clear the IPRST bit. The SAES, and PKA can again be used for any tasks. They are unprotected by the CCB until CCOP is written different from 0.

ECDSA signature blob usage for ECDSA signature

Table 190 summarizes the ECDSA signing operation using the encrypted private key d, the reference blob IV, and the computed GCM tag of *Table 189*. Coupling and chaining traffic options are described in *Section 25.4.4*. This sequence starts by setting CCOP to 0xC3 in the CCB_CR register.

Table 190. Blob use steps for ECDSA signature (CCOP = 0b11000011)

OPSTEP	MODE in PKA	GCMPH	Coupling or chaining operations	End-step event(1)	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x24 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt the blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set AES-GCM up in 256-bit encryption mode, with the DHUK or the decrypted key in register (if applicable). – Write hash z.
0x12		0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13	0x24	0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in the SAES, triggered after each 64-bit write.
0x14		0x2	SAES –> PKA	DATAOKF set	– Write encrypted d in SAES_DINR, and runs AES decryption round. – Write incrementally private key d in the PKA, using 0xCCB magic number. A special rule must be used for the last 64-bit write (see step 7 in the sequence detailed after this table). – Repeat for each 16-byte block of data.
0x16			RNG –> PKA	RNGOKF set, GCMPH = 0x3	Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0x17		0x3	SAES –> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x24	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)		N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM is read as 0.
0x1A		N/A	N/A	N/A	Read **signature (r,s)** in the PKA RAM.

1. The application must clear and/or perform the described event for the CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons..

The sequence described in *Table 190* is detailed below. Refer to the table for the OPSTEP values and related coupling and chaining modes.

1. Write CCOP = 0xC3 in CCB_CR.
2. Enable the PKA in the correct mode, writing in PKA_CR MODE=0x24 and EN=1(repeat if the EN bit stays clear). Wait for INITOK=1 in PKA_SR.
3. Write the hash of the message in the PKA RAM.
4. Initialize the ECC signature blob key in the SAES. This key can be the DHUK (KEYSEL = 0x1 or 0x4), or a key decrypted in 256-bit wrapped key mode by the DHUK (KEYSEL = 0x1 or 0x4, KMOD = 0x1, MODE = 0x1). Refer to *Section 28: Secure AES coprocessor (SAES)* for details.
5. Set the GCM chaining mode in decryption in the SAES (CHMOD = 0x3, GCMPH = 0x0, MODE = 0x2, DATATYPE = 0x0). Then:
   a) Configure the 256-bit key size using KEYSIZE.
   b) Write to SAES_IVRx registers the value saved in non-volatile memory.
   c) Set EN in SAES_CR, and wait until CCF is set in SAES_ISR (end of GCM init).
   d) Clear CCF flag in SAES_ICR.
   e) Write to CCB_REFTAGR registers, the ECDSA signature blob reference tag value saved in non-volatile memory.
6. Select the header phase of the running GCM chaining mode (GCMPH = 0x1). Write the protected operation (ECDSA signature) mandatory parameters in the PKA RAM, exactly as done during the blob creation. See step 5 in *ECDSA signature blob creation* for details.
7. Select the payload phase of the running GCM chaining mode (GCMPH = 0x2). Write the protected private key d in the PKA RAM, following the below sequence (starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8):
   a) Writetwo 64-bit words of encrypted private key d in SAES_DINR. Wait until CCF is set in SAES_ISR (end of AES decryption). An SAES interrupt can be triggered when this flag is set.
   b) Clear the CCF flag in the SAES_ICR register. Then, for both 64-bit words, write four times the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The CCB transfers the clear-text content of SAES_DOUTR to the PKA.
   c) For the final 64-bit word (mandatory zeroed word): If *d_size* defined in step 6 in *ECDSA signature blob creation* is not proportional to 16-bytes (for example, for 256- and 512-bit curves), the final 64 bits must be written with 0s.
8. When DATAOKF = 1 in PKA_SR (private key d ok), clear this flag. Then write to the integer k parameter addresses in the PKA memory, starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8. The CCB draws the value of k from the RNG. The PKA then runs a special sanity check to verify random compliance with NIST standard. Clear the error flag, then restart step 7 if the PKA sets RNGERRF when BUSY is cleared.
9. When RNGOKF = 1 in PKA_SR (random k ok), clear this flag. Then select the final phase of the running GCM chaining mode (GCMPH = 0x3). Write the last GCM block in SAES_DINR. Then wait until CCF is set in SAES_ISR (end of GCM final).
10. Read four times SAES_DOUTR (returns 0s). If PKA parameters were written exactly like during the blob creation, and the correct private key d was used, and all expected DATAOKF/RNGOKF flags were raised then cleared, the application can set START bit

in PKA_CR to run the ECDSA signature operation. Otherwise, IPRST in CCB_CR must be used to restart the sequence from step 1.

11. Clear CCOP by setting IPRST in CCB_CR. After CCB_BUSY is cleared in CCB_SR, clear the IPRST bit. The SAES, and PKA can again be used for any tasks. They are unprotected by the CCB until CCOP in CCB_CR is written different from 0.

ECDSA signature blob use for public-key computation

The ECC public key computation using the encrypted private key d, the reference blob IV, and the computed GCM tag of *Table 189* is summarized in *Table 191*. The additional ECDSA verification at the end of the sequence must be used before saving a new ECDSA signature blob in non-volatile memory. Shown coupling and chaining traffic options are described in *Section 25.4.4*. This sequence starts by setting CCOP to 0x81 in the CCB_CR register.

Table 191. Blob use steps for signing public key computation (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable).
0x12	0x20	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13		0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in SAES, triggered after each 2x32-bit write.
0x14		0x2	SAES -> PKA	DATAOKF set, GCMPH = 0x3	– Write encrypted d in SAES DINR and run AES decryption round. – Write incrementallyscalar multiplier k in the PKA, using 0xCCB magic number. – Repeat for each 16 bytes block of data.
0x17		0x3	SAES -> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x20	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)		N/A	N/A	PROCENDF set	The PKA computes the operation. PKA RAM is read as 0.
0x1A	0x20	N/A	N/A	N/A	– Read **public key point Q** in PKA RAM

Table 191. Blob use steps for signing public key computation (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1A	0x20	N/A	N/A	IPRST set in the CCB	– Read public key point Q in PKA RAM – Set IPRST in CCB
0x0	0x26	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR. Before writing new ECDSA signature blob in non-volatile memory do the following: – Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x26 and EN=1. Wait for INITOK=1. – Write the hash z used during blob creation (see *Table 189*) – Write ECDSA verification parameters in PKA, including the public key coordinates computed in step 0x1A. – Start the operation setting START bit in PKA_CR – Wait for PROCENDF bit is set. If the signature is valid save the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

25.5.3 ECC scalar multiplication

This operation consists in the computation of k x P, where P is a point on a curve over prime fields, and “x” is the elliptic curve scalar point multiplication. The computation result is a point that belongs to the same curve, or a point at infinity.

The scalar multiplication operation is protected against side-channel attacks. When CCOP = 0x0 in CCB_CR, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0x81, the scalar multiplier k can be manipulated by the application only if encrypted, using a special blob called “ECC key blob”.

Scalar multiplication “ECC key” blob creation

The scalar multiplication operation is prepared by generating then encrypting the scalar multiplier k, and computing the reference GCM tag. This process is summarized in *Table 192*. Coupling and chaining operations described in *Section 25.4.4*. This sequence starts by setting CCOP to 0x80 or 0x82 in CCB_CR register.

Table 192. Blob creation steps for scalar multiplication (CCOP = 0b100000<i>0)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event[1]	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in 256-bit encryption mode with DHUK or the decrypted key in register (if applicable) – Write base point G coordinates as input in PKA RAM.
0x2		0x0	RNG –> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. Registers IVR1 to 3 are loaded with randoms. – Read back **blob IV** in IVR registers.
0x3	0x20	0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write ECC scalar multiplication parameters in the PKA RAM, clearing CCF flags in SAES, triggered after each 64-bit write.
0x6 (<i>=1)	0x20	0x2	RNG –> PKA	RNGOKF set	Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0x4 (<i>=0)			N/A	DATAOKF set	Write incrementally k in the PKA.
0x8	0x20	0x2	PKA –> SAES	DATAOKF set, GCMPH = 0x3	– Read incrementally k from the PKA (writing 0xCCB magic numbers), and runs AES encryption rounds. – Read **encrypted k** in SAES DOUTR. – Repeat for each 16-byte block of data..
0xA[2]		0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR For the first two steps keep the SAES enabled (EN bit set).
0x19[3]	0x20	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM reads as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read reference public key point Q in PKA RAM, and save it in SRAM to verify the new blob. – Set IPRST in CCB.
0x0	N/A	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

Scalar multiplication blob use for example for ECC decryption

ECC scalar multiplication computation using the encrypted k, the reference blob IV and the computed GCM tag of *Table 192* is summarized in *Table 193*. Shown coupling and chaining traffic options are described in *Section 25.4.4*. This sequence starts by setting CCOP to 0x81 in CCB_CR register.

Table 193. Blob use steps for scalar multiplication (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally, decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable). – Write input point P coordinates in the PKA RAM. When computing a public key, write basepoint G coordinates.
0x12	0x20	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CBB_REFTAGR.
0x13		0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC scalar multiplication parameters in the PKA RAM, clearing CCF flags in the SAES, triggered after each 64-bit write.
0x14		0x2	SAES -> PKA	DATAOKF set, GCMPH = 0x3	– Write encrypted k in SAES_DINR, and runs AES decryption round. – Write incrementally scalar multiplier k in the PKA, using 0xCCB magic number. – Repeat for each 16 bytes block of data.
0x17		0x3	N/A	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x20	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR. Do not use SAES during this step (under reset).
0x19(2)				PROCENDF set	The PKA computes the operation. The PKA RAM is read as 0.
0x1A				N/A	Read **kP point coordinates** in the PKA RAM. If this point is the public key verify it matches the reference public key computed in *Table 192* before saving the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

25.5.4 RSA modular exponentiation

The modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of A^e mod n.

This modular exponentiation operation (MODE = 0x3) is protected against side-channel attacks. When CCOP = 0x0, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0x45, the exponent e and phi value can only be manipulated encrypted by application, using a special blob called “RSA key blob”.

Modular exponentiation “RSA key” blob creation

Modular exponentiation operation is prepared by generating then encrypting the scalar multiplier *k* and computing the reference GCM tag. This process is summarized in *Table 194*. The coupling and chaining operations described in *Section 25.4.4*. This sequence starts by setting CCOP to 0x44 in CCB_CR register.

Table 194. Blob creation steps for modular exponentiation (CCOP = 0b01000100)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x3 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in 256-bit encryption mode with DHUK or the decrypted key in register (if applicable). – Write a constant K as operand A in the PKA RAM.
0x2		0x0	RNG -> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. SAES_IVR1 to 3 registers are loaded with randoms. – Read back blob IV in SAES_IVR registers.
0x3	0x03	0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write protected modular exponentiation parameters (PKA mode 0x3) in the PKA RAM, clearing CCF flags in the SAES triggered after each 2x32-bit write.
0x4	0x3	0x2	N/A	DATAOKF set	Write incrementally clear-text exponent e.
0x5				DATAOKF set	Write incrementally clear-text phi.
0x8			PKA -> SAES	DATAOKF set	– Read incrementallye from the PKA (writing 0xCCB magic numbers), and runs AES encryption rounds. – Read **encrypted e** in SAES_DOUTR. – Repeat for each 16 bytes block of data.
0x9				DATAOKF set, GCMPH = 0x3	– Read incrementally phi from the PKA (writing 0xCCB magic numbers), and run AES encryption rounds. – Read **encrypted phi** in SAES_DOUTR. – Repeat for each 16 bytes block of data
0xA(2)	0x3	0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR. For the first two steps keep the SAES enabled (EN bit set).

Table 194. Blob creation steps for modular exponentiation (CCOP = 0b01000100)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action in step
0x19(3)	0x3	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM is read as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read the reference modular exponentiation K^e mod *n* in PKA RAM, and save it in SRAM to verify the new blob. – Set IPRST in CCB
0x0	N/A	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

Modular exponentiation blob use (for example for RSA decryption)

The modular exponentiation computation using the encrypted *e* and *phi*, the reference blob IV, and the computed GCM tag of *Table 194* is summarized on *Table 195*. Shown coupling and chaining traffic options are described in *Section 25.4.4*. This sequence starts by setting CCOP to 0x45 in CCB_CR register.

Table 195. Blob use steps for modular exponentiation (CCOP = 0b01000101)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x3 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable). – Write operand A in the PKA RAM. Write constant K as operand A defined in *Table 194* when verifying the created blob.

Table 195. Blob use steps for modular exponentiation (CCOP = 0b01000101)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x12	0x03	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13		0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write protected modular exponentiation parameters (PKA mode 0x3) in the PKA RAM, clearing CCF flags in the SAES, triggered after each -bit write.
0x14		0x2	SAES –> PKA	DATAOKF set	– Write encrypted e in SAES_DINR, and runs AES decryption round. – Write incrementally exponent e in the PKA, using 0xCCB magic number. – Repeat for each 16-byte block of data.
0x15				DATAOKF set, GCMPH = 0x3	– Write encrypted phi in SAES_DINR, and runs AES decryption round. – Write incrementally phi in the PKA, using 0xCCB magic number. – Repeat for each 16-byte block of data.
0x17		0x3	SAES –> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x03	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)				PROCENDF set	The PKA computes the operation, PKA RAM is read as 0.
0x1A				N/A	Read $\mathbf{A^e}$ **mod** n in the PKA RAM. If the result is K^e mod n verify it matches the reference computed in *Table 194* before saving the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

25.6 CCB interrupts

The CCB does not support any interrupt.

25.7 CCB registers

The following section provides information on registers.

Reserved bits (marked as Res.) must be kept at their reset values, unless otherwise specified.

For general information relative to register description, refer to Document conventions.

These registers are accessible through the AHB interface of the CCB (32-bit words only). All reads are supported. Writes accesses must be 32-bit word only (other access types generate an AHB error).

25.7.1 CCB control register (CCB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Following a CCB hardware reset, the above reset value applies if OPERR[5:0] = 0x0 and no TAMP_EVT bit is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCOP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: CCB reset

Set this bit to start or abort any PKA protected operation defined in *Section 25.5*. IPRST bit must be low while writing to any CCB register.

After setting this bit, the application must clear it when CCB_BUSY and OPSTEP are cleared in CCB_SR (IPRST clear is ignored otherwise). After this clear all CCB registers are read with their reset valuesSetting IPRST clears any data stored in the SAES and the PKA.

When IPRST and CCB_BUSY are set, SAES registers are not accessible (read as 0, write ignored), and writes to EN and START bits in PKA_CR are ignored.

This bit is set by CCB when OPERR[5:0] ≠ 0 or any TAMP_EVT bit is set.

Bits 30:8 Reserved, must be kept at reset value.

Bits 7:0 **CCOP[7:0]**: Coupling and chaining operation

These bits must be set according to the chosen PKA protected operation (see *Section 25.5*).

0x044: Modular exponentiation blob creation with priv key from the CPU

0x045: Modular exponentiation blob use

0x080: ECC scalar multiplication blob creation with priv key from the CPU

0x082: ECC scalar multiplication blob creation with priv key from the RNG

0x081: ECC scalar multiplication blob use, or ECDSA signature blob use for public key computation

0x0C0: ECDSA signature blob creation with priv key from the CPU

0x0C2: ECDSA signature blob creation with priv key from the RNG

0x0C3: ECDSA signature blob use for ECDSA signature

Note: When an operation not listed here is written by the application, the write to CCOP[7:0] is ignored. All these operations implement protections against side-channel attacks. Write to CCOP is ignored when CCB_BUSY is set in CCB_SR.

25.7.2 CCB status register (CCB_SR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is reset by a system reset, or after clearing IPRST in CCB_CR. The CCB reset input from the RCC has no effect on this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	TAMP_EVT5	TAMP_EVT4	TAMP_EVT3	TAMP_EVT2	TAMP_EVT1	TAMP_EVT0	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCB_BUSY
		r	r	r	r	r	r								r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	OPERR[5:0]						Res.	Res.	Res.	OPSTEP[4:0]				
		r	r	r	r	r	r				r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **TAMP_EVTi**: Tamper i flag (i = 5 to 0)

0: No event

1: Tamper event i has been raised. Global tamper event is raised. See *Section 25.3* for details on the events.

This bit is cleared by writing 0 to IPRST bit in CCR_CR. When at least one TAMP_EVT bit is set, CCB sets IPRST bit.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **CCB_BUSY**: CCB busy

This flag is set when CCB is busy, or when OPSTEP[4:0] ≠ 0 following a CCB reset (hardware reset or use of IPRST in CCB_CR).

0: CCB idle

1: CCB busy or PKA RAM is being cleared following a peripheral reset.

When IPRST and CCB_BUSY are set, the SAES registers are not accessible (write ignored, read returns 0), and writes to EN or START bits in PKA_CR are ignored.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **OPERR[5:0]**: Operation error

When an error is detected during a protected PKA operation, the CCB raises IPRST in CCB_CR, and OPSTEP[4:0] is set to 0x1F. The bitfield is cleared by setting IPRST to 0.

0x0: No error detected during protected PKA operation (if applicable)

0x1: CCB RCC reset has been detected when OPSTEP > 0x0

0x2: SAES RCC reset has been detected when OPSTEP > 0x0

0x3: PKA RCC reset has been detected when OPSTEP > 0x0

0x4: RNG RCC reset has been detected when OPSTEP > 0x0

0x5: The RCC has gated the CCB clock when OPSTEP > 0x0.

0x6: The RCC has gated the SAES clock when OPSTEP > 0x0.

0x7: The RCC has gated the PKA clock when OPSTEP > 0x0.

0x8: The RCC has gated the RNG clock when OPSTEP > 0x0.

0x9: Random in SAES_IV1 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xA: Random in SAES_IV2 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xB: Random in SAES_IV3 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xC: When OPSTEP = 0x17 SAES GCM TAG comparison with CCB_REFTAG failed, or a register different from SAES_DOUT was read in the SAES.

0xD: KEYSIZE ≠ 256 bits in SAES_CR when the SAES is enabled, and OPSTEP > 0x0.

0xE: CHMOD ≠ GCM in SAES_CR when 0x1 < OPSTEP < 0x18, or the SAES is not enabled, or KEYVALID is cleared when GCMPH > 0x0.

0xF: KMOD different from wrapped key mode in SAES_CR when the SAES is enabled, and OPSTEP = 0x1, or 0x1A.

0x10: KEYSEL ≠ 0x1 or 0x4 in SAES_CR when the SAES is enabled, KEYVALID is set, and OPSTEP = 0x1.

0x11: GCMPH not correct (not incremented) in SAES_CR when OPSTEP > 0x1.

0x12: MODE in SAES_CR does not match the expected value (selected by CCOP in CCB_CR) when OPSTEP > 0x1.

0x13: BUSY = 1 in SAES_SR when OPSTEP= 0x18 or 0x19. SAES must not be used when PKA is computing a protected operation.

0x14: EN = 0 in PKA_CR when OPSTEP > 0x2 (except 0x12). In other words, PKA must be enabled in any OPSTEP except 0x1, 0x2, or 0x12.

0x15: INITOK = 0 in PKA_SR when OPSTEP > 0x2 (except 0x12).

0x16: Authorized by local firewall, but unexpected AHB error detected when OPSTEP > 0x0.

0x17: LMF = 1 in PKA_SR (only ECDSA verification available) when OPSTEP > 0x0.

0x18: CCB_REFTAGRx registers are equal to 0 when OPSTEP > 0x12.

0x1A: Security, privilege protections inconsistent (see *Section 5: Global TrustZone® controller (GTZC)* for the peripherals SAES, PKA, RNG, and CCB when OPSTEP > 0x0. This error is also triggered when the protections change while OPSTEP > 0x0,

0x1B: MODE in PKA_CR does not match the expected value (selected by CCOP in CCB_CR) when OPSTEP > 0x0.

0x1C: OPSTEP end-step event not found at OPSTEP= 0x0 (SAES KEYVALID is set). Use CCB IPRST before starting a coupling and chaining operation.

0x1D: OPSTEP end-step event not found at OPSTEP = 0x1.

0x1E: OPSTEP end-step event not found at OPSTEP = 0x2.

0x1F: OPSTEP end-step event not found at OPSTEP = 0x3.

0x20: OPSTEP end-step event not found at OPSTEP = 0xA.

0x21: OPSTEP end-step event not found at OPSTEP = 0x12.

0x22: OPSTEP end-step event not found at OPSTEP = 0x13.

0x23: OPSTEP end-step event not found at OPSTEP = 0x17.

For error codes 0x1C to 0x23, details on end-step events are found in *Section 25.5*. Those errors are also triggered when values written in SAES_CR register do not correspond to the selected CCOP and the expectations in the current OPSTEP.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **OPSTEP[4:0]**: Operation step

This read-only information indicates the current step of the coupling and chaining operation (indicated by CCOP). See *Section 25.5* for details. .

This bitfield can be cleared only using IPRST in CCB_CR. OPSTEP[4:0] = 0x1F when the IPRST procedure is in progress.

25.7.3 CCB reference tag register (CCB_REFTAGRx)

Address offset: 0x010 + 0x4 * x (x = 0 to 3)

Reset value: 0x0000 0000

Writes to this register are ignored when CCB_BUSY is set in the CCB_SR register. The register is cleared when IPRST is set and CCB_BUSY is cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFTAG{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFTAG{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFTAG{i + 32 * x}**: Reference tag bits {i + 32 * x} (i = 31 to 0)

The application must write in these registers, the reference GCM tag of the required operation blob (respectively ECC signature, ECC key, or RSA key). This enables the PKA protected operation (respectively ECC signature/public key computation, scalar multiplication, or modular exponentiation). Refer to *Section 25.5* for details.

Write to this register is ignored unless OPSTEP = 0x12 in CCB_SR.

25.7.4 CCB register map

Table 196. CCB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

26 True random number generator (RNG)

26.1 RNG introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is an NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator can be certified NIST SP 800-90B. It can also be tested using the German BSI statistical tests of AIS-31 (T0 to T8).

26.2 RNG main features

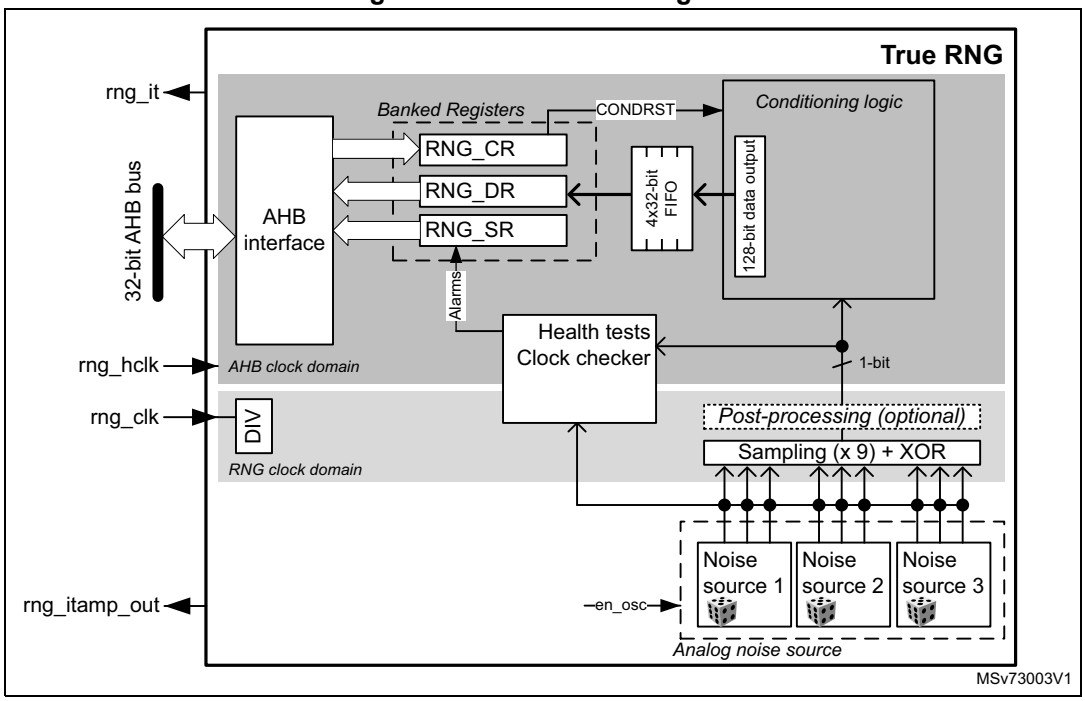
- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by an NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a non-deterministic random bit generator (NDRBG).
- In the default configuration, it produces four 32-bit random samples every 412 AHB clock cycles if $f_{AHB} < f_{threshold}$ (256 RNG clock cycles otherwise).
- Embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- Can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- Has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).

26.3 RNG functional description

26.3.1 RNG block diagram

Figure 173 shows the RNG block diagram.

Figure 173. RNG block diagram



26.3.2 RNG internal signals

Table 197 describes internal signals available at the RNG level, not at the STM32 product level (on pads).

Table 197. RNG internal input/output signals

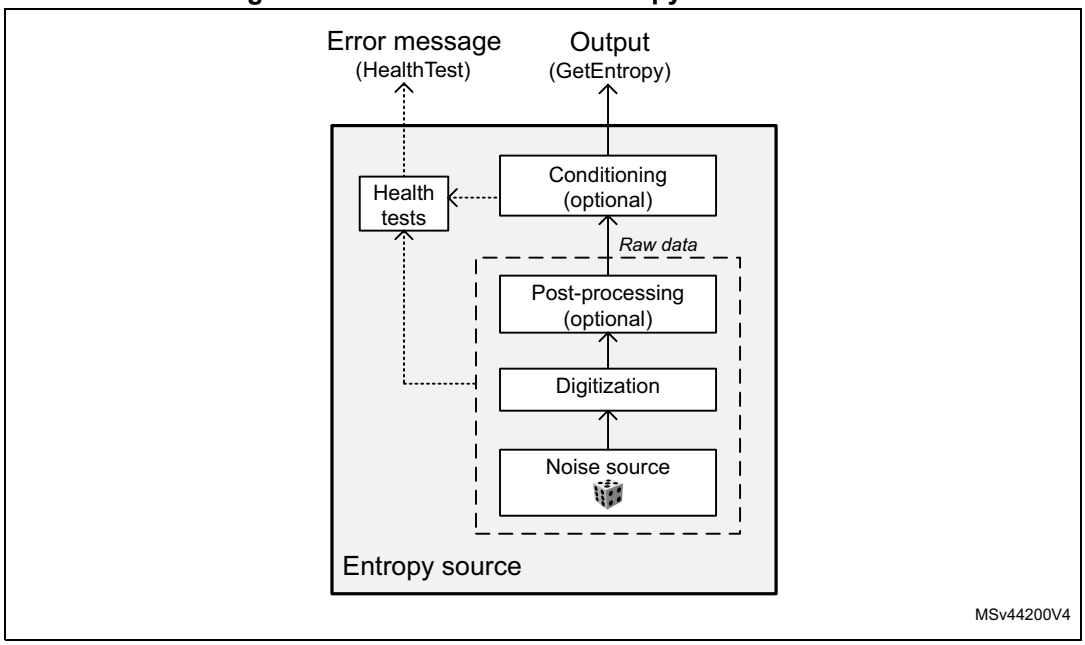
Signal name	Signal type	Description
rng_it	Digital output	RNG global interrupt request
rng_hclk	Digital input	AHB clock
rng_clk	Digital input	RNG dedicated clock, asynchronous to rng_hclk
rng_itamp_out	Digital output	RNG internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, RNG stops delivering random samples. A reset and a new initialization are needed to use it again.

26.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary, it integrates all the required NIST components shown in *Figure 174*: an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block, and two interfaces used to interact with the entropy source (GetEntropy and HealthTest).

Figure 174. NIST SP800-90B entropy source model



Noise source

This component contains the nondeterministic, entropy-providing activity, ultimately responsible for the uncertainty associated with the bit string output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x3), each based on three XOR-ed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in *Section 26.3.8*. Multiple oscillators are also disabled for configuration A (see *Table 199*).
- The XOR-ing of all the noise sources into a single analog output.
- A sampling stage of this output is clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent from the AHB interface clock frequency (rng_hclk), with the possibility, for the software, to decrease the sampling frequency by using the integrated divider.

Note: The recommended clock frequencies and associated divider value are detailed in Section 26.6.

Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In the non-NIST configuration B (as defined in *Section 26.6.2*) a normalization debiasing is applied: half of the bits are taken from the sampled noise source, the other half from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bit string output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The time intervals required between two random number generations, and between the RNG initialization and availability of the first sample are detailed in *Section 26.5*.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in *Section 26.5*.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When the interrupts are enabled, an interrupt is generated when this flag transitions from 0 to 1. The interrupt is then cleared automatically by the RNG, as explained above.

Health checks

This component ensures that the entire entropy source (with its noise source) starts, then operates as expected, obtaining the assurance that failures are caught quickly, with high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the default RNG_HTCR0 configuration.

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   - Repetition count test, flagging an error when the noise source has provided more than 28 consecutive bits at a constant value (0 or 1).
   - Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 684 times.
   - Known-answer tests, to verify the conditioning stage.
2. Continuous health tests, running indefinitely on the outputs of the noise source (XORed output and individual oscillator outputs, see *Figure 173: RNG block diagram*):
   - Repetition count test, similar to the one running in startup tests.
   - Adaptive proportion test, similar to the one running in startup tests.
3. Vendor specific continuous test:

  - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than the AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in *Section 26.3.4*). Other kinds of on-demand testing (software based) are *not supported*.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in *Section 26.3.7*.

Note: An interrupt can be generated when an error is detected.

The health test thresholds are modified by changing the value in the corresponding RNG_HTCRx registers. See Section 26.6 for details.

26.3.4 RNG initialization

The RNG simplified state machine is shown in *Figure 175*.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering the startup behavior test on the raw data samples and known-answer tests.
3. Start-up health tests are completed, with the conditioning stage ready to use.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in *Section 26.5*.

Figure 175. RNG initialization overview

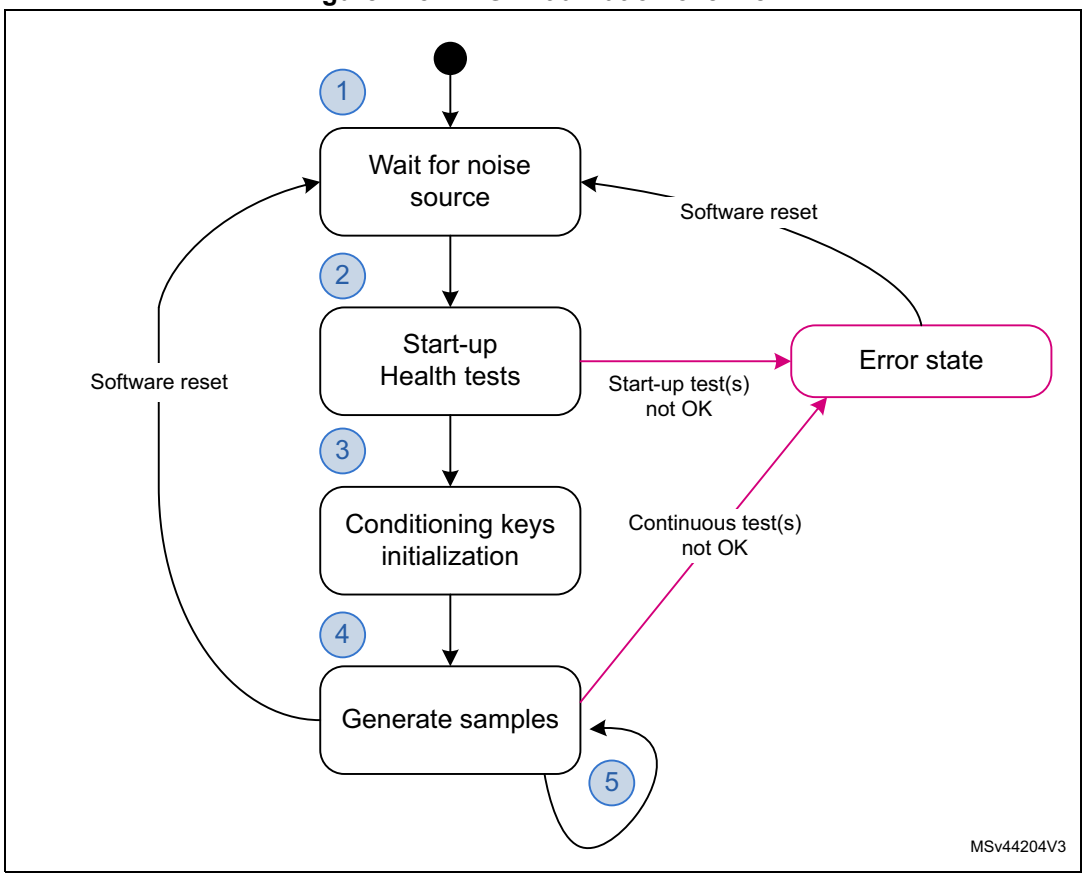


Figure 175 also highlights a possible software reset sequence, implemented by:

1. Write RNGEN = 0, then wait for BUSY = 0 in the RNG_SR register.
2. Write bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
3. Write RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
4. Wait for a random number to be ready, after initialization completes.

Note: When the RNG is reset by RCC (hardware reset), the configuration for optimal randomness is lost in the registers.

26.3.5 RNG operation

Normal operation

To run the RNG using interrupts, the following steps are recommended:

1. Check in *Section 26.6* if a specific RNG configuration is required for the application.
   – If this is the case, when bits RNGEN and BUSY=0, write in the RNG_CR register bit CONDRST = 1, together with the correct RNG configuration. Then perform a second write with bit CONDRST = 0, interrupt enable bit IE = 1, and RNG enable bit RNGEN = 1.

- If this is not the case, perform a write to the RNG_CR register with interrupt enable bit IE = 1 and RNG enable bit RNGEN = 1.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data are available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in *Section 26.3.7* must be used.

To run the RNG in polling mode the following steps are recommended:

1. Check in *Section 26.6* if a specific RNG configuration is required for the application.
   - If this is the case, when bits RNGEN and BUSY = 0, write in the RNG_CR register bit CONDRST = 1, together with the correction RNG configuration. Then perform a second write to the RNG_CR register with bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If this is not the case, only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If the above conditions are true, read the content of the RNG_DR register up to four consecutive times. If valid data are available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, use the recovery sequence described in *Section 26.3.7*.

Note: When data are not ready (DRDY = 0) RNG_DR returns 0. It is recommended to verify that RNG_DR is different from 0. When this happens, a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required, it is possible to select a faster configuration by using the configuration B, described in *Section 26.6*. The gain in random number generation speed is summarized in *Section 26.5*.

Low-power operation

If power consumption is a concern, low-power strategies can be used, as described in *Section 26.3.8*.

Software post-processing

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in *Section 26.3.3*.

26.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in *Section 26.6*.

*Note: When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider **must be higher** than the AHB clock frequency divided by 32, otherwise the clock checker flags a clock error (CECS = 1 in the RNG_SR register).*

See *Section 26.3.1* for details (AHB and RNG clock domains).

26.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see *Section 26.3.6*), and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

When CECS is set, values are available in the RNG_DR register, but it must not be used as described in *Section 26.3.5*.

Note: CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred.

When SECS is set, values are available in the RNG_DR register, but it must not be used as described in *Section 26.3.5*.

To manage a seed error, follow the recommended sequence below. It requires the CONFIGLOCK bit to be cleared.

- When ARDIS is cleared (auto-reset enabled):
  - Clear the SEIS bit in the RNG_SR register
  - If SECS is cleared RNG can be used as usual. If SECS is still set in RNG_SR it means a new seed error occurred (unlikely). In this case, executes following step 1)
- When ARDIS is set (auto-reset disabled) the following sequence must be used to recover from a seed error.

1. Read both RNG_HTSRx registers. Using the previous HTSR values saved in RAM, compute the accumulated number of errors per oscillator (can be RPERR or ADERR errors). In a *nsmr* variable, mask the oscillators with accumulated number of errors greater than 3. This variable is used in step 3). Save the updated HTSR values in RAM.
   - During the first iteration, initialize *nsmr* variable with the RNG_NSCR value.
2. If fewer than 6 oscillators are active in the *nsmr* variable, reinitialize it with the RNG_NSCR value.
   - When RNG configuration is Configuration B, and the third time you reach this loop, go to Step 3 changing the RNG configuration to Configuration C. Both configurations are defined in *Section 26.6.2*.
3. Write CONDRST at 1 in RNG_CR, then update RNG_NSMR with *nsmr* value. Refer to *Section 26.7.8* for details.
4. Write CONDRST at 0 to finalize the reset of the RNG conditioning logic.
5. Wait for the CONDRST bit to be cleared by hardware, or poll for BUSY bit= 0. Then clear the SEIS interrupt status bit in the RNG_SR register.
6. If SECS is still set in RNG_SR it means a new seed error occurred (unlikely). In this case go back to step 1). If SECS is cleared, restart the generation of random numbers by setting RNGEN in RNG_CR.

If application has set the CONFIGLOCK bit (not recommended), do the following:

- When ARDIS is cleared (auto-reset enabled) clear the SEIS interrupt status bit in the RNG_SR register before drawing random numbers again.
- When ARDIS is set (auto-reset disabled), the following sequence must be used to fully recover from a seed error:

1. Write CONDRST at 1 and at 0 in the RNG_CR register to reset the conditioning logic.
2. Wait for the CONDRST bit to be cleared by hardware, or poll for BUSY = 0. Then clear the SEIS interrupt status bit in the RNG_SR register.
3. If SECS is still set in RNG_SR it means a new seed error occurred (unlikely). In this case go back to step 1).

Note: After a seed error RNG restarts generating random numbers when SECS is cleared.

RNG tamper errors

When an unexpected error is found by the RNG, an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral, using the central reset management or the global SoC reset. A proper initialization of the RNG is required again.

Note: Seed errors do not trigger tamper errors.

26.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while the RNGEN = 0, the following features are available to the software:

- If there are valid words in the output buffer, four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register, four additional random numbers can be still be read from the RNG_DR register. If it is not the case, RNG must be re-enabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode), and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in *Section 26.5*.

When disabling the RNG, the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when the RNGEN bit is set to 1, unless the application resets the conditioning logic using the CONDRST bit in the RNG_CR register.

When the application wants to gate the RNG kernel clock, the software must issue the following sequence: first, disable the RNG by clearing the RNGEN bit in the RNG_CR register, then wait for the BUSY bit to be cleared in the RNG_SR, and finally, disable the RNG kernel clock using the RCC.

Before entering a power mode where RNG is deactivated (like Stop mode), the software must first disable the RNG by clearing the RNGEN bit in the RNG_CR register, then wait for the BUSY bit to be cleared in the RNG_SR.

Note: The power modes where RNG is deactivated (retained or not available) can be found in the PWR section.

26.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see *Section 26.3.7*
- Clock error, see *Section 26.3.7*

Dedicated interrupt enable control bits are available as shown in *Table 198*.

Table 198. RNG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
RNG	Data ready flag	DRDY	IE	None (automatic)
	Seed error flag	SEIS	IE	Write CONDRST to 1 then to 0 unless ARDIS is cleared (see *Section 26.3.7*). Write 0 to SEIS.
	Clock error flag	CEIS	IE	Write 0 to CEIS

The user can enable or disable the above interrupt sources globally by using the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

26.5 RNG processing time

In the recommended configuration described in *Table 199*, the time between two sets of four 32-bit data is either:

- 206 x N AHB cycles if $f_{AHB} < f_{threshold}$ (conditioning stage is limiting), or
- 128 x N RNG cycles $f_{AHB} \geq f_{threshold}$ (noise source stage is limiting).

If f_{RNG}= 48 MHz, $f_{threshold}$ = 1.6 x f_{RNG} = 77 MHz. The value of N is defined in *Section 26.6*.

Note: When CLKDIV is different from 0, f_{RNG} must take into account the internal divider ratio.

26.6 RNG entropy source validation

26.6.1 Introduction

To assess the amount of entropy available from the RNG, the peripheral has been tested using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite.

26.6.2 Validation conditions

The RNG true random number generator has been tested in the following conditions:

- RNG clock rng_clk = 48 MHz, with CED bit cleared in RNG_CR.
- Configurations are described in *Table 199* and *Table 200*. Only configuration A can be certified NIST SP800-90B. Refer to *Table 201* to select the best configuration for the application.
- Configuration B or C can be used when configuration A is not present in AN4230, or is not flagged as certified.

Table 199. RNG configurations

Configuration	RNG_CR bits					Loop number (N)	RNG_HTCR0 register	RNG_NSCR register
	NISTC bit	RNG_ CONFIG1 [7:0]	CLKDIV [3:0]	RNG_ CONFIG2 [2:0]	RNG_ CONFIG3 [3:0](1)			
A	Refer to *NIST compliant RNG configuration* table in AN4230 available from *www.st.com*. This application note also indicates if this configuration is part of an existing NIST SP800-90B Entropy Certificate listed on *https://csrc.nist.gov/projects/cryptographic-module-validation-program.*							
B	1	0x83	0x0	0x0	0xF	3	0x0000 AAC7(2)	Default
C	1	0x84	0x5(3)	0x0	0xF	4		Default

1. RNG_CONFIG1[3:0] = i defines the loop number N. If i = 0, N =1. If NISTC = 0, N = 2 regardless of i.
2. This value can be fixed in the RNG driver (it does not depend upon the STM32 product).
3. The noise source sampling must be 48 MHz or less. If the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in *Section 26.7.1* for details.

Table 200. Additional health test configurations

Configuration	RNG_HTCR1 register (oscillator set 1)	RNG_HTCR2 register (oscillator set 2)	RNG_HTCR3 register (oscillator set 3)
A	Refer to NIST compliant RNG configuration table in AN4230 available from www.st.com.		
B and C	default	default	default

Table 201. Configuration selection

Section criteria	Configuration A	Configuration B	Configuration C
Suitable to generate NIST compliant cryptographic keys	Yes	No	
Entropy(1)	Certified	Not certified	
Speed(2)	Baseline	Faster	Baseline

1. For configurations B and C entropy is verified using the AIS-31 test suite (T0 to T8).
2. When the speed is not enough for the application, an NIST compliant DRBG can be used to increase throughput.

For details on data collection and the running of statistical test suites refer to AN4230 "*Introduction to random number generation validation using the NIST statistical test suite for STM32 MCUs and MPUs*", available on *www.st.com*.

26.7 RNG registers

The RNG is associated with a control register, a data register, and a status register.

26.7.1 RNG control register (RNG_CR)

Address offset: 0x000

Reset value: 0x0080 0D00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CONFIGLOCK	CONDRST	Res.	Res.	RNG_CONFIG1[7:0]								CLKDIV[3:0]			
rs	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNG_CONFIG2[2:0]			NISTC	RNG_CONFIG3[3:0]				ARDIS	Res.	CED	Res.	IE	RNGEN	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw		rw		rw	rw		

Bit 31 **CONFIGLOCK**: RNG configuration lock

Set this bit to lock the RNG configuration. Since CONFIGLOCK prevents the implementation of robust seed error management described in *Section 26.3.7*, it is recommended not to use it.

0: Writes to the RNG_NSMR, RNG_NSCR, RNG_HTCR and the RNG_CR configuration bits [29:4] are allowed.

1: Writes to the RNG_NSMR, RNG_NSCR, RNG_HTCR and the RNG_CR configuration bits [29:4] are ignored until the next RNG reset.

Once set, this bit can only be cleared when RNG is reset (set once bit).

Bit 30 **CONDRST**: Conditioning soft reset

Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_NSMR, RNG_NSCR, RNG_CR and RNG_HTCR are not changed by CONDRST.

This bit must be set to 1 in the same access that sets any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.

Before setting this bit to 1 RNGEN must be set to 0, and BUSY flag must be cleared in RNG_SR.

When CONDRST is set to 0, wait for BUSY flag to be cleared in RNG_SR. CONDRST bit then reads as 0.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **RNG_CONFIG1[7:0]:** RNG configuration 1

Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in *Section 26.6*.

Writing to this bitfield is only effective when CONFIGLOCK = 0. The new value is only taken into account if CONDRST bit is set in the same access.

Bits 19:16 **CLKDIV[3:0]**: Clock divider factor

This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).

0x0: internal RNG clock after divider is similar to incoming RNG clock.

0x1: two RNG clock cycles per internal RNG clock.

0x2: 2^2 (= 4) RNG clock cycles per internal RNG clock.

...

0xF: 2^{15} RNG clock cycles per internal clock (for example. an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)

Writing to this bitfield is only effective when CONFIGLOCK = 0. The new value is only taken into account if CONDRST bit is set in the same access.

Bits 15:13 **RNG_CONFIG2[2:0]:** RNG configuration 2

Reserved to the RNG configuration (bitfield 2). Refer to the RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC**: NIST custom

0: Hardware default values for NIST compliant RNG. In this configuration for 128-bit output, two conditioning loops are performed and 256 bits of noise source are used.

1: Custom values for NIST compliant RNG. See *Section 26.6* for recommended configurations.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bits 11:8 **RNG_CONFIG3[3:0]:** RNG configuration 3

Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details.

If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7 **ARDIS**: Auto reset disable

Set this bit to deactivate the auto-reset feature.

0: Auto-reset is enabled

1: Auto-reset is disabled

Keeping the auto-reset enabled (automatic clearance of the SECS bit) simplifies the management of noise source errors, as described in *Section 26.3.7*.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CED:** Clock error detection

0: Clock error detection is enabled.

1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE:** Interrupt enable

0: RNG interrupt is disabled

1: RNG interrupt is enabled. An interrupt is pending as soon as the DRDY, SEIS, or CEIS flag is set in the RNG_SR register.

Bit 2 **RNGEN:** True random number generator enable

This bit enables/disables the true random number generator.

0: True random number generator disabled.

1: True random number generator enabled.

Clearing RNGEN powers off the analog noise sources and gates the logic clocked by the RNG clock.

When clearing this bit verify that BUSY flag is cleared in RNG_SR before updating this register again.

Bits 1:0 Reserved, must be kept at reset value.

26.7.2 RNG status register (RNG_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEIS	CEIS	BUSY	Res.	SECS	CECS	DRDY
									rc_w0	rc_w0	r		r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SEIS:** Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.

0: No faulty sequence detected

1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5 **CEIS:** Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$)

1: The RNG clock before the internal divider is detected too slow ($f_{RNGCLK} < f_{HCLK}/32$)

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 4 **BUSY:** Busy

This flag indicates whether RNG is idle or busy.

0: Idle

1: Busy

RNG is flagged as busy when a conditioning soft reset (using CONDRST) is in progress. It is also flagged busy when RNG is activated by application setting RNGEN bit, or when a connected peripheral fetches randoms via the dedicated RNG hardware bus.

More information on BUSY usage can also be found in *Section 26.3.8*.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SECS:** Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: At least one of the following faulty sequence has been detected:

– Start-up or continuous repetition count test on noise source failed.

– Start-up or continuous adaptive proportion test on noise source failed.

– Start-up post-processing/conditioning sanity check failed.

After enabling the RNG, SECS bit clears once startup health tests completes successfully. If SECS does not clear, run the software reset sequence with CONDRST described in *Section 26.3.4*.

Bit 1 **CECS:** Clock error current status

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.

1: The RNG clock is too slow ($f_{RNGCLK} < f_{HCLK}/32$).

CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0 **DRDY:** Data ready

This flag is raised to indicate valid (non-0) random data available in the RNG_DR register. It is cleared by hardware upon reading the RNG_DR register (which empties the RNG buffer). The DRDY flag can also be raised upon disabling RNG (upon clearing the RNGEN bit).

0: No valid random data ready.

1: Valid random data ready.

Raising DRDY generates an interrupt if enabled with the IE bit of the RNG_CR register.

26.7.3 RNG data register (RNG_DR)

Address offset: 0x008

Reset value: 0x0000 0000

This register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RNDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RNDATA[31:0]:** Random data

32-bit random data, valid when DRDY = 1. When DRDY = 0, the RNDATA value is 0.

The 0 value means that a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

26.7.4 RNG noise source control register (RNG_NSCR)

Address offset: 0x00C

Reset value: 0x0000 01FF

Writing in RNG_NSCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in RNG_CR. Writing to this register is ignored if CONFIGLOCK= 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN_OSC3[2:0]			EN_OSC2[2:0]			EN_OSC1[2:0]		
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:6 **EN_OSC3[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 3. The bitfield has no effect otherwise.

Bits 5:3 **EN_OSC2[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 2. The bitfield has no effect otherwise.

Bits 2:0 **EN_OSC1[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 1. The bitfield has no effect otherwise.

26.7.5 RNG health test control register x (RNG_HTCRx)

Address offset: 0x010 + 0x4 * x (x=0 to 3)

Reset value: 0x0000 72AC, 0x0003 FFFF, 0x0003 FFFF, 0x0003 FFFF

Writing in RNG_HTCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in the RNG_CR. Writing to this register is ignored if CONFIGLOCK = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HTCFG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

HTCFG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **HTCFG[31:0]:** health test configuration

This configuration is used by RNG to configure the health tests (repetition count test, adaptive proportion test) at position x. See *Section 26.6* for the recommended value. With its default value, health tests have a very small probability of triggering any error at position x.

Note: The RNG behavior, including the read to this register, is not guaranteed if a different value from the recommended value is written.

26.7.6 RNG health test status register 0 (RNG_HTSR0)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	RPERR9	RPERR8	RPERR7	RPERR6	RPERR5	RPERR4	RPERR3	RPERR2	RPERR1	RPERRX
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:1 **RPERR{i}:** Repetitive error for oscillator *i* (i=1 to 9)

This bit is set when the health test logic associated to the oscillator *i* finds a repetitive test error. The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error. Repetition count test is defined in *Health checks* section.

0: No repetitive test error found in oscillator *i*.
1: Repetitive test error found in oscillator *i*.

Bit 0 **RPERRX:** Repetitive error after the XOR

This bit is set when the health test logic finds a repetitive test error after the XOR clock tree (see *Figure 173*). The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error.

0: No repetitive test error found after the XOR clock tree.
1: Repetitive test error found after the XOR clock tree.

26.7.7 RNG health test status register 1 (RNG_HTSR1)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	ADERR9	ADERR8	ADERR7	ADERR6	ADERR5	ADERR4	ADERR3	ADERR2	ADERR1	ADERRX
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:1 **ADERR{i}:** Adaptative error for oscillator *i* (i=1 to 9)

This bit is set when the health test logic associated to the oscillator *i* finds an adaptative test error. The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error. Adaptive proportion test is defined in *Health checks* section.

0: No adaptative test error found in oscillator *i*.
1: Adaptative test error found in oscillator *i*.

Bit 0 **ADERRX:** Adaptative error after the XOR

This bit is set when the health test logic finds an adaptative test error after the XOR clock tree (see *Figure 173*). The bit is cleared when application clears SEIS bit in RNG_SR If ARDIS is cleared auto-reset prevents RNG to capture more than one test error.

0: No adaptative test error found after the XOR clock tree.
1: Adaptative test error found after the XOR clock tree.

26.7.8 RNG noise source mask register (RNG_NSMR)

Address offset: 0x030

Reset value: 0x0000 01FF

Writing to this register is ignored if CONFIGLOCK = 1. It is recommended to have at least 6 oscillators running when loop number N = 3 (or higher). See *Section 26.6.2* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **MOSC{i}:** Mask oscillator i (i = 1 to 9)

Clear this bit to masks the oscillator *i*, and deactivate its related health tests. The bit has no effect if the oscillator *i* is deactivated with the bit RNG_NSCR[i].

Application can mask an oscillator when it is not contributing to the generation of entropy.

0: Oscillator *i* is masked, and related health tests are deactivated.
1: Oscillator *i* is not masked. Related health tests are running.

26.7.9 RNG register map

Table 202. RNG register map and reset map

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

27 AES hardware accelerator (AES)

In this section, any references to SAES only apply to STM32C59x/5A3 products. The STM32C53x/542/55x/562 products do not have the SAES peripheral.

27.1 AES introduction

The AES hardware accelerator (AES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST.

AES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits.

AES has the possibility to load by hardware the key stored in SAES peripheral, under SAES control.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required).

27.2 AES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Using dedicated key bus, optional key sharing with side-channel resistant SAES peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data

- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software (in CPU mode only, not in DMA mode) to suspend a message if AES needs to process another message with a higher priority, then resume the original message

27.3 AES implementation

The devices have one AES peripheral, implemented as per the following table. It can use the key generated by the SAES peripheral. For comparison, the SAES peripheral is also included in the table.

Table 203. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection	-	X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256

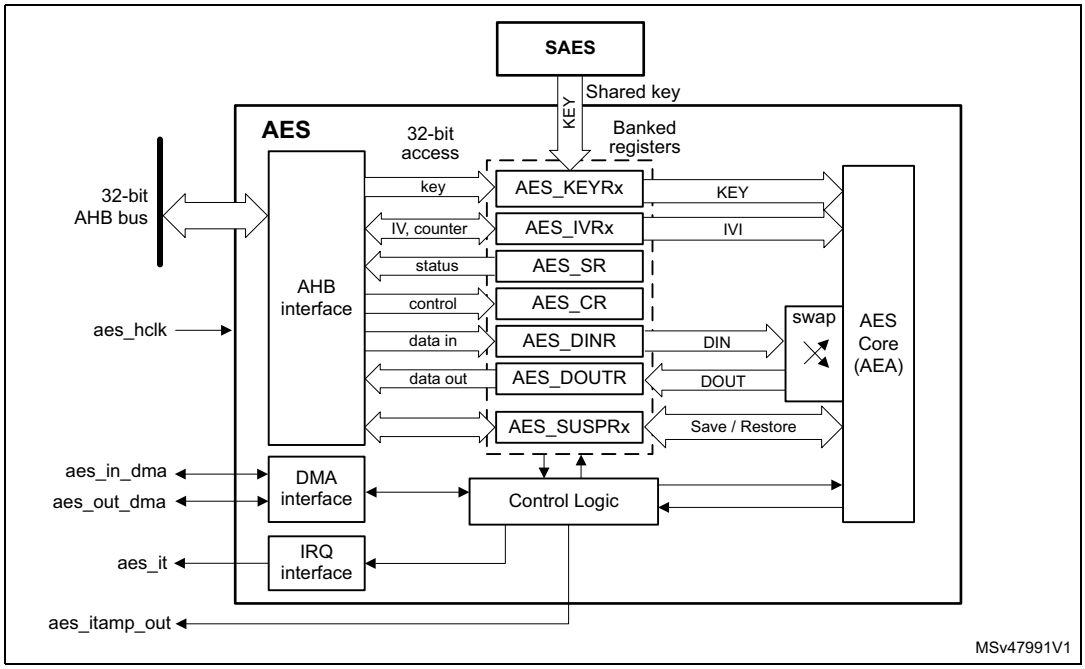
1. X = supported.

27.4 AES functional description

27.4.1 AES block diagram

Figure 176 shows the block diagram of AES.

Figure 176. AES block diagram



27.4.2 AES internal signals

Table 204 describes the user relevant internal signals interfacing the AES peripheral.

Table 204. AES internal input/output signals

Signal name	Signal type	Description
aes_hclk	Input	AHB bus clock
aes_it	Output	AES interrupt request
aes_in_dma	Input/Output	AES incoming data DMA single request/acknowledge
aes_out_dma	Input/Output	AES processed data DMA single request/acknowledge
aes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, AES automatically clears key registers. A reset is required for AES to be usable again.

27.4.3 AES reset and clocks

The AES peripheral is clocked by the AHB bus clock. It has a dedicated reset bit controlled through the RCC.

27.4.4 AES symmetric cipher implementation

The AES hardware accelerator (AES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 205*. Those functions can be certified NIST PUB 140-3.

Table 205. AES approved symmetric key functions

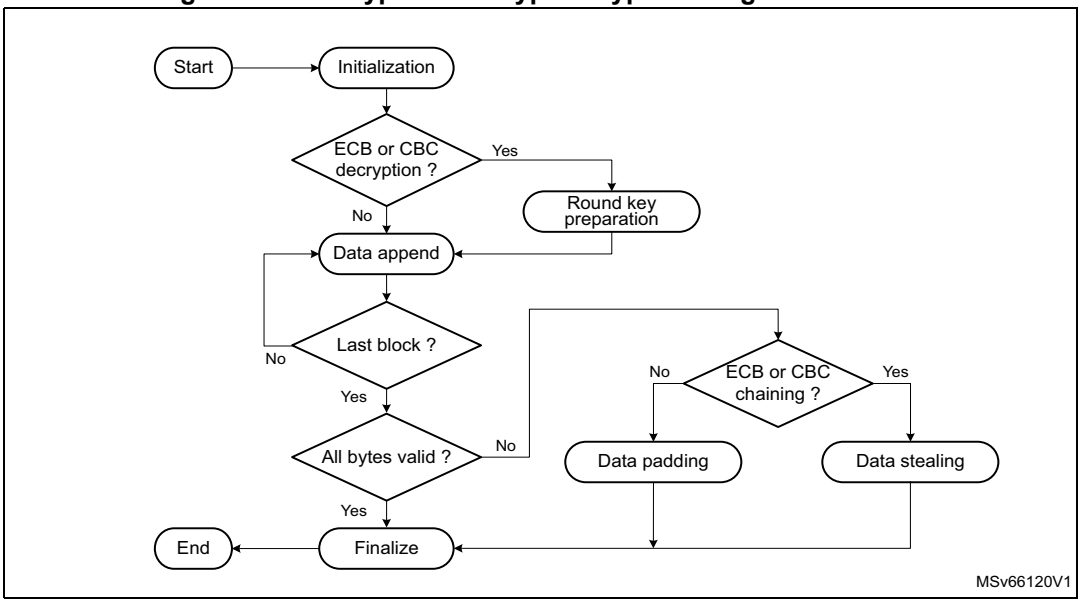
Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

AES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any AES processing, following the sequence described in *Section 27.4.8*.

27.4.5 AES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 177. Encryption/ decryption typical usage



Initialization

The AES peripheral is initialized according to the chaining mode. Refer to *Section 27.4.9: AES basic chaining modes (ECB, CBC)* and *Section 27.4.10: AES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 27.4.7: AES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. Enable the AES peripheral when KEYVALID is set, by setting the EN bit of the AES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_ISR register, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).
3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the AES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES, by setting the CCFIE bit of the AES_IER register.
2. Enable the AES peripheral when KEYVALID is set, by setting EN (if not already done).
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the AES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and AES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in *Section 27.6: AES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the NPBLB[3:0] bitfield must be set up before processing the block, for AES to compute a correct tag.
3. Enable the AES peripheral when KEYVALID is set, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

When appending data using DMA, the suspend/resume operation as described in *Section 27.4.8* is not supported.

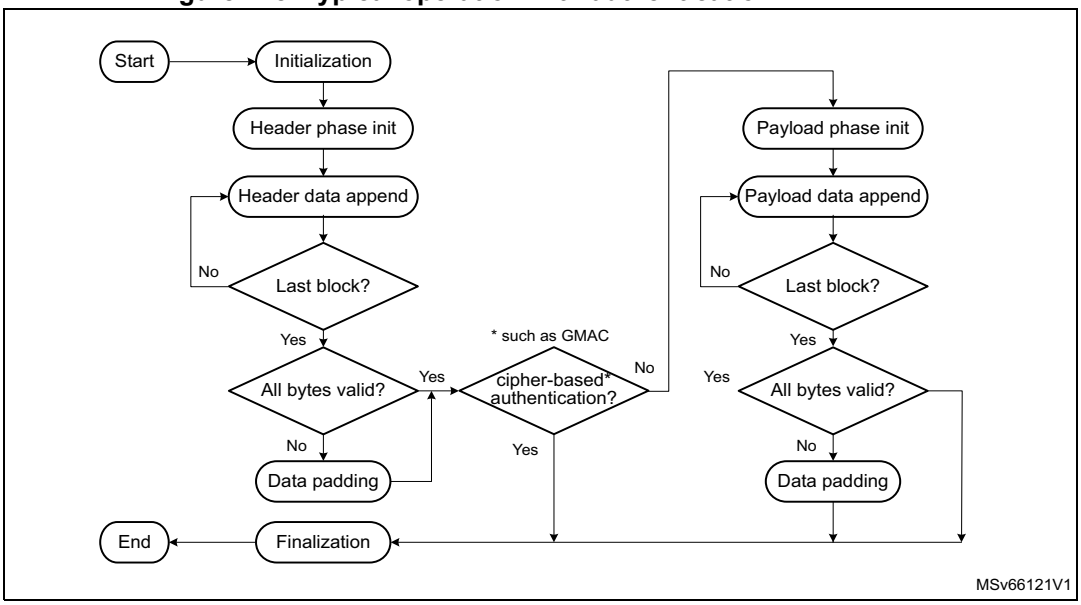
Note: The CCF flag has no use with this method because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

27.4.6 AES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 178. Typical operation with authentication



Section 27.4.11: AES Galois/counter mode (GCM) and *Section 27.4.13: AES counter with CBC-MAC (CCM)* describe detailed sequences supported by AES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by AES is described in *Section 27.4.12: AES Galois message authentication code (GMAC)*.

27.4.7 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since AES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since AES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

27.4.8 AES suspend and resume operations

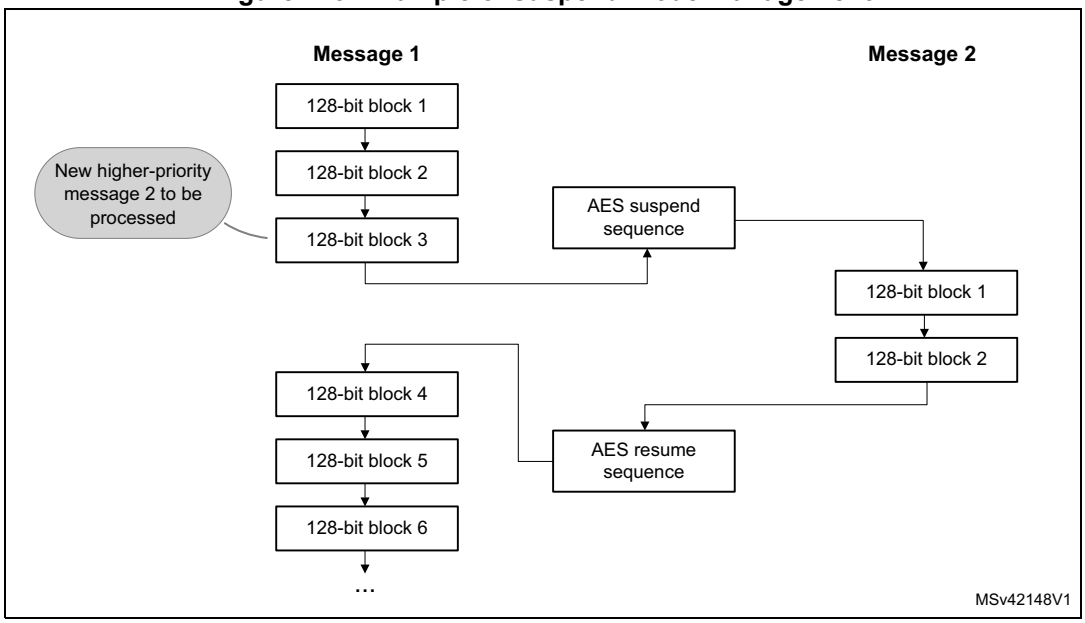
A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as AES is enabled again, to receive a next data block.

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

Figure 179 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 179. Example of suspend mode management



A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

27.4.9 AES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 180 and *Figure 181* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 180. ECB encryption

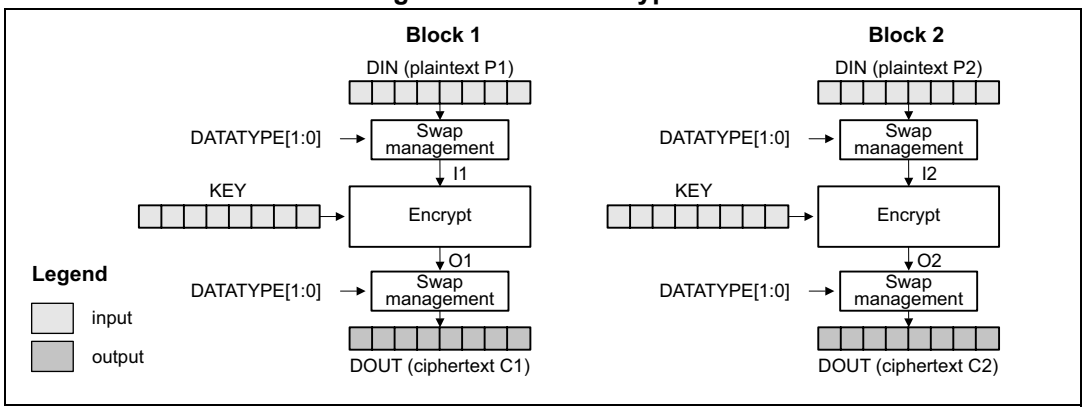


Figure 181. ECB decryption

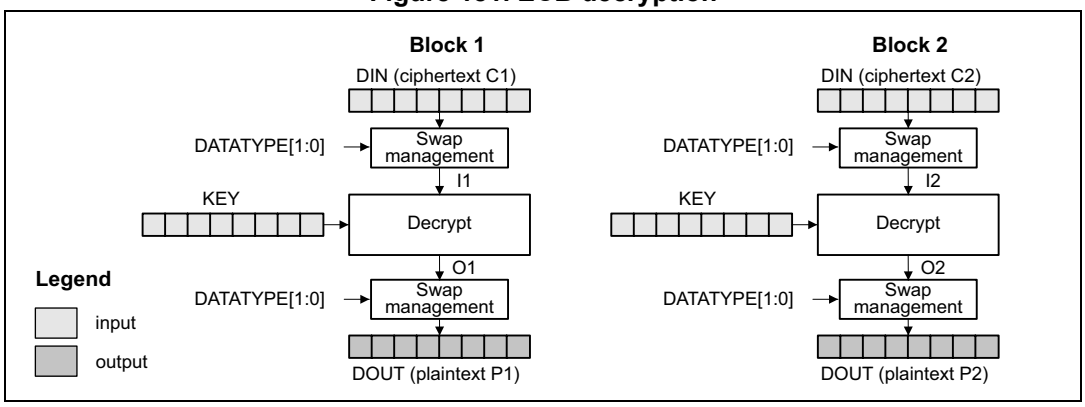

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 182 and *Figure 183* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 182. CBC encryption

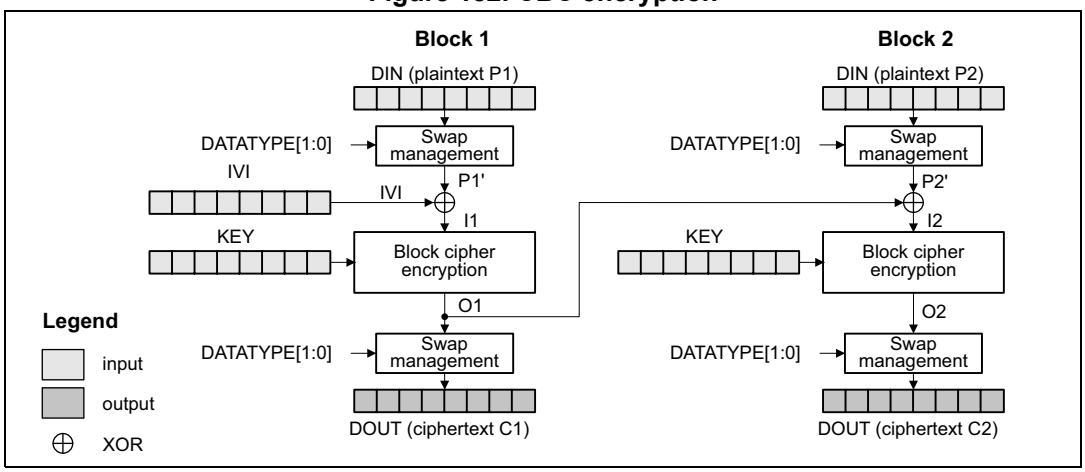

Figure 183. CBC decryption

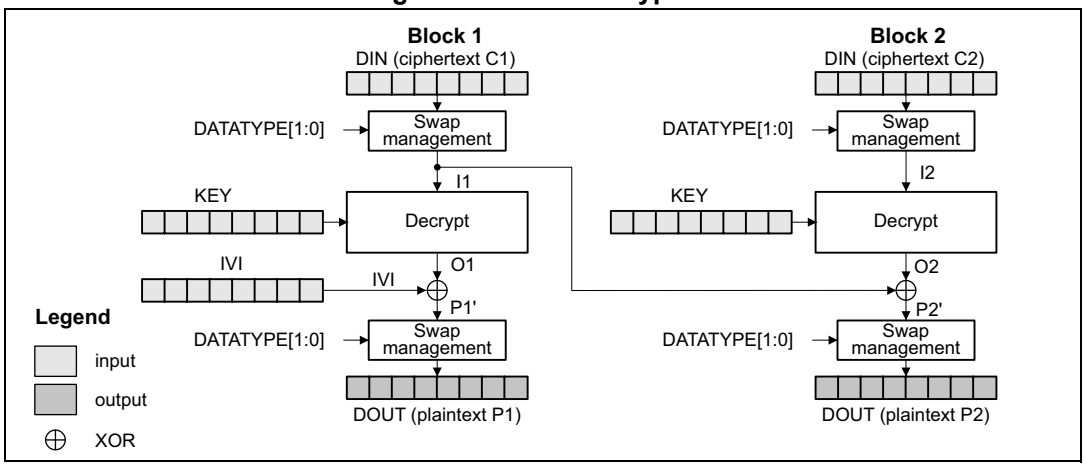


For more details, refer to NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 27.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.
7. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 27.4.7*.
   b) Append the cleartext block into AES as described in *Section 27.4.5*, then read the AES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
8. Finalize the sequence: disable the AES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 27.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
4. Wait until KEYVALID is set (the key loading completed).
5. Enable the AES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
6. Wait until the CCF flag in the AES_ISR register is set.
7. Clear the CCF flag, by setting the CCF bit of the AES_ICR register. The decryption key is available in the AES core and AES is disabled automatically.
8. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
9. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
10. Enable the AES peripheral, by setting EN.
11. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 27.4.7*.
    b) Append the ciphertext block into AES as described in *Section 27.4.5*, then read the AES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
12. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the AES_ISR register is set (computation completed).
2. Read four times the AES_DOUTR register to save the last processed block.
3. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
4. Save initialization vector registers (only required in CBC mode as the AES_IVRx registers are altered during the data processing).

5. Disable the AES peripheral, by clearing EN.
6. Save the AES_CR register and clear the key registers if they are not needed, to process the higher-priority message.

To resume the processing of a message, proceed as follows:

1. Disable the AES peripheral, by clearing EN.
2. Restore the AES_CR register (with correct KEYSIZE) then restore the AES_KEYRx registers. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 27.4.14*).
3. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).
4. Restore the AES_IVRx registers, using the saved configuration (only required in CBC mode).
5. Enable the AES peripheral, by setting EN.

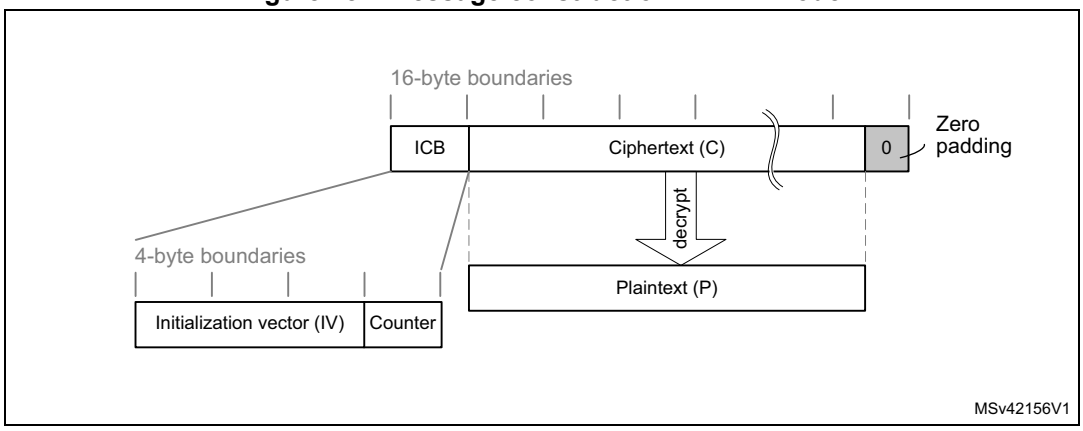
Note: It is not required to save the key registers as the application knows the original key.

27.4.10 AES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 184*.

Figure 184. Message construction in CTR mode



The structure of this message is:

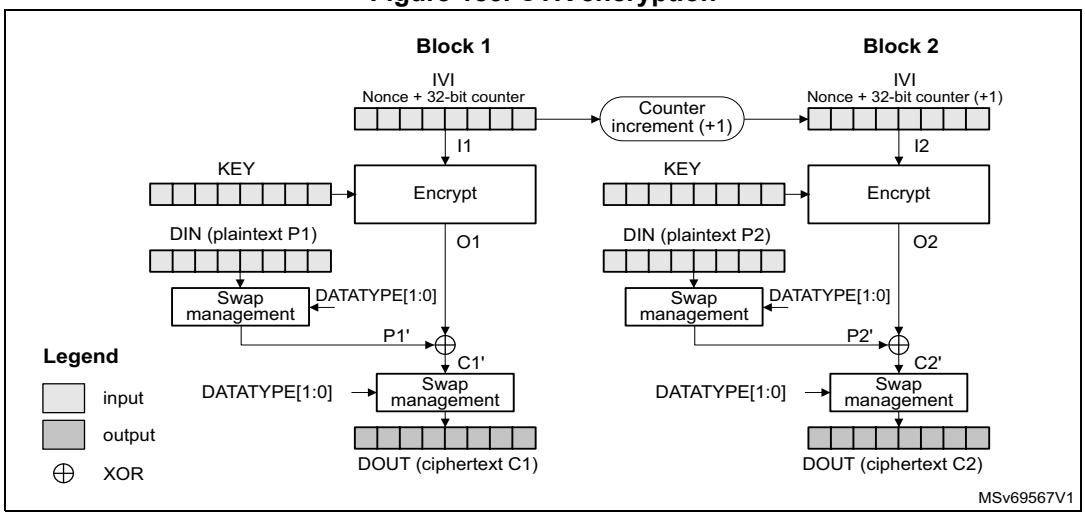
- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 185 describes the counter (CTR) chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 185. CTR encryption



Initialization vectors in AES must be initialized as shown in *Table 206*.

Table 206. Counter mode initialization vector definition

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 27.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers according to *Table 206*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.

7. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in *Section 27.4.5*, then read the AES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
8. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 27.4.9: AES basic chaining modes (ECB, CBC)*.

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

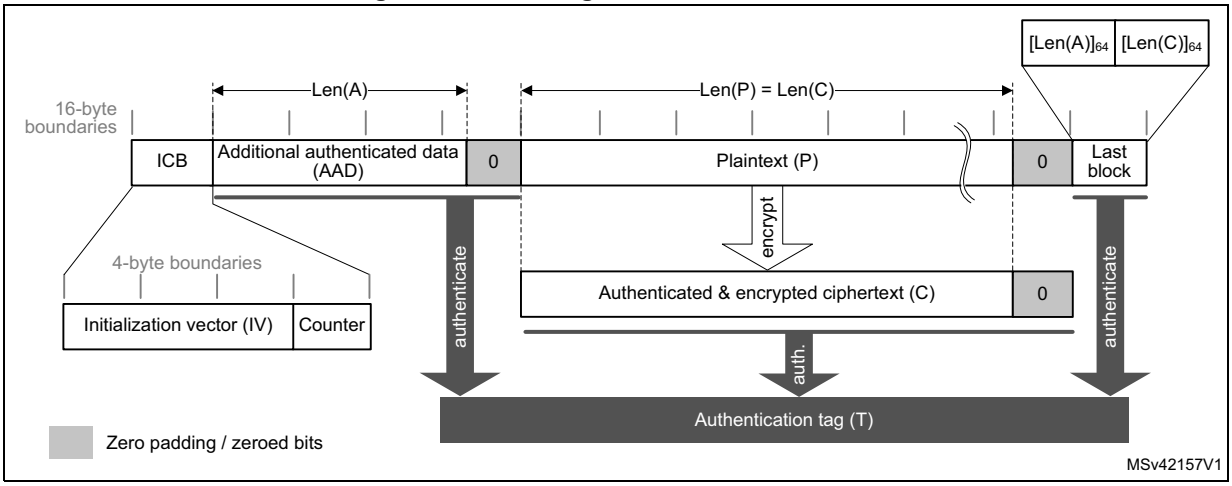
Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

27.4.11 AES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 186. Message construction in GCM



The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 208*.

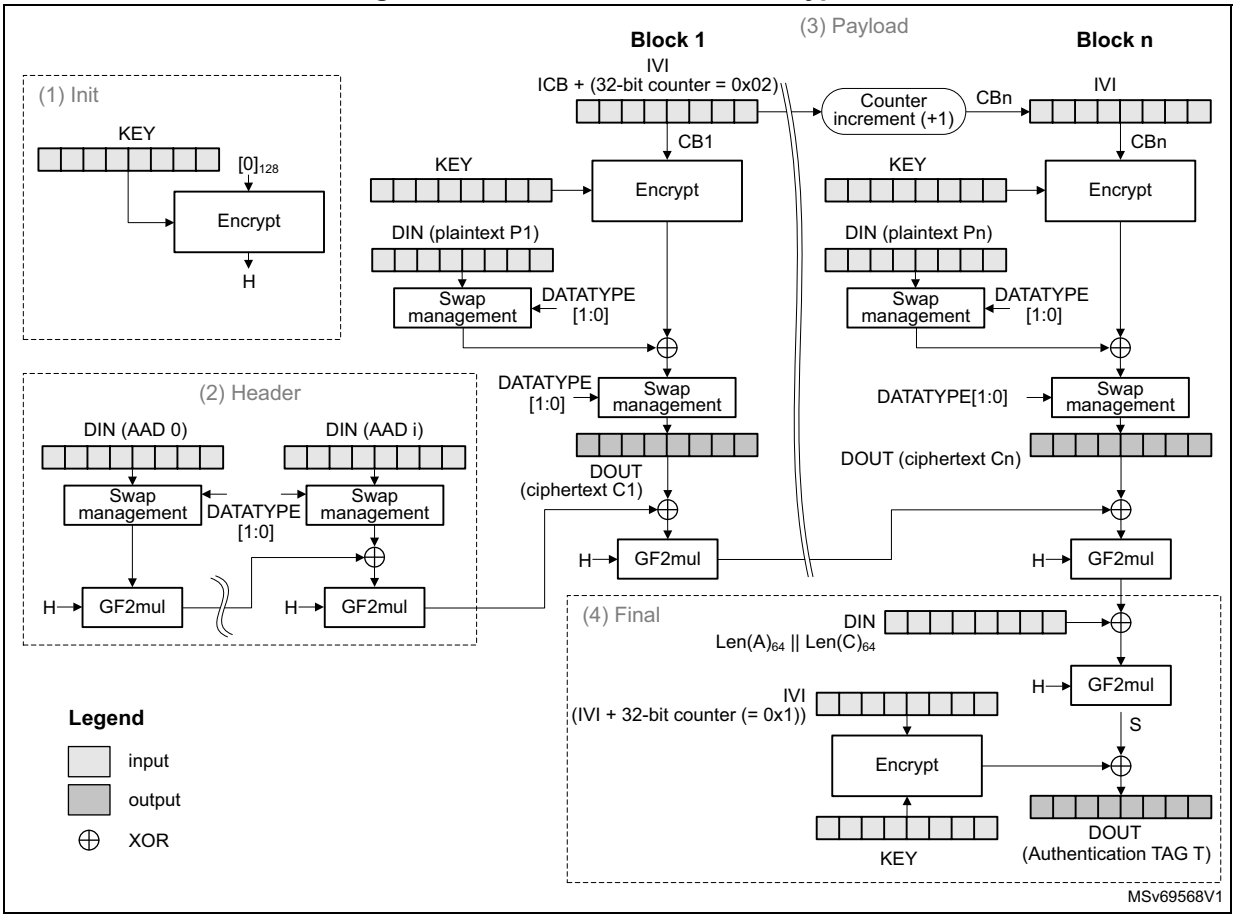
The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 187 describes the GCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 187. GCM authenticated encryption



The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 207*.

Table 207. Initialization of IV registers in GCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 208*.

Table 208. GCM last block definition

Word order to AES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 27.4.6*, with the following sequence of events:

GCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the GCM initialization phase, by writing CPHASE[1:0] with 0x0.
3. Write the initialization vector in AES_IVRx registers according to *Table 207*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
7. Wait until the CCF flag is set in the AES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
8. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

GCM header phase

9. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to CPHASE[1:0]. Do not change the other configurations written during GCM initialization.
   b) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 27.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

11. Initialize payload phase:
    a) Select the GCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the AES peripheral by setting EN.

12. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 27.4.5*, then read the AES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

13. Select the GCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
14. Write the final GCM block into the AES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 208*.
15. Wait until the CCF flag in the AES_ISR register is set.
16. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
18. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the AES_ISR register is set (computation completed).
2. In the payload phase, read four times the AES_DOUTR register to save the last-processed block.
3. Clear the CCF flag of the AES_ISR register, by setting the CCF bit of the AES_ICR register. When GCM encryption payload phase is selected, verify that BUSY is cleared in AES_SR, to ensure that GF2mul hash function is completed.
4. Save the AES_SUSPRx registers in the memory.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing EN.
7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:

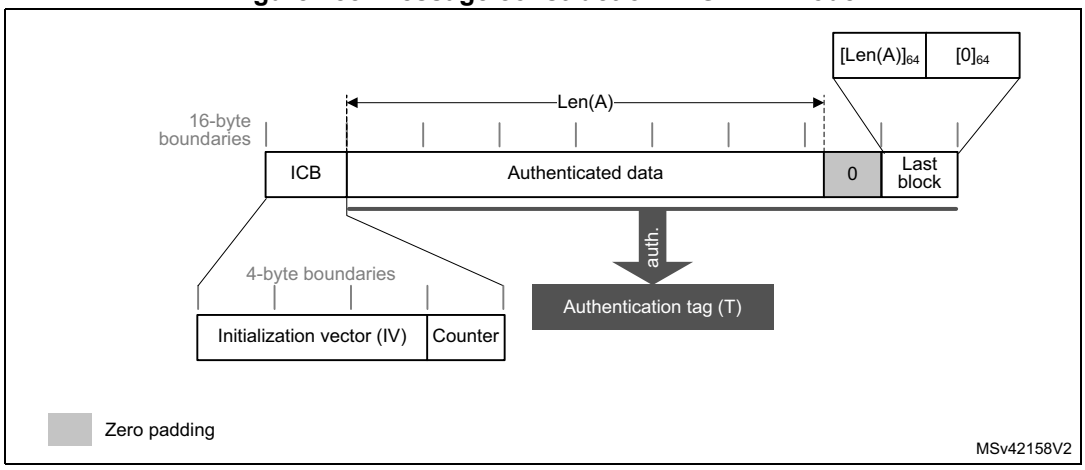
1. Disable the AES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
3. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
4. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
5. Enable the AES peripheral, by setting EN.

27.4.12 AES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

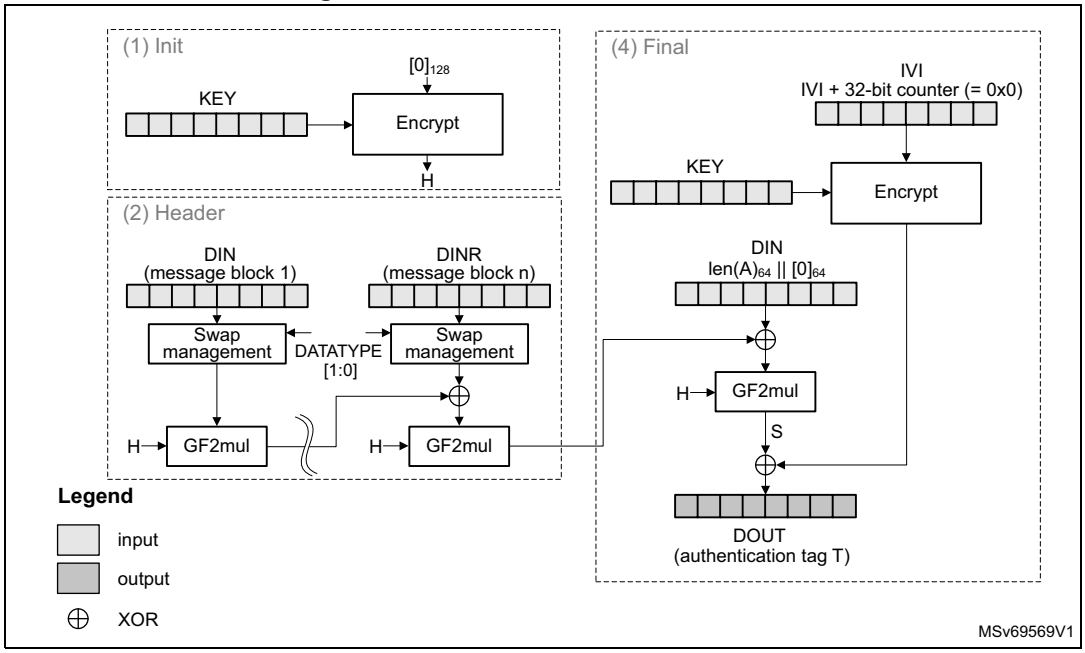
Figure 188. Message construction in GMAC mode



For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 189 describes the GMAC chaining implementation in the AES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 189. GMAC authentication mode



The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

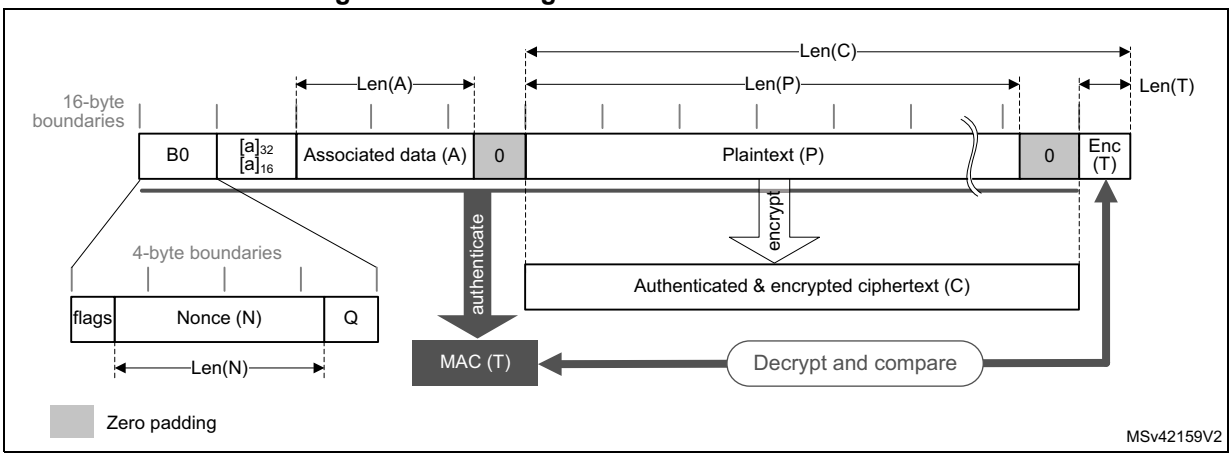
27.4.13 AES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 190. Message construction in CCM mode



The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 190*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.
- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 190*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000

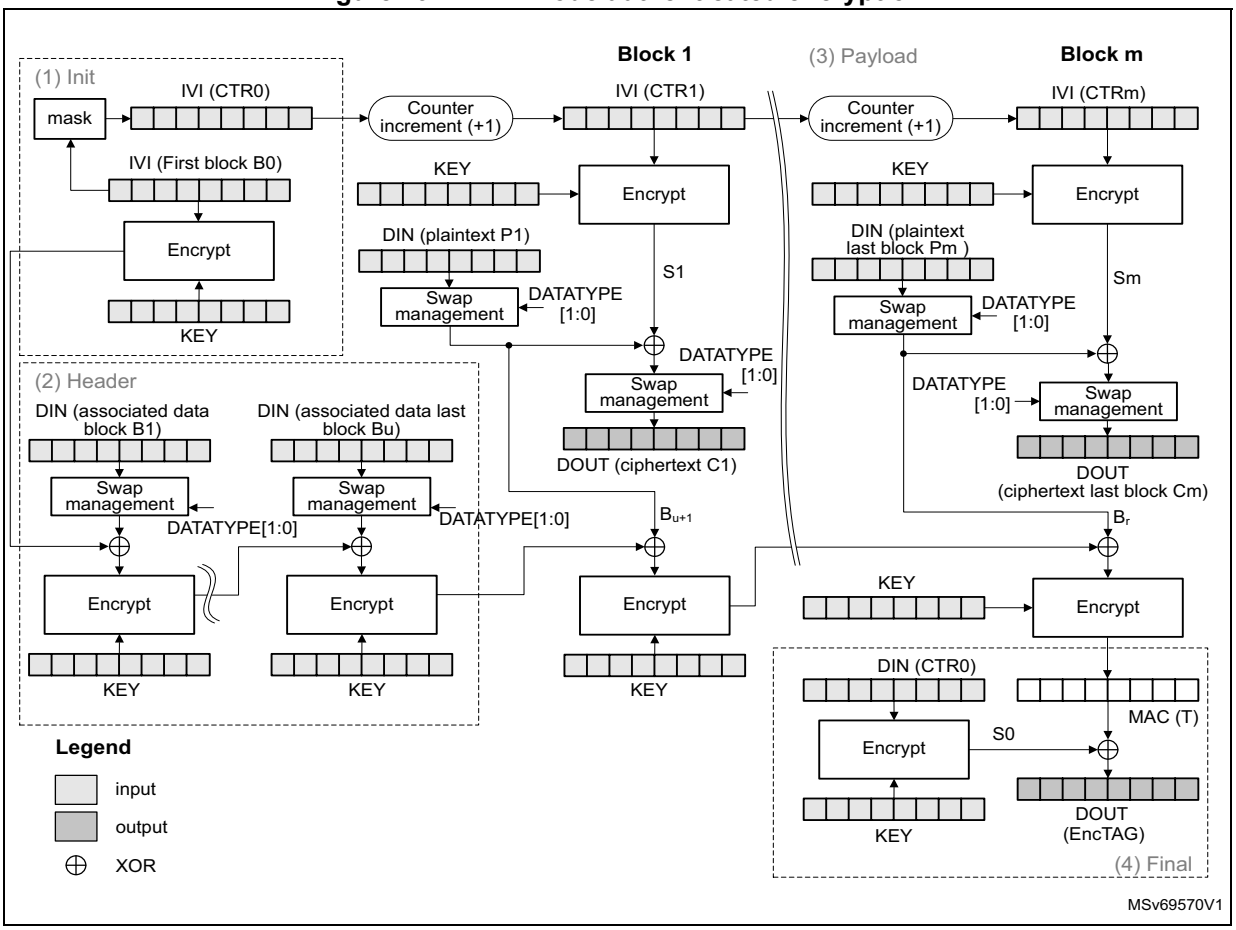
CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C, *Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 191 describes the CCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 191. CCM mode authenticated encryption



The first block of a CCM message (B0) must be prepared by the application as defined in *Table 209*.

Table 209. Initialization of IV registers in CCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The five most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

AES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 27.4.6*, with the following sequence of events:

CCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the CCM initialization phase, by writing CPHASE[1:0] with 0x0.
3. Write the B0 data in AES_IVRx registers according to *Table 209*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 27.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
7. Wait until the CCF flag in the AES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.

CCM header phase

9. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the CCM header phase, by writing CPHASE[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
   c) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 27.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

11. Initialize payload phase:
    a) Select the CCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the AES peripheral, by setting EN.
12. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 27.4.5*, then read the AES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

13. Select the CCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
14. Wait until CCF flag in the AES_ISR register is set.
15. Get the CCM authentication tag, by reading the AES_DOUTR register four times.
16. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
17. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

To suspend the processing of a message in header or payload phase, proceed as follows:

1. Wait until the CCF flag of the AES_ISR register is set (computation completed).
2. In the payload phase, read four times the AES_DOUTR register to save the last-processed block.
3. Clear the CCF flag in the AES_ISR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the AES peripheral, by clearing EN.

7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:

1. Disable the AES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
3. Restore AES_IVRx registers using the saved configuration.
4. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 27.4.14*).
5. Enable the AES peripheral, by setting EN.

27.4.14 AES key sharing with secure AES co-processor

The AES peripheral can use the SAES peripheral as security co-processor. The secure application prepares the key in the robust SAES peripheral and when it is ready, the AES application can load this prepared key through a dedicated hardware key bus.

The recommended sequence is described hereafter and in the section *SAES operations with shared keys* in the *SAES* section of this document.

1. In SAES peripheral, the application encrypts (wraps) the key to share in Shared-key mode (KMOD[1:0] at 0x2).
2. Each time the shared key is required in AES peripheral, the application decrypts it in the SAES peripheral in Shared-key mode (KMOD[1:0] at 0x2).
3. Once the shared key is decrypted (unwrapped) and loaded in SAES_KEYRx registers it can be shared with AES. To load the shared key in AES, the application sets KEYSIZE as appropriate and writes KMOD[1:0] with 0x2. When KEYVALID is cleared, the key is automatically transfered by hardware into the AES_KEYRx registers and the BUSY flag in the AES_SR register set.
4. Once the key transfer is completed, the BUSY flag is cleared and the KEYVALID flag set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if the KEIF flag is set in the AES_ISR register, either the KEYSIZE value is incorrect or an unexpected event occurred during the transfer (such as DPA error, tamper event or KEYVALID cleared before the end of the transfer). When such errors occur, reset both peripherals through their IPRST bits and restart the whole key sharing process.

When the key sharing sequence is completed, the AES is initialized with a valid, shared key. The application can then process data in normal key mode, by writing KMOD[1:0] with 0x0.

Note: This sequence in AES peripheral can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES peripheral is unused and duly remains in key sharing state.

27.4.15 AES data registers and data swapping

Data input and output

A 16-byte data block enters the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the AES peripheral with four successive 32-bit word reads of the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 210* “no swapping” option for details.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both AES input and output.

Note: The data in AES key registers (AES_KEYRx) and initialization vector registers (AES_IVRx) are not sensitive to the swap mode selection.

The AES data swapping feature is summarized in *Table 210* and *Figure 192*.

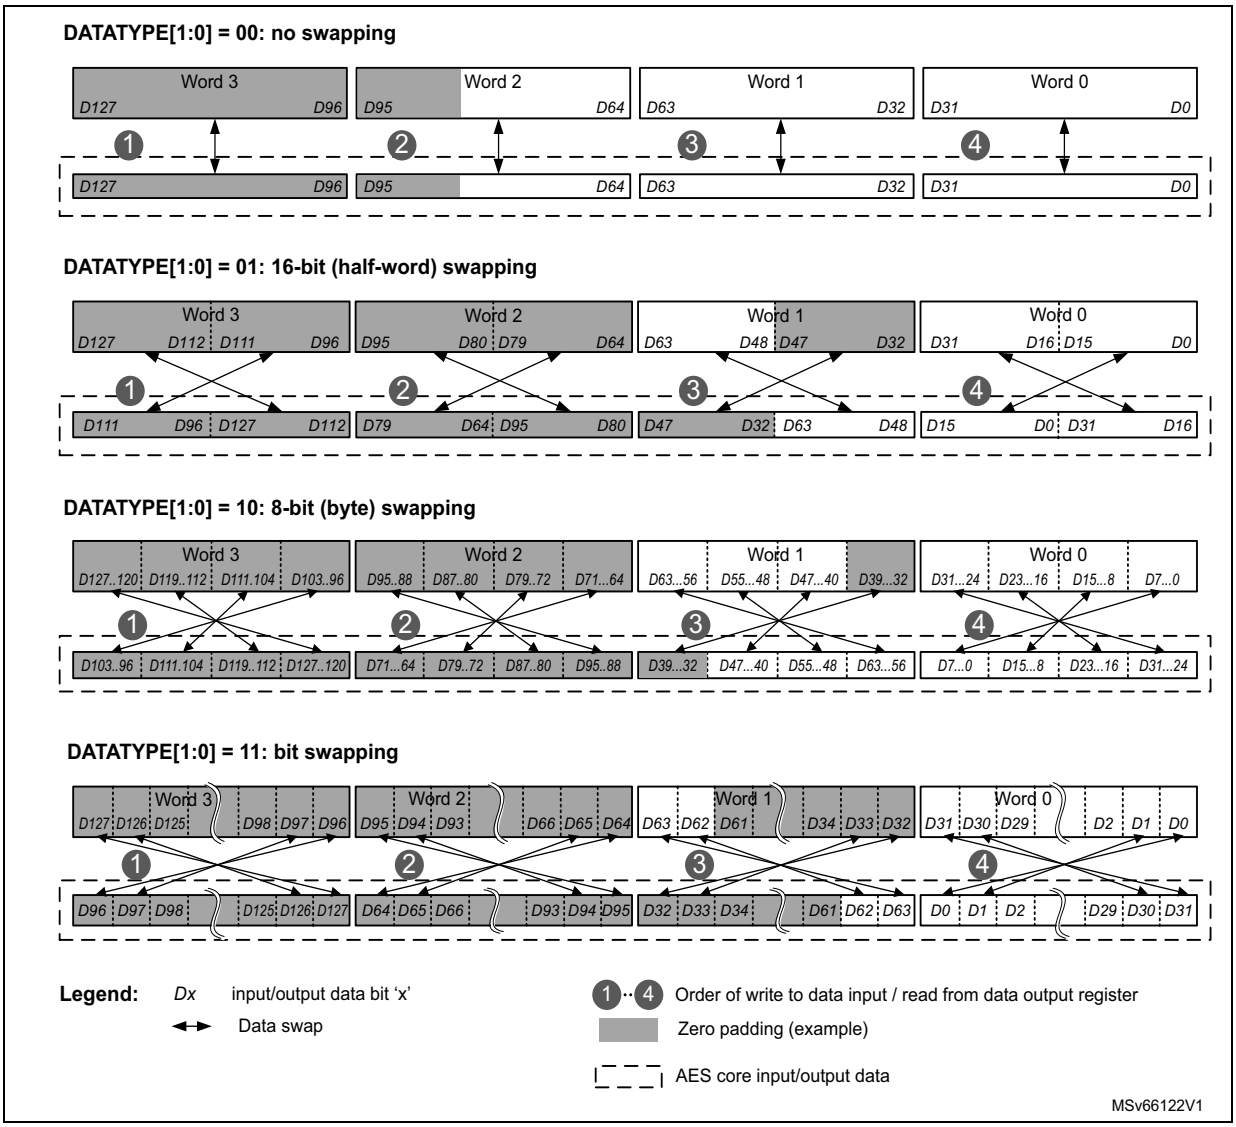
Table 210. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**

Table 210. AES data swapping example (continued)

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100
		Address @, word[63..32]: 0x04EE F672 0000 0100 1110 1110 1111 0110 0111 0010 Address @ + 0x4, word[31..0]: 0x2E04 CE96 0010 1110 0000 0100 1100 1110 1001 0110

Figure 192. 128-bit block construction according to the data type



Data padding

Figure 192 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

27.4.16 AES key registers

The eight AES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 211*. Reads are not allowed for security reason.

Note: In memory and in AES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 211. Key endianness in AES_KEYRx registers (128/256-bit keys)

AES_KEYR7 [31:0]	AES_KEYR6 [31:0]	AES_KEYR5 [31:0]	AES_KEYR4 [31:0]	AES_KEYR3 [31:0]	AES_KEYR2 [31:0]	AES_KEYR1 [31:0]	AES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the AES_KEYRx registers are ignored when AES peripheral is enabled (EN bit set). The application must check this before modifying key registers.

The entire key must be written before starting an AES computation.

In normal key mode (KMOD[1:0] at 0x0), the key registers must always be written in either ascending or descending order. The write sequence becomes:

- AES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- AES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 27.4.18*).

27.4.17 AES initialization vector registers

The four AES_IVRx registers store the initialization vector (IV) information, as shown in *Table 212*. They can only be written if the AES peripheral is disabled (EN cleared).

Note: In memory and in AES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 212. IVI bitfield spread over AES_IVRx registers

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, AES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

27.4.18 AES error management

The AES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the AES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: AES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 27.5: AES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Write error flag (WRERRF)

Unexpected write attempt of the AES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: AES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 27.5: AES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the AES_ISR register and clear the KEYVALID bit of the AES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 27.4.16: AES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.

- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 27.4.14: AES key sharing with secure AES co-processor* for details.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to *Section 27.5: AES interrupts*.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring AES.

27.5 AES interrupts

There are multiple individual maskable interrupt sources generated by the AES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)

See *Section 27.4.18: AES error management* for details on AES errors.

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable AES interrupt sources individually by setting/clearing the corresponding enable bit of the AES_IER register.

The status of the individual maskable interrupt sources can be read from the AES_ISR register. They are cleared by setting the corresponding bit of the AES_ICR register.

Table 213 gives a summary of the available features.

Table 213. AES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
AES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)

1. Bit of the AES_ICR register.
2. Flag of the AES_SR register, mirrored by the flag RWEIF of the AES_ISR register.

27.6 AES DMA requests

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the AES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

AES only supports single DMA requests.

Suspend and resume operations are not supported in DMA mode.

Detailed usage of DMA with AES can be found in *Appending data using DMA* subsection of *Section 27.4.5: AES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into AES. AES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the AES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 27.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from AES. AES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the AES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, AES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when AES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

27.7 AES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 214. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles
128-bit	Encryption or decryption(1)	ECB, CBC, CTR	51
	Key preparation	-	59
256-bit	Encryption or decryption(1)	ECB, CBC, CTR	75
	Key preparation	-	82

1. Excluding key preparation time (ECB and CBC only).

Table 215. Processing latency for GCM and CCM (in clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Encryption/ Decryption	GCM	64	35	51	59
		CCM	63	55	114	58
256-bit	Encryption/ Decryption	GCM	88	35	75	75
		CCM	87	79	162	82

1. Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle).

27.8 AES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

27.8.1 AES control register (AES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	Res.	Res.	Res.	Res.	Res.	KMOD[1:0]		NPBLB[3:0]				Res.	KEYSIZE	Res.	CHMOD[2]
rw						rw	rw	rw	rw	rw	rw		rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CPHASE[1:0]		DMAOUTEN	DMAINEN	Res.	Res.	Res.	Res.	CHMOD[1:0]		MODE[1:0]		DATATYPE[1:0]		EN
	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: AES peripheral software reset

Setting the bit resets the AES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the AES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the AES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable.

0x2: Shared key mode. If shared key mode is properly initialized in SAES peripheral, the AES peripheral automatically loads its key registers with the data stored in the SAES key registers. The key value is available in AES key registers when BUSY bit is cleared and KEYVALID is set in the AES_SR register. Key error flag KEIF is set otherwise in the AES_ISR register.

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **KEYSIZE:** Key size selection
This bitfield defines the key length in bits of the key used by AES.
0: 128-bit
1: 256-bit
Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **CPHASE[1:0]:** Chaining phase selection
This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable
This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable
This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode
This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode
This bitfield selects the AES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the AES_DINR register or read from the AES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 27.4.15: AES data registers and data swapping*.

0x0: No swapping (32-bit data).

0x1: Half-word swapping (16-bit data)

0x2: Byte swapping (8-bit data)

0x3: Bit-level swapping

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the AES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the AES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

– The bit cannot be set as long as KEYVALID is cleared

27.8.2 AES status register (AES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in AES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KMOD[1:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KMOD[1:0] is different from zero, the BUSY flag is automatically set by AES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is usually set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 27.4.16: AES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether AES is idle or busy.
0: Idle
1: Busy
AES is flagged as idle when disabled (when EN is low) or when the last processing is completed.
AES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), or transferring a shared key from the SAES peripheral.
When GCM encryption payload phase is selected, this flag must be at zero before suspending current process to manage a higher-priority message.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the AES_DINR register occurred. When set WRERRF bit has no impact on the AES operations.
0: No error
1: Unexpected write to AES_DINR register occurred during computation or data output phase.
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the AES_DOUTR register occurred. When set RDERRF bit has no impact on the AES operations.
0: No error
1: Unexpected read to AES_DOUTR register occurred during computation or data input phase.
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 0 Reserved, must be kept at reset value.

27.8.3 AES data input register (AES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.
Reads return zero.

27.8.4 AES data output register (AES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

27.8.5 AES key register 0 (AES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the AES_CR register.

Writes to AES_KEYRx registers are ignored when AES is enabled (EN bit set). When the key comes from the SAES peripheral (KMOD[1:0] at 0x2), writes to key registers are also ignored and they result in setting the KEIF bit of the AES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

27.8.6 AES key register 1 (AES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEY[111:96]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[127:96]**: Cryptographic key, bits [127:96]

Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

27.8.9 AES initialization vector register 0 (AES_IVR0)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IVI[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

AES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in AES_CR register

27.8.10 AES initialization vector register 1 (AES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

27.8.17 AES suspend registers (AES_SUSPRx)

Address offset: 0x040 + 0x4 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

AES_SUSPRx registers contain the complete internal register states of the AES when the GCM, GMAC or CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 27.4.8: AES suspend and resume operations* for more details.

Clearing EN bit of the AES_CR register clears this register to zero.

AES_SUSPRx registers are not used in other chaining modes than GCM, GMAC or CCM.

27.8.18 AES interrupt enable register (AES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIE	RWEIE	CCFIE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE:** Key error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable

This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

27.8.19 AES interrupt status register (AES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	RWEIF	CCF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers.

0: No key error detected

1: Key information failed to load into key registers

The flag setting generates an interrupt if the KEIE bit of the AES_IER register is set. It also clears the key registers and the KEYVALID flag in the AES_SR register.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

KEIF is raised upon any of the following events:

–AES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE set, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse).

–AES fails to load the key shared by the SAES peripheral (KMOD[1:0] = 0x2).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the AES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the AES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

27.8.20 AES interrupt clear register (AES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	RWEIF	CCF
													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag clear
Setting this bit clears the KEIF status bit of the AES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear
Setting this bit clears the RWEIF status bit of the AES_ISR register, and clears both RDERRF and WRERRF flags in the AES_SR register.

Bit 0 **CCF:** Computation complete flag clear
Setting this bit clears the CCF status bit of the AES_ISR register.

28 Secure AES coprocessor (SAES)

This section only applies to STM32C59x/5A3 products.

28.1 SAES introduction

The secure AES coprocessor (SAES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.

SAES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/ decryption (wrapped-key mode) and key sharing with faster AES peripheral (shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by the application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.

28.2 SAES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 480 or 680 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Hardware secret key encryption/ decryption (Wrapped-key mode)
- Using dedicated key bus, optional key sharing with faster AES peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
  - Optional 128-bit or 256-bit hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together

- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software (in CPU mode only, not in DMA mode) to suspend a message if SAES needs to process another message with a higher priority, then resume the original message

28.3 SAES implementation

The devices have one SAES peripheral, implemented as per the following table. It shares the key with the AES peripheral. For comparison, the AES peripheral is also included in the table.

Table 217. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection	-	X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256

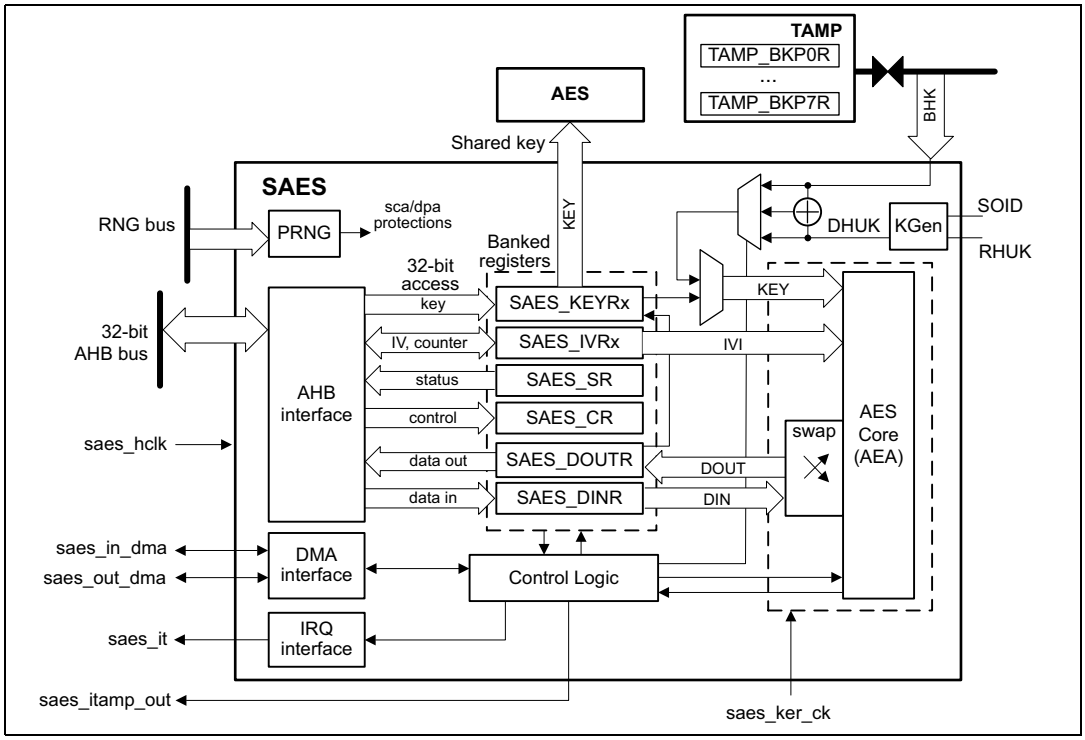
1. X = supported.

28.4 SAES functional description

28.4.1 SAES block diagram

Figure 193 shows the block diagram of SAES.

Figure 193. SAES block diagram



Note: AES represents the AES peripheral.

28.4.2 SAES internal signals

Table 218 describes the user relevant internal signals interfacing the SAES peripheral.

Table 218. SAES internal input/output signals

Signal name	Signal type	Description
saes_hclk	Input	AHB bus clock
saes_ker_ck	Input	SAES kernel clock.
saes_it	Output	SAES interrupt request
saes_in_dma	Input/Output	SAES incoming data DMA single request/acknowledge
saes_out_dma	Input/Output	SAES processed data DMA single request/acknowledge
saes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, SAES automatically clears key registers. A reset is required for SAES to be usable again.
RHUK	Input	256-bit root hardware unique key (nonvolatile, unique per device and secret to software), used to internally compute the derived hardware unique key (DHUK)

Table 218. SAES internal input/output signals (continued)

Signal name	Signal type	Description
BHK(1)	Input	256-bit boot hardware key (BHK) stored in tamper-resistant backup registers and written during boot. Once written, this key cannot be read nor written by any application until the next product reset.
SOID	Input	Static operating ID hardware input used during each DHUK computation. Its change causes the erasure of key registers and sets the KEIF flag.

1. Connected to a set of backup registers in TAMP peripheral that are written, then read/write locked, by the application software (see *Section 28.4.17* for details).

28.4.3 SAES reset and clocks

The SAES peripheral is clocked by the AHB bus clock. It has a dedicated reset bit and a dedicated kernel clock, controlled through the RCC.

The SAES reset in RCC is mandatory when a hardware tamper event occurs in SAES. Refer to *Managing tamper errors* in *Section 28.4.19* for details.

After clocking then releasing the reset of the SAES peripheral in the RCC, SAES automatically draws random numbers from the RNG, setting the BUSY bit of the SAES_SR register. Refer to the *RNG error interrupt flag (RNGEIF)* in *Section 28.4.19* for details.

This background task must be completed before the device enters a low-power mode.

28.4.4 SAES symmetric cipher implementation

The secure AES coprocessor (SAES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 219*. Those functions can be certified NIST PUB 140-3.

Table 219. SAES approved symmetric key functions

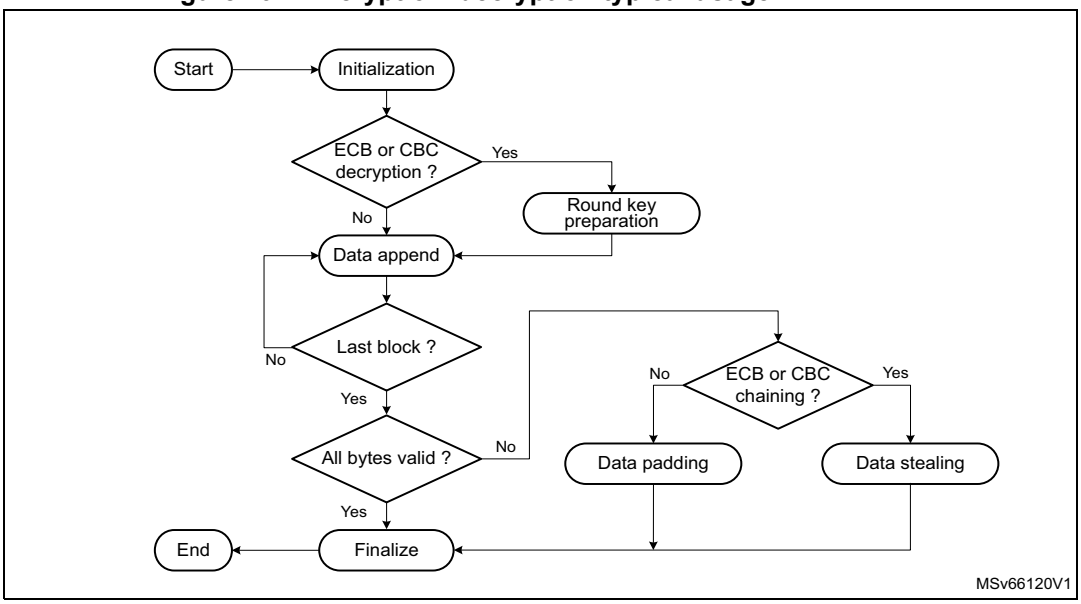
Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

SAES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any SAES processing, following the sequence described in *Section 28.4.8*.

28.4.5 SAES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 194. Encryption/ decryption typical usage



Initialization

The SAES peripheral is initialized according to the chaining mode. Refer to *Section 28.4.9: SAES basic chaining modes (ECB, CBC)* and *Section 28.4.10: SAES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 28.4.7: SAES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. Enable the SAES peripheral when KEYVALID is set, by setting the EN bit of the SAES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_ISR register, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using

NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).

3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the SAES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES, by setting the CCFIE bit of the SAES_IER register.
2. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the SAES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note: SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and SAES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in *Section 28.6: SAES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the

NPBLB[3:0] bitfield must be set up before processing the block, for SAES to compute a correct tag.

3. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

When appending data using DMA, the suspend/resume operation as described in *Section 28.4.8* is not supported.

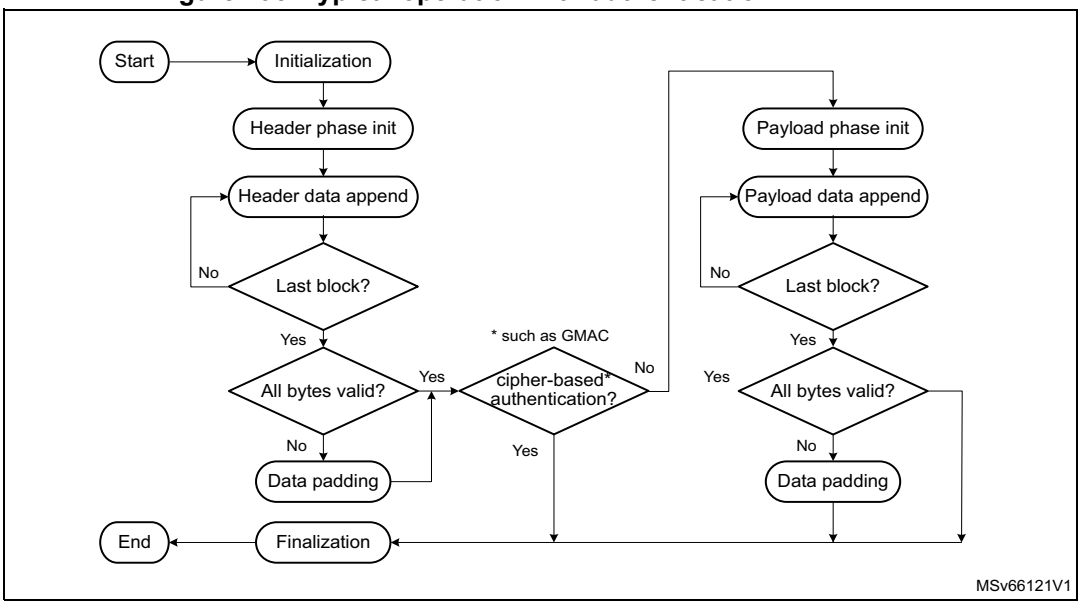
Note: The CCF flag has no use with this method because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

28.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 195. Typical operation with authentication



Section 28.4.11: SAES Galois/counter mode (GCM) and *Section 28.4.13: SAES counter with CBC-MAC (CCM)* describe detailed sequences supported by SAES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by SAES is described in *Section 28.4.12: SAES Galois message authentication code (GMAC)*.

28.4.7 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A*, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since SAES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since SAES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

28.4.8 SAES suspend and resume operations

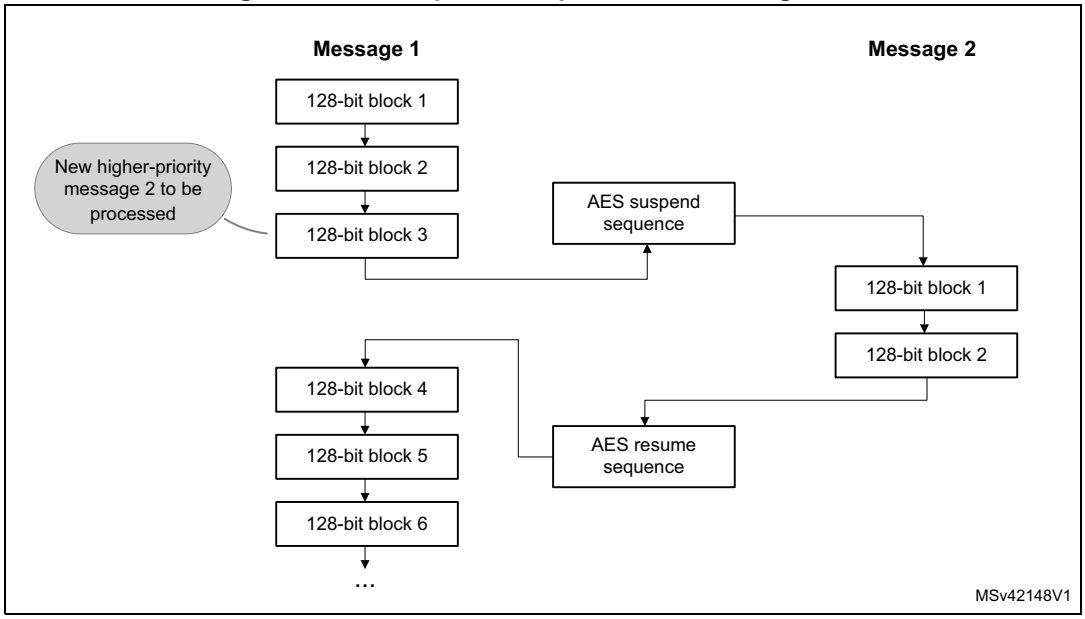
A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as SAES is enabled again, to receive a next data block.

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

Figure 196 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 196. Example of suspend mode management



A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

28.4.9 SAES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 197 and *Figure 198* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 197. ECB encryption

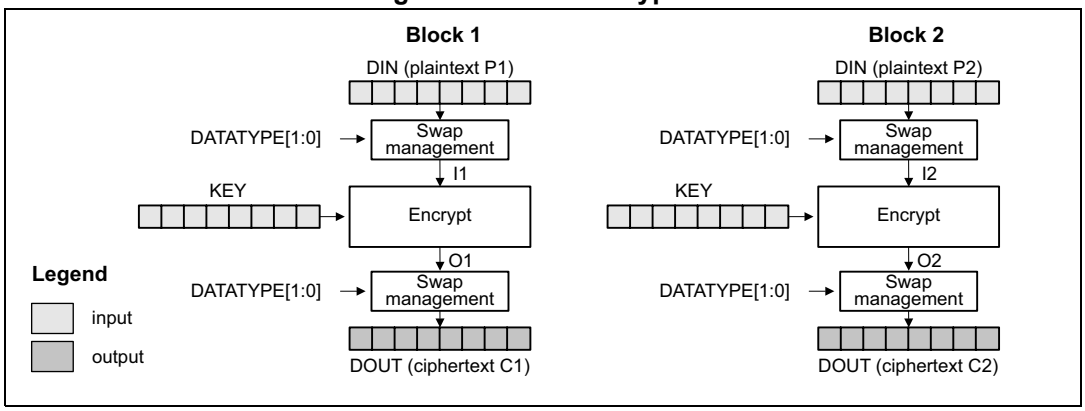


Figure 198. ECB decryption

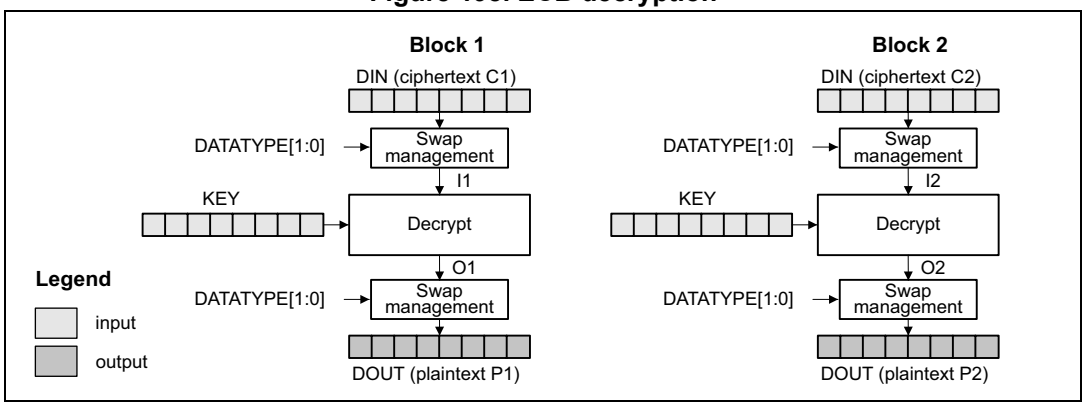

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 199 and *Figure 200* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 199. CBC encryption

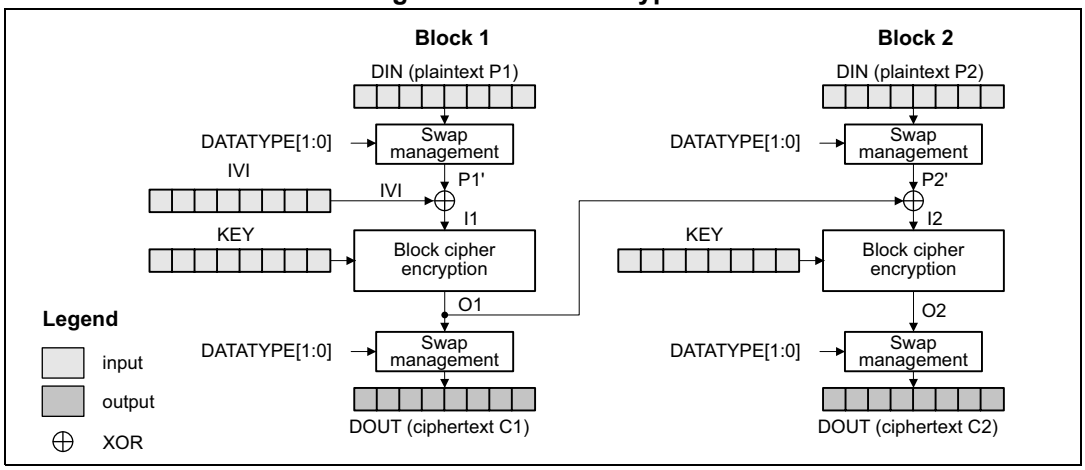

Figure 200. CBC decryption

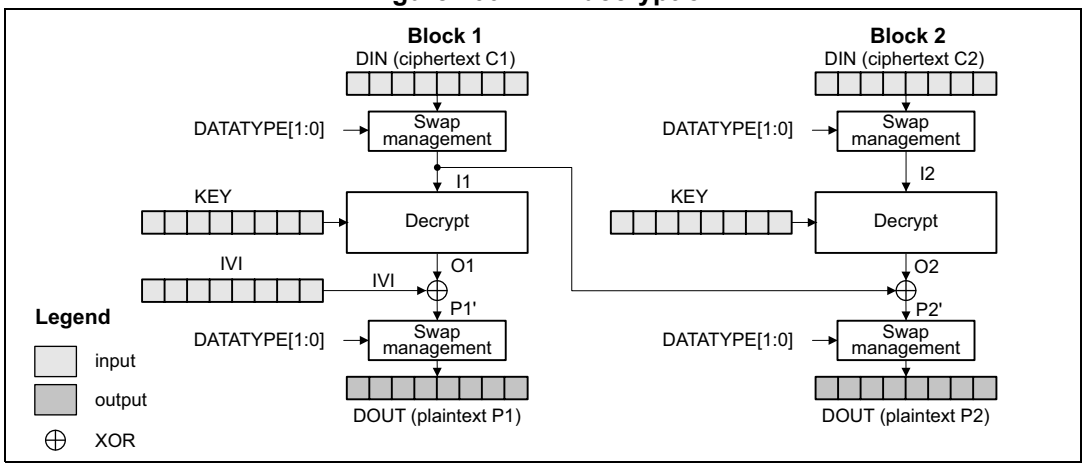


For more details, refer to NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 28.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 28.4.14* (wrapped keys) and *Section 28.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 28.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 28.4.7*.
   b) Append the cleartext block into SAES as described in *Section 28.4.5*, then read the SAES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 28.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 28.4.14* (wrapped keys) and *Section 28.4.15* (shared keys).
4. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 28.4.17: SAES key registers* for details.
5. Wait until KEYVALID is set (the key loading completed).

6. Enable the SAES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
7. Wait until the CCF flag in the SAES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register. The decryption key is available in the AES core and SAES is disabled automatically.
9. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
10. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
11. Enable the SAES peripheral, by setting EN.
12. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 28.4.7*.
    b) Append the ciphertext block into SAES as described in *Section 28.4.5*, then read the SAES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
13. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The following sequences are valid for normal key mode (KMOD[1:0] at 0x0).

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the SAES_ISR register is set (computation completed).
2. Read four times the SAES_DOUTR register to save the last processed block.
3. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
4. Save initialization vector registers (only required in CBC mode as the SAES_IVRx registers are altered during the data processing).
5. Disable the SAES peripheral, by clearing EN.
6. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher-priority message.

To resume the processing of a message, proceed as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Restore the SAES_CR register (with correct KEYSIZE) then restore the SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from key registers, refer to *Section 28.4.17: SAES key registers* for details.
3. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).
4. Restore the SAES_IVRx registers, using the saved configuration (only required in CBC mode).
5. Enable the SAES peripheral, by setting EN.

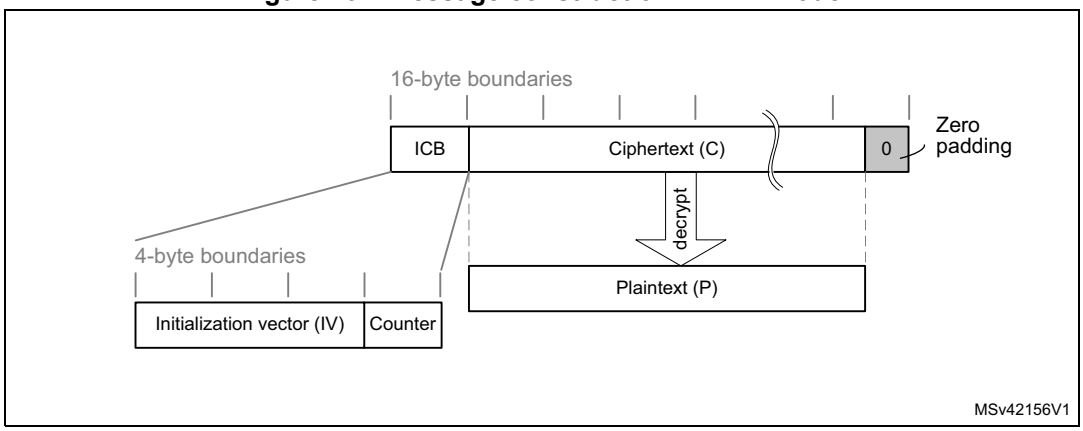
Note: It is not required to save the key registers as the application knows the original key.

28.4.10 SAES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 201*.

Figure 201. Message construction in CTR mode



The structure of this message is:

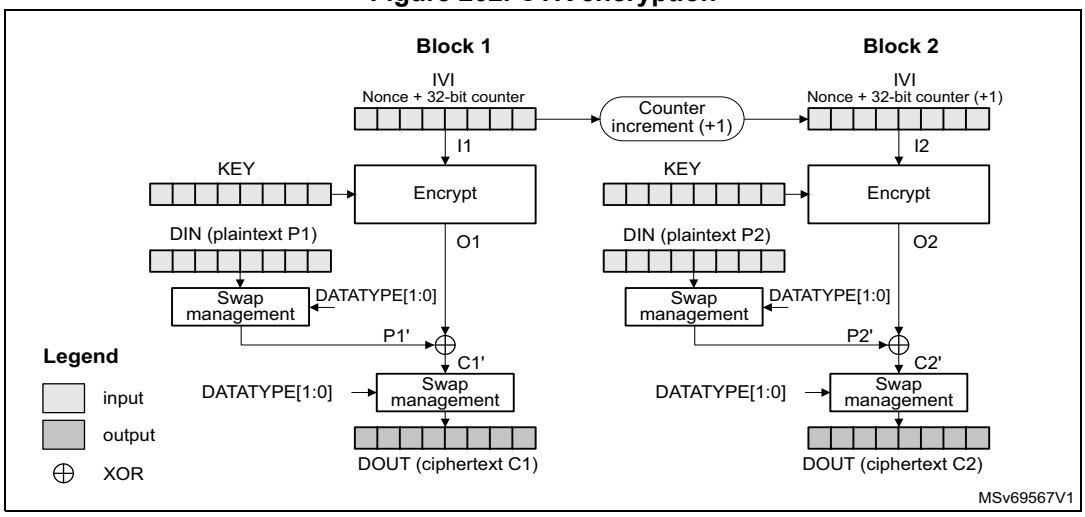
- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 202 describes the counter (CTR) chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 202. CTR encryption



Initialization vectors in SAES must be initialized as shown in *Table 220*.

Table 220. Counter mode initialization vector definition

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 28.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 28.4.14* (wrapped keys) and *Section 28.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers according to *Table 220*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 28.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.

8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in *Section 28.4.5*, then read the SAES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 28.4.9: SAES basic chaining modes (ECB, CBC)*.

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

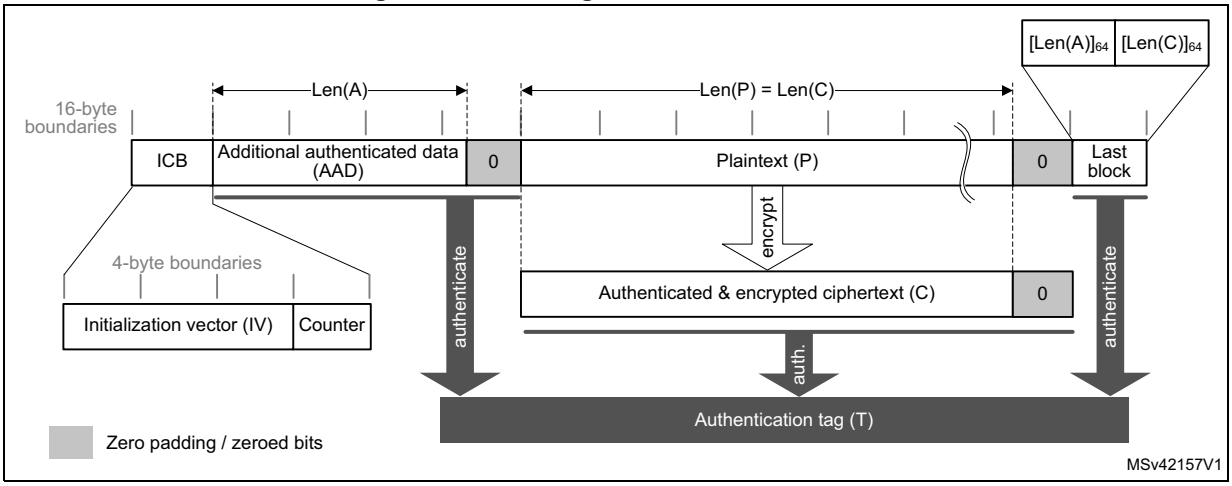
Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

28.4.11 SAES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 203. Message construction in GCM



The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed 2^{32} - 2 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 222*.

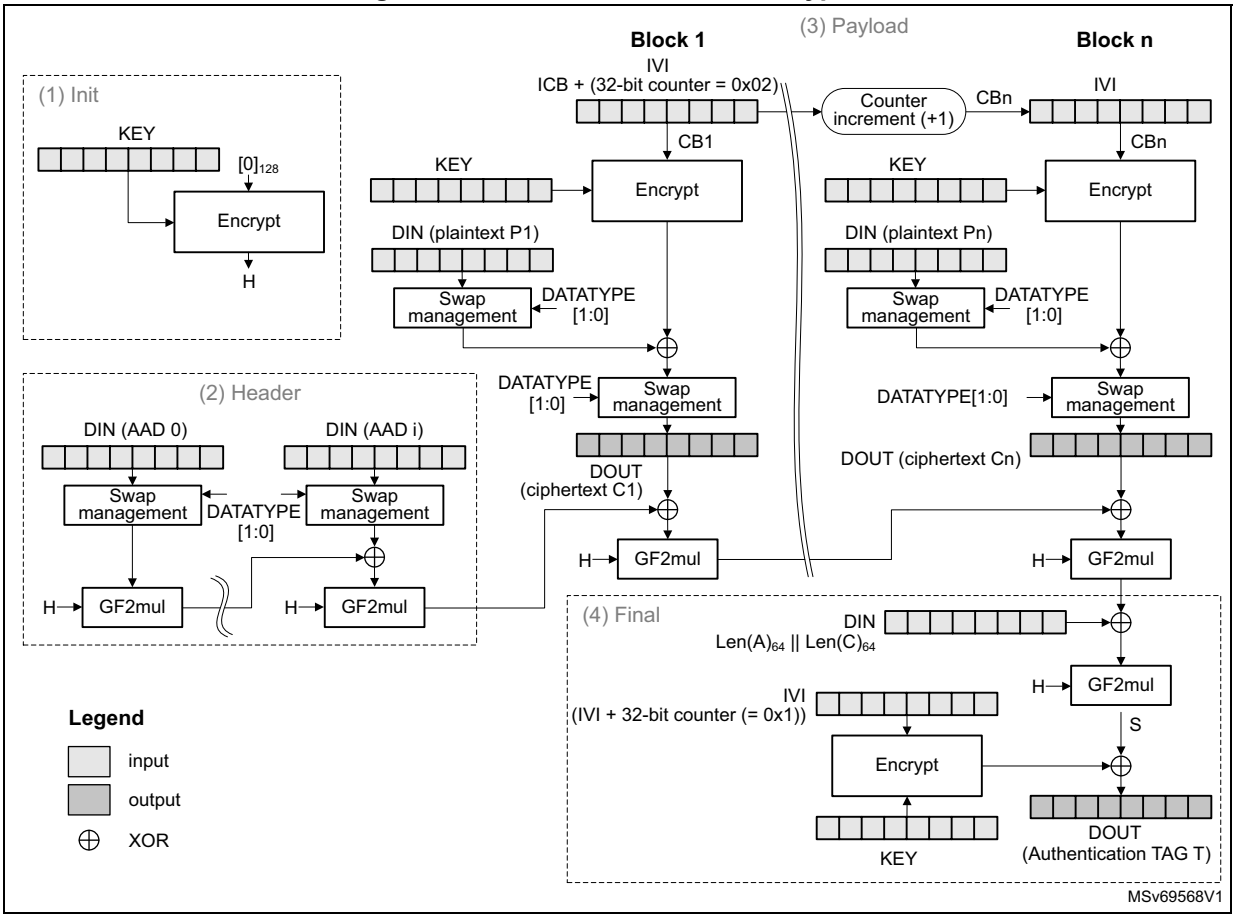
The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 204 describes the GCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 204. GCM authenticated encryption



The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 221*.

Table 221. Initialization of IV registers in GCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 222*.

Table 222. GCM last block definition

Word order to SAES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 28.4.6*, with the following sequence of events:

GCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 28.4.14* (wrapped keys) and *Section 28.4.15* (shared keys).
   - Select the GCM initialization phase, by writing CPHASE[1:0] with 0x0.
4. Write the initialization vector in SAES_IVRx registers according to *Table 221*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 28.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
8. Wait until the CCF flag is set in the SAES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
9. Clear the CCF flag by setting the CCF bit of the SAES_ICR register.

GCM header phase

10. Initialize header phase:
    a) Select the GCM header phase, by writing 0x1 to CPHASE[1:0]. Do not change the other configurations written during GCM initialization.
    b) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 28.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

12. Initialize payload phase:
    a) Select the GCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral by setting EN.

13. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 28.4.5*, then read the SAES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

14. Encryption only: wait until the BUSY flag in the SAES_SR register is cleared.
15. Select the GCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
16. Write the final GCM block into the SAES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 222*.
17. Wait until the CCF flag in the SAES_ISR register is set.
18. Get the GCM authentication tag, by reading the SAES_DOUTR register four times.
19. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
20. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to SAES_DINR normally (no swapping), while swapping is applied to tag data read from SAES_DOUTR.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode

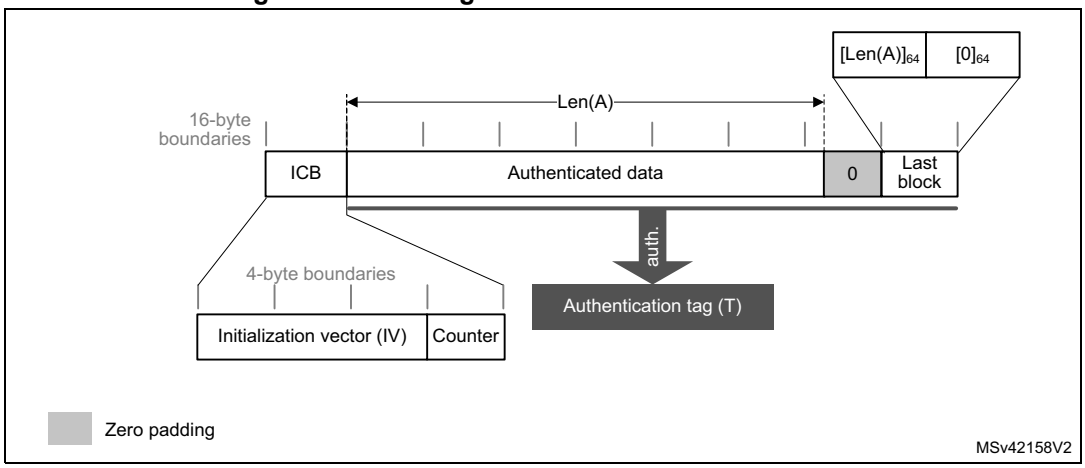
Suspend/resume operations are not supported in GCM mode.

28.4.12 SAES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

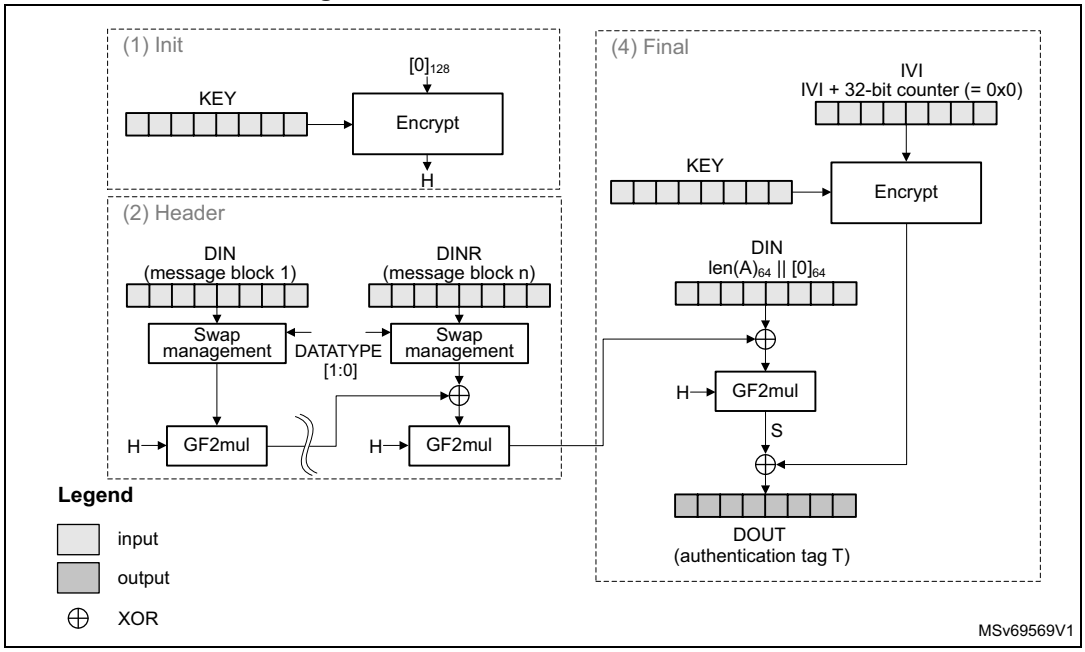
Figure 205. Message construction in GMAC mode



For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 206 describes the GMAC chaining implementation in the SAES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 206. GMAC authentication mode



The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

Suspend/resume operations are not supported in GMAC mode.

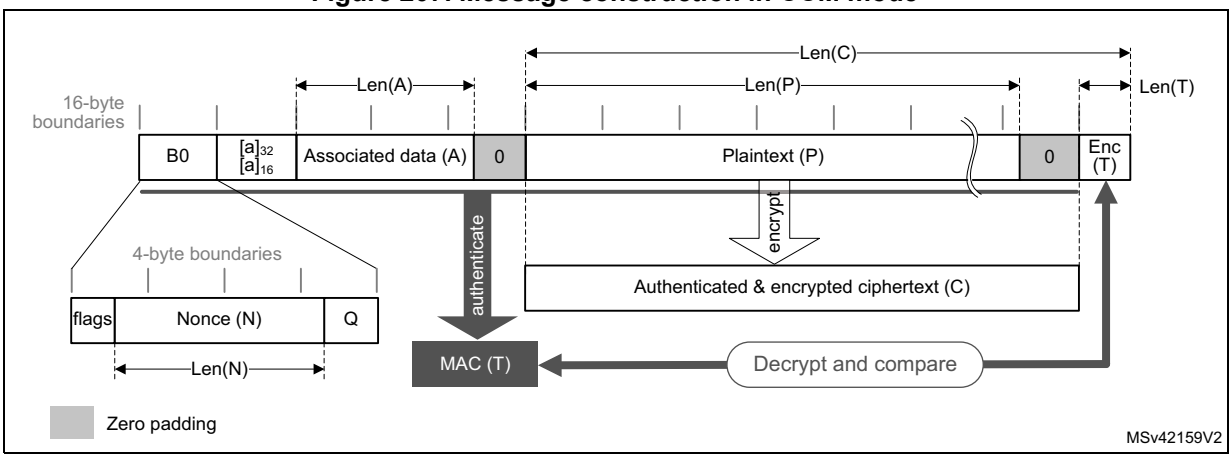
28.4.13 SAES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 207. Message construction in CCM mode



The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 207*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 207*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000

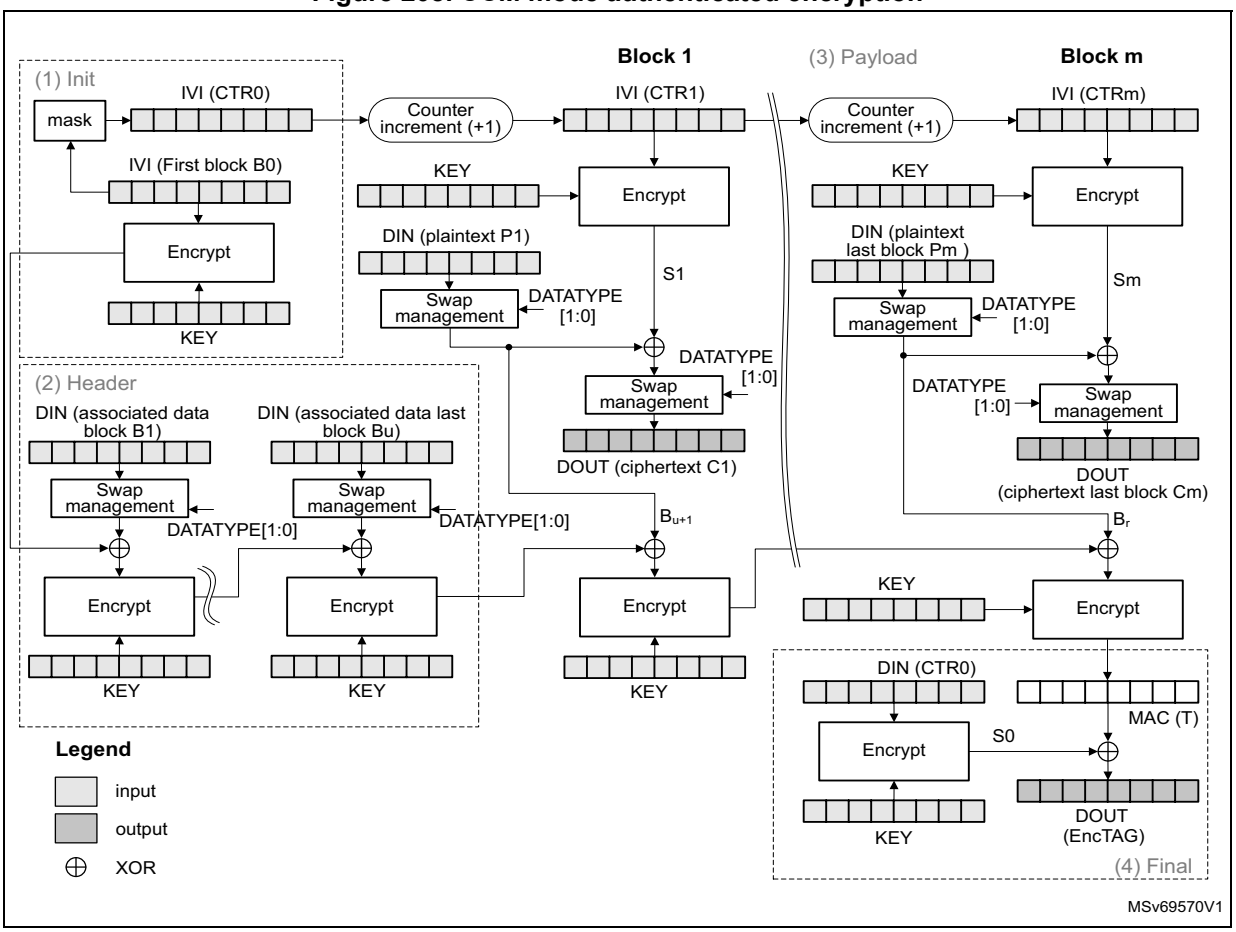
CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C*, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 208 describes the CCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 208. CCM mode authenticated encryption



The first block of a CCM message (B0) must be prepared by the application as defined in *Table 223*.

Table 223. Initialization of IV registers in CCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The five most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

SAES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 28.4.6*, with the following sequence of events:

CCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 28.4.14* (wrapped keys) and *Section 28.4.15* (shared keys).
   - Select the CCM initialization phase, by writing CPHASE[1:0] with 0x0.
4. Write the B0 data in SAES_IVRx registers according to *Table 223*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 28.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
8. Wait until the CCF flag in the SAES_ISR register is set.
9. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

CCM header phase

10. Initialize header phase:
    a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
    b) Select the CCM header phase, by writing CPHASE[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
    c) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 28.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

12. Initialize payload phase:
    a) Select the CCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral, by setting EN.
13. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 28.4.5*, then read the SAES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

14. Select the CCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
15. Wait until CCF flag in the SAES_ISR register is set.
16. Get the CCM authentication tag, by reading the SAES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
18. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from SAES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

To suspend the processing of a message in header or payload phase, proceed as follows:

1. Wait until the CCF flag of the SAES_ISR register is set (computation completed).
2. In the payload phase, read four times the SAES_DOUTR register to save the last-processed block.
3. Clear the CCF flag in the SAES_ISR register, by setting the CCF bit of the SAES_ICR register.
4. Save the SAES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the SAES peripheral, by clearing EN.
7. Save the current SAES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding SAES_SUSPRx registers.
3. Restore SAES_IVRx registers using the saved configuration.
4. Restore the initial setting values in the SAES_CR and SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from the key registers, refer to *Section 28.4.17: SAES key registers* for details.
5. Enable the SAES peripheral, by setting EN.

28.4.14 SAES operation with wrapped keys

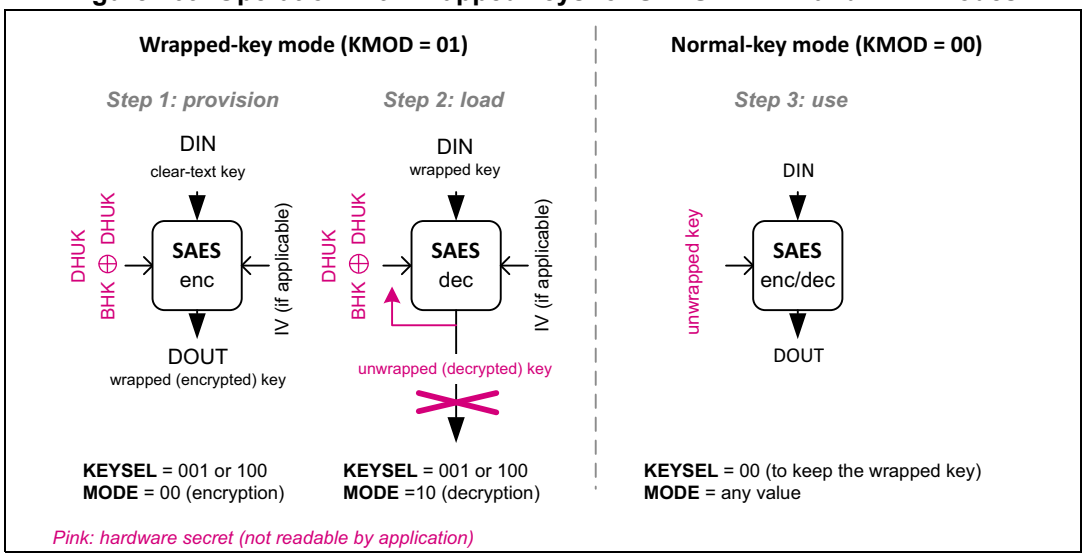
SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Operation with wrapped keys for SAES in ECB and CBC modes

Figure 209 summarizes how to wrap or unwrap keys for SAES in ECB and CBC modes. To protect the wrapped key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 209. Operation with wrapped keys for SAES in ECB and CBC modes



Note: DHUK value depends on privilege, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

Key wrapping for SAES

The recommended sequence to wrap (that is, encrypt) a key is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (MODE[1:0] at 0x0)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. This information is used both for the encryption key and for the key to be encrypt.
   - Select wrapped key mode by writing KMOD[1:0] with 0x1
4. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to *Section 28.4.17* for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (DHUK loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see *Table 225*).
9. Wait until CCF flag is set in the SAES_ISR register.
10. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF flag, by setting the CCF bit in SAES_ICR register.
11. Repeat steps *8.* to *10.* if KEYSIZE is set.
12. Disable the SAES peripheral, by clearing EN.

Note: Encryption in Wrapped-key mode is only supported when ECB or CBC is selected.

Key unwrapping for SAES

The recommended sequence to unwrap (or decrypt) a wrapped (encrypted) key using ECB/CBC is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the chaining mode used during the wrapping process (CHMOD[2:0] at 0x0 or 0x1) in *key derivation* mode (MODE[1:0] at 0x1)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size used during the wrapping process, with KEYSIZE. This information is used both for the decryption key and for the key to decrypt.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. With KEYSEL[2:0], select the same key source as when the key was wrapped/encrypted.
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN bit in SAES_CR to enable the peripheral
7. Wait until CCF flag is set in the SAES_ISR register.
8. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The decryption key is available in the AES core, and SAES is disabled automatically.
9. Select the *decryption* mode (MODE[1:0] at 0x2). Other parameters are unchanged.
10. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
11. Enable the SAES peripheral, by setting EN.
12. Write the SAES_DINR register four times to input the key to decrypt (MSB first, see *Table 225*).
13. Wait until CCF flag is set in the SAES_ISR register. Then clear the CCF flag by setting the CCF bit in SAES_ICR register. Reading SAES_DOUTR returns zero and triggers a read error (RDERRF).
14. Repeat steps *12.* and *13.* if KEYSIZE is set.
15. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the decrypted wrapped key is immediately usable by the application for any AES operation (normal key mode, that is, with KMOD[1:0] = 0x0).

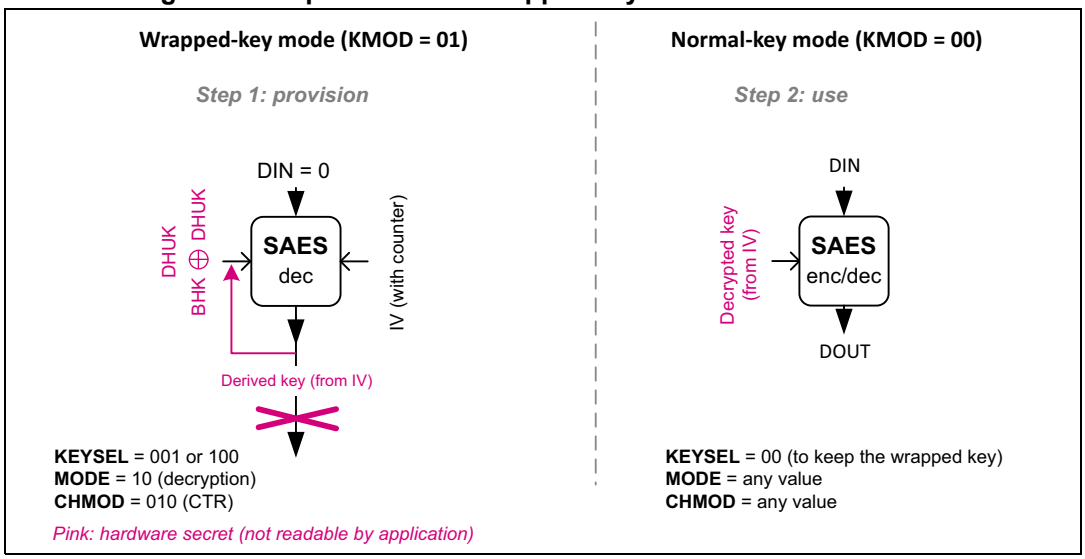
Note: When KMOD[1:0] = 0x1 (wrapped key) and MODE[1:0] = 0x2 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERRF).

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

Operation with wrapped keys for SAES in CTR mode

Figure 210 summarizes how to unwrap keys for SAES in CTR mode. To protect the derived key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 210. Operation with wrapped keys for SAES in CTR mode



Note: DHUK value depends on privilege, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

The recommended sequence for SAES wrapped key mode using CTR is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the CTR chaining mode (CHMOD[2:0] at 0x2) in decryption mode (MODE[1:0] at 0x2). Other MODE[1:0] values are not supported.
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. It is used for encryption key and for the key to share.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Write the initialization vector in SAES_IVRx registers, keeping the two least significant bits of SAES_IVR0 at zero.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to *Section 28.4.17* for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Wait until CCF flag is set in the SAES_ISR register.
9. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The derived hardware secret key is available in SAES_KEYRx registers.
10. Repeat steps *8.* and *9.* if KEYSIZE is set.
11. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the hardware secret key derived from the public data in the SAES_IVRx registers is then immediately usable by the application for any AES operation (normal key mode, that is, with KMOD[1:0] = 0x0).

Note: The configuration KMOD[1:0] at 0x1 (wrapped key), CHMOD[2:0] at 0x2 (CTR chaining), and MODE at 0x0 (encryption) disables the peripheral, by automatically clearing the EN bit of the SAES_*CR register.*

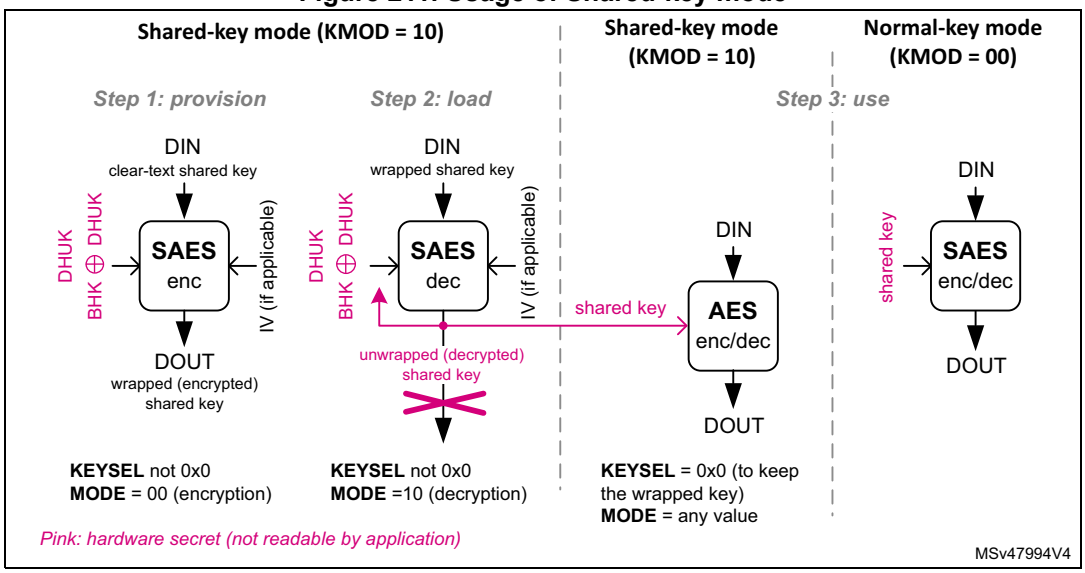
28.4.15 SAES operation with shared keys

SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES peripheral, without exposing them in clear-text (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

Figure 211 summarizes how to wrap or unwrap keys to share with *AES* peripheral. To protect the shared key, DHUK must be selected, by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 211. Usage of Shared-key mode



Note: DHUK value depends on privilege, KMOD[1:0], KSHAREID, KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

In the step 3, AES represents the AES peripheral.

Key wrapping for AES peripheral

Before SAES can share a key with the AES peripheral, the key must be encrypted (wrapped) once. The encryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 211*. See *Key wrapping for SAES* for details.

Note: Encryption in Shared-key mode is only supported when ECB or CBC is selected.

Key unwrapping for AES peripheral (shared key)

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted (unwrapped) in SAES, then loaded by AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 211*. See *Key unwrapping for SAES* for details.

In shared key mode when decryption mode is selected (MODE[1:0] at 0x2), a read access to the SAES_DOUTR register triggers a read error (RDERRF).

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be written with 0x0 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] at 0x2 and KEYVALID set. The sequence in the AES key share target peripheral is described in *AES key sharing with secure AES co-processor* of the corresponding section in this document. It can be run multiple times (for example, to manage a suspend/resume situation) as long as SAES is unused and duly remains in key sharing state.

Note: When KMOD[1:0] is at 0x2 and BUSY set in the AES peripheral, and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

28.4.16 SAES data registers and data swapping

Data input and output

A 16-byte data block enters the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the SAES peripheral with four successive 32-bit word reads of the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 224* “no swapping” option for details.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both SAES input and output.

Note: The data in SAES key registers (SAES_KEYRx) and initialization vector registers (SAES_IVRx) are not sensitive to the swap mode selection.

The SAES data swapping feature is summarized in *Table 224* and *Figure 212*.

Table 224. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100

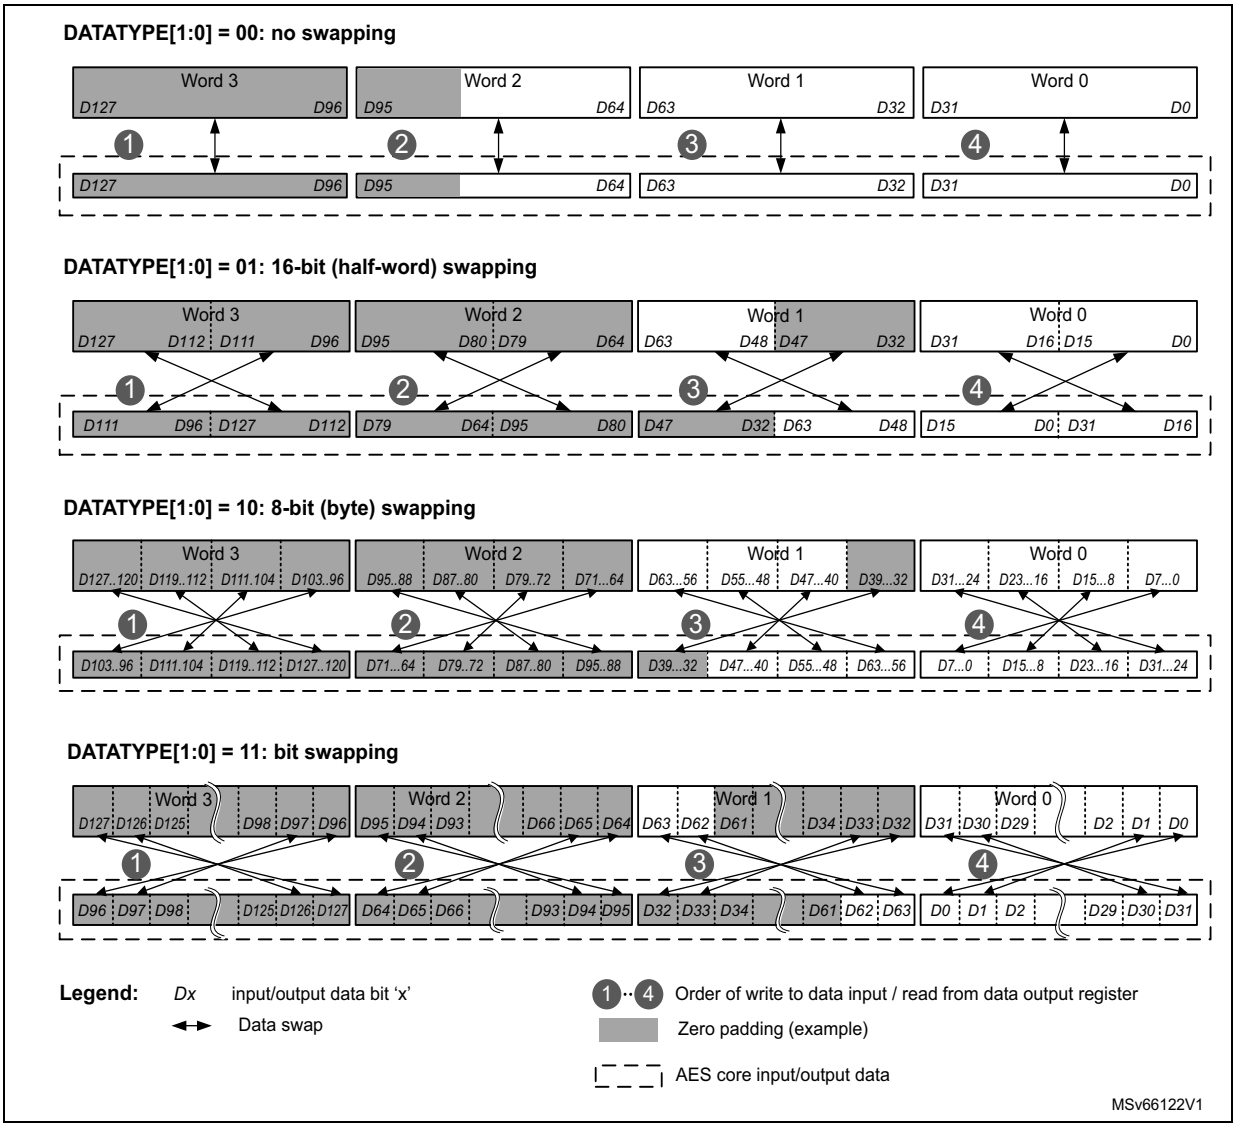
Figure 212. 128-bit block construction according to the data type



Data padding

Figure 212 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

28.4.17 SAES key registers

The eight SAES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 225*. Reads are not allowed for security reason.

Note: In memory and in SAES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 225. Key endianness in SAES_KEYRx registers (128/256-bit keys)

SAES_KEYR7 [31:0]	SAES_KEYR6 [31:0]	SAES_KEYR5 [31:0]	SAES_KEYR4 [31:0]	SAES_KEYR3 [31:0]	SAES_KEYR2 [31:0]	SAES_KEYR1 [31:0]	SAES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
TAMP_BKP7R [31:0]	TAMP_BKP6R [31:0]	TAMP_BKP5R [31:0]	TAMP_BKP4R [31:0]	TAMP_BKP3R [31:0]	TAMP_BKP2R [31:0]	TAMP_BKP1R [31:0]	TAMP_BKP0R [31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the SAES_KEYRx registers are ignored when SAES peripheral is enabled (EN bit set) and KEYSEL[2:0] is different from zero. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation.

In normal key mode (KMOD[1:0] at 0x0), with KEYSEL[2:0] at 0x0, the key registers must always be written in either ascending or descending order. The write sequence becomes:

- SAES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- SAES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 28.4.19*).

Key selection

With KEYSEL[2:0] at 0x0, the application must write the key in the SAES_KEYRx registers.

With KEYSEL[2:0] at 0x1, a derived hardware unique key (DHUK), computed inside SAES from a nonvolatile and secret root hardware unique key, is loaded directly into key registers, based on KEYSIZE information.

With KEYSEL[2:0] at 0x2, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to *Table 225*.

With KEYSEL[2:0] at 0x4, the XOR combination of DHUK and BHK is entirely transferred into key registers upon performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to *Table 225*.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID is cleared. The recommended method to clear KEYVALID is to set IPRST. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] at 0x2).

For all KEYSEL[2:0] values, initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transfered to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see *Section 28.4.19*).

Note: DHUK, BHK and their XOR combination are not readable by software.

28.4.18 SAES initialization vector registers

The four SAES_IVRx registers store the initialization vector (IV) information, as shown in *Table 226*. They can only be written if the SAES peripheral is disabled (EN cleared).

Note: In memory and in SAES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 226. IVI bitfield spread over SAES_IVRx registers

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, SAES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

28.4.19 SAES error management

The SAES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the SAES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: Unless otherwise indicated, SAES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 28.5: SAES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Write error flag (WRERRF)

Unexpected write attempt of the SAES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: Unless otherwise indicated, SAES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 28.5: SAES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the SAES_ISR register and clear the KEYVALID bit of the SAES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 28.4.17: SAES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.
- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 28.4.15: SAES operation with shared keys* for details.
- **Hardware secret key loading error:** triggered upon failing load of DHUK or BHK into SAES. KEYSEL[2:0] at 0x1 (DHUK), 0x2 (BHK) or 0x4 (DHUK XOR BHK) is not functional.

The KEIF flag is cleared with corresponding bit of the SAES_ICR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to *Section 28.5: SAES interrupts*.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring SAES.

RNG error interrupt flag (RNGEIF)

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the RNGEIE bit of the SAES_IER register is set. For more details, refer to *Section 28.5: SAES interrupts*.

Upon an RNG error:

- Make sure that the RNG peripheral is properly configured.
- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear RNGEIF or reset the peripheral by setting IPRST. The clearance of the BUSY flag then indicates the completion of the random number fetch from RNG.

Note: To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

Managing tamper errors

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, reset the SAES peripheral through RCC or global reset.

28.5 SAES interrupts

There are multiple individual maskable interrupt sources generated by the SAES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)
- RNG error (RNGEIF)

See *Section 28.4.19: SAES error management* for details on SAES errors.

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable SAES interrupt sources individually by setting/clearing the corresponding enable bit of the SAES_IER register.

The status of the individual maskable interrupt sources can be read from the SAES_ISR register. They are cleared by setting the corresponding bit of the SAES_ICR register.

Table 227 gives a summary of the available features.

Table 227. SAES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
SAES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)
	RNG error flag	RNGEIF	RNGEIE	set RNGEIF(1)

1. Bit of the SAES_ICR register.
2. Flag of the SAES_SR register, mirrored by the flag RWEIF of the SAES_ISR register.

28.6 SAES DMA requests

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the SAES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

SAES only supports single DMA requests.

Suspend and resume operations are not supported in DMA mode.

Detailed usage of DMA with SAES can be found in *Appending data using DMA* subsection of *Section 28.4.5: SAES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into SAES. SAES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the SAES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 28.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from SAES. SAES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the SAES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, SAES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when SAES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

28.7 SAES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 228. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles(1)
128-bit	Encryption or decryption(2)	ECB, CBC, CTR	**480**
	Key preparation	-	**145**
256-bit	Encryption or decryption(2)	ECB, CBC, CTR	**680**
	Key preparation	-	**230**

1. SAES kernel clock
2. Excluding key preparation time (ECB and CBC only).

Table 229. Processing latency for GCM and CCM (in SAES kernel clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	490	72(2)	480(3)	490
		CCM	490	490	800	490
256-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	650	72(2)	690(3)	650
		CCM	650	680	1350	650

1. Data insertion can include wait states forced by SAES on the AHB bus (maximum 3 cycles, typical 1 cycle).
2. SAES AHB clock cycles instead of kernel clock cycle (Galois multiplier only).
3. As a worst case in encryption mode, add extra 72 AHB clock cycles for the last block computation.

28.8 SAES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

28.8.1 SAES control register (SAES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	KEYSEL[2:0]			KSHAREID[1:0]		KMOD[1:0]		NPBLB[3:0]				Res.	KEYSIZE	Res.	CHMOD[2]
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CPHASE[1:0]		DMAOUTEN	DMAINEN	Res.	Res.	Res.	Res.	CHMOD[1:0]		MODE[1:0]		DATATYPE[1:0]		EN
	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: SAES peripheral software reset

Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:28 **KEYSEL[2:0]**: Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

0x0: Software key, loaded in key registers SAES_KEYx

0x1: Derived hardware unique key (DHUK)

0x2: Boot hardware key (BHK)

0x4: XOR of DHUK and BHK

Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL[2:0] is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK when KEYVALID is cleared.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 27:26 **KSHAREID[1:0]**: Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0] at 0x2 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

0x0: AES peripheral

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the SAES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable and no specific use or protection applies to SAES_DINR and SAES_DOUTR registers.

0x1: Wrapped key for SAES mode. Key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

0x2: Shared key mode. After a successful decryption process (unwrapping), SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] at 0x2 and KEYVALID=1. When a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **KEYSIZE:** Key size selection

This bitfield defines the key length in bits of the key used by SAES.

0: 128-bit

1: 256-bit

When KMOD[1:0] is at 0x1 or 0x2, KEYSIZE also defines the length of the key to encrypt or decrypt.

Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **CPHASE[1:0]:** Chaining phase selection

This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.

0x0: Initialization phase

0x1: Header phase

0x2: Payload phase

0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable

This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from SAES via DMA.

0: Disable

1: Enable

Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable

This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to SAES via DMA.

0: Disable

1: Enable

Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode

This bitfield selects the AES chaining mode:

0x0: Electronic codebook (ECB)

0x1: Cipher-block chaining (CBC)

0x2: Counter mode (CTR)

0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)

0x4: Counter with CBC-MAC (CCM)

others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode

This bitfield selects the SAES operating mode:

0x0: Encryption

0x1: Key derivation (or key preparation), for ECB/CBC decryption only

0x2: Decryption

0x3: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 28.4.16: SAES data registers and data swapping*.

0x0: No swapping (32-bit data).

0x1: Half-word swapping (16-bit data)

0x2: Byte swapping (8-bit data)

0x3: Bit-level swapping

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the SAES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the SAES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

The bit cannot be set as long as KEYVALID is cleared, or when SAES is in one of the following configurations:

- KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x3 (GCM)
- KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x2 (CTR), MODE[1:0] at 0x0 (encryption).

28.8.2 SAES status register (SAES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in SAES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KEYSEL[2:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KEYSEL[2:0] is different from zero, the BUSY flag is automatically set by SAES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the SAES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 28.4.17: SAES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether SAES is idle or busy.

0: Idle

1: Busy

SAES is flagged as idle when disabled (when EN is low) or when the last processing is completed.

SAES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), fetching random number from the RNG, or transferring a shared key to the target peripheral.

When GCM encryption payload phase is selected, this flag must be at zero before suspending current process to manage a higher-priority message. BUSY must also be cleared before selecting the GCM final phase.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the SAES_DINR register occurred. When set WRERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected write to SAES_DINR register occurred during computation or data output phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the SAES_DOUTR register occurred. When set RDERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected read to SAES_DOUTR register occurred during computation or data input phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 0 Reserved, must be kept at reset value.

28.8.3 SAES data input register (SAES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.

Reads return zero.

28.8.4 SAES data output register (SAES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

Read when KMOD[1:0] is at 0x1 or 0x2 while MODE[1:0] is at 0x2 and EN is set triggers a read error.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

28.8.5 SAES key register 0 (SAES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the SAES_CR register.

Writes to SAES_KEYRx registers are ignored when SAES is enabled (EN bit set). When KEYSEL[2:0] is different from 0 and KEYVALID is 0, writes to key registers are also ignored and they result in setting the KEIF bit of the SAES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

28.8.6 SAES key register 1 (SAES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[63:48]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[47:32]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[63:32]**: Cryptographic key, bits [63:32]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

28.8.7 SAES key register 2 (SAES_KEYR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[79:64]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[95:64]**: Cryptographic key, bits [95:64]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

28.8.8 SAES key register 3 (SAES_KEYR3)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[127:112]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[111:96]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[127:96]**: Cryptographic key, bits [127:96]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

28.8.9 SAES initialization vector register 0 (SAES_IVR0)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IVI[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]
SAES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable).
Write to this register is ignored when EN bit is set in SAES_CR register

28.8.10 SAES initialization vector register 1 (SAES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IVI[63:48]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IVI[47:32]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[63:32]**: Initialization vector input, bits [63:32]
Refer to the SAES_IVR0 register for description of the IVI[128:0] bitfield.

28.8.11 SAES initialization vector register 2 (SAES_IVR2)

Address offset: 0x028

Reset value: 0x0000 0000

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

28.8.17 SAES suspend registers (SAES_SUSPRx)

Address offset: 0x040 + 0x4 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

SAES_SUSPRx registers contain the complete internal register states of the SAES when the CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 28.4.8: SAES suspend and resume operations* for more details.

Clearing EN bit of the SAES_CR register clears this register to zero.

SAES_SUSPRx registers are not used in other chaining modes than CCM.

28.8.18 SAES interrupt enable register (SAES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIE	KEIE	RWEIE	CCFIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIE:** RNG error interrupt enable
This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

Bit 2 **KEIE:** Key error interrupt enable
This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable
This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable
This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

28.8.19 SAES interrupt status register (SAES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag

This read-only bit is set by hardware when an error is detected on RNG bus interface (for example bad entropy).

0: RNG bus is functional

1: Error detected on RNG bus interface (random seed fetching error)

The flag setting generates an interrupt if the RNGEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register. The clear action triggers the reload of a new random number from the RNG peripheral.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers or when the key register use is forbidden.

0: No key error detected

1: Key information failed to load into key registers or the key register use is forbidden

The flag setting generates an interrupt if the KEIE bit of the SAES_IER register is set. It also clears the key registers and the KEYVALID flag in the SAES_SR register.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

KEIF is raised upon any of the following events:

–SAES fails to load the DHUK (KEYSEL[2:0] = 0x1 or 0x4).

–SAES fails to load the BHK (KEYSEL[2:0] = 0x2 or 0x4).

–AES fails to load the key shared by SAES peripheral (KMOD[1:0] = 0x2).

–SAES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE set, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the SAES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the SAES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

28.8.20 SAES interrupt clear register (SAES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												w	w	w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag clear
Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2 **KEIF:** Key error interrupt flag clear
Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear
Setting this bit clears the RWEIF status bit of the SAES_ISR register, and clears both RDERRF and WRERRF flags in the SAES_SR register.

Bit 0 **CCF:** Computation complete flag clear
Setting this bit clears the CCF status bit of the SAES_ISR register.

28.8.21 SAES register map

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

29 Hash processor (HASH)

29.1 HASH introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-2 family) and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of any length less than 2^{64} bits (for SHA-1, SHA-224 and SHA-256) or less than 2^{128} bits (for SHA-384, SHA-512).

29.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, *Secure Hash Standard* (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, *Digital Signature Standard (DSS)*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 2104, *HMAC: Keyed-Hashing for Message Authentication* and Federal Information Processing Standards Publication FIPS PUB 198-1, *The Keyed-Hash Message Authentication Code (HMAC)*
- Fast computation of SHA-1, SHA2-224, SHA2-256, SHA2-384, and SHA2-512
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 98 clock cycles for processing one 1024-bit block of data using either SHA2-384 or SHA2-512 algorithm
  - Support for SHA-2 truncated outputs (SHA2-512/224, SHA2-512/256)
- Support for HMAC mode with all supported algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Supported word swapping format: bits, bytes, half-words, and 32-bit words
- Single 32-bit, write-only, input register associated to an internal input FIFO that can receive a single data block of size depending on the selected algorithm
- Automatic padding to complete the input bit string to fit digest minimum block size
- AMBA AHB target peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- 8 × 32-bit words (H0 to H7) for output message digest
- Automatic data flow control supporting direct memory access (DMA) using one channel.
- Support for both single and fixed DMA burst transfers of four words.
- Interruptible message digest computation, on a per-block basis
  - Reloadable digest registers

– Hashing computation suspend/resume mechanism, including DMA

29.3 HASH implementation

The devices have a single instance of HASH peripheral.

The following table provides information on the hash algorithm implementation on different devices.

Table 231. HASH implementation on different devices

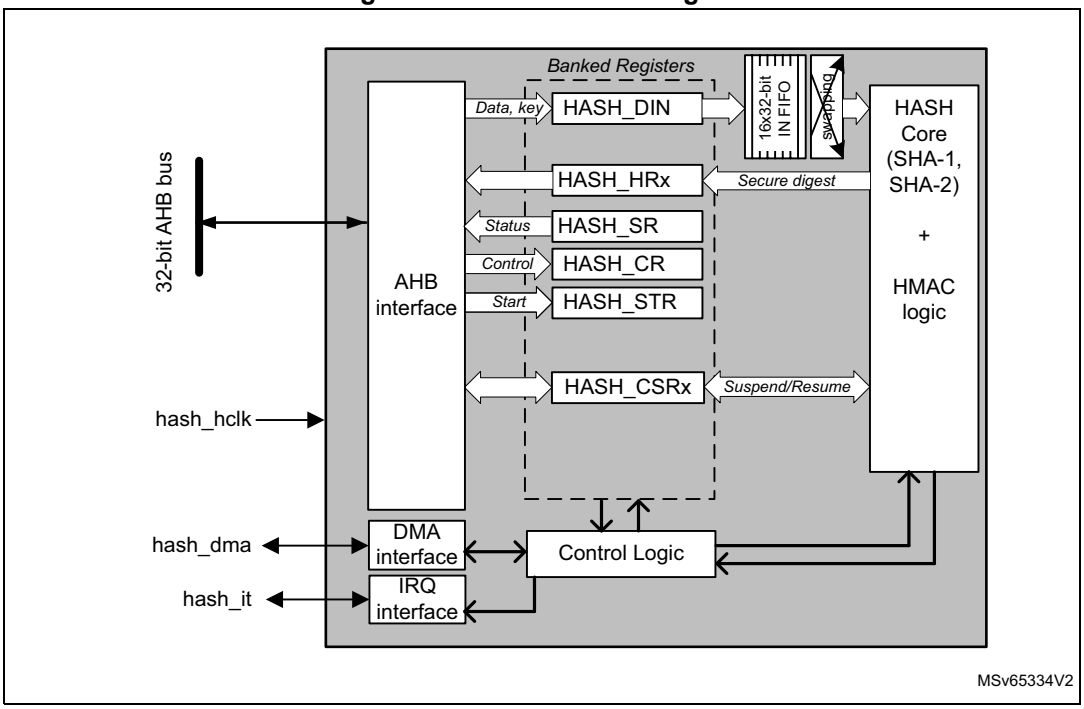
Hash algorithm	STM32C53x/C54x	STM32C55x/C56x	STM32C59x/C5Ax
SHA-1	X	X	X
SHA2-224	X	X	X
SHA2-256	X	X	X
SHA2-384	-	-	X
SHA2-512	-	-	X

29.4 HASH functional description

29.4.1 HASH block diagram

Figure 213 shows the block diagram of the hash processor.

Figure 213. HASH block diagram



29.4.2 HASH internal signals

Table 232 describes a list of useful to know internal signals available at HASH level, not at product level (on pads).

Table 232. HASH internal input/output signals

Signal name	Signal type	Description
hash_hclk	digital input	AHB bus clock
hash_it	digital output	Hash processor global interrupt request
hash_dma	digital input/output	DMA burst request/ acknowledge

29.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard.

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message is presented on the input, the HASH processing core produces a fixed-length output string called a message digest (see *Table 233*).

Table 233. Information on supported hash algorithms

Algorithm	Message digest size (in bits)	Block size (in bytes)(1)	Message length	Bit string message
SHA-1	160	64	$< 2^{64}$ bits	Yes
SHA2-224	224			
SHA2-256	256			
SHA2-384	384	128	$< 2^{128}$ bits	Yes
SHA2-512	512(2)			

1. Block size = (NBWE-1) * 4 bytes. NBWE[4:0] bitfield can be read from the HASH_SR register after ALGO and INIT bits are written in the HASH_CR register.
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes).

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process since the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017).

29.4.4 Message data feeding

The message (or data file) to be processed by the HASH must be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with

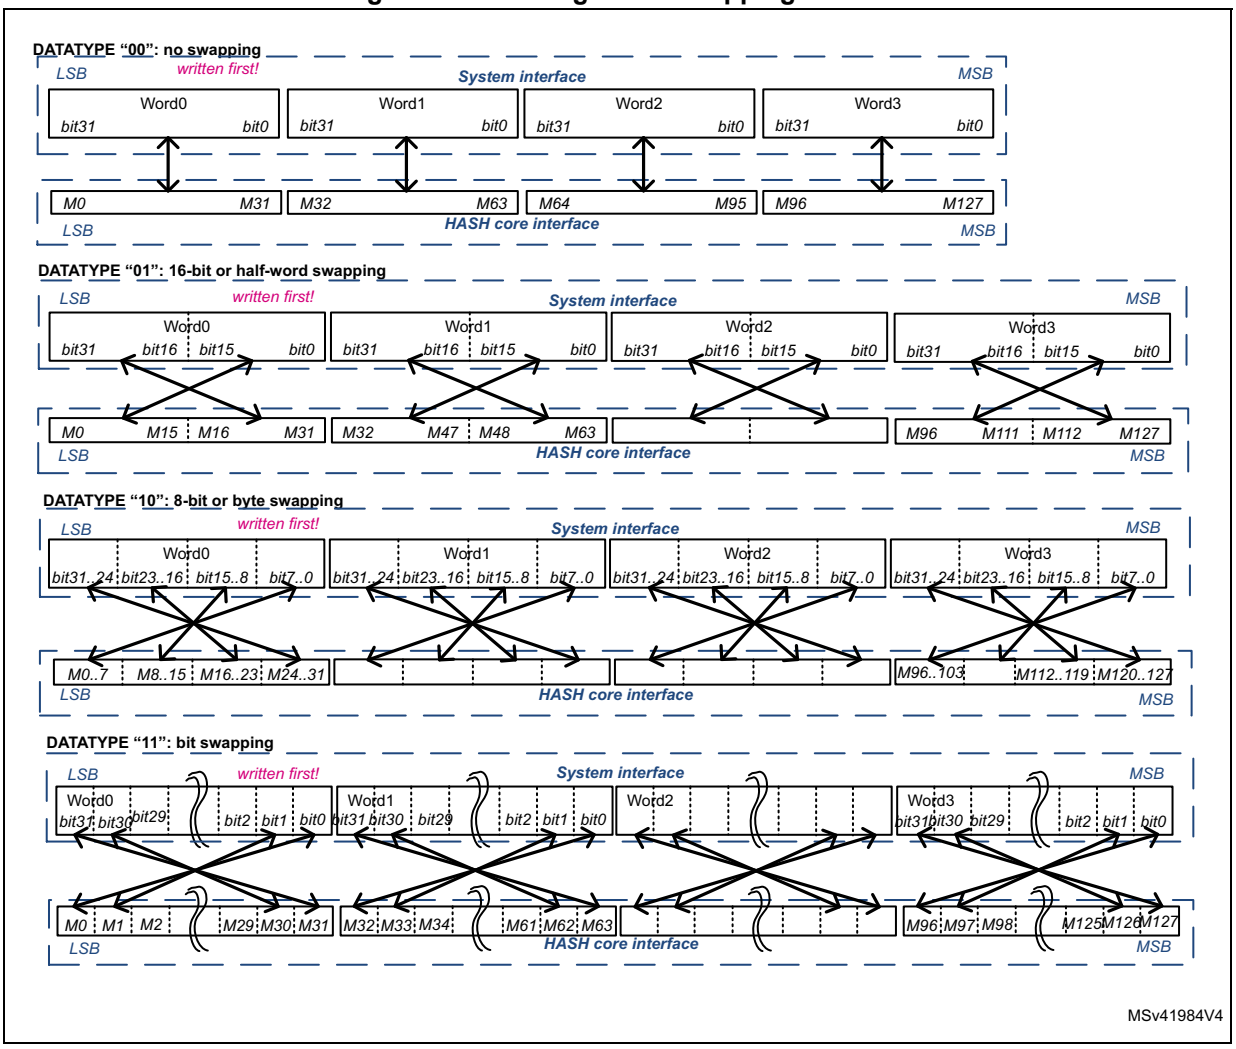
hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “**01100001 01100010 01100011**” is represented by a 32-bit word **0x00636261**, and 8-bit words **0x61626300**.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence, HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (for example byte swapping when data are ASCII text stream) there must be a bit, byte, half-word, or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. *Figure 214* shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR)

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 214. Message data swapping feature



29.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. Block sizes can be found in *Table 233: Information on supported hash algorithms*.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in *Section 29.4.4: Message data feeding*, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO. In order to perform the hash computation on this data the application must follow below sequence.

1. Initialize the hash processor using the HASH_CR register:
   - Write to the HASH_CR register to select the right algorithm using the ALGO bitfield, and set the INIT bit (other bits are kept at zero). Then read the NBWE bitfield from the HASH_SR register to deduce the algorithm block size, which equals **(NBWE-1) * 4**. This step is not required if the block size is already known (see *Table 233* for details).
   - Select the right algorithm using the ALGO[3:0] field. If needed, program the correct swapping operation on the message input words using the DATATYPE[1:0] bitfield.
   - When HMAC mode is required, set the MODE bit as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (otherwise keep LKEY cleared). Refer to *Section 29.4.7: HMAC operation* for details.
   - Update NBLW[4:0] in the HASH_STR register to define the number of valid bits in the last word of the message if it is different from 32 bits. NBLW information is used to correctly perform the automatic message padding before the final message digest computation.
2. Complete the initialization by setting the INIT bit in HASH_CR register. Also set the DMAE bit if data are transferred via DMA.

Caution: When programming step 2, it is important that the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW) are set up before or at the same time.

3. Start filling data by writing to the HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   - Data are filled by software:

     Partial digest computations are triggered each time the application writes the first word of the next block, the block size being defined by NBWE bits in HASH_SR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.

     The final digest computation is triggered when the last block is entered and the software sets the DCAL bit. If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see *Section 29.4.6* for details).
   - Data are filled as a single DMA transfer (MDMAT = 0):

     Partial digest computations are triggered automatically each time the FIFO is full.

     The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register by DMA (DCAL bit is set by hardware). If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to enabling the DMA (see *Section 29.4.6* for details).
   - Data are filled using multiple DMA transfers (MDMAT = 1):

     Partial digest computations are triggered as for single DMA transfers (refer to the above description). However, the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH_DIN register (DCAL bit is not set by hardware). It enables the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must clear MDMAT bit before the last DMA

transfer in order to trigger the final digest computation as it is done for single DMA transfers.

4. Once the digest calculation is completed (DCIS = 1), the resulting digest can be read from the output registers, as described in *Table 234*. When set, the DMAEN bit is automatically cleared by hardware.

Table 234. Hash processor outputs

Algorithm	Valid output registers	Most significant bit	Digest size (in bits)
SHA-1	HASH_H0 to HASH_H4	HASH_H0[31]	160
SHA2-224	HASH_H0 to HASH_H6	HASH_H0[31]	224
SHA2-256	HASH_H0 to HASH_H7		256
SHA2-384	HASH_H0 to HASH_H11	HASH_H0[31]	384
SHA2-512	HASH_H0 to HASH_H15		512(1)

1. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes)

For more information about HMAC detailed instructions, refer to *Section 29.4.7: HMAC operation*.

Aborting HASH operation

HASH can be disabled at any time by writing 0x4 to HASH_CR, after stopping any running DMA transfer to HASH (if applicable).

29.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block size transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

Padding processing

Detailed hashing sequences with padding are described in *Section 29.4.5: Message digest computing*. As mentioned in these sequences, the padding is done automatically using the information provided in NBLW[4:0].

Hashing example

Below is an example of SHA-1 digest computation with HASH. Message processing and padding are defined in Federal Information Processing Standards PUB 180-4.

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24 (‘**U**’ means don’t care):

```
byte 0    byte 1   byte 2   byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW has to be loaded with the value 24: a “**1**” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are automatically appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The message length value, **L**, in two-word format (that is 00000000 00000018) is appended. Hence, the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered using following sequence:

1. **0xUU636261** is written to the HASH_DIN register (where ‘**U**’ means don’t care)
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits)
3. **0x100** is written to the HASH_STR register to run the final digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0 to 4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_HR0 = 0xA9993E36
HASH_HR1 = 0x4706816A
HASH_HR2 = 0xBA3E2571
HASH_HR3 = 0x7850C26C
HASH_HR4 = 0x9CD0D89D
```

29.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

```
HMAC(message)= Hash((Key | pad) XOR opad |
               Hash((Key | pad) XOR ipad | message))
```

Where:

- **opad** = $[0x5C]_n$ (outer pad) and **ipad** = $[0x36]_n$ (inner pad)
- $[X]_n$ represents a repetition of X *n* times, where *n* equal to the byte size of the underlying hash function data block (n = 64 when block size is 512 bits).
- **pad** is a sequence of zeroes needed to extend the key to the length *n* defined above. If the key length is greater than *n*, the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- | represents the concatenation operator.

Note: HMAC mode of the hash processor can be used with all supported algorithms.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software sets the INIT bit, with the MODE bit set and the ALGO bits selecting the desired algorithm. The LKEY bit must also be set if the key being used is longer than the block size. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading that is by writing the key data into HASH_DIN register and then completing the transfer by setting DCAL bit and the correct NBLW to HASH_STR register.
3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software sets DCAL bit in HASH_STR register, the NBLW bitfield must be programmed at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in *Section 29.4.5: Message digest computing*.
4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register, and then completing the transfer by setting DCAL bit and programming the correct NBLW to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 29.4.11: HASH processing time.

Endianness management details can be found in Section 29.4.4: Message data feeding.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST. SHA-1 block size is 64 bytes.

Let us assume that the original message is the ASCII binary-coded form of "**`Sample message for keylen = blocklen`**", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is, no padding), specified by NIST. As key length = 64, LKEY bit is cleared in HASH_CR register

   ```
   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F
   ```

2. **Message** input (length = 34, that is, padding required). HASH_STR must be set to **`0x20`** to start message padding and inner hash computation (see **'U**' as don't care)

   ```
   53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
   6E3D626C 6F636B6C 656EUUUU
   ```

3. **Outer hash key** input (length = 64, that is, no padding). A key identical to the inner hash key is entered here.
4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers, as shown below:

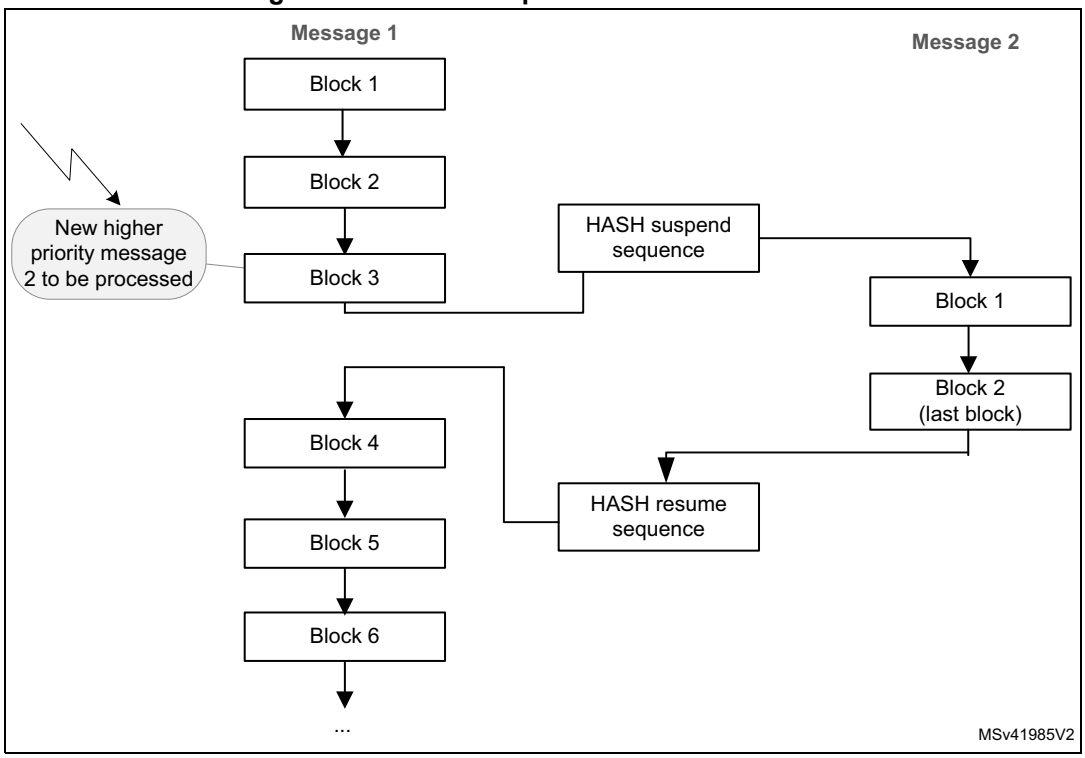
   ```
   HASH_HR0 = 0x5FD596EE
   HASH_HR1 = 0x78D5553C
   HASH_HR2 = 0x8FF4E72D
   HASH_HR3 = 0x266DFD19
   HASH_HR4 = 0x2366DA29
   ```

29.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in *Figure 215*.

Figure 215. HASH suspend/resume mechanism



To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.

Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0 then poll if the DINIS status bit is set.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37, when SHA-1 or SHA2-256 is selected, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing
   - HASH_CSR0 to HASH_CSR90, when SHA2-384 or SHA2-512 (truncated or not) is selected, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR, HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing as described below.

In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see *Figure 215*).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data via the DMA to complete the current burst transfer.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR and HASH_CR registers. Also save a number of HASH_CSRx registers depending on the SHA algorithm that is used:
   - When SHA-1 or SHA2-256 is selected, save HASH_CSR0 to HASH_CSR37, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing.
   - When SHA2-384 or SHA2-512 is selected, save HASH_CSR0 to HASH_CSR90, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

29.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information, refer to *Section 29.4.5: Message digest computing*.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

`NBLW = Len(Message)% 32` where "**`x%32`**" gives the remainder of x divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

29.4.10 HASH error management

No error flags are generated by the hash processor.

29.4.11 HASH processing time

Table 235 summarizes the time required to process an intermediate block for each mode of operation.

Table 235. Processing time (in clock cycle)

Mode of operation	Block size (in bytes)	FIFO load(1)	Computation phase	Total
SHA-1	64	16	66	**82**
SHA2-224		16	50	**66**
SHA2-256				
SHA2-384	128	32	66	**98**
SHA2-512(2)				

1. Add the time required to load the block into the processor.
2. SHA2-512 includes SHA2-512/224 and SHA2-512/256 modes.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key

29.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the device interrupt controller. Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit enables the interrupt.

The status of each maskable interrupt source can be read from the HASH_SR register. *Table 236* gives a summary of the available features.

Table 236. HASH interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
HASH	Digest computation completed	DCIS	DCIE	Clear DCIS or set INIT
	Data input buffer ready to get a new block	DINIS	DINIE	Clear DINIS or write to HASH_DIN

29.6 HASH registers

The hash core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

29.6.1 HASH control register (HASH_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALGO[3:0]				LKEY
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MDMAT	DINNE	NBW[3:0]				Res.	MODE	DATATYPE[1:0]		DMAE	INIT	Res.	Res.
		rw	r	r	r	r	r		rw	rw	rw	rw	w		

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **ALGO[3:0]**: Algorithm selection

These bits select the hash algorithm. This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect

When the ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

0000: SHA-1

0001: reserved

0010: SHA2-224

0011: SHA2-256

1100: SHA2-384

1101: SHA2-512/224

1110: SHA2-512/256

1111: SHA2-512

Bit 16 **LKEY**: Long key selection

The application must set this bit if the HMAC key is greater than the block size corresponding to the hash algorithm (see *Table 233: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.

This selection is only taken into account when the INIT and MODE bits are set (HMAC mode selected). Changing this bit during a computation has no effect.

0: HMAC key is shorter or equal to the block size (short key). The actual key value written in HASH_DIN is used during the HMAC computation.

1: HMAC key is longer than the block size (long key). The hash of the key is used instead of the real key during the HMAC computation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.

1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

Refer to DINNE bit of HASH_SR for a description of DINNE bit.

This bit is read-only.

Bits 11:8 **NBW[3:0]:** Number of words already pushed

Refer to NBWP[3:0] bitfield of HASH_SR for a description of NBW[3:0] bitfield.

This bitfield is read-only.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **MODE:** Mode selection

This bit selects the normal or the keyed HMAC mode for the selected algorithm. This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

0: Hash mode selected

1: HMAC mode selected. LKEY bit must be set if the key being used is longer than the algorithm block size.

Bits 5:4 **DATATYPE[1:0]:** Data type selection

This bitfield defines the format of the data entered into the HASH_DIN register:
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data or bit string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE:** DMA enable

Setting this bit enables DMA transfers. After this bit is set, it is cleared by hardware while the last data of the message is written into the hash processor.
Clearing this bit while a DMA transfer is ongoing does not abort the current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is set.
Setting INIT bit does not clear DMAE bit.
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.

Bit 2 **INIT:** Initialize message digest calculation

This is a write-only bit always returning zero upon reading. Setting this bit resets the hash processor core, so that HASH is ready to compute the message digest of a new message. Clearing this bit has no effect.

Bits 1:0 Reserved, must be kept at reset value.

29.6.2 HASH data input register (HASH_DIN)

Address offset: 0x004

Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks defined by the hash algorithm (see *Table 233: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.

When the HASH_DIN register is programmed, the value presented on the AHB bus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB bus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:

- by writing first data of the next block into the HASH_DIN register, if the DMA is not used
- automatically, if the DMA is used

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by setting the DCAL bit in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is cleared.

Reading the HASH_DIN register returns zeros.

Note: When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DATAIN[31:0]:** Data input

Writing this register pushes the current register content into the FIFO, and the register takes the new value presented on the AHB bus.

Do not write to this register when BUSY is set.

Reading this register returns zeros.

29.6.3 HASH start register (HASH_STR)

Address offset: 0x008

Reset value: 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by setting the DCAL bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCAL	Res.	Res.	Res.	NBLW[4:0]				
							w				rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **DCAL:** Digest calculation

This is a write-only bit always returning zero upon reading. Setting this bit starts the message padding using the previously written value of NBLW, and starts the calculation of the final message digest with all the data words written to the input FIFO since the INIT bit was last set.

Do not set DCAL when BUSY is set.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NBLW[4:0]:** Number of valid bits in the last word

When the last word of the message bit string is written to HASH_DIN register, the hash processor takes only the valid bits, specified as below, after internal data swapping.

The above mechanism is valid only if DCAL = 0. If NBLW bits are written while DCAL is set, the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.

Reading NBLW bits returns the last value written to NBLW.

0x00: All the 32 bits of the last data written are valid message bits, that is M[31:0]

0x01: Only one bit of the last data written (after swapping) is valid, that is M[0]

0x02: Only two bits of the last data written (after swapping) are valid, that is M[1:0]

0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]

...

0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]

Note:

29.6.4 HASH digest registers

These registers contain the message digest result defined as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224, SHA2-512/224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256, SHA2-512/256 digest result.
- HASH_HR0 to HASH_HR11 registers return the SHA2-384 digest result.
- HASH_HR0 to HASH_HR15 registers return the SHA2-512 digest result

In all cases, the digest most significant bit is stored in HASH_HR0[31], and unused HASH_HRx registers reads as zero.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

Note: When starting a digest computation for a new message (by setting the INIT bit), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses (register aliasing).

HASH aliased digest register x (HASH_HRAx)

Address offset: 0x00C + 0x4 * x, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DCIE:** Digest calculation completion interrupt enable
0: Digest calculation completion interrupt disabled
1: Digest calculation completion interrupt enabled.

Bit 0 **DINIE:** Data input interrupt enable
0: Data input interrupt disabled
1: Data input interrupt enabled

29.6.6 HASH status register (HASH_SR)

Address offset: 0x024

Reset value: 0x0011 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NBWE[4:0]				
											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DINNE	Res.	NBWP[4:0]					Res.	Res.	Res.	Res.	Res.	BUSY	DMAS	DCIS	DINIS
r		r	r	r	r	r						r	r	rc_w0	rc_w0

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **NBWE[4:0]:** Number of words expected
This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register.
NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR. It is set to the expected block size (0x10) when the partial digest calculation ends.

Bit 15 **DINNE:** DIN not empty
This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is set.
0: No data are present in the data input buffer
1: The input buffer contains at least one word of data

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **NBWP[4:0]:** Number of words already pushed

This bitfield is the exact number of words in the message that have already been pushed into the FIFO. NBWP is incremented by 1 when a write access is performed to the HASH_DIN register.

When a digest calculation starts, NBWP is updated to NBWP- block size (in words), and NBWP goes to zero when the INIT bit is set.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy bit

0: No block is currently being processed
1: The hash core is processing a block of data

Bit 2 **DMAS:** DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS:** Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by setting the INIT bit in the HASH_CR register.

0: No digest available in the HASH_HRx registers (zeros are returned)

1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

Bit 0 **DINIS:** Data input interrupt status

This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH_DIN register.

When DINIS = 0, HASH_CSRx registers reads as zero.

0: Less than 16 locations are free in the input buffer
1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.

29.6.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task. When the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + 0x4 * x, (x = 0 to 53)

Reset value: 0x0022 0002 (HASH_CSR0)

Reset value: 0x0000 0000 (others)

30 Public key accelerator (PKA)

This section applies entirely to the STM32C5A3xx devices. It only applies partly (functionality limited to ECDSA signature verification) to the STM32C59xxx devices.

30.1 PKA introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, the accelerator performs all computations with no further hardware or software elaboration required to process the inputs or the outputs.

For manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.

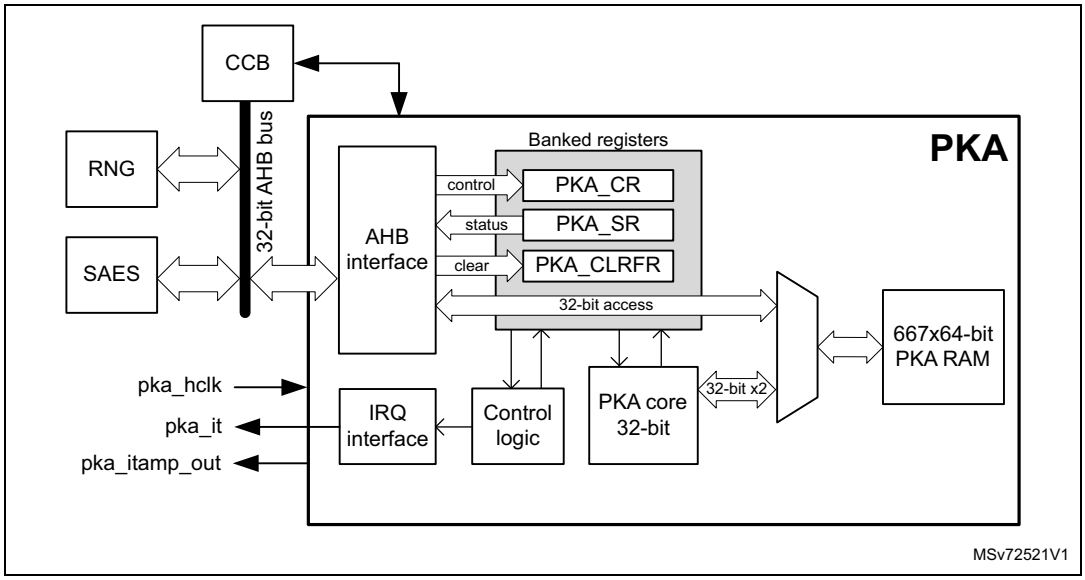
30.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Support for CCB chaining operations required to protect private key used in PKA protected operations
- Hardware protections to monitor usage of private keys during protected operation initialization

30.3 PKA functional description

30.3.1 PKA block diagram

Figure 216. PKA block diagram



30.3.2 PKA internal signals

Table 238 lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

Table 238. Internal input/output signals

Signal name	Signal type	Description
pka_hclk	Digital input	AHB bus clock
pka_it	Digital output	Public key accelerator IP global interrupt request
pka_itamp_out	Digital output	PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). A tamper is also generated if application does not respect the maximum supported size of operands, or when PKA finds a fault in critical configuration registers(1). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.

1. When tamper is active, the AHB interface is blocked: RAM and register reads are 0-ed and writes are ignored. There is no PKA RAM erase.

30.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 2000 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored. Once EN bit is set, refer to *Section 30.3.6* for details about PKA initialization sequence.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).

30.3.4 PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b$ (mod p). More information can be found in *Section 30.5.1*.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in *Table 239* and *Table 240*, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

Table 239. PKA integer arithmetic functions list

Table 240. PKA prime field (Fp) elliptic curve functions list

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x28	101000	Point on elliptic curve Fp check	*Section 30.4.14*
0x20	100000	ECC scalar multiplication kP (protected)	*Section 30.4.15*
0x23	100011	ECC complete addition	*Section 30.4.18*
0x24	100100	ECDSA sign (protected)	*Section 30.4.16*
0x26	100110	ECDSA verification	*Section 30.4.17*
0x27	100111	ECC double base ladder	*Section 30.4.19*
0x2F	101111	ECC projective to affine	*Section 30.4.20*

Each of these operating modes has an associated code that has to be written to the MODE[5:0] bitfield in the PKA_CR register. If the application selects any value that is not documented below the write to MODE[5:0] bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in *Table 239* and *Table 240* are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) and any intermediate values are automatically erased when PKA RAM is cleared at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

Caution: For security reason it is very important to select protected modular exponentiation (MODE[5:0] = 0x3) when performing RSA decryption.

Montgomery space and fast mode operations

For efficiency reasons, the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming, the application can decide to use a faster mode of operation during which the precomputed Montgomery parameter is supplied before starting the operation. The performance improvement is detailed in *Section 30.5.2: Computation times*.

The only operation using fast mode is the modular exponentiation (MODE[5:0] = 0x02).

30.3.5 Typical applications for PKA

Introduction

The PKA can be used to accelerate a number of public key cryptographic functions such as:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement

The following publications specify the listed functions:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories
- IEEE1363-2000, IEEE Standard Specifications for Public-Key Cryptography, January 2000
- ANSI X9.62-2005, Public Key Cryptography for the Financial Services Industry, The Elliptic Curve Digital Signature Algorithm (ECDSA), November 2005

Refer to these documents for full details. This document limits itself to describing principles.

RSA key pair

For the following RSA operations, a public key and a private key information are defined as follows:

- Alice transmits her public key (*n*, *e*) to Bob. Numbers *n* and *e* are very large positive integers.
- Alice keeps secret her private key d, also a very large positive integer. Alternatively, this private key can also be represented by a quintuple (p, q, dp, dq, qInv).

For more information, refer to the RSA specification.

RSA encryption/decryption principle

As recommended by the PKCS#1 specification, Bob, to encrypt message M using Alice's public key (*n*, *e*), must go through the following steps:

1. Compute the encoded message EM = ENCODE(M), where ENCODE is an encoding method.
2. Turn EM into an integer *m*, with $0 \leq m < n$ and (*m*, *n*) being coprimes.
3. Compute ciphertext $c = m^e \bmod n$.
4. Convert the integer c into a string ciphertext C.

Alice, to decrypt ciphertext c using her private key *d*, follows the steps indicated below:

1. Convert the ciphertext C to an integer ciphertext representative c.
2. If necessary, retrieve the prime factors (p, q) using (n, e, d) information, then compute phi = (p - 1) × (q - 1). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext $m = c^d \bmod n = (m^e)^d \bmod n$. If the private key is the quintuple (p, q, dp, dq, qInv), then plaintext *m* is obtained by performing the operations:
   a) $m_1 = c^{dp} \bmod p$
   b) $m_2 = c^{dq} \bmod q$
   c) $h = qInv\ (m_1 - m_2) \bmod p$
   d) $m = m_2 + h\ q$
4. Convert the integer message representative *m* to an encoded message EM.
5. Recover message M = DECODE(EM), where DECODE is a decoding method.

To accelerate these operations with the PKA, use *Modular exponentiation* $A^e \bmod n$ if the private key is *d*, or *RSA CRT exponentiation* if the private key is the quintuple (p, q, dp, dq, qInv).

Note: The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.

For the decryption process, the protected version of modular exponentiation (MODE[5:0] = 0x3) is strongly recommended for security reason. For the encryption process, the MODE[5:0] = 0x3 setting cannot be used as it requires the knowledge of the private key.

Elliptic curve selection

For the following ECC operations, the curve parameters are defined as follows:

- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in *Section 30.5.1: Supported elliptic curves*.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (that is, $n \times G$ = identity element O).

ECDSA message signature generation

This section describes the ECDSA (elliptic curve digital signature algorithm) signature generation function principle.

Alice, to sign a message *m* using her private key integer d_A, goes through the following steps:

1. Calculate e = HASH(*m*), where HASH is a cryptographic hash function.
2. Let z be the L_n leftmost bits of e, where L_n is the bit length of the group order *n*.
3. Select a cryptographically secure random integer k where $0 < k < n$.
4. Calculate the curve point $(x_1, y_1) = k \times G$.
5. Calculate $r = x_1 \bmod n$. If $r = 0$ go back to step 3.
6. Calculate $s = k^{-1} (z + rd_A) \bmod n$. If $s = 0$ go back to step 3.
7. The signature is the pair (*r*, *s*).

The PKA accelerates the steps 4. to 7. by using:

- *ECDSA sign*, or
- All of the following operations:
  - *ECC Fp scalar multiplication* $k \times P$
  - *Modular reduction* A mod n
  - *Modular inversion* A^{-1} mod n
  - *Modular addition* and *Modular and Montgomery multiplication*

ECDSA signature verification

This section describes the ECDSA (elliptic curve digital signature algorithm) signature verification function principle.

Bob, to authenticate Alice's signature, must have a copy of her public key curve point Q_A. Bob can verify that Q_A is a valid curve point by going through the following steps:

1. Check that Q_A is not equal to the identity element O
2. Check that Q_A is on the agreed curve
3. Check that $n \times Q_A = O$.

Then Bob executes the following procedure:

1. Verify that r and s are integer in [1, n-1]
2. Calculate e = HASH(m), where HASH is the agreed cryptographic hash function
3. Let z be the L_n leftmost bits of e
4. Calculate $w = s^{-1}$ mod n
5. Calculate $u_1 = zw$ mod n and $u_2 = rw$ mod n
6. Calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$
7. The signature is valid if $r = x_1$ (mod n), it is invalid otherwise.

The PKA accelerates the steps 4. to 7. by using *ECDSA verification*.

30.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit in the PKA_CR register enables the PKA peripheral. The PKA becomes available when the INITOK bit is set in the PKA_SR register. When EN = 0, the PKA peripheral is kept under reset, with its memory still accessible by the application through the AHB interface.

Note: When the PKA is in the process of clearing its memory, the EN bit cannot be set.

When setting the EN bit in PKA_CR, make sure that the MODE[5:0] bitfield value corresponds to an authorized PKA operation (see OPERRF in Section 30.3.8).

Clearing the EN bit while a calculation is in progress aborts the operation. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only the PKA registers can be accessed, with writes to EN bits ignored.

If the INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable the PKA again.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in *Section 30.4*.

Executing a PKA operation

To execute any of the supported PKA operations, proceed as follows:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE[5:0] bitfield of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1), any access by the application to PKA RAM is ignored, and the RAMERRF flag is set in PKA_SR.

Selecting an illegal or unknown operation in step *2* triggers an OPERRF error and prevents the PROCENDF flag from being set and the procedure step *3* from being completed. See *Section 30.3.8* for details.

Using precomputed Montgomery parameters (PKA fast mode)

As explained in *Section 30.3.4*, when computing many operations with the same modulus, it can be beneficial for the application to compute the corresponding Montgomery parameter only once (see, for example, *Section 30.4.5*). This is referred to as *fast mode*.

To use the PKA peripheral in fast mode, follow this recommended procedure:

1. Load the modulus size and value information into the PKA RAM. Refer to *Section 30.5.1* for detail.
2. Configure the PKA_CR register to *Montgomery parameter computation* mode (MODE[5:0] = 0x1), then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set. Then, read the corresponding Montgomery parameter from the PKA memory and clear the PROCENDF bit by setting PROCENDFC in PKA_CLRFR.
4. Continue with the required PKA operation, loading the Montgomery information R2 mod *m* on top of the regular input data. Relevant addresses are provided in *Section 30.4*.

30.3.7 Private keys protection using CCB

Chaining modes

As shown in *Figure 217*, setting CCOP to a value different from 0 in the CCB peripheral automatically activates a chaining mechanism between PKA, RNG, and SAES, depending on the OPSTEP value (see *Table 241*), then sets the CCEN bit in the PKA_SR register.

For the effect of different OPSTEP values in each protected operation (ECDSA signature, scalar multiplication, modular exponentiation), refer to *Section 30.3.7: Private keys protection using CCB*.

Figure 217. Chaining of PKA with SAES or RNG

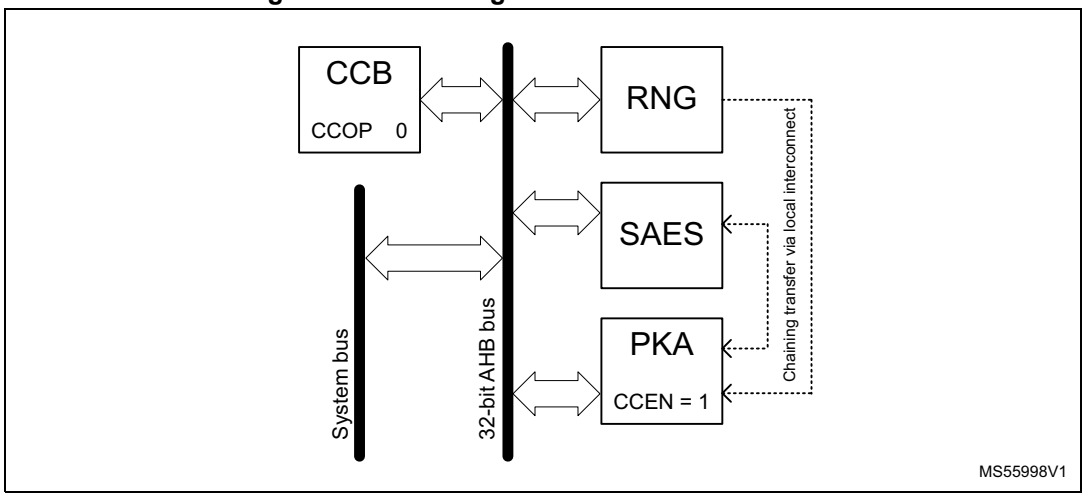

Table 241. Chaining mode to/from PKA

CCOP		OP STEP	Expected MODE[5:0] (1)	Chaining traffic(2)	Protected parameter written to PKA RAM	Expected flags(3)
x	0xC3	0x1	0x24	N/A	Hash (unprotected)	N/A
ECDSA signature	0xC0 or 0xC2	0x3	0x24	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0xC3	0x13				
		0x14		SAES → PKA	Decrypted private key d	DATAOKF or CMF error
		0x16		RNG → PKA	Random integer k	RNGOKF or CMF error
	0xC0	0x4		N/A	Clear text private key d	DATAOKF or CMF error
	0xC2	0x6		RNG → PKA	Random private key d	RNGOKF or CMF error
	0xC0 or 0xC2	0x8		PKA → SAES	Clear-text private key d	DATAOKF or CMF error
Scalar multiplication	0x80 or 0x82	0x3	0x20	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0x81	0x13				
		0x14		SAES → PKA	Decrypted k	DATAOKF or CMF error
	0x80	0x04		N/A	Clear text scalar mult k	
	0x82	0x6		RNG → PKA	Random scalar mult k	RNGOKF or CMF error
	0x80 or 0x82	0x8		PKA → SAES	Clear-text scalar mult k	DATAOKF or CMF error

Table 241. Chaining mode to/from PKA (continued)

CCOP		OP STEP	Expected MODE[5:0] (1)	Chaining traffic(2)	Protected parameter written to PKA RAM	Expected flags(3)
Modular exponentiation	0x44	0x3	0x3	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0x45	0x13				
		0x14		SAES → PKA	Decrypted exponent e	DATAOKF or CMF error
		0x15			Decrypted phi	
	0x44	0x4		N/A	Clear text exponent e	
		0x5			Clear text phi	
		0x8		PKA → SAES	Clear text exponent e	
		0x9			Clear text phi	

1. This mode must be written in PKA_CR before the START bit is set in PKA_CR.
2. Chaining traffic triggered by the CPU access to PKA RAM. “N/A” means no chaining traffic, only CPU traffic.
3. In PKA_SR bits 8 to 15 (“CMF error” refers to error flag bits 8 to 14).
4. In this mode chaining traffic includes the 32-bit data word plus the 32-bit physical address to PKA RAM.
5. Defined in *Table 242*.

When the application uses a PKA protected operation (with its private key), it must load the related blob information in the PKA RAM and in the SAES_DINR register. If the information exactly matches the conditions of the blob generation (the choice and order of writing protected parameters in PKA RAM, the selection of blob encryption key, and the usage of the original encrypted secrets), the CCB allows it to set the START bit in PKA_CR. When the PKA ignores the setting of the START bit, the application must reset the CCB using the IPRST bit in CCB_CR, then start the protected operation sequence again.

A protected application typically uses the PKA in the following sequence composed of three phases.

Step 1: Public phase

Before using a protected operation, the application may need to write unprotected parameters to the PKA RAM, as defined in *Table 241*.

Step 2: Integrity protected phase

To use a PKA operation, the application must load specific parameters in PKA RAM. When CCEN bit is set in PKA_SR, the integrity protected parameters defined in *Table 242* must always be written in the same way. Integrity protection is enforced in specific OPSTEPs, as defined in *Table 241*.

Typical issues with integrity of protected operation parameters are:

- The blob encryption key loaded in SAES registers is not correct.
- At least one confidentiality protected parameter defined in *Table 243* has an incorrect value, or was not properly written (DATAOKF = 0 or RNGOKF = 0, see *PKA status register (PKA_SR)*).
- At least one integrity protected parameter defined in *Table 242* has an incorrect value, is written at an incorrect address, or its write sequence to PKA RAM does not match

the sequence used during the blob creation. On this specific point, the application must follow the sequence detailed in *Table 242* when writing each item described in the column *Parameters*.

CCB feeds integrity protected parameters to SAES during the header phase of AES-GCM (GCMPH = 0x1).

Table 242. Integrity protected parameters list

Protected operation blob(1)	Parameters
ECC key blob	Curve prime order *n* length, curve modulus *p* length, curve coefficient *a* sign, curve coefficient |*a*|, curve coefficient *b*, curve modulus value *p*, curve prime order *n*
ECC signature blob	Same as scalar multiplication operation, adding curve base point G coordinates *x* and *y*
RSA key blob	Exponent *e* length, operand length, modulus value *n*

1. See *Table 243* for more details.

Step 3: Confidentiality phase

To use any PKA protected operation, the application must load confidentiality protected parameters in the PKA RAM. When the CCEN bit is set in PKA_SR, the parameters defined in *Table 243* are protected in confidentiality by:

- Making PKA RAM write-only
- Triggering a MODE[5:0] error (MDERRF) in PKA_SR when MODE[5:0] bitfiled in PKA_CR does not match the expected value when application sets START bit in PKA_CR
- Monitoring the correct management of protected parameters through DATAOKF and RNGOKF flags (see *PKA status register (PKA_SR)*)
- Optionally, generating ECC secrets from the on-chip TRNG when CCOP = 0xC2 or 0x82 and OPSTEP = 0x6, and when CCOP = 0xC3 and OPSTEP = 0x16. The PKA performs a sanity check before accepting this random value (see the RNGERRF flag).

Confidentiality protected parameters are described in *Table 243*. CCB feeds them to SAES during the payload phase of the AES-GCM (GCMPH = 0x2).

Table 243. Confidentiality protected parameter list

PKA operation	Secrets	Protected operation blob(1)	Start offset in PKA RAM	Size(2)
Modular exponentiation (protected, MODE[5:0] = 0x3)	Exponent e	RSA key blob	@0x14B8	ROS
	Phi value		@0xC68	
Scalar multiplication (MODE[5:0] = 0x20)	Scalar k	ECC key blob	@0x12A0	EOS
ECDSA signature (MODE[5:0] = 0x24)	Integer k	Not available	@0x12A0	EOS
	Private key d	ECC signature blob	@0xF28	

1. Information blob where confidentiality and integrity protected parameters are stored (see also *Table 242*)
2. See *Section 30.4.1* for details

Step 4: Running PKA protected operation

Set the START bit in PKA_CR. When the whole sequence executes correctly, the PKA RAM becomes inaccessible for reading and writing. Input parameters are automatically erased when the PROCENDF flag in PKA_SR is set, or if the application aborts the current operation by clearing the EN bit in PKA_CR.

30.3.8 PKA error management

The following error flags in the PKA_SR register are set to indicate errors that may occur when using the PKA:

- **ADDRERRF** flags that the access to PKA RAM falls outside the expected range.
- **RAMERRF** flags an AHB access to the PKA RAM occurring while the PKA core uses the PKA RAM. While the flag is set, reads form the PKA RAM return 0 and writes are ignored.
- **OPERRF** flags that the selected operating mode using MODE[5:0] bitfield is not listed in PKA operating modes (see the bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). While the flag is set, writes to the MODE[5:0] bitfield are ignored.
- An ongoing chaining mode sequence error raises the chaining mode flag **CMF** and the corresponding error flag:
  - **INCRERRF** flags increment error
  - **DATAZF** flags data zeroed error
  - **TRZERRF** flags trailing zeros error
  - **MDERRF** flags mode error
  - **RNGERRF** flags RNG error

  For details on each flag and on enabling the chaining mode sequence, see *Section 30.7.2*.

For each error flag, the PKA generates an interrupt if enabled with the corresponding bit in the PKA_CR register (see *Section 30.6* for details).

The ADDRERRF, OPERRF, and RAMERRF error flags are cleared by setting the ADDRERRFC, OPERRFC, and RAMERRFC bit in PKA_CLRFR, respectively. The OPERRF error flag must be cleared before a new operation is initiated via the PKA_CR register.

Upon an ongoing chaining mode sequence error, the application must set the CMFC bit in the PKA_CLRFR register, then restart the ongoing protected operation sequence in the CCB peripheral.

Note: The PKA can be re-initialized at any moment by clearing the EN bit in the PKA_CR register.

30.4 PKA operating modes

30.4.1 Introduction

The operations supported by the PKA are detailed in the following subsections, which define the format of both input data and results stored in the PKA RAM.

Warning: Before starting any operation, ensure that all input parameters to the PKA are valid and consistent, as the PKA assumes their correctness. Additionally, input parameters must not exceed the operand sizes specified in the operation tables.

The following information applies to all PKA operations:

- The PKA core processes 64-bit words in its RAM. Accordingly, in the PKA section of this document, 'word' denotes a 64-bit unit.
- When writing an element as input in the PKA RAM, append an additional 64-bit word of zeros after the most significant word, except when the operand size is fixed at one word.
- All RAM storage addresses refer to the least significant word of the data. To obtain the actual address, the application must add the base address of the PKA to the indicated offset.
- Supported operand sizes are:
  - **ROS (RSA operand size)**: Data size is calculated as *(rsa_size / 64) + 1* words, where *rsa_size* is the modulus length in bits. For example, a 1024-bit RSA operand corresponds to 17 words (1088 bits).
  - **EOS (ECC operand size)**: Data size is *(ecc_size / 64) + 1* words, where *ecc_size* is the prime modulus length in bits. For example, a 192-bit ECC operand corresponds to four words (256 bits).

  Note: Both ROS and EOS include the additional zero word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Any fractional results in the formulas must be rounded to the nearest integer, as the PKA core processes data in 64-bit words.

Note: The maximum ROS is 66 words (4160-bit maximum exponent size), while the maximum EOS is 11 words (640-bit max operand size).

Example 1: Understanding endianness in PKA memory during ECC Fp scalar multiplication preparation

Write the *x*-coordinate of point P for an ECC P256 curve (EOS = 5 words) by placing the least significant bit at bit 0 of the word at address offset 0x578, and the most significant bit at bit 63 of the word at address offset 0x590. Then, write a zero word (0x0000000000000000) at address offset 0x598.

Example 2: Writing the curve coefficient '*a*' for ECC Fp scalar multiplication

To write the value *a* = -3 for a curve with a modulus length of 224 bits (rounded up to five 64-bit words), write the PKA memory with data as in the following table:

Table 244. Example of *'a'* curve coefficient for ECC Fp scalar

RAM offset	Value	Note
0x410	0x0000000000000001	Curve coefficient *a* sign without extra word
0x418	0x0000000000000011	Value of |*a*| LSB

Table 244. Example of *'a'* curve coefficient for ECC Fp scalar

RAM offset	Value	Note
0x420	0x0000000000000000	-
0x428	0x0000000000000000	-
0x430	0x0000000000000000	Value of |*a*| MSB
0x438	0x0000000000000000	Additional zero word

30.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter (R^2 mod n) used by the PKA to convert operands into the Montgomery residue system representation. This operation can be very useful for fast mode operation because passing the Montgomery parameter as input saves the time for its computation.

Note: This operation also supports ECC curves when specifying the prime modulus length and EOS size.

The following table summarizes operation instructions for Montgomery parameter computation.

Table 245. Montgomery parameter computation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x01	PKA_CR	6 bits
	Modulus length	(in bits, 0 ≤ value < 4160)	RAM@0x408	64 bits
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	ROS
OUT	Result: R^2 mod *n*	-	RAM@0x620	

30.4.3 Modular addition

The following table summarizes operation instructions for modular addition operation that calculates *A* + *B* mod *n*.

Table 246. Modular addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0E	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	(0 ≤ *A* < *n*)	RAM@0xA50	ROS
	Operand *B*	(0 ≤ *B* < *n*)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: *A* + *B* mod *n*	(0 ≤ result < *n*)	RAM@0xE78	

30.4.4 Modular subtraction

Modular subtraction operation calculates:

- ***A* - *B* mod *n***, when $A \geq B$
- ***A* + *n* - *B* mod *n***, when $A < B$

The following table summarizes the operation instructions.

Table 247. Modular subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0F	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \leq A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \leq B < n$)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: *A* - *B* mod *n*	($0 \leq$ result $< n$)	RAM@0xE78	

30.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications, the PKA accelerates a multiplication that has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \bmod n$

The method to perform these operations is described next. The *x* function is this operation, and the *A*, *B*, and *C* operands are in the natural domain.

1. Inward or outward conversion to or from the Montgomery domain
   a) Assuming that *A* is an integer in the natural domain:
      – Compute *r2modn* using *Montgomery parameter computation*.
      – The result of $AR = A \times r2modn \bmod n$ is *A* in the Montgomery domain.
   b) Assuming that *BR* is an integer in the Montgomery domain:
      – The result of $B = BR \times 1 \bmod n$ is *B* in the natural domain.
      – Similarly, the *AR* value computed in *a)* can be converted into the natural domain by computing $A = AR \times 1 \bmod n$.
2. Simple modular multiplication $A \times B \bmod n$
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute $AR = A \times r2modn \bmod n$. The output is in the Montgomery domain.
   c) Compute $AB = AR \times B \bmod n$. The output is in the natural domain.
3. Multiple modular multiplication $A \times B \times C \bmod n$
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute $AR = A \times r2modn \bmod n$. The output is in the Montgomery domain.
   c) Compute $BR = B \times r2modn \bmod n$. The output is in the Montgomery domain.
   d) Compute $ABR = AR \times BR \bmod n$. The output is in the Montgomery domain.
   e) Compute $CR = C \times r2modn \bmod n$. The output is in the Montgomery domain.
   f) Compute $ABCR = ABR \times CR \bmod n$. The output is in the Montgomery domain.
   g) (optional) Repeat the two previous steps if multiplying with additional operands is required.
   h) Compute $ABC = ABCR \times 1 \bmod n$ to retrieve the result in the natural domain.

The following table summarizes the operation instructions.

Table 248. Montgomery multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x10	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < n$)	RAM@0xC68	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: $A \times B \bmod n$(1)	-	RAM@0xE78	

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples *2* and *3*).

30.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It calculates of $A^e \bmod n$.

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on *Table 249* and *Table 250*. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on *Table 251*, for security reason.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

Note: When MODE[5:0] = 0x03, the error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

Operation instructions for modular exponentiation are summarized in *Table 249* (normal mode), *Table 250* (fast mode), and *Table 251* (protected mode). Fast mode usage is explained in *Section 30.3.6*.

Table 249. Modular exponentiation (normal mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x00	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	

Table 250. Modular exponentiation (fast mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x02	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
IN/OUT	Montgomery parameter R^2 mod *n*	(mandatory)	RAM@0x620	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	

Table 251. Modular exponentiation (protected mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x03	PKA_CR	6 bits
	Exponent *e* length	(in bits, not null)	RAM@0x400	64 bits
	Modulus or operand length	(in bits, not null)	RAM@0x408	
	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0x16C8	ROS
	Exponent *e*	($0 \le e < n$)	RAM@0x14B8	
	Modulus value *n*	(odd integer only, $n < 2^{4096}$)	RAM@0x0838	
	Phi value(1)	-	RAM@0x0C68	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	
ERROR	Error A^e mod *n*	No errors: 0xD60D Errors: 0xCBC9	RAM@0x1298	64 bits

1. Euler totient function of n[1] with phi = (p - 1) × (q - 1), where p and q are prime factors of modulus n (see NIST SP800-56B Appendix C or *RSA encryption/decryption principle* for details). As optimization it is recommended to keep phi information as part of the key pair generation. Alternative is to store the key as (p, q, e, d) instead of (N, e, d, *phi*), in this case, to derive N and *phi* using PKA arithmetic multiplier: $N = p \times q$, and *phi* = (p - 1) × (q - 1).

30.4.7 Modular inversion

The modular inversion operation calculates multiplicative inverse A^{-1} mod n. If the modulus n is prime, for all values of A ($1 \le A < n$) modular inversion output is valid. If the modulus n is not prime, A has an inverse only if the greatest common divisor between A and n is 1.

If the operand A is a divisor of the modulus n the result is a multiple of a factor of n.

The following table summarizes the operation instructions.

Table 252. Modular inversion

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x08	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result: A^{-1} mod *n*	0 < result < *n*	RAM@0xE78	

30.4.8 Modular reduction

The modular reduction operation calculates the remainder of A divided by n.

The following table summarizes the operation instructions.

Table 253. Modular reduction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0D	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x400	64 bits
	Modulus length	(in bits, 8 < value < 4160)	RAM@0x408	
	Operand *A*	($0 \le A < 2n < 2^{4160}$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result *A* mod *n*	($0 <$ result $< n$)	RAM@0xE78	

30.4.9 Arithmetic addition

The arithmetic addition operation calculates *A* + *B*.

The following table summarizes the operation instructions.

Table 254. Arithmetic addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x09	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	Result: *A* + *B*	($0 \le$ result $< 2^{M+1}$)	RAM@0xE78	ROS + 1

30.4.10 Arithmetic subtraction

The arithmetic subtraction operation calculates:

- ***A* - *B***, when $A \ge B$
- $\boldsymbol{A + 2^{int(M / 32) \times 32 + 1} - B}$, when $A < B$ and the residue of $M / 32$ is greater than zero
- $\boldsymbol{A + 2^{int(M / 32) \times 32} - B}$, when $A < B$ and the residue of $M / 32$ is zero

For the last two list items, the 32-bit word following the most significant word of the output is 0xFFFF FFFF, as the result is negative.

The following table summarizes the operation instructions.

Table 255. Arithmetic subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0A	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le < A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le < B < 2^M$)	RAM@0xC68	
OUT	Result: *A* - *B*	($0 \le$ result $< 2^M$)	RAM@0xE78	

30.4.11 Arithmetic multiplication

The arithmetic multiplication operation calculates A × B.

The following table summarizes the operation instructions.

Table 256. Arithmetic multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0B	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	Result: *A* × *B*	($0 \le$ result $< 2^{2M}$)	RAM@0xE78	2xROS

30.4.12 Arithmetic comparison

The arithmetic comparison operation yields the following results:

- **0xED2C**, when *A* = *B*
- **0x7AF8**, when *A* > *B*
- **0x916A**, when *A* < *B*

The following table summarizes the operation instructions.

Table 257. Arithmetic comparison

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0C	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	If result *A* = *B*	0xED2C, 0x7AF8, or 0x916A	RAM@0xE78	64 bits

30.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- *p* and *q* are precomputed primes, stored as part of the private key
- $d_P = d \bmod (p - 1)$
- $d_Q = d \bmod (q - 1)$ and
- $q_{inv} = q^{-1} \bmod p$

These values allow the recipient to compute the exponentiation m = A^d (mod pq) more efficiently as follows:

- $m_1 = A^{dP} \bmod p$
- $m_2 = A^{dQ} \bmod q$
- $h = q_{inv} (m_1 - m_2) \bmod p$, with $m_1 > m_2$
- $m = m_2 + hq \bmod pq$

Operation instructions for computing CRT exponentiation A^d mod pq are summarized in *Table 258*.

Table 258. CRT exponentiation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x07	PKA_CR	6 bits
IN	Operand length	(in bits, not null)	RAM@0x408	64 bits
IN	Operand d_P	($0 < d_P < 2^{M/2}$)	RAM@0x730	ROS / 2
	Operand d_Q	($0 < d_Q < 2^{M/2}$)	RAM@0xE78	
	Operand q_{inv}	($0 < q_{inv} < 2^{M/2}$)	RAM@0x948	
	Prime p(1)	($0 < p < 2^{M/2}$)	RAM@0xB60	
	Prime q(1)	($0 < q < 2^{M/2}$)	RAM@0x1088	
IN	Operand A	($0 < A < 2^M$)	RAM@0x12A0	ROS
OUT	Result: A^d mod pq	($0 \leq$ result < pq)	RAM@0x838	

1. Must be different from 2.

30.4.14 Point on elliptic curve Fp check

This operation checks whether a given point P (x, y) satisfies or not the curves over prime fields equation $y^2 = (x^3 + ax + b) \bmod p$, where a and b are elements of the curve.

The following table summarizes the operation instructions.

Table 259. Point on elliptic curve *Fp* check

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x28	PKA_CR	6 bits
	Modulus length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(|*b*| < *p*)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, 0 < *p* < 2640)	RAM@0x470	
	Point P coordinate *x*	(*x* < p)	RAM@0x578	
	Point P coordinate *y*	(*y* < *p*)	RAM@0x5D0	
	Montgomery parameter R^2 mod *n*	-	RAM@0x4C8	
OUT	Result: point *P* on curve	0xD60D: point on curve 0xA3B7: point not on curve 0xF946: *x* or *y* coordinate is not smaller than modulus *p*	RAM@0x680	64 bits

30.4.15 ECC Fp scalar multiplication

This operation calculates $k \times P\,(x_P, y_P)$, where *P* is a point on a curve over prime fields and *x* is the elliptic curve scalar point multiplication. The result is a point that belongs to the same curve or a point at infinity.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation *point on elliptic curve* can be used to avoid this.

The following table summarizes the operation instructions.

Table 260. ECC Fp scalar multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x20	PKA_CR	6 bits
IN	Curve prime order *n* length	(in bits, not null,)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	

Table 260. ECC Fp scalar multiplication (continued)

Parameters with direction		Value (note)	Storage	Size
IN	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Scalar multiplier *k*	($0 \le k < n$)	RAM@0x12A0	
	Point P coordinate x_P	($x_P < p$)	RAM@0x578	
	Point P coordinate y_P	($y_P < p$)	RAM@0x470	
	Curve prime order *n*	(integer prime)	RAM@0xF88	
OUT	Result: *k* × *P* coordinate *x'*	(result < *p*)	RAM@0x578	EOS
	Result: *k* × *P* coordinate *y'*	(result < *p*)	RAM@0x5D0	
ERROR	Error *k* × *P*	No errors: 0xD60D Errors: 0xCBC9	RAM@0x680	64 bits

When performing this operation the following special cases must be noted:

- For *k* = 0 this function returns a point at infinity (0, 0) if curve parameter *b* is nonzero, (0, 1) otherwise. For *k* different from 0 it might happen that a point at infinity is returned. When the application detects this behavior, a new computation must be carried out.
- For *k* < 0 (that is, a negative scalar multiplication is required) the multiplier absolute value
  k = |-*k*| must be provided to the PKA. After the computation completion, the formula -*P* = (*x*, -*y*) can be used to compute the *y* coordinate of the effective final result (the *x* coordinate remains the same).

Note: The error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

30.4.16 ECDSA sign

Table 261 (input parameters) and *Table 262* (output parameters) summarize the ECDSA signing operation.

Upon an output error different from 0xD60D, the application must generate a new *k* and repeat the ECDSA sign operation.

Note: As long as this operation is ongoing (BUSY = 1), the PKA control register and the PKA memory are not accessible. The access is restored when the PKA clears the BUSY bit.

The operation completion with errors due to unexpected hardware events triggers a PKA tamper event in the TAMP peripheral and blocks access to the PKA RAM until the hardware erases the event. Missing programmed input point on the input ECC curve also triggers a PKA tamper event. The use of the *point on elliptic curve* PKA operation prevents this.

Table 261. ECDSA sign - Inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x24	PKA_CR	6 bits
	Curve prime order *n* length (*nlen*)	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Integer *k*(1)	($0 \leq k <$ n)	RAM@0x12A0	
	Curve base point *G* coordinate *x*	($x < p$)	RAM@0x578	
	Curve base point *G* coordinate *y*	($y < p$)	RAM@0x470	
	Hash of message *z*	(hash size equal to *nlen*)(2)	RAM@0xFE8	
	Private key *d*	($0 < d < n$)	RAM@0xF28	
	Curve prime order *n*	(integer prime)	RAM@0xF88	

1. This integer is usually a cryptographically secure random number, but in some cases *k* can be deterministically generated.
2. To match the hash parameter size to the length of the curve prime order *n,* pad the result with zeros or use the hash truncation.

Table 262. ECDSA sign - Outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Signature part *r*	($0 < r < n$)	RAM@0x730	EOS
	Signature part *s*	($0 < s < n$)	RAM@0x788	
ERROR	Result of signature	0xD60D: successful computation, no error 0xCBC9: failed computation 0xA3B7: signature part r is equal to 0 0xF946: signature part s is equal to 0	RAM@0xFE0	64 bits

Note: The error code is not affected when the PKA automatically clears the PKA RAM at the end of this protected operation. The error output 0xD60D does not affect the result output either.

Extended ECDSA support

The PKA also supports the extended ECDSA signature, which accepts the same inputs as the standard ECDSA signature (see *Table 261*) and produces similar outputs (see *Table 262*), with the addition of the point *kG* coordinates. The following table defines these additional outputs.

Table 263. Extended ECDSA sign - additional outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Curve point *kG* coordinate x_1	($0 \le x_1 < p$)	RAM@0x1400	EOS
	Curve point *kG* coordinate y_1	($0 \le y_1 < p$)	RAM@0x1458	

30.4.17 ECDSA verification

Table 264 (input parameters) and *Table 265* (output parameters) summarize the ECDSA verification operation.

Upon an output error different from 0xD60D, the signature is not verified.

Table 264. ECDSA verification - inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x26	PKA_CR	6 bits
	Curve prime order *n* length (*nlen*)	(in bits, not null)	RAM@0x408	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x4C8	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x468	
	Curve coefficient |*a*|	(absolute value, $\|a\| < p$)	RAM@0x470	EOS
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x4D0	
	Curve base point *G* coordinate *x*	($x < p$)	RAM@0x678	
	Curve base point *G* coordinate *y*	($y < p$)	RAM@0x6D0	
	Public-key curve point *Q* coordinate x_Q	($x_Q < p$)	RAM@0x12F8	
	Public-key curve point *Q* coordinate y_Q	($y_Q < p$)	RAM@0x1350	
	Signature part *r*	($0 < r < n$)	RAM@0x10E0	
	Signature part *s*	($0 < s < n$)	RAM@0xC68	
	Hash of message *z*	(hash size equal to *nlen*)(1)	RAM@0x13A8	
	Curve prime order *n*	(integer prime)	RAM@0x1088	

1. To match the hash parameter size to the length of the curve prime order *n,* pad the result with zeros or use the hash truncation.

Table 265. ECDSA verification - outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Result: ECDSA verify	– 0xD60D: valid signature – 0xA3B7: invalid signature	RAM@0x5D0	64 bits
	Computed signature part *r*	– ($0 < r < n$)	RAM@0x578	EOS

30.4.18 ECC complete addition

The ECC complete addition operation calculates the sum of two points on an elliptic curve.

Operation instructions are summarized in *Table 266*.

Note: The two input points and the resulting point are represented in Jacobian coordinates (X,Y,Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. To convert resulting point to Jacobian coordinates conversion (x, y)= (X / Z^2, Y / Z^3) can be used.

Table 266. ECC complete addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x23	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	– 0x0: positive 0x1: negative	RAM@0x410	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Curve coefficient |*a*|	(absolute value, $\|a\| < p$)	RAM@0x418	
	First point P coordinate *X*	($x < p$)	RAM@0x628	
	First point P coordinate *Y*	($y < p$)	RAM@0x680	
	First point P coordinate *Z*	($z < p$)	RAM@0x6D8	
	Second point Q coordinate *X*	($x < p$)	RAM@0x730	
	Second point Q coordinate *Y*	($y < p$)	RAM@0x788	
	Second point Q coordinate *Z*	($z < p$)	RAM@0x7E0	
OUT	Result coordinate *X*	($x < p$)	RAM@0xD60	
	Result coordinate *Y*	($y < p$)	RAM@0xDB8	
	Result coordinate *Z*	($z < p$)	RAM@0xE10	

30.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of $k \times P + m \times Q$, where (P, Q) are two points on an elliptic curve and (k, m) are two scalars. Operation instructions are summarized in *Table 267*.

If the resulting point is the point at infinity (error code 0xA3B7), the resulting coordinate equals to (0, 0).

Note: The two input points are represented in Jacobian coordinates (X, Y , Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. The result is represented in affine coordinates (x ,y)

This operation requires the input point Z coordinate to be equal to 1 (input point represented in affine coordinates).

Table 267. ECC double base ladder

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x27	PKA_CR	6 bits
	Curve prime order *n* length	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	– 0x0: positive – 0x1: negative	RAM@0x410	EOS
	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Integer *k*	($0 < k < 2^{640}$)	RAM@0x520	
	Integer *m*	($0 < m < 2^{640}$)	RAM@0x578	
	First point *P* coordinate *X*	($x < p$)	RAM@0x628	
	First point *P* coordinate *Y*	($y < p$)	RAM@0x680	
	First point *P* coordinate *Z*	($z < p$)	RAM@0x6D8	
	Second point *Q* coordinate *X*	($x < p$)	RAM@0x730	
	Second point *Q* coordinate *Y*	($y < p$)	RAM@0x788	
	Second point *Q* coordinate *Z*	($z < p$)	RAM@0x7E0	
OUT	Result coordinate *x*	($x < p$)	RAM@0x578	EOS
	Result coordinate *y*	(y < *p*)	RAM@0x5D0	
	Error code	– Point not at infinity: 0xD60D – Point at infinity: 0xA3B7	RAM@0x520	64 bits

30.4.20 ECC projective to affine

ECC projective to affine operation calculates the conversion between the representation of a point P in homogeneous projective coordinates and the representation of the point P in affine coordinates. Namely, if the point is represented by the triple (*X*, *Y*, *Z*), it calculates the affine coordinates (*x*, *y*) = (*X* / *Z*, *Y* / *Z*).

All the operations are performed modulo the modulus p of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0,0).

Operation instructions are summarized in *Table 268*.

Table 268. ECC projective to affine

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x2F	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	64 bits
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS

30.5 Example of configurations and processing times

30.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, $y^2 = x^3 + ax + b$ (mod p).

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.
The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer *p*, used as the modulus for all point arithmetic in the finite field *GF(p)*
- the (usually prime) integer *n*, the order of the group generated by *G*, defined below
- the base point of the curve *G*, defined by its coordinates (*Gx*, *Gy*)
- the integers *a* and *b*, coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define *a* as negative, PKA supports two representations:

1. ***a* defined as *p*-|*a*|** in the finite field *GF(p)*, for example ***p*-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**F**
   Curve coefficient a sign= 0x0 (positive)
   Curve coefficient a = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**C**
2. ***a* defined as negative**, for example **-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF
   Curve coefficient a sign= 0x**1** (negative)
   Curve coefficient a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 0000000**3**

Table 269 summarizes the family of curves supported by PKA for ECC operations.

30.5.2 Computation times

The following tables summarize the PKA computation times, expressed in AHB clock cycles.

Table 270. Modular exponentiation

Exponent length (in bits)	Mode	Modulus length (in bits)			
		1024	2048	3072	4096
3	Normal	124600	491000	684000	1133200
	Fast	22700	82000	178000	311000
17	Normal	135700	531400	772400	1288000
	Fast	33800	122500	266500	465800
2^{16} + 1	Normal	180000	693700	1126200	1907200
	Fast	78200	284700	620400	1085000
1024	Protected	9958000	-	-	-
	Normal	5850000	-	-	-
	Fast	5748000	-	-	-
	CRT(1)	1775000	-	-	-
2048	Protected	-	63886000	-	-
	Normal	-	42240000	-	-
	Fast	-	41832000	-	-
	CRT(1)	-	11670000	-	-
3072	Protected	-	-	199403000	-
	Normal	-	-	136830000	-
	Fast	-	-	136325000	-
	CRT(1)	-	-	36886000	-
4096	Protected	-	-	-	454318000
	Normal	-	-	-	316000000
	Fast	-	-	-	315226000
	CRT(1)	-	-	-	84577000

1. CRT stands for chinese remainder theorem optimization (MODE[5:0] bitfield= 0x07).

Table 271. ECC scalar multiplication(1)

Modulus length (in bits)							
160	192	256	320	384	512	521	640
-	1590000	3083000	5339000	8518000	17818000	21053000	31826000

1. These times depend on the number of 1s included in the scalar parameter, and include the computation of Montgomery parameter R2.

Table 272. ECDSA signature average computation time(1) (2)

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
-	1500000	2744000	4579000	7184000	14455000	16685000	24965000

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 273. ECDSA verification average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
1011000	1495000	2938000	5014000	7979000	16804000	19254000	29582000

Table 274. ECC double base ladder average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
967000	1419000	2768000	4784000	7547000	15854000	18257000	28257000

Table 275. ECC projective to affine average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
47600	78000	148300	253000	419000	838400	1049300

Table 276. ECC complete addition average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
10000	12000	18000	26000	39000	63000	89000

Table 277. Point on elliptic curve Fp check average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
3400	4200	6100	8300	10900	17200	-	-

Table 278. Montgomery parameters average computation times(1)

Modulus length (in bits)							
192	**256**	**320**	**512**	**1024**	**2048**	**3072**	**4096**
8600	8710	11870	17000	102000	410000	506000	822000

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

30.6 PKA interrupts

There are five individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see *Section 30.3.8*
2. Access to unmapped address (ADDRERRF), see *Section 30.3.8*
3. PKA RAM access while PKA operation is in progress (RAMERRF), see *Section 30.3.8*
4. PKA end of operation (PROCENDF)
5. Chaining mode flags (CMF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the *PKA control register (PKA_CR)*. Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

CMF interrupt is triggered by the end of an operation (DATAOKF, RNGOKF) or by a chaining mode error (see *Section 30.3.8*). Chaining modes are described in *Section 30.3.7*.

Table 279 gives a summary of the available features.

Table 279. PKA interrupt requests

Acronym	Event	Event flag	Enable control bit	Clear method
PKA	Unsupported operation	OPERRF	OPERRIE	Set OPERRFC bit
	Access to unmapped address error	ADDRERRF	ADDRERRIE	Set ADDRERRFC bit
	PKA RAM access error	RAMERRF	RAMERRIE	Set RAMERRFC bit
	PKA end of operation	PROCENDF	PROCENDIE	Set PROCENDFC bit
	Chaining mode flag	CMF	CMFIE	Set CMFC bit

30.7 PKA registers

30.7.1 PKA control register (PKA_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMFIE	OPERRIE	ADDRERRIE	RAMERRIE	Res.	PROCENDIE	Res.
									rw	rw	rw	rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MODE[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	START	EN
		rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMFIE**: Chaining mode flags interrupt enable
0: No interrupt is generated when any flag in bits 8 to 15 is set in PKA_SR.
1: An interrupt is generated when any flag in bits 8 to 15 is set in PKA_SR.

Bit 21 **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:8 **MODE[5:0]**: PKA operation code

000000: Montgomery parameter computation then modular exponentiation
000001: Montgomery parameter computation only
000010: Modular exponentiation only (Montgomery parameter must be loaded first)
000011: Modular exponentiation (protected, used when manipulating secrets)
100000: Montgomery parameter computation then ECC scalar multiplication (protected)
100100: ECDSA sign (protected)
100110: ECDSA verification
101000: Point on elliptic curve Fp check
000111: RSA CRT exponentiation
001000: Modular inversion
001001: Arithmetic addition
001010: Arithmetic subtraction
001011: Arithmetic multiplication
001100: Arithmetic comparison
001101: Modular reduction
001110: Modular addition
001111: Modular subtraction
010000: Montgomery multiplication
100011: ECC complete addition
100111: ECC double base ladder
101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE[5:0] bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE[5:0] different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE[5:0] bit is ignored.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **START**: start the operation

Set this bit to start the operation selected by the MODE[5:0] bitfield, using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

Note: START is ignored if PKA is busy.

Bit 0 **EN**: PKA enable

0: Disable PKA

1: Enable PKA; PKA becomes functional when INITOK is set by hardware in PKA_SR. When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE[5:0] bitfield for details.

Note: When EN = 0, PKA RAM can still be accessed by the application.

30.7.2 PKA status register (PKA_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMF	OPERRF	ADDRERRF	RAMERRF	Res.	PROCENDF	BUSY
									r	r	r	r		r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RNGERRF	MDERRF	TRZERRF	DATAZF	INCRERRF	DATAOKF	RNGOKF	Res.	Res.	Res.	Res.	Res.	CCEN	LMF	INITOK
	r	r	r	r	r	r	r						r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMF**: Chaining mode flags

This status bit is only used when CCEN status bit is set in this register.

0: No chaining mode events.

1: Ongoing chaining mode sequence triggered at least one flag status in bits 8 to 14 of this register.

This bit is cleared using CMFC bit in PKA_CLRFR.

Bit 21 **OPERRF**: Operation error flag

0: No event error

1: An illegal or unknown operation has been selected in PKA_CR register

This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag

0: No address error

1: Address access is out of range (unmapped address)

This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag

0: No PKA RAM access error

1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).

This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag

0: Operation in progress

1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag

This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.

0: No operation is in progress (default)

1: An operation is in progress

When CCEN = 1 PKA sets BUSY bit when it runs a sanity check on a random number that CCB wrote to the PKA RAM during a chaining sequence (see *Section 30.3.7*).

If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RNGERRF**: RNG error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No random number drawn from RNG, or generated ECC private key is NIST compliant.

1: Random number drawn from RNG did not pass NIST “key pair generation by testing candidates” equivalent algorithm (see FIPS 186-4 annex B.4.2). The last chaining operation must be restarted, otherwise the selected PKA operation remains unusable.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 13 **MDERRF**: Mode error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No mode error

1: The value written in MODE[5:0] of PKA_CR registers is different from the expected value corresponding to the CCOP mode selected in the CCB peripheral. Refer to *Section 30.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 12 **TRZERRF**: Trailing zeroes error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No trailing 0s error

1: Clear-text coming from CPU, or decrypted data coming from SAES does not have the required trailing 0s.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 11 **DATAZF**: Data zeroed error flag

This read-only chaining mode error flag is active only when CCEN is set in this register. DATAZF is set when PKA finds the complete data written to PKA RAM equal to 0, with all the expected 32-bit words null. This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 10 **INCRERRF**: Increment error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No increment error

1: During the reading or writing of protected parameters from or to the PKA RAM, the application did not properly incremented the address. Refer to *Section 30.3.7* for details.

During the read or write of an operand, and before DATAOKF or RNGOKF is set, the INCRERRF flag stays cleared if the application reads or writes again this operand (starting from the lowest address). This bit is cleared by setting the CMFC bit in PKA_CLRFR.

Bit 9 **DATAOKF**: Data OK flag

This read-only chaining mode status flag is active only when CCEN is set in this register.

0: Data not OK (if applicable), otherwise no event.

1: Sequential writes or reads to or from the PKA RAM successfully transfered the expected amount of data from or to SAES. Alternatively, the CPU wrote the correct amount of data in the PKA RAM. Refer to *Section 30.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 8 **RNGOKF**: RNG OK flag

This read-only chaining mode status flag is active only when CCEN is set in this register.

0: Random number not OK (if applicable). No event otherwise.

1: Sequential writes to PKA RAM successfully transfered the expected amount of random data from the RNG. Refer to *Section 30.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **CCEN**: Coupling and chaining mode enable

This bit is set when the application configures the CCB to run coupling and chaining sequences that perform protected PKA operation using the SAES and (optionally) RNG peripherals.

0: Access to PKA RAM and programming of PKA_CR has no extra limitation.

1: The PKA RAM is write-only until START is set (it is no access then), and the MODE[5:0] value written in PKA_CR must correspond to the CCOP mode selected in the CCB peripheral. The application must also follow the coupling and chaining sequences described in *Section 30.3.7*.

Bit 1 **LMF**: Limited mode flag

This bit is updated when EN bit in PKA_CR is set

0: All values documented in MODE[5:0] bitfield can be used.

1: Only ECDSA verification (MODE[5:0] = 0x26) is supported by the PKA.

Bit 0 **INITOK**: PKA initialization OK

This bit is asserted when PKA initialization is complete.

0: PKA is not initialized correctly. START bit cannot be set.

1: PKA is initialized correctly and can be used normally.

When RNG is not able to output proper random numbers or when SAES is using the RNG bus, INITOK remains at 0. If it happens, make sure the RNG peripheral is properly clocked and initialized, and the SAES peripheral is clocked with BUSY bit cleared in SAES_SR to release the RNG bus, then enable PKA again.

30.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMFC	OPERRFC	ADDRERRFC	RAMERRFC	Res.	PROCENDFC	Res.
									w	w	w	w		w	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMFC**: Clear chaining mode flag

0: No action

1: Clear the CMF flag and the chaining mode status bits in 8 to 15 in PKA_SR

Bit 21 **OPERRFC**: Clear operation error flag

0: No action

1: Clear the OPERRF flag in PKA_SR

Bit 20 **ADDRERRFC**: Clear address error flag

0: No action

1: Clear the ADDRERRF flag in PKA_SR

Bit 19 **RAMERRFC**: Clear PKA RAM error flag

0: No action

1: Clear the RAMERRF flag in PKA_SR

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDFC**: Clear PKA end of operation flag
0: No action
1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

Note: Reading PKA_CLRFR returns all 0s.

30.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA.AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

Note: PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 30.3.3: PKA reset and clocks.

30.7.5 PKA register map

Table 280. PKA register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.2: Memory organization* for the register boundary addresses.

31 Advanced-control timers (TIM1/TIM8)

31.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit autoreload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 31.3.35: Timer synchronization*.

31.2 TIM1/TIM8 main features

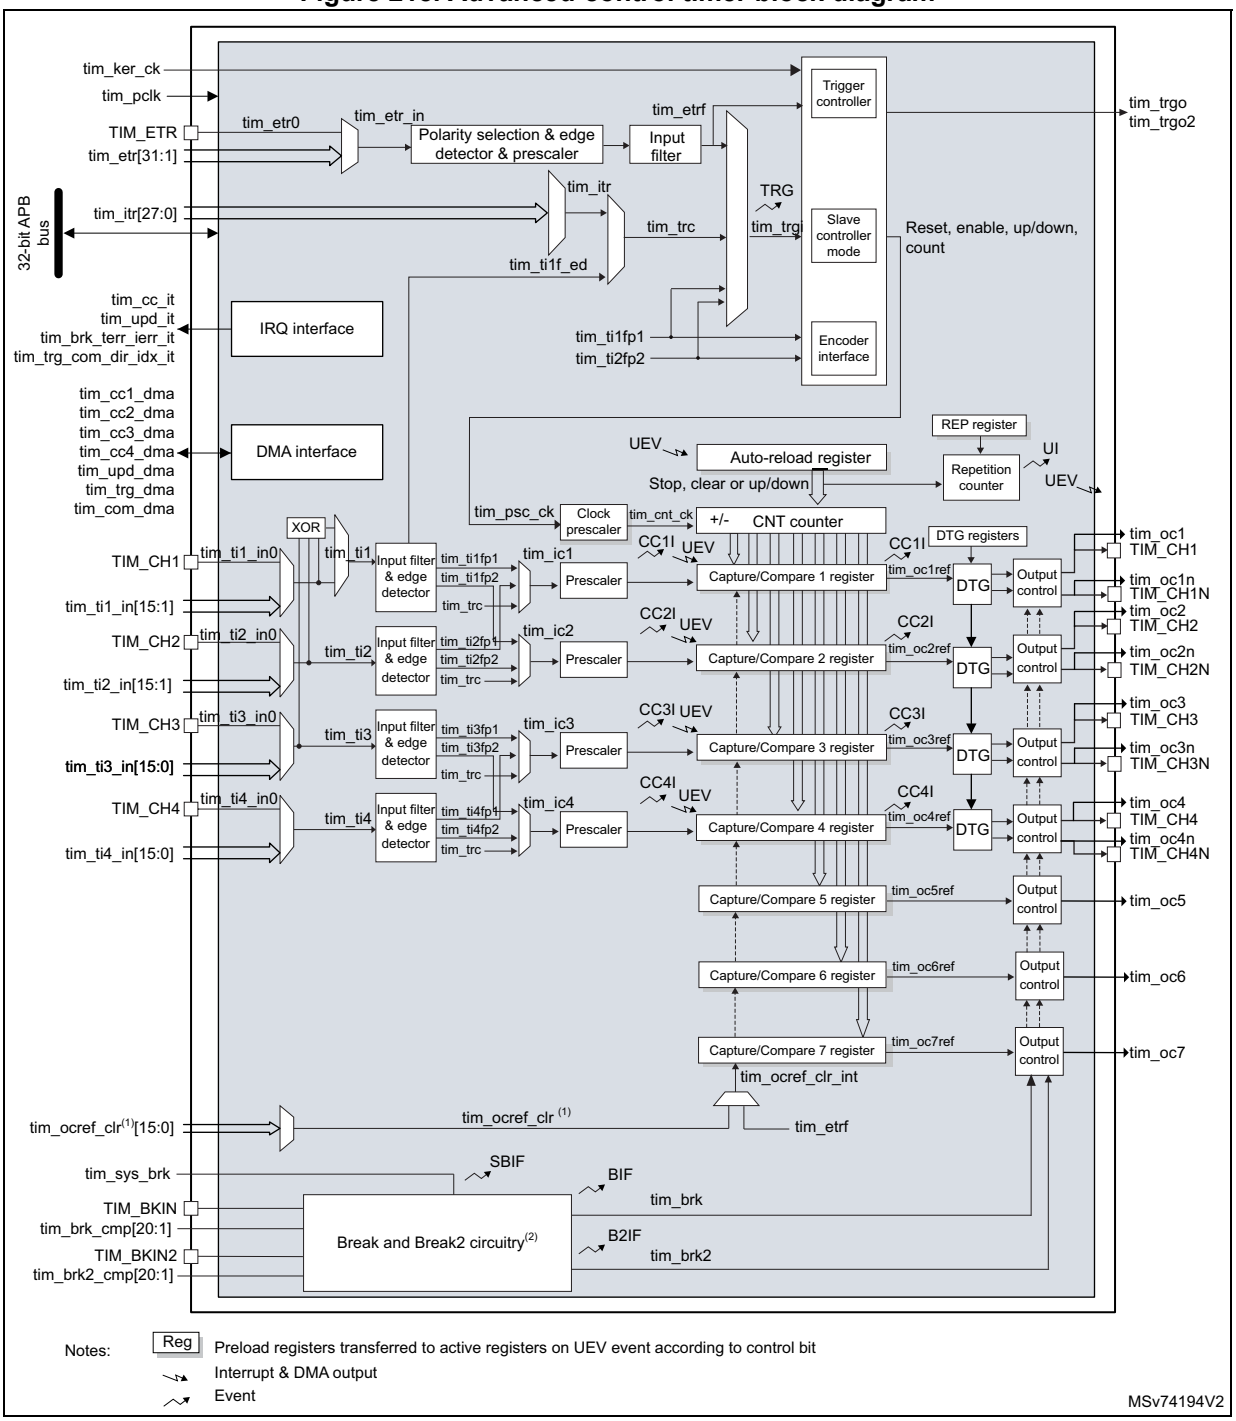
TIM1/TIM8 timer features include:

- 16-bit up, down, up/down autoreload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency by any factor from 1 to 65536.
- Seven independent channels for:
  - Input capture (but channels 5, 6 and 7)
  - Output compare
  - PWM generation (edge and center-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization, or count by internal/external trigger)
  - Input capture
  - Output compare
- Incremental encoders, quadrature encoders and hall-sensors support
- Trigger input for external clock or cycle-by-cycle current management
- ADC synchronization for jitter-free sampling points

31.3 TIM1/TIM8 functional description

31.3.1 Block diagram

Figure 218. Advanced-control timer block diagram



1. This feature is not available on all timers, refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals*.
2. See *Figure 269: Break and Break2 circuitry overview* for details.

31.3.2 TIM1/TIM8 pins and internal signals

The tables in this section summarize the TIM inputs and outputs

Table 281. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2 TIM_CH3 TIM_CH4	Input/Output	Timer multi-purpose channels. Each channel can be used for capture, compare or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock), external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.
TIM_CH1N TIM_CH2N TIM_CH3N TIM_CH4N	Output	Timer complementary outputs, derived from TIM_CHx outputs with the possibility to have deadtime insertion.
TIM_ETR	Input	External trigger input. This input can be used as external trigger or as external clock source. This input can receive a clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
TIM_BKIN TIM_BKIN2	Input / Output	Break and Break2 inputs. These inputs can also be configured in bidirectional mode.

Table 282. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0] tim_ti3_in[15:0] tim_ti4_in[15:0]	Input	Internal timer inputs bus. The tim_ti1_in[15:0] and tim_ti2_in[15:0] inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock) and for quadrature encoder signals.
tim_etr[31:0]	Input	External trigger internal input bus. These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulsewidth control. These inputs can receive clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
tim_itr[27:0]	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo/tim_trgo2	Output	Internal trigger outputs. These triggers are used by other timers and /or other peripherals.

Table 282. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_ocx (x = 1 to 4)	Output	Internal output compare signals of channels 1 to 4. These outputs can be used for triggering/synchronizing other internal peripherals.
tim_ocxn (x = 1 to 4)	Output	Internal timer complementary outputs, derived from tim_ocx internal outputs with the possibility to have deadtime insertion.
tim_ocx (x = 5 to 7)	Output	Internal output compare signals of channels 5 to 7. These outputs can be used for triggering/synchronizing other internal peripherals.
tim_ocref_clr[15:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim ocxref signals, typically for hardware cycle-by-cycle pulsewidth control.
tim_brk_cmp[20:1]	Input	Break input for internal signals
tim_brk2_cmp[20:1]	Input	Break2 input for internal signals
tim_sys_brk[n:0]	Input	System break input. This input gathers the MCU's system level errors.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock
tim_cc_it	Output	Timer capture/compare interrupt
tim_upd_it	Output	Timer update event interrupt
tim_brk_terr_ierr_it	Output	Timer break, break2, transition error and index error interrupt
tim_trgi_com_dir_idx_it	Output	Timer trigger, commutation, direction and index interrupt
tim_cc1_dma tim_cc2_dma tim_cc3_dma tim_cc4_dma	Output	Timer capture / compare 1..4 dma requests
tim_upd_dma	Output	Timer update dma request
tim_trgi_dma	Output	Timer trigger dma request
tim_com_dma	Output	Timer commutation dma request

Table 283, *Table 284*, *Table 285*, and *Table 286* list the sources connected to the tim_ti[4:1] input multiplexers.

31.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related autoreload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:

- Counter register (TIM_CNT)
- Prescaler register (TIM_PSC)
- Autoreload register (TIM_ARR)
- Repetition counter register (TIM_RCR)

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIM_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIM_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

Note: An update overrun status bit (UIOVRF in TIM_SR register) indicates that an update request occurred while an update interrupt is pending (update interrupt flag set). This bit is useful when debugging closed loop applications, to indicate that:

- the update interrupt service routine is too long with respect to the interval between consecutive update events

- the update interrupt service routine was served too late with respect to the subsequent update event

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIM_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIM_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor from 1 to 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIM_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 219 and *Figure 220* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 219. Counter timing diagram with prescaler division change from 1 to 2

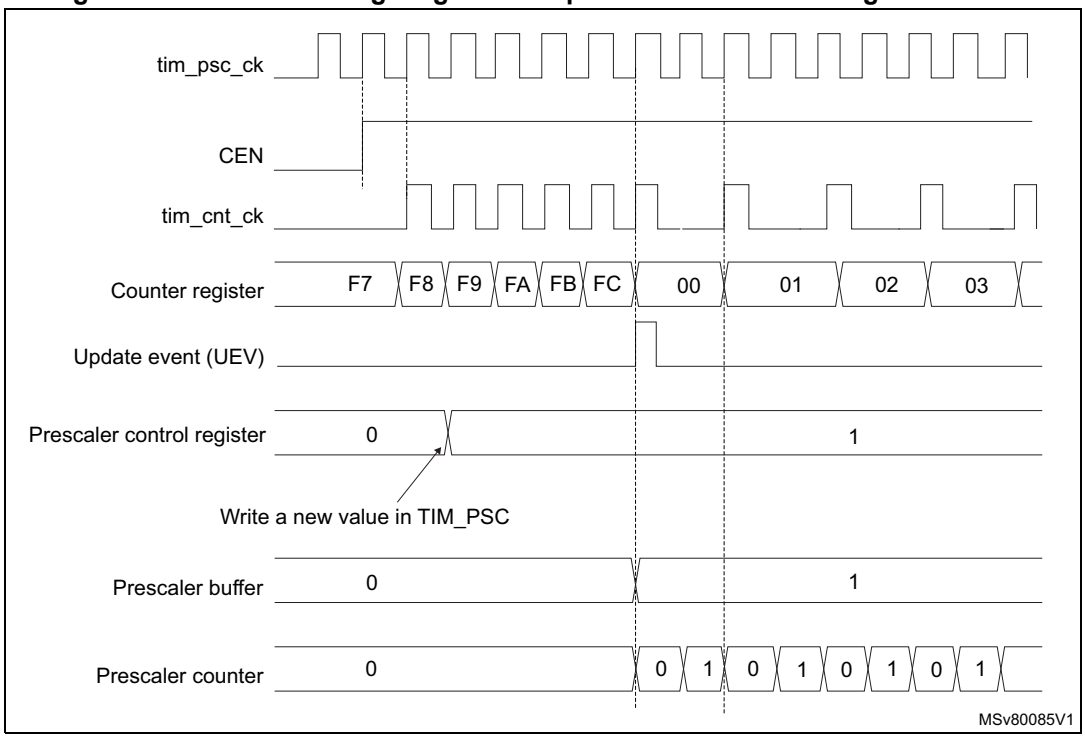

Figure 220. Counter timing diagram with prescaler division change from 1 to 4

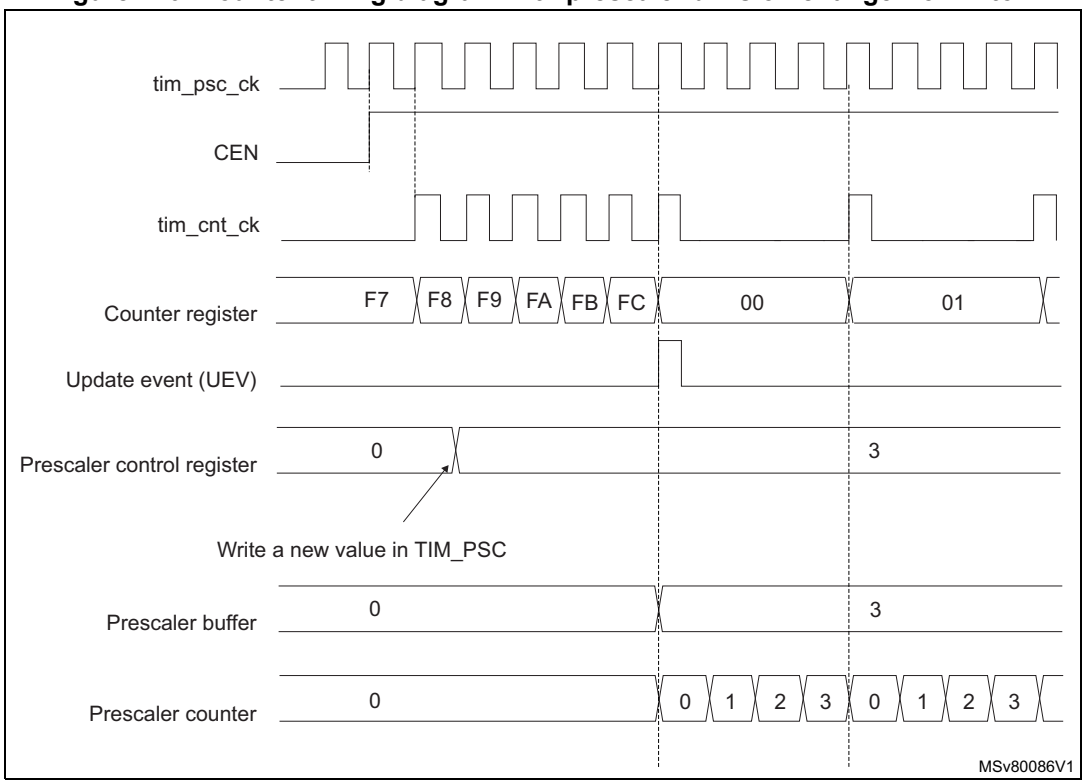

31.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIM_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register,
- The autoreload shadow register is updated with the preload value (TIM_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 221. Counter timing diagram, internal clock divided by 1

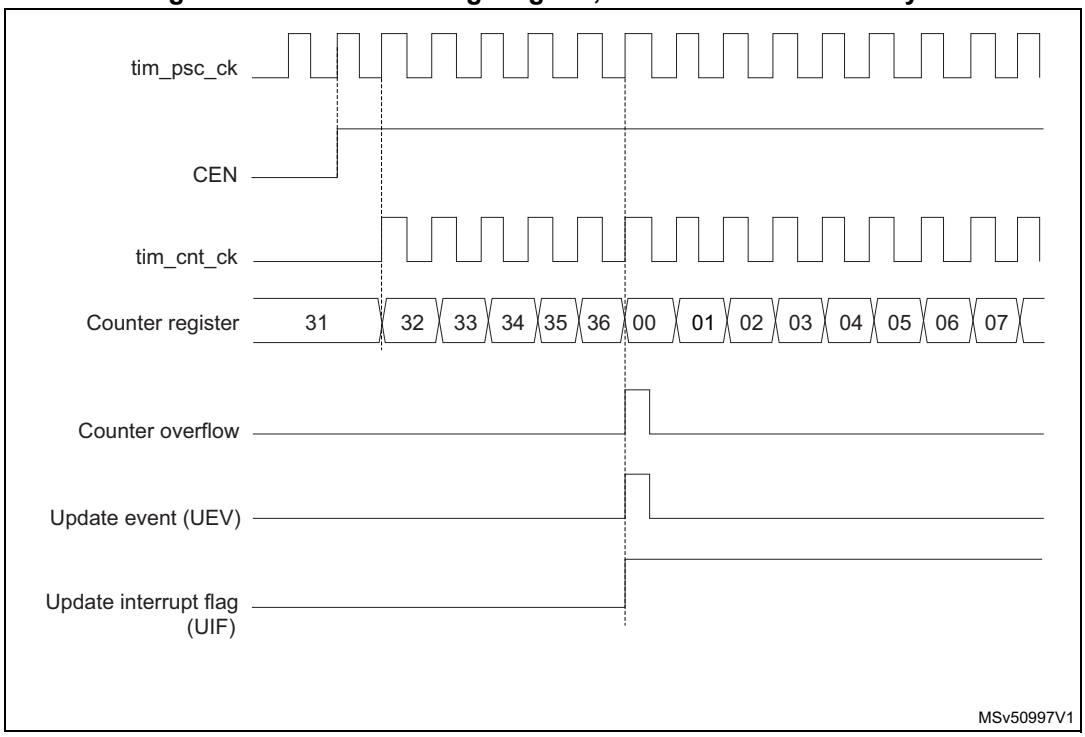

Figure 222. Counter timing diagram, internal clock divided by 2

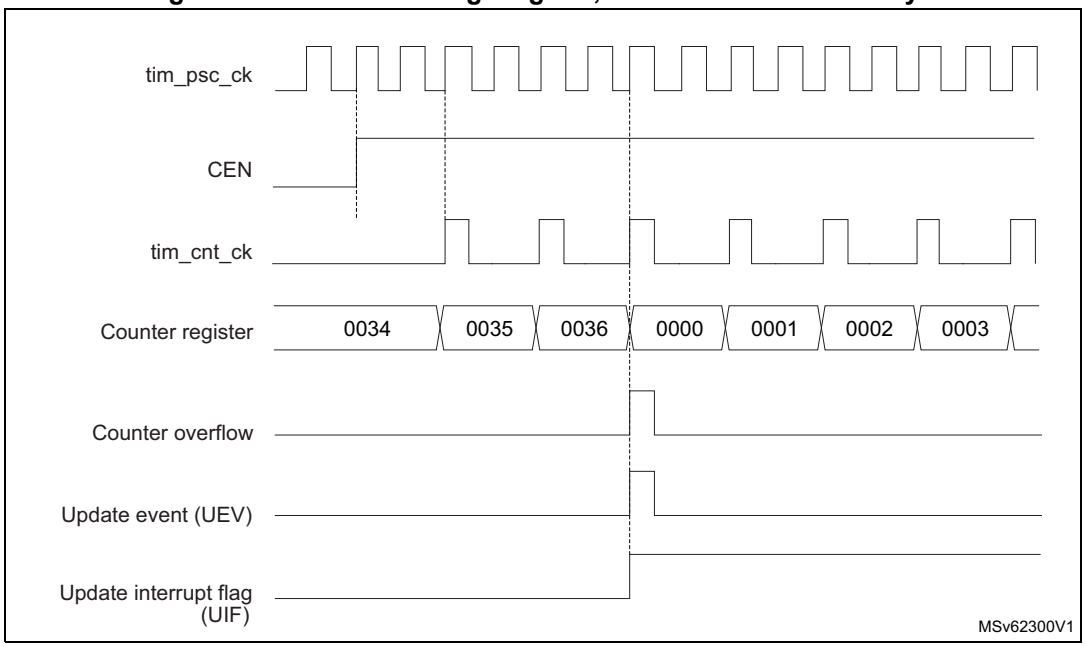

Figure 223. Counter timing diagram, internal clock divided by 4

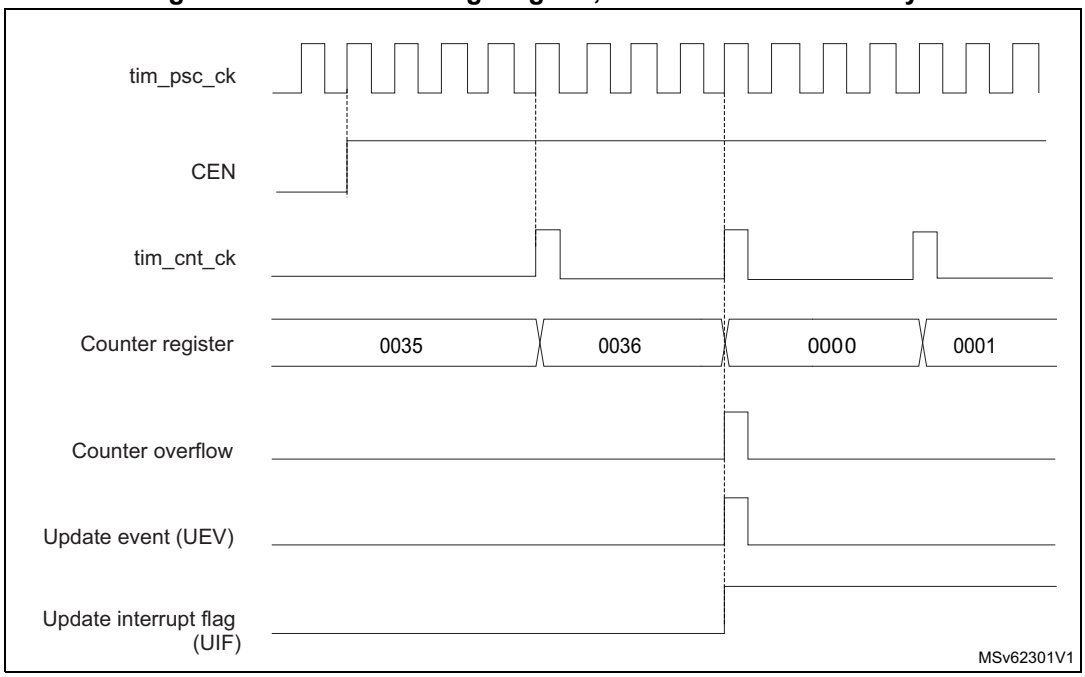

Figure 224. Counter timing diagram, internal clock divided by N

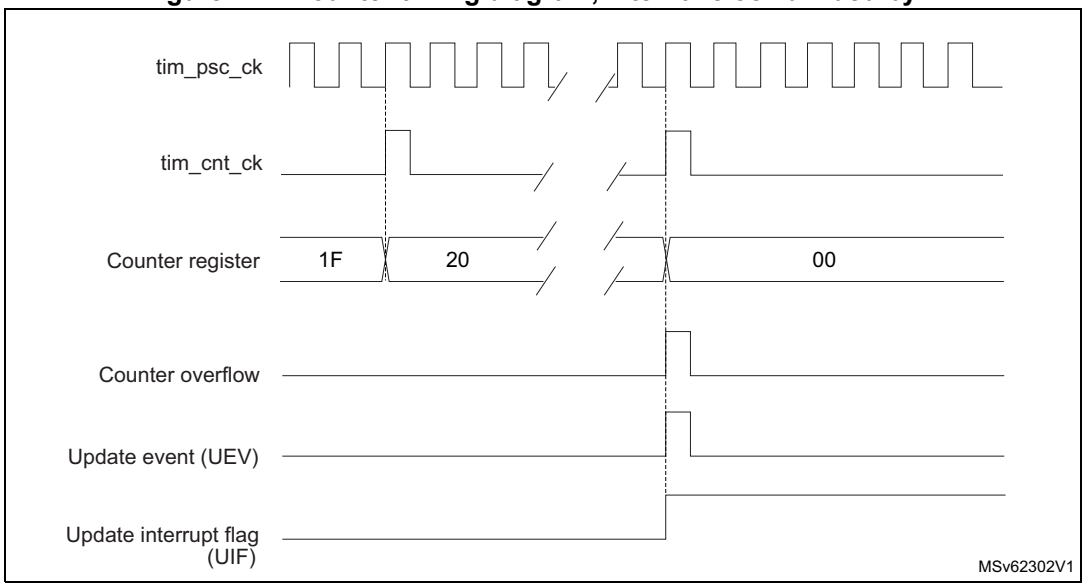

Figure 225. Counter timing diagram, update event when ARPE = 0 (TIM_ARR not preloaded)

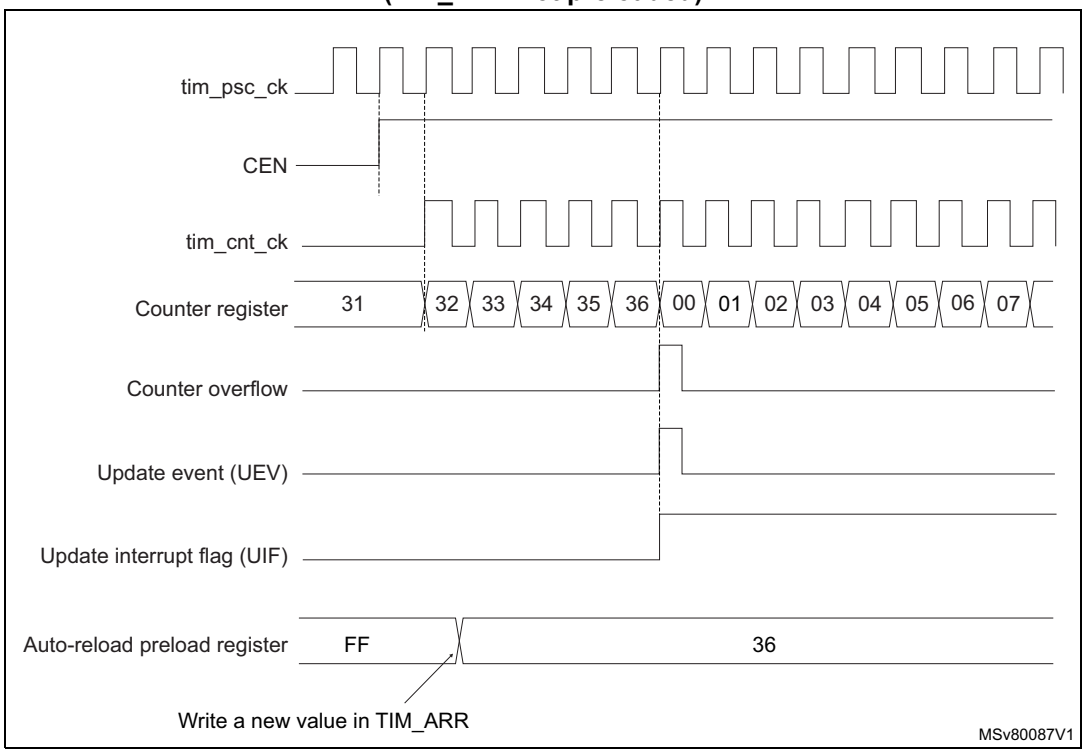

Figure 226. Counter timing diagram, update event when ARPE = 1 (TIM_ARR preloaded)

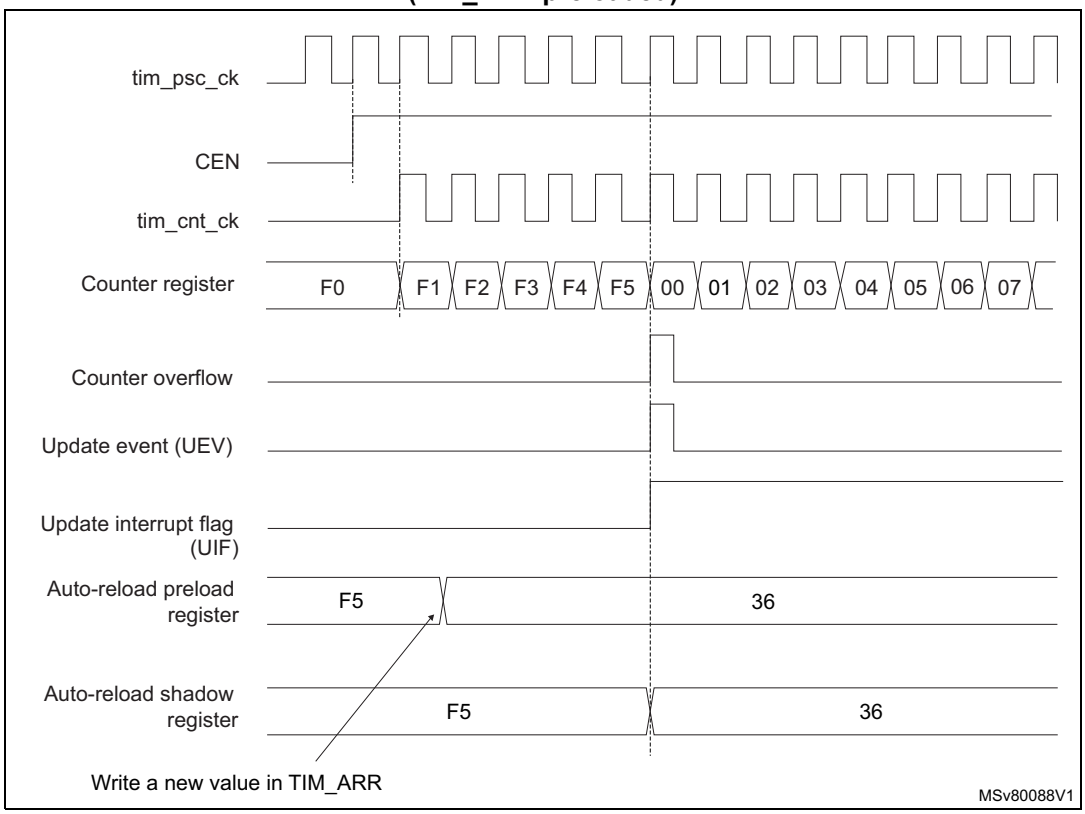

Downcounting mode

In downcounting mode, the counter counts from the autoreload value (content of the TIM_ARR register) down to 0, then restarts from the autoreload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIM_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current autoreload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that the autoreload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 227. Counter timing diagram, internal clock divided by 1

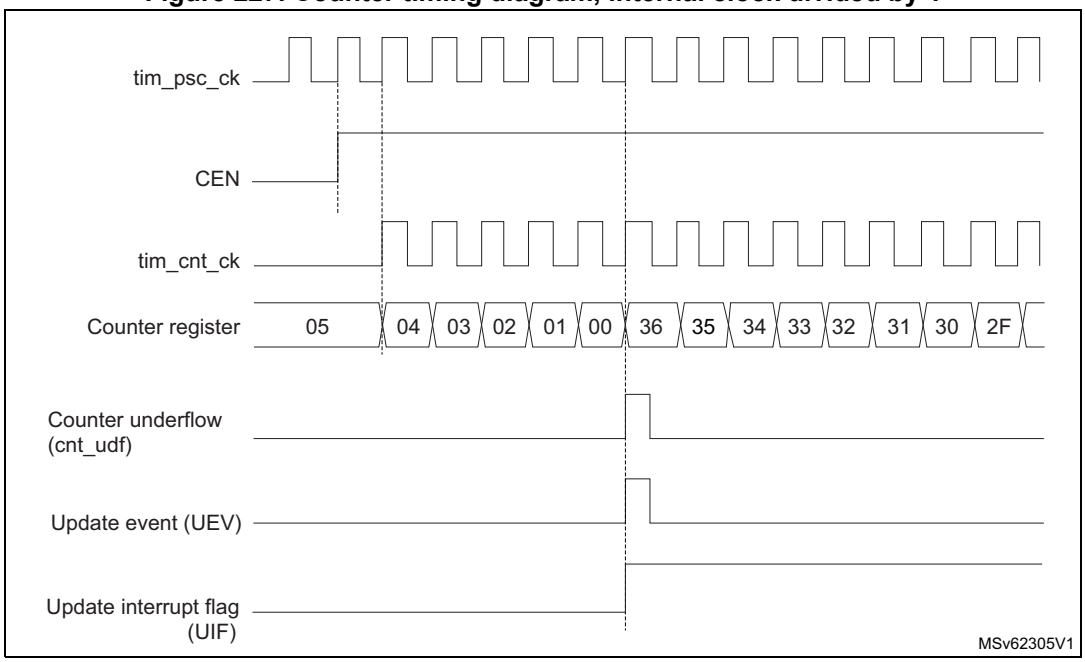

Figure 228. Counter timing diagram, internal clock divided by 2

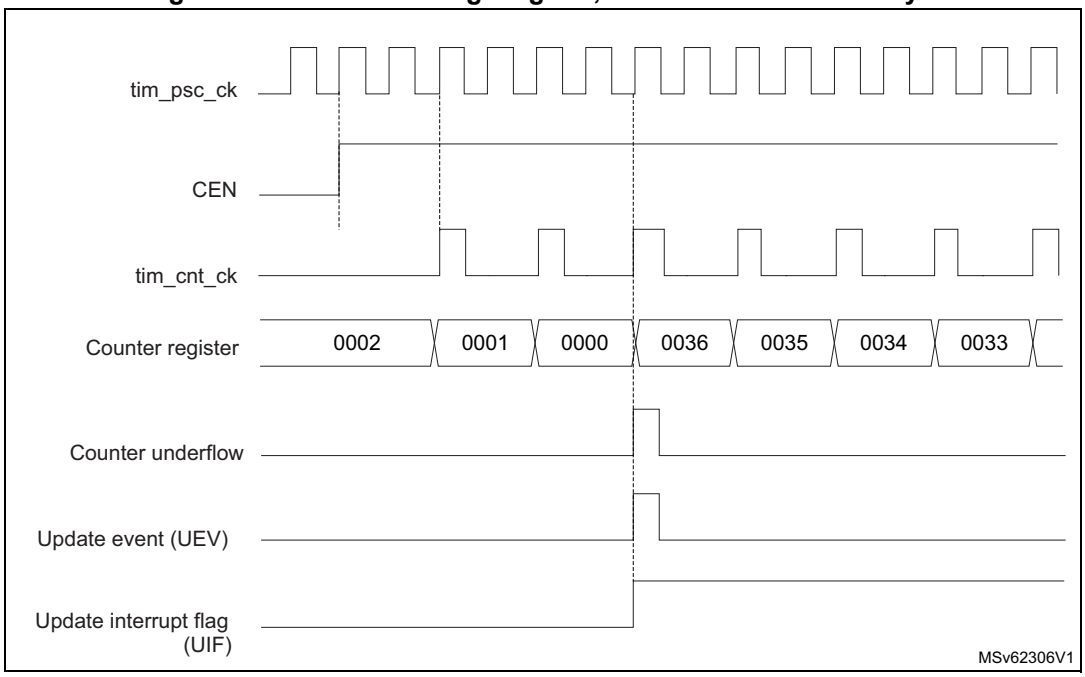

Figure 229. Counter timing diagram, internal clock divided by 4

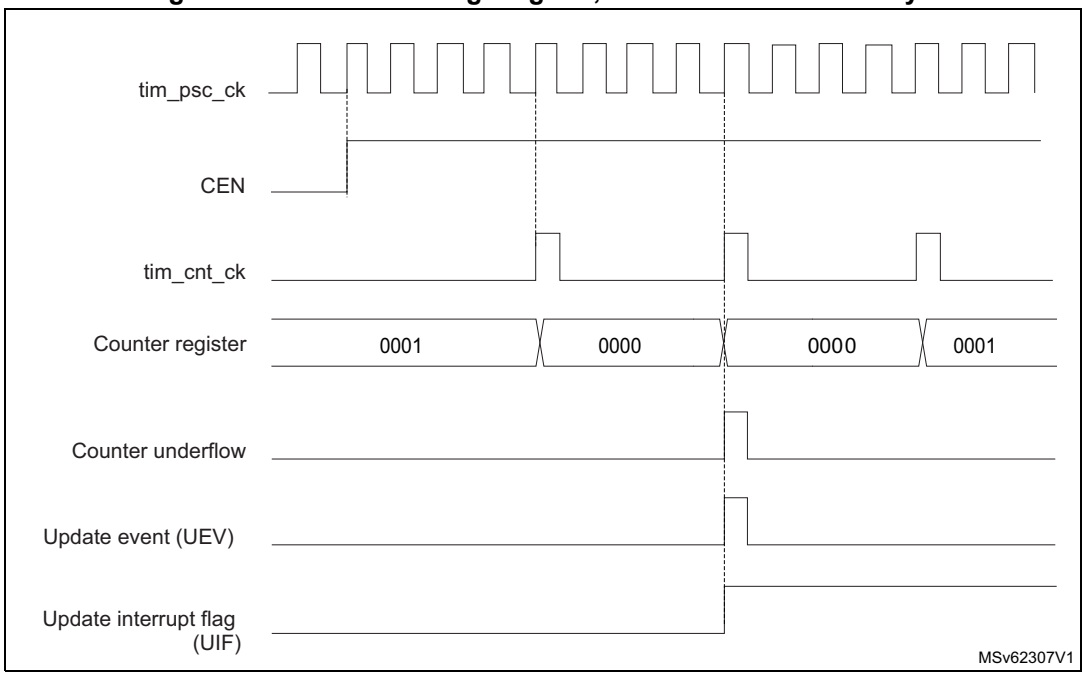

Figure 230. Counter timing diagram, internal clock divided by N

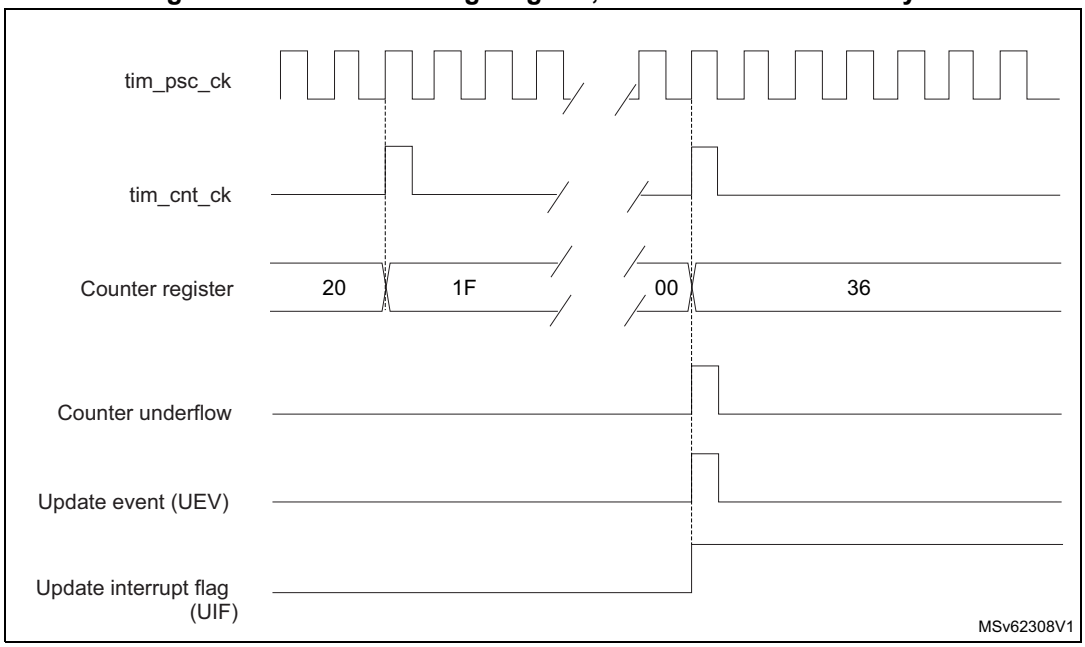

Figure 231. Counter timing diagram, update event when repetition counter is not used

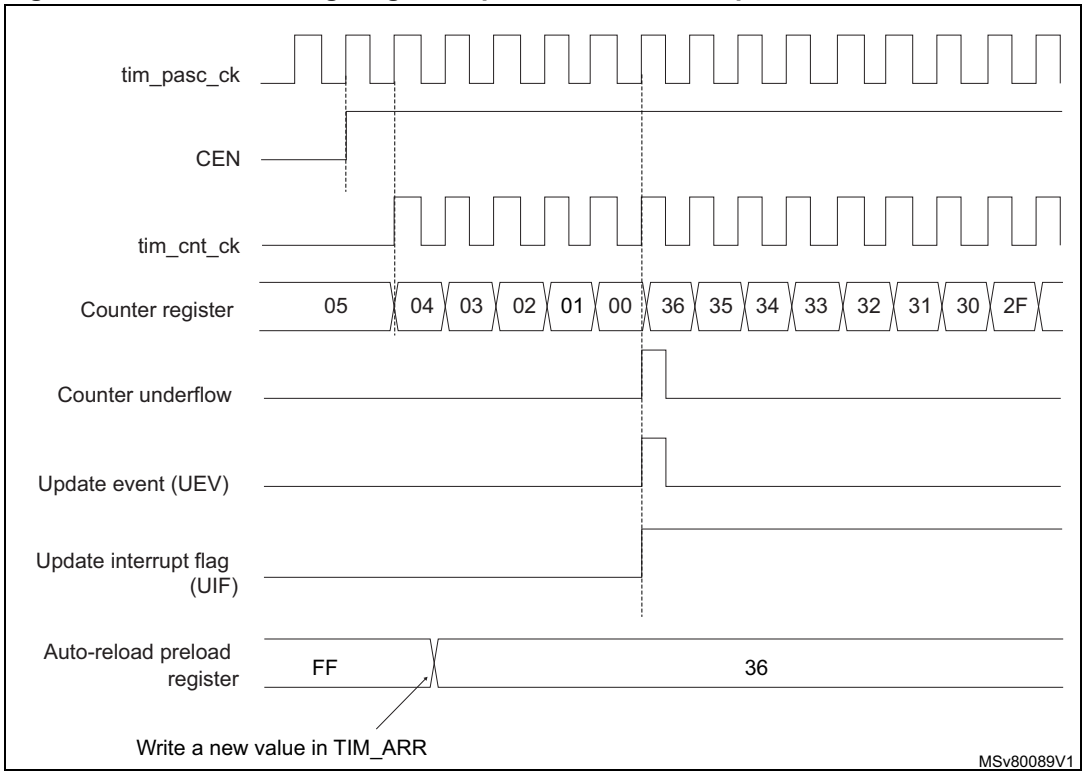


Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register) – 1, generates a counter overflow event, then counts from the

autoreload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIM_CR1 register are not equal to 00. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = 01), the counter counts up (Center aligned mode 2, CMS = 10) the counter counts up and down (Center aligned mode 3, CMS = 11).

In this mode, the DIR direction bit in the TIM_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current autoreload value.

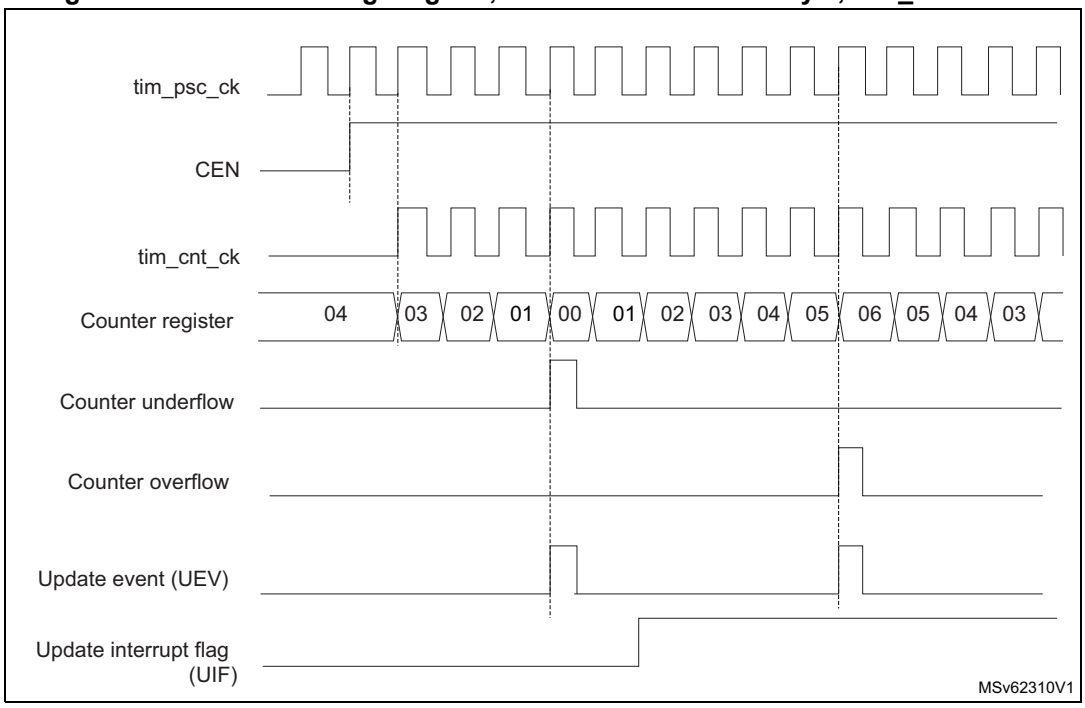
In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register)
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that if the update source is a counter overflow, the autoreload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 232. Counter timing diagram, internal clock divided by 1, TIM_ARR = 0x6



1. Here, center-aligned mode 1 is used (for more details refer to *Section 31.6: TIM1/TIM8 registers*).

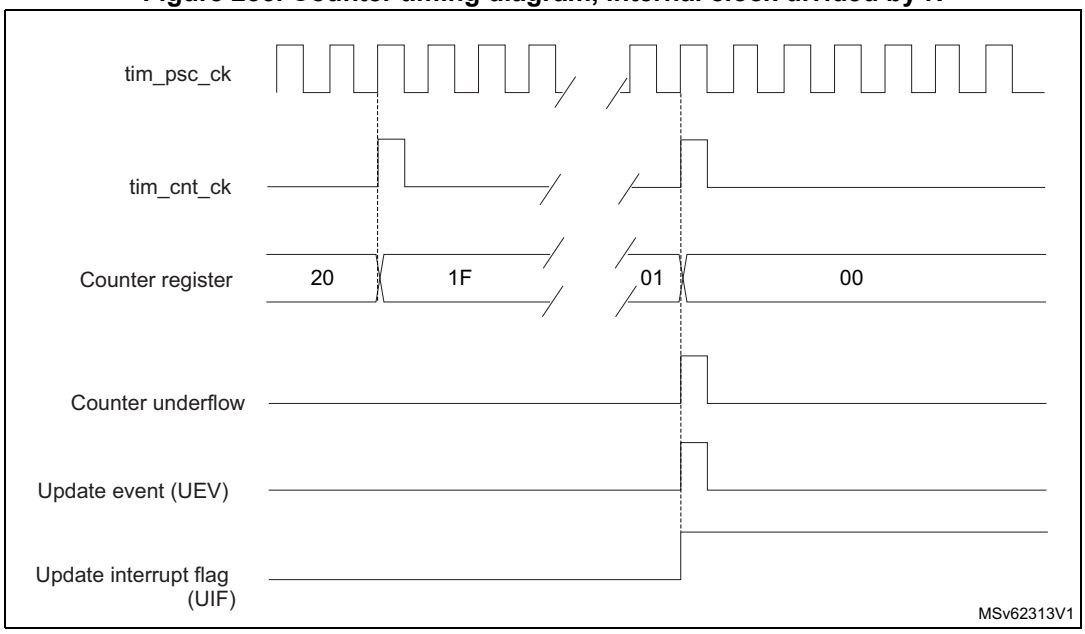

Figure 236. Counter timing diagram, update event with ARPE = 1 (counter underflow)

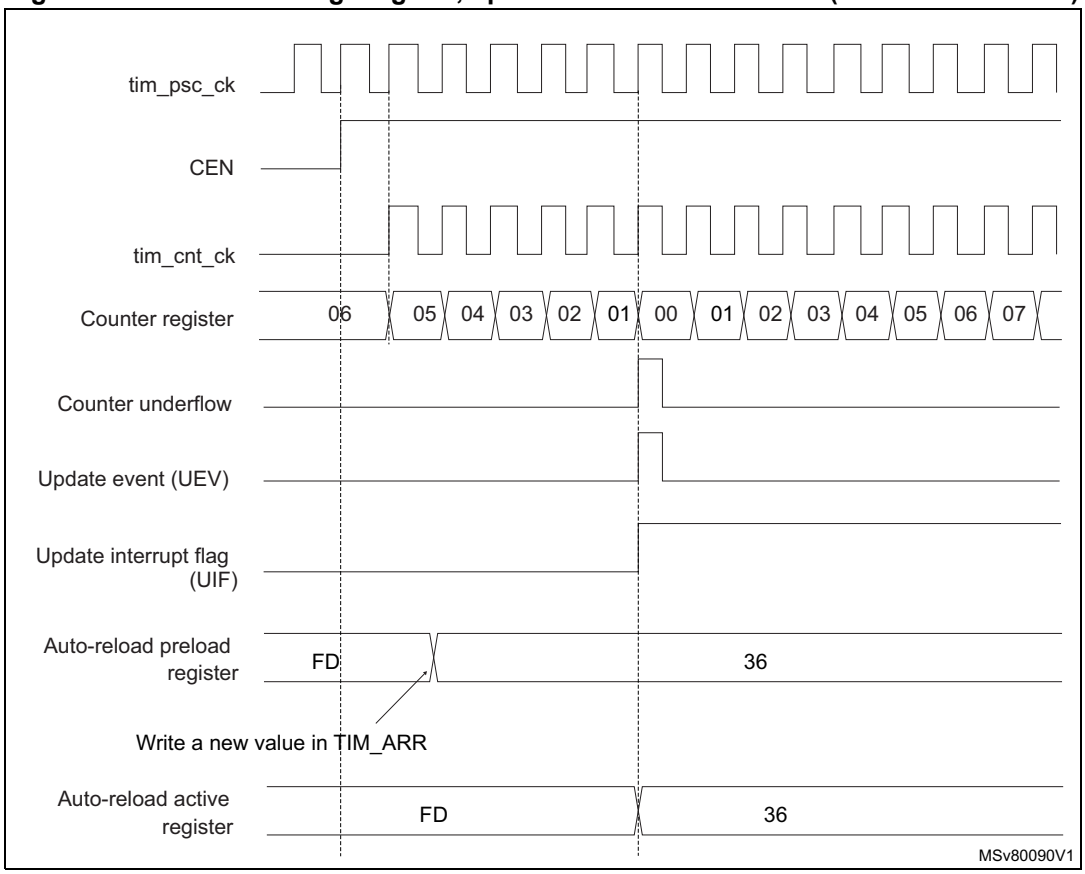

Figure 237. Counter timing diagram, Update event with ARPE = 1 (counter overflow)

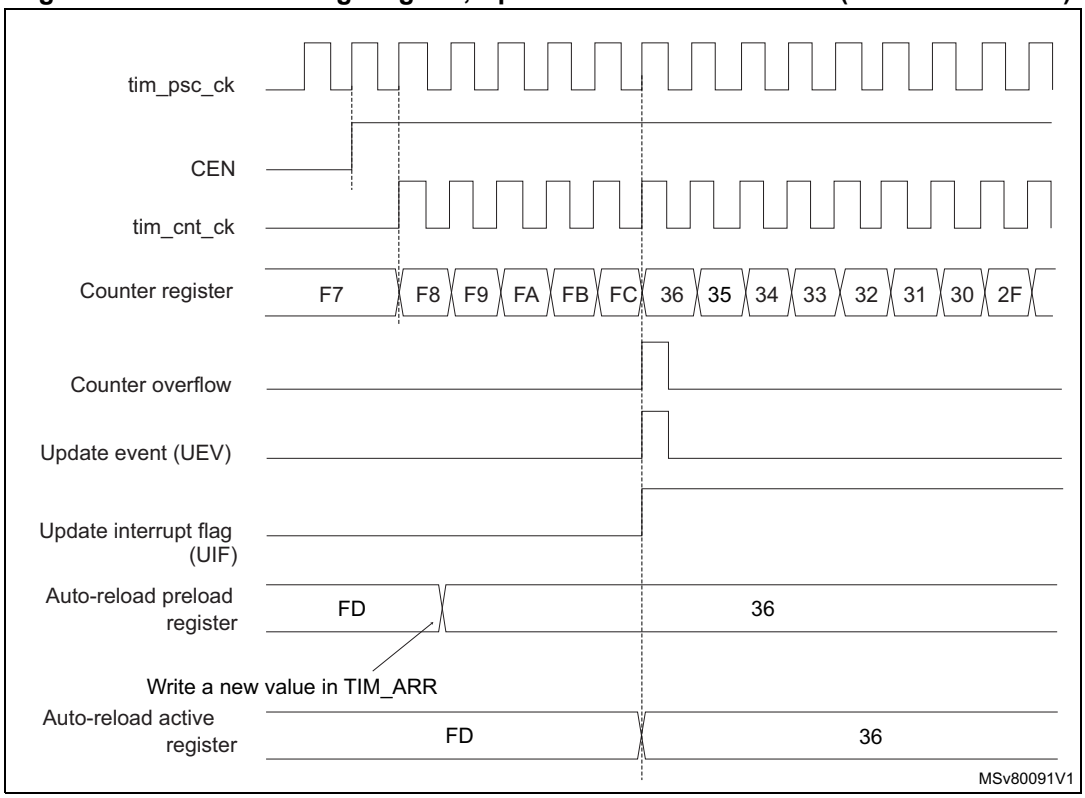


31.3.5 Repetition counter

Section 31.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIM_ARR autoreload register, TIM_PSC prescaler register, but also TIM_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIM_RCR repetition counter register.

The repetition counter is decremented:

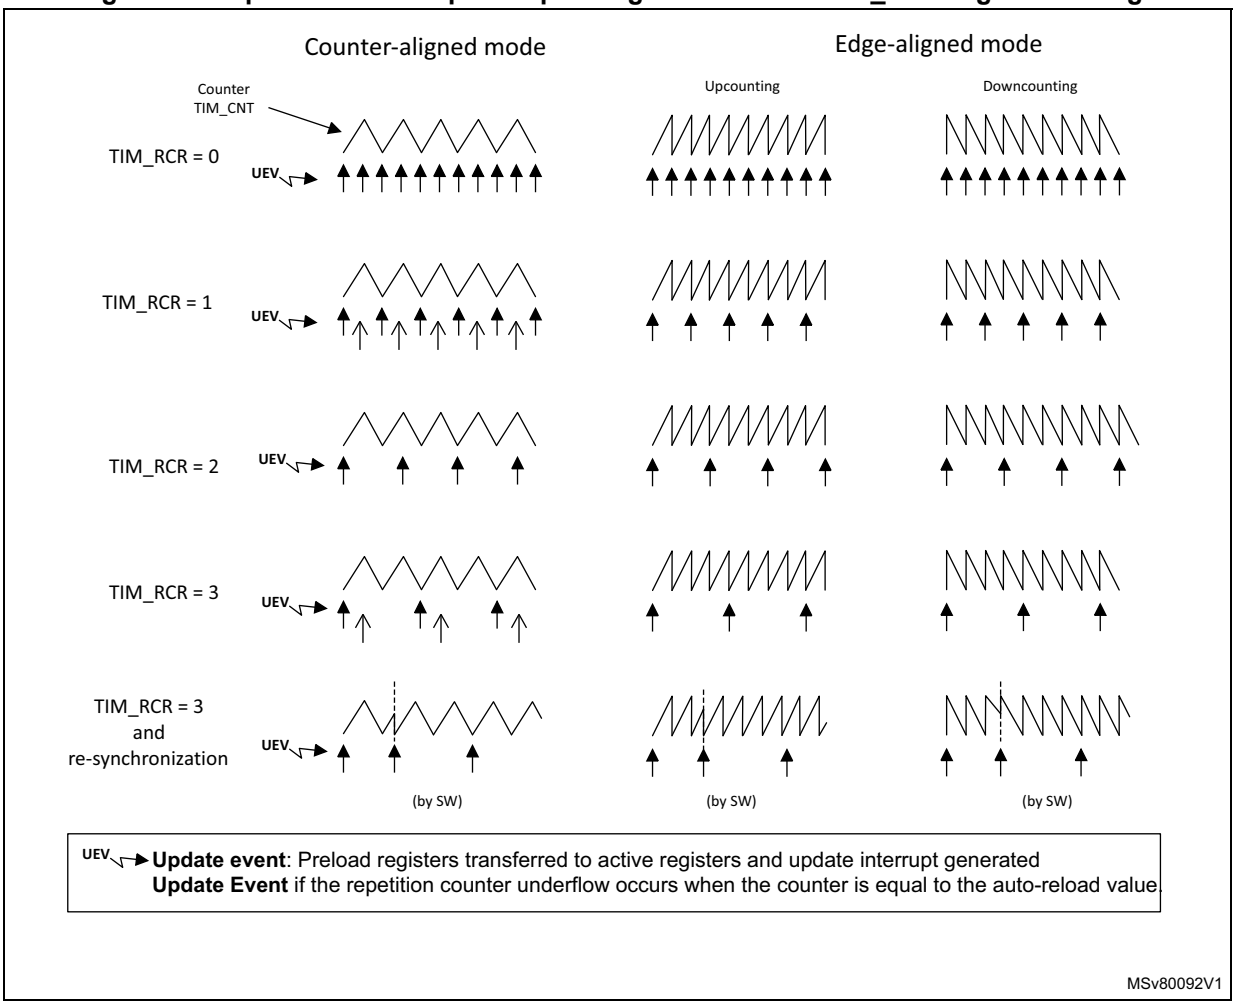
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode. Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is $2xT_{ck}$, due to the symmetry of the pattern.

The repetition counter is an autoreload type; the repetition rate is maintained as defined by the TIM_RCR register value (refer to *Figure 238*). When the update event is generated by software (by setting the UG bit in TIM_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIM_RCR register.

In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

Figure 238. Update rate examples depending on mode and TIM_RCR register settings



31.3.6 External trigger input

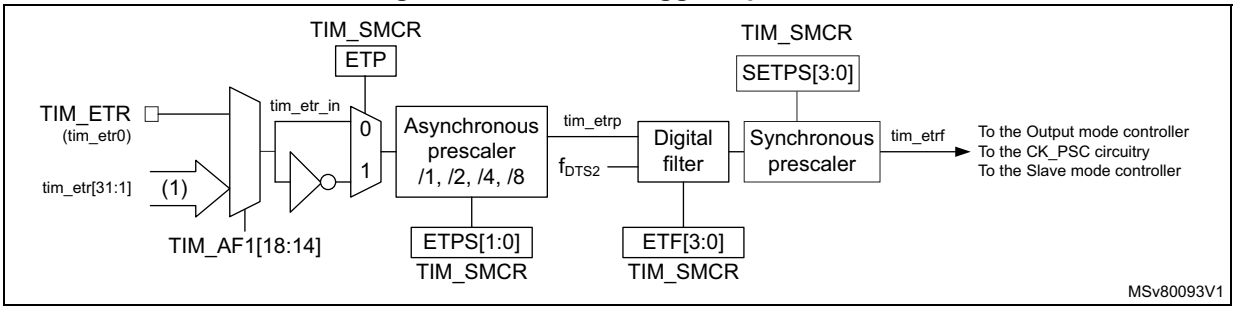
The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see *Section 31.3.7*)
- trigger for the slave mode (see *Section 31.3.35*)
- PWM reset input for cycle-by-cycle current regulation (see *Section 31.3.9*)

Figure 239 below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIM_SMCR register. The trigger frequency can be decreased with the prescalers programmed by the ETPS[1:0] and SETPS[3:0] bitfields and digitally filtered as per the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an

external clock, to condition the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

Figure 239. External trigger input block



The external trigger input block features 2 prescalers with different functionalities:

- An asynchronous prescaler (division by 1, 2, 4 or 8), able to process tim_etr_in signals with frequencies above tim_ker_ck
- A linear synchronous prescaler (division by 1,2,3,..15), only able to operate with tim_etrp signal frequencies below tim_ker_ck/3

Note: When tim_etrf is used as PWM reset input for cycle-by-cycle current regulation (see Section 31.3.23), SETPS[3:0] must be set to 0 (no prescaling).

Note: The SETPS[3:0] bitfield is always preloaded: a new value will become active only once an update event has occured.

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[4:0] bitfield in the TIM_AF1 register.

Refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals* for the list of sources connected to the etr_in input in the product.

31.3.7 Clock selection

The counter clock can be provided by the following clock sources:

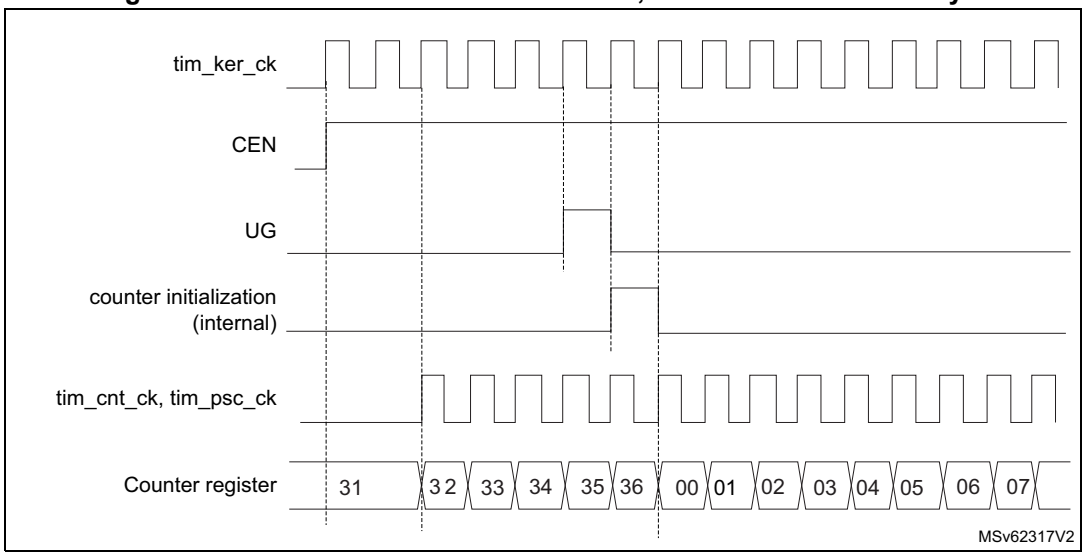
- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS = 000), then the CEN, DIR (in the TIM_CR1 register) and UG bits (in the TIM_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 240 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

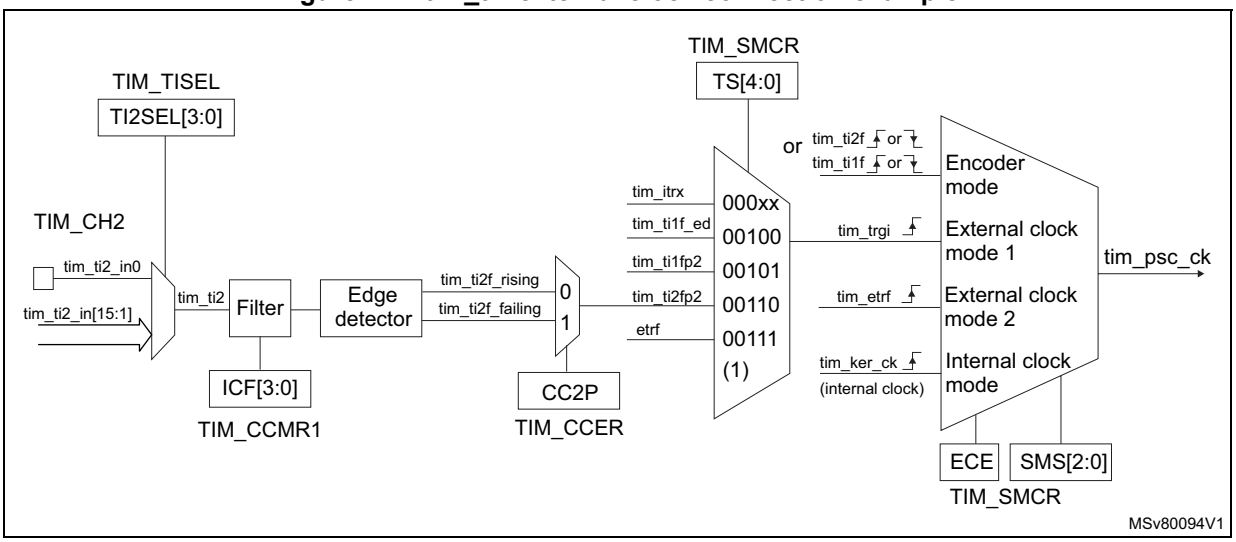
Figure 240. Control circuit in normal mode, internal clock divided by 1



External clock source mode 1

This mode is selected when SMS = 00111 in the TIM_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 241. tim_ti2 external clock connection example



1. Codes ranging from 01000 to 11111 are reserved.

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

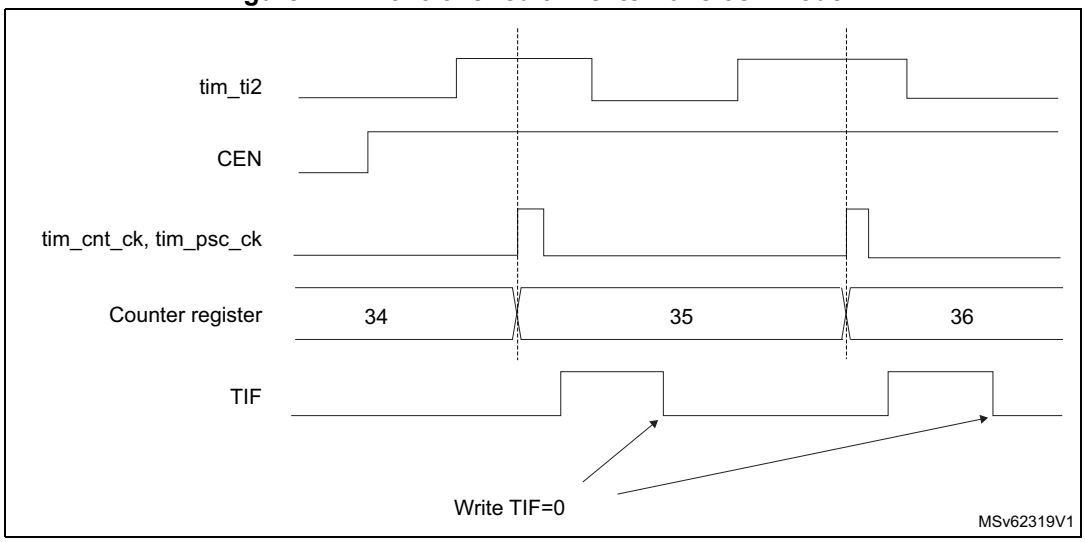
1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = 01 in the TIM_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIM_CCMR1 register (if no filter is needed, keep IC2F = 0000).
3. Select rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIM_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS = 00110 in the TIM_SMCR register.
6. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 242. Control circuit in external clock mode 1



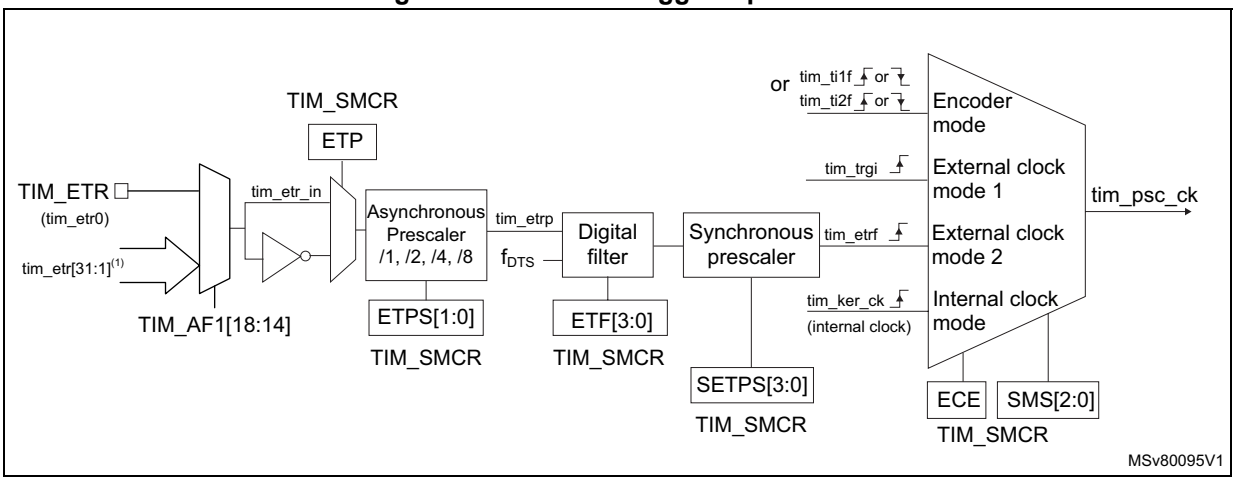
External clock source mode 2

This mode is selected by writing ECE = 1 in the TIM_SMCR register.

The counter counts at each rising or falling edge on the external trigger input tim_etr_in.

The *Figure 243* gives an overview of the external trigger input block.

Figure 243. External trigger input block



1. Refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals*.

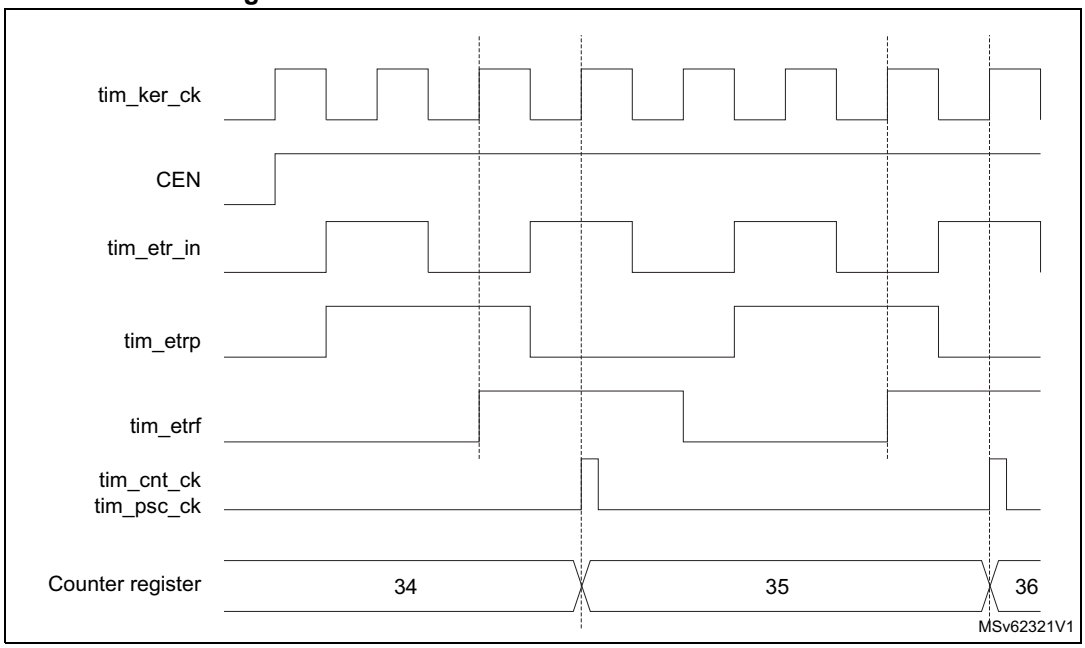
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0] = 0000 in the TIM_SMCR register.
2. Set the prescaler by writing ETPS[1:0] = 01 and SETPS[3:0] = 0 in the TIM_SMCR register
3. Select rising edge detection on the tim_etr_in input by writing ETP = 0 in the TIM_SMCR register
4. Enable external clock mode 2 by writing ECE = 1 in the TIM_SMCR register.
5. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of tim_ker_ck frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.

Figure 244. Control circuit in external clock mode 2



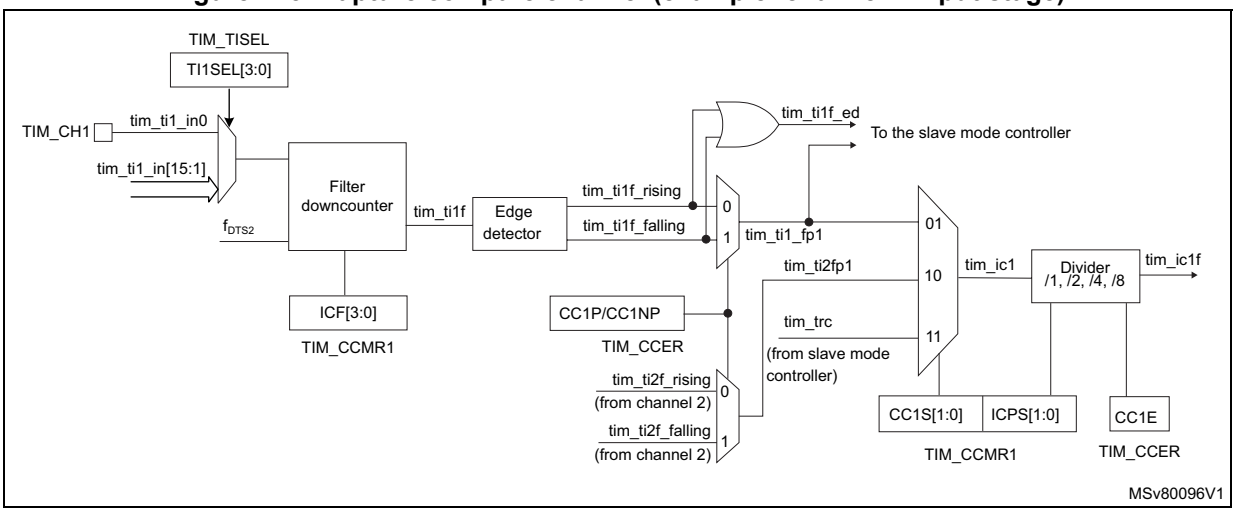
31.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

Figure 245 to *Figure 248* give an overview of one capture/compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 245. Capture/compare channel (example: channel 1 input stage)



The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 246. Capture/compare channel 1 main circuit

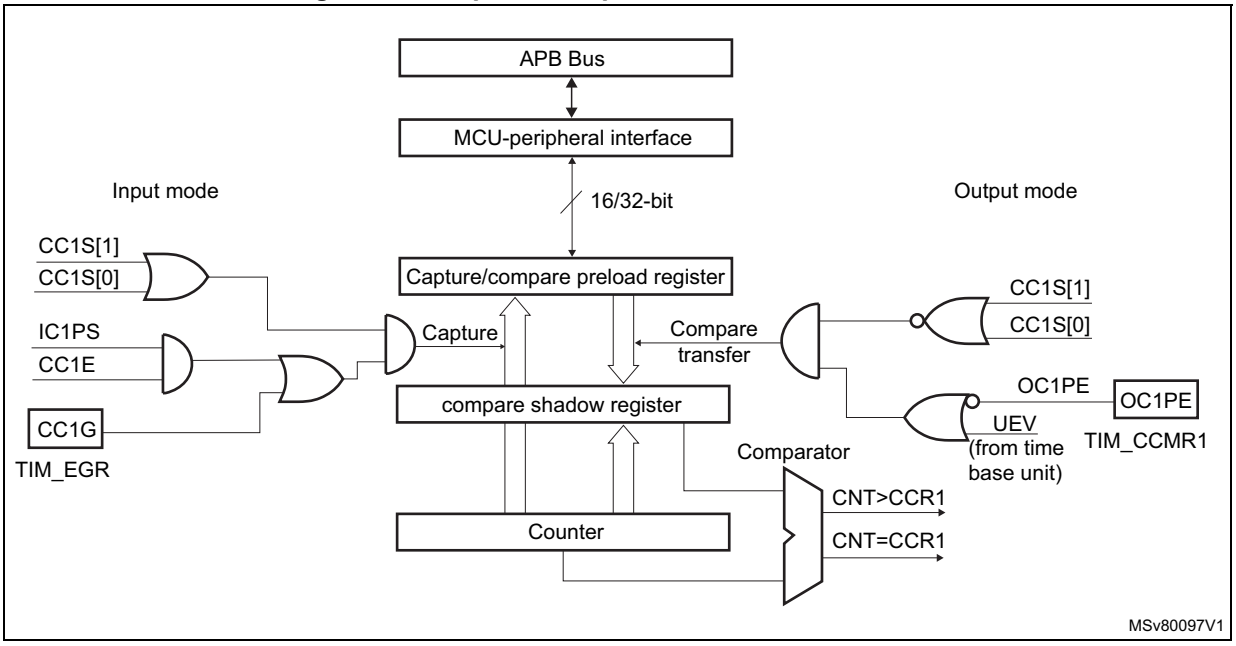


Figure 247. Output stage of capture/compare channel (channel 1, idem ch. 2, 3 and 4)

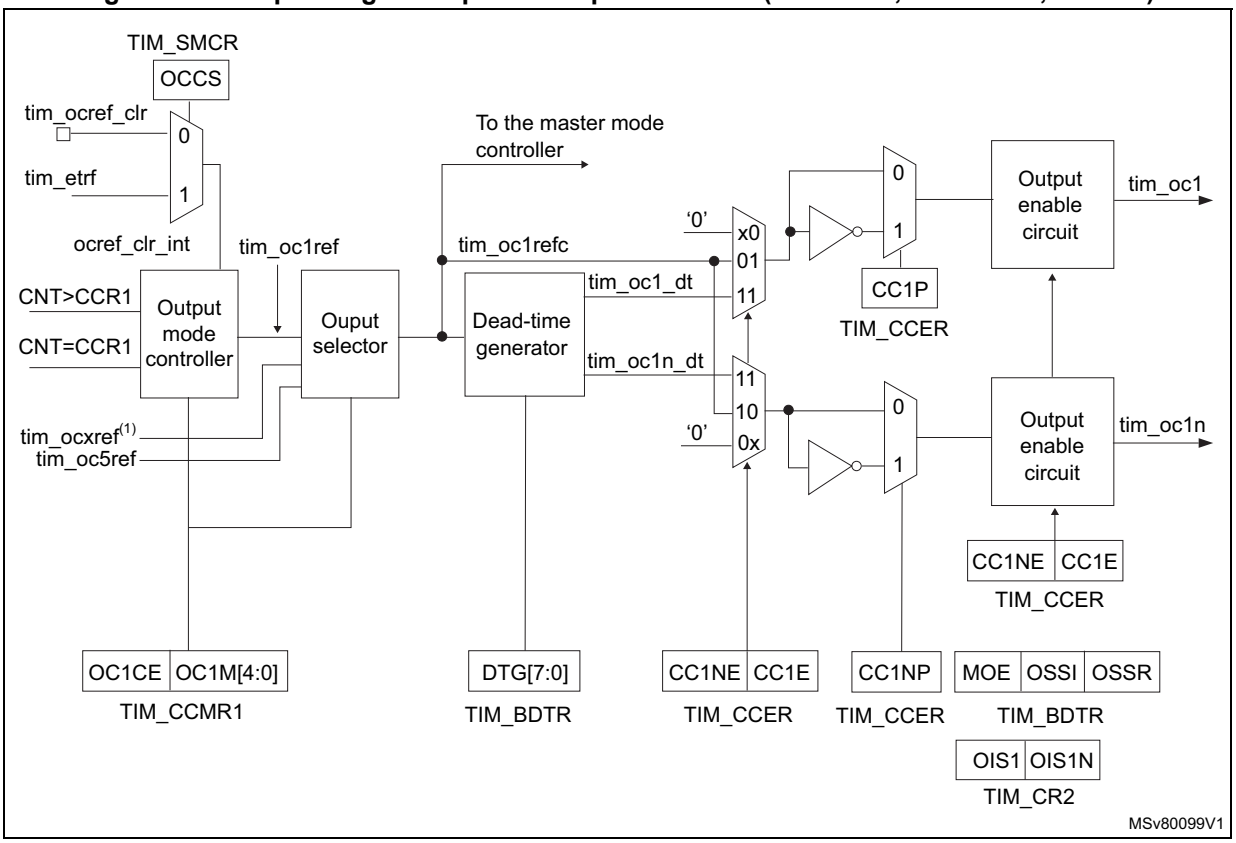
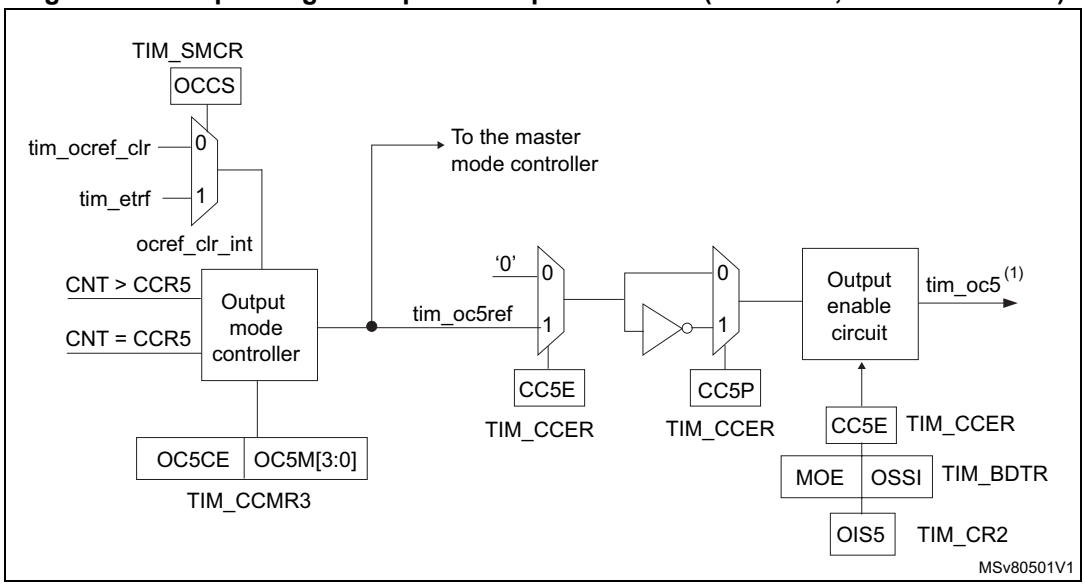


1. tim_ocxref, where x is the rank of the complementary channel

Figure 248. Output stage of capture/compare channel (channel 5, idem ch. 6 and 7)



1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

31.3.9 Input capture mode

In Input capture mode, the capture/compare registers (TIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIM_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIM_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIM_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIM_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

- Select the active input: TIM_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIM_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input, and the TIM_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIM_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at must five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on tim_ti1 when eight consecutive samples with the new level have been detected (sampled at f_{DTS2} frequency). Then write IC1F bits to 0011 in the TIM_CCMR1 register.
- Select the edge of the active transition on the tim_ti1 channel by writing CC1P and CC1NP bits to 0 in the TIM_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIM_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIM_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIM_DIER register, and/or the DMA request by setting the CC1DE bit in the TIM_DIER register.

When an input capture occurs:

- The TIM_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIM_EGR register.

31.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIM_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges.

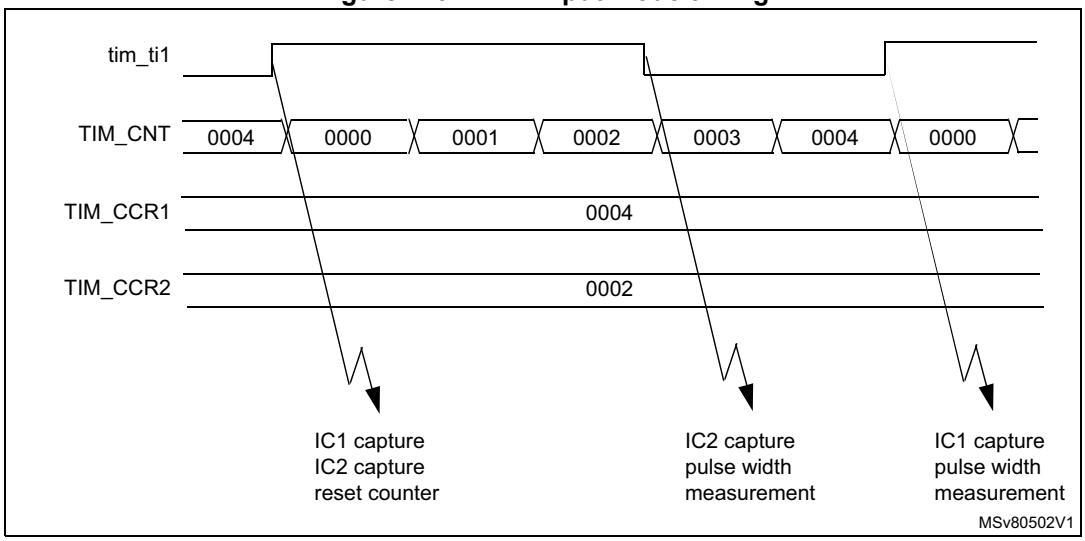
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These two ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_ti1 can be measured using the following procedure:

- Select the active input for TIM_CCR1: write the CC1S bits to 01 in the TIM_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp1 (used both for capture in TIM_CCR1 and counter clear): write the CC1P and CC1NP bits to 0 (active on rising edge).
- Select the active input for TIM_CCR2: write the CC2S bits to 10 in the TIM_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp2 (used for capture in TIM_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP = 10 (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIM_SMCR register (tim_ti1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIM_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to 1 in the TIM_CCER register.

Figure 249. PWM input mode timing



31.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIM_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 00101 in the OCxM bits in the corresponding TIM_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 00100 in the TIM_CCMRx register.

Anyway, the comparison between the TIM_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

31.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 to 7 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIM_CCMRx register) and the output polarity (CCxP bit in the TIM_CCER register). The output pin can keep its level (OCxM = 00000), be set active (OCxM = 00001), be set inactive (OCxM = 00010) or can toggle (OCxM = 00011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIM_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIM_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIM_DIER register, CCDS bit in the TIM_CR2 register for the DMA request selection).

The TIM_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIM_CCMRx register.

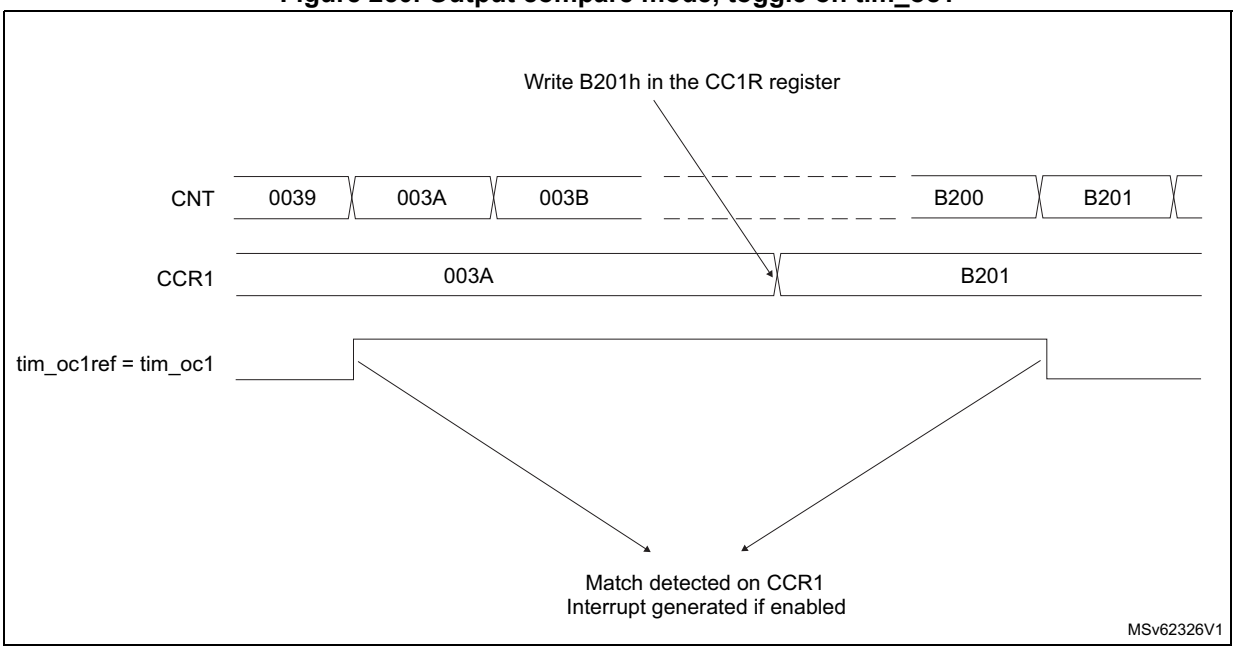
In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIM_ARR and TIM_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 00011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIM_CR1 register.

The TIM_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIM_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 250*.

Figure 250. Output compare mode, toggle on tim_oc1



31.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIM_ARR register and a duty cycle determined by the value of the TIM_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 00110 (PWM mode 1) or 00111 (PWM mode 2) in the OCxM bits in the TIM_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIM_CCMRx register, and eventually the autoreload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIM_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIM_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIM_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI, and OSSR bits (TIM_CCER and TIM_BDTR registers). Refer to the TIM_CCER register description for more details.

In PWM mode (1 or 2), TIM_CNT and TIM_CCRx are always compared to determine whether TIM_CCRx ≤ TIM_CNT or TIM_CNT ≤ TIM_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIM_CR1 register.

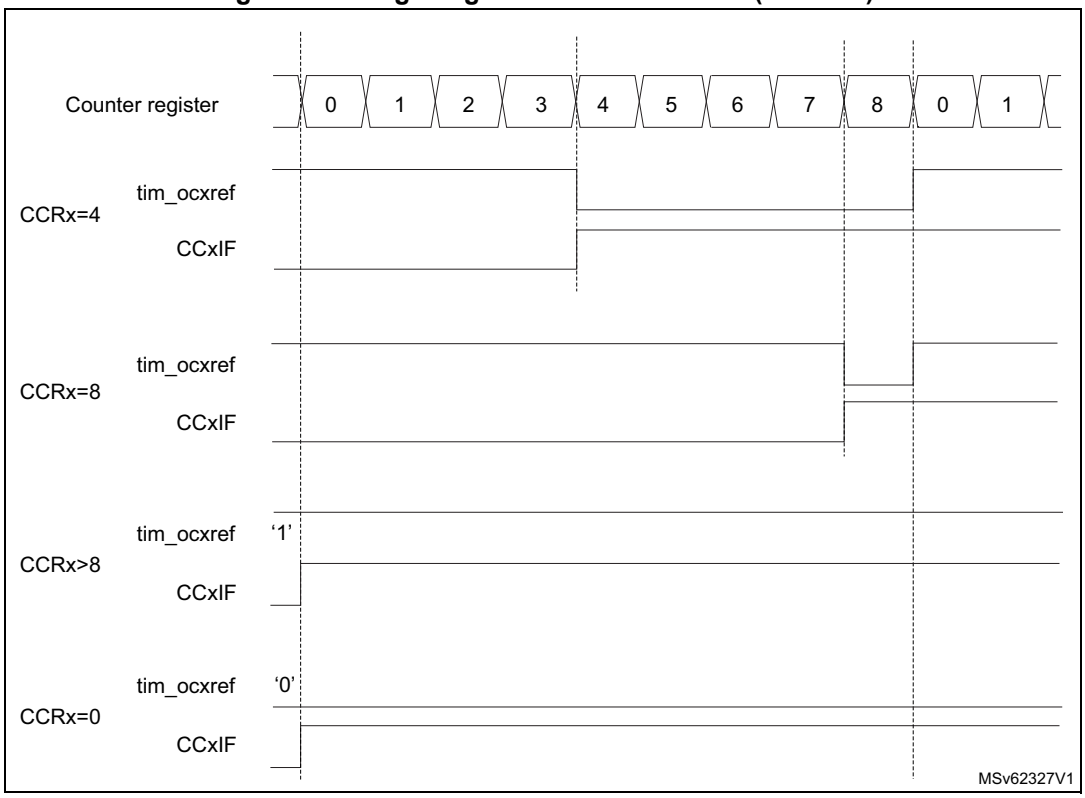
PWM edge-aligned mode

- Upcounting configuration

  Upcounting is active when the DIR bit in the TIM_CR1 register is low. Refer to *Upcounting mode*.

  In the following example, the mode is PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIM_CNT < TIM_CCRx else it becomes low. If the compare value in TIM_CCRx is greater than the autoreload value (in TIM_ARR) then tim_ocxref is held at 1. If the compare value is zero then tim_ocxref is held at 0. *Figure 251* shows some edge-aligned PWM waveforms in an example where TIM_ARR = 8.

Figure 251. Edge-aligned PWM waveforms (ARR = 8)



- Downcounting configuration

  Downcounting is active when DIR bit in TIM_CR1 register is high. Refer to the *Downcounting mode*

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIM_CNT > TIM_CCRx else it becomes high. If the compare value in TIM_CCRx is greater than the autoreload value in TIM_ARR, then tim_ocxref is held at 1. 0% PWM is not possible in this mode.

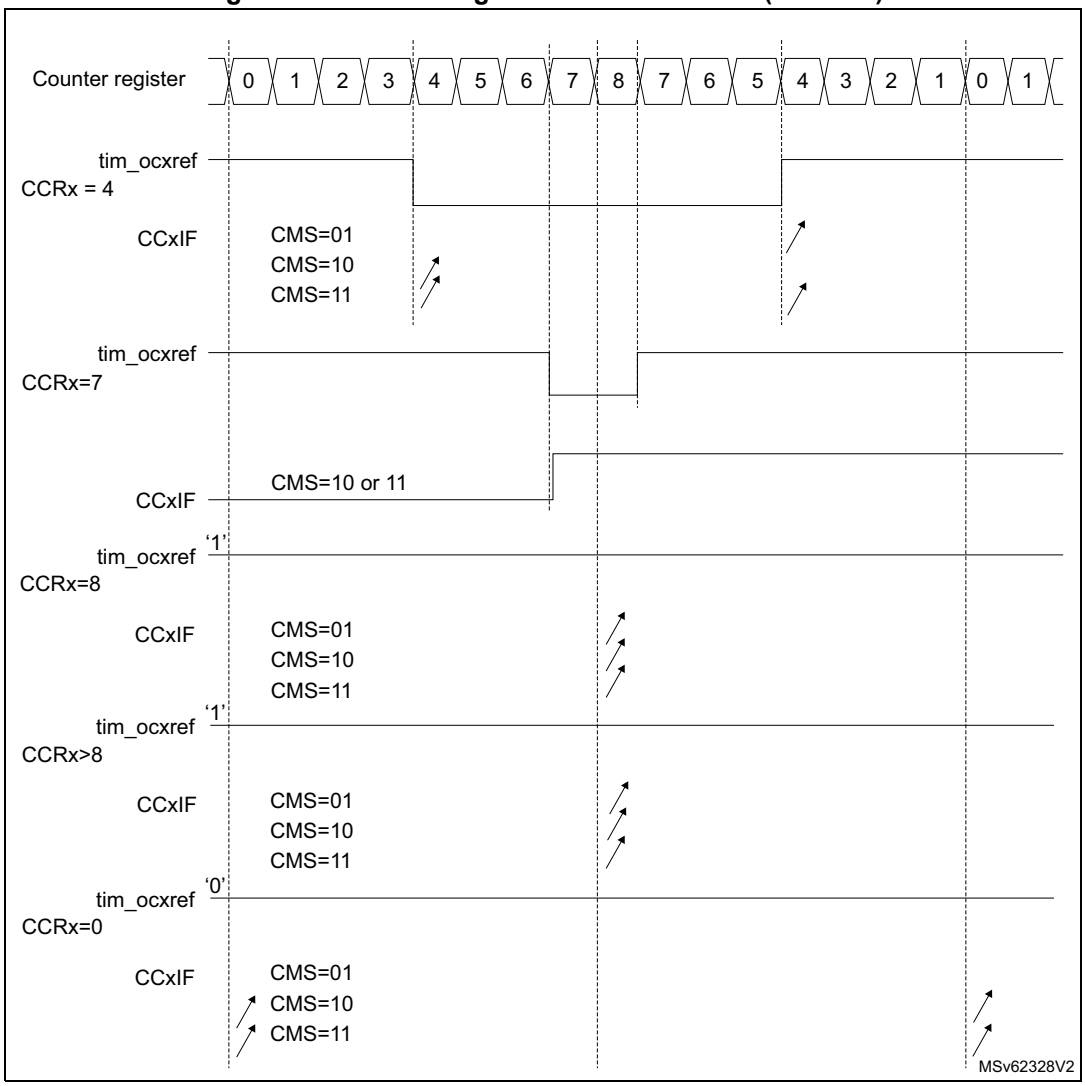
PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIM_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIM_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting)*.

Figure 252 shows some center-aligned PWM waveforms in an example where:

- TIM_ARR = 8
- PWM mode is the PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIM_CR1 register.

Figure 252. Center-aligned PWM waveforms (ARR = 8)



Hints on using center-aligned mode:

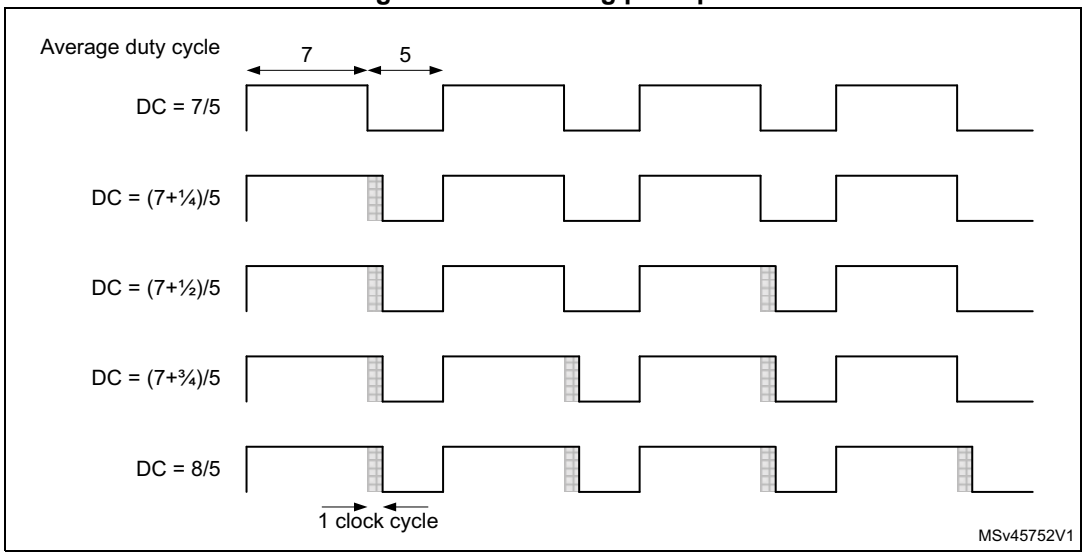
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIM_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the autoreload value is written in the counter (TIM_CNT > TIM_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIM_ARR value is written in the counter but no update event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIM_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIM_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. *Figure 253* presents the dithering principle applied to four consecutive PWM cycles.

Figure 253. Dithering principle



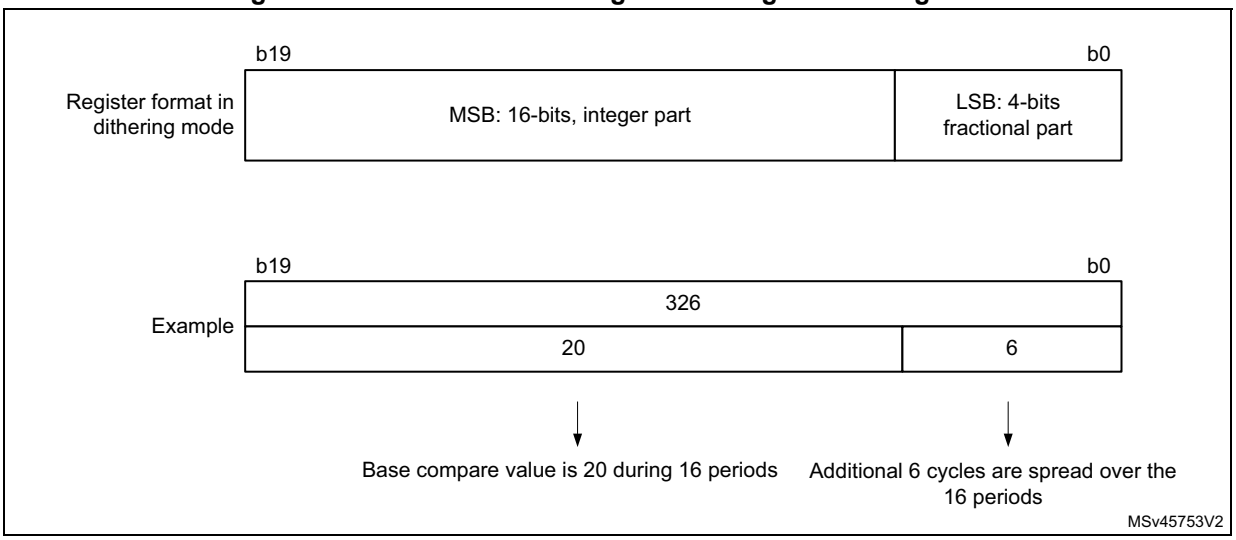
When the dithering mode is enabled, the register coding is changed as follows (see *Figure 254* for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

Note: The following sequence must be followed when resetting the DITHEN bit:

1. *CEN and ARPE bits must be reset.*
2. *The DITHEN bit must be reset.*
3. *The CCIF flags must be cleared.*
4. *The CEN bit can be set (eventually with ARPE = 1).*

Figure 254. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

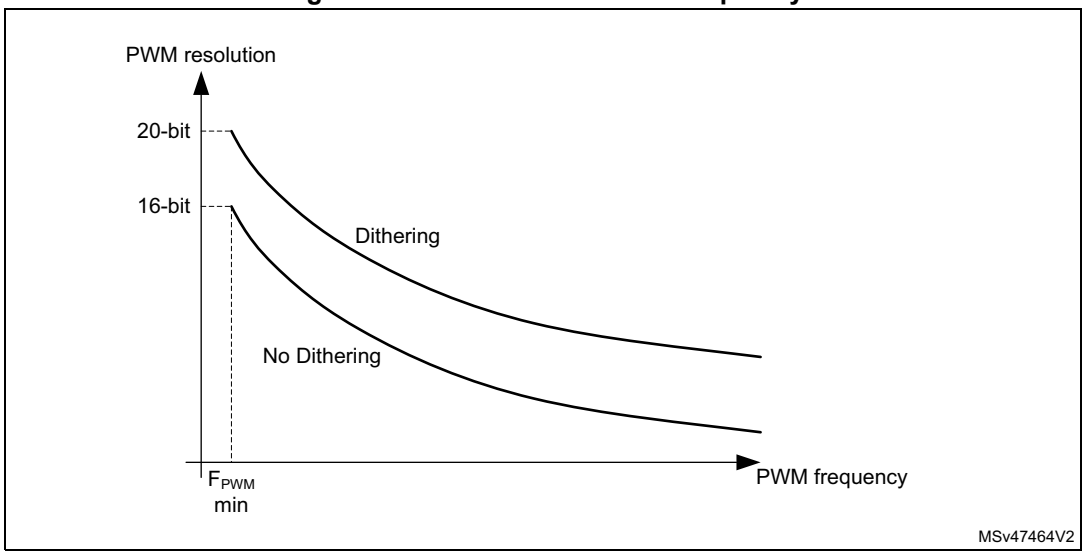
$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIM_ARR and TIM_CCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

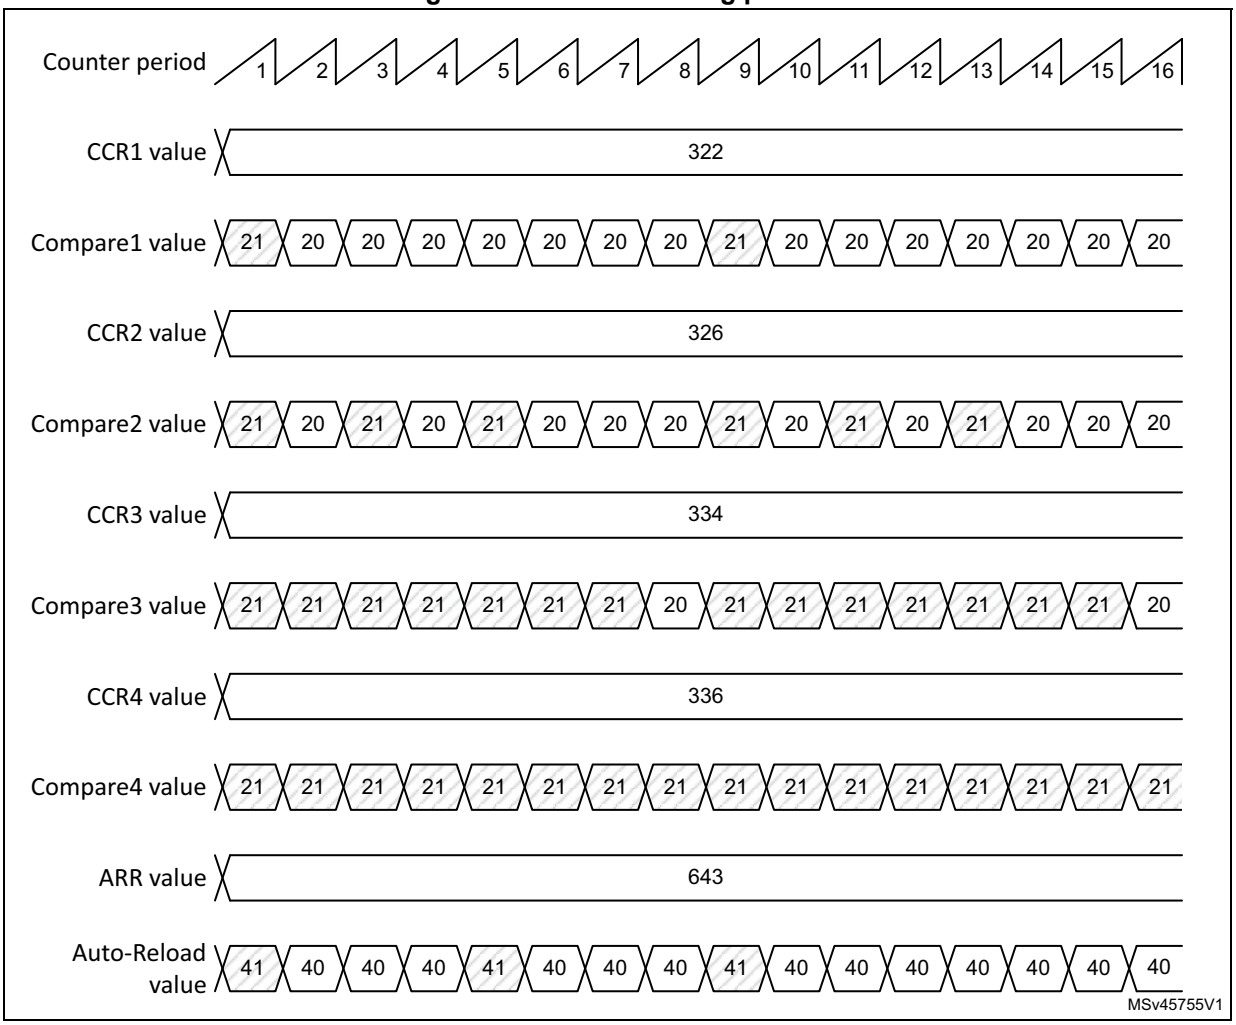
As shown on *Figure 255*, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 255. PWM resolution vs frequency



The duty cycle and/or period changes are spread over 16 consecutive periods, as described in *Figure 256*.

Figure 256. PWM dithering pattern



The autoreload and compare values increments are spread following specific patterns described in *Table 293*. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 293. CCR and ARR register change dithering pattern

LSB value	PWM period															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16

1111	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	-

The dithering mode is also available in center-aligned PWM mode (CMS bits in TIM_CR1 register are not equal to 00). In this case, the dithering pattern is applied over eight consecutive PWM periods, considering the up and down counting phases as shown in *Figure 257*.

Figure 257. Dithering effect on duty cycle in center-aligned PWM mode

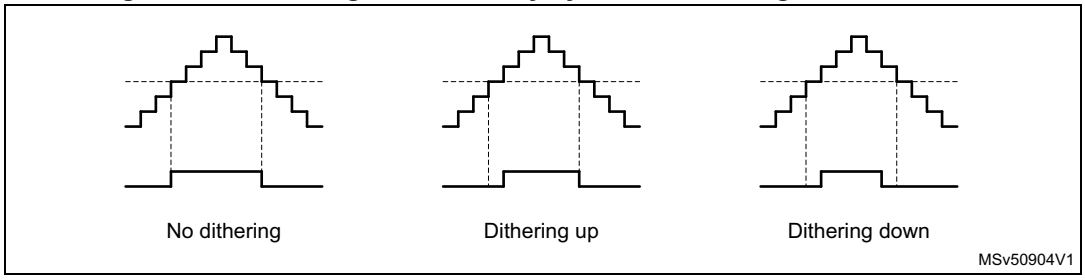

Table 294 shows how the dithering pattern is added in center-aligned PWM mode.

Table 294. CCR register change dithering pattern in center-aligned PWM mode

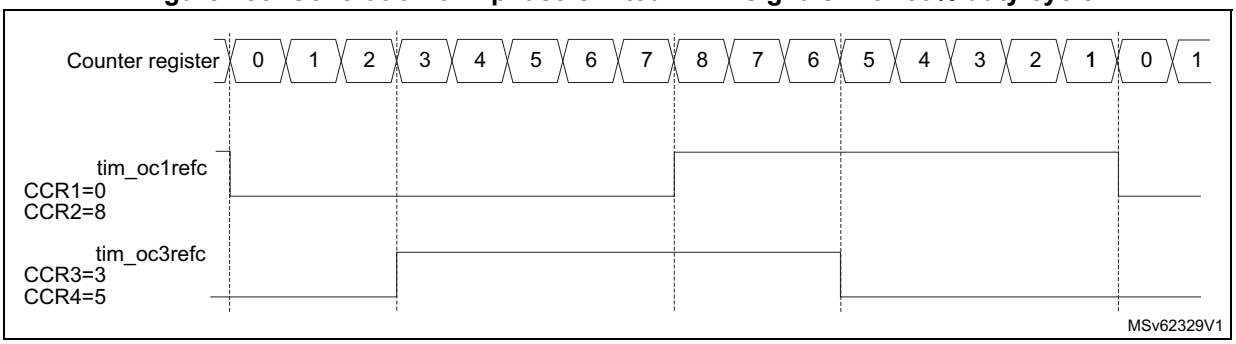
31.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and the phase-shift are determined by a pair of TIM_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle, for instance:

- tim_oc1refc is controlled by TIM_CCR1 and TIM_CCR2
- tim_oc3refc is controlled by TIM_CCR3 and TIM_CCR4
- ...

Figure 258 represents an example of signals that can be generated using asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

Figure 258. Generation of 2 phase-shifted PWM signals with 50% duty cycle



Multiple asymmetric PWM modes are available to combine different pairs of TIM_CCRx registers and generate the required waveform, as listed in *Table 295*. The selection is done

with the OCxM[4:0] bitfield in TIM_CCMRx registers. For each pair of TIM_CCRx registers, two options are given (e.g. Asymmetric PWM mode 3 and 4), one being in PWM mode 1 (channel active as long as the counter is below the TIM_CCRx value), the other one in PWM mode 2 (channel active when the counter is above the TIM_CCRx value).

For the asymmetric PWM modes 1 to 6, it is mandatory to have the same PWM mode for both channels. For instance, it is mandatory to have OC1M[4:0] = OC2M[4:0] = 00110 for the asymmetric PWM mode 1 on oc1refc.

For the asymmetric PWM modes 7 to 10, it is mandatory to have opposite PWM mode for both channels (one being in PWM mode 1 and the other in PWM mode 2). Refer to the *Table 295* for configuration.

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the regular tim_oc2ref signal on channel 2 or a tim_oc2refc signal resulting from asymmetric PWM mode 1.

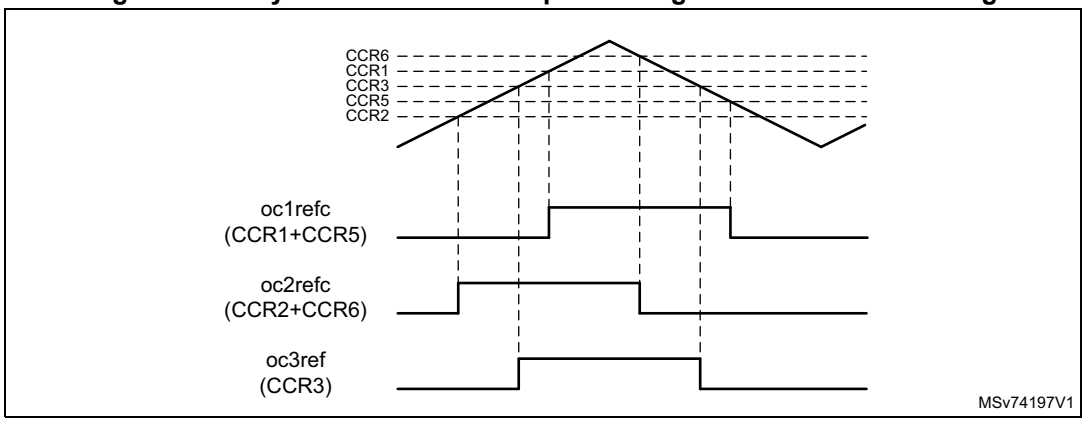
1. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value). PWM mode 2: channel active when the counter is above the TIM_CCRx value. Unless explicitly mentioned, the PWM mode must be identical for the 2 channels used for the asymmetric mode
2. oc5ref, oc6ref, oc4ref and oc7ref must be programmed in PWM mode 2
3. oc5ref, oc6ref, oc4ref and oc7ref must be programmed in PWM mode 1

The *Figure 259* represents an example suitable for single-shunt current sensing techniques requiring phase-shifted PWMs, for 3-phase motor control. This is done using asymmetric PWM mode 3 and 5:

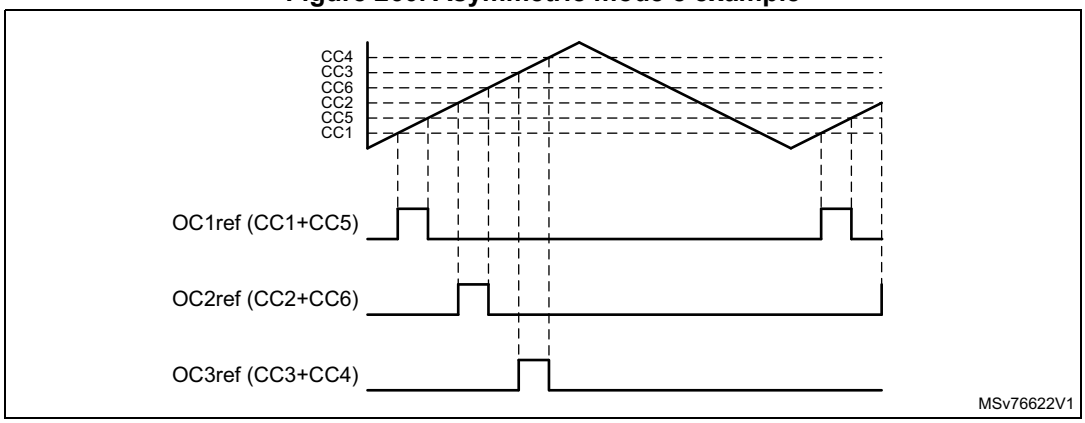
- Channel 1 is configured in asymmetric PWM mode 4
- Channel 2 is configured in asymmetric PWM mode 5
- Channel 3 is configured in regular PWM mode 2
- Compare 4 and 7 are available for ADC triggering purpose

Figure 259. Asymmetric mode example for single-shunt current sensing



The *Figure 260* represents an example of the waveforms that can be generated with asymmetric modes 7 to 10.

Figure 260. Asymmetric mode 8 example



31.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and delay are determined by the two TIM_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs, as summarized in the below:

Table 296. Combined PWM mode overview

Output compare mode	OCxM[4:0]	oc1refc	oc2refc	oc3refc	oc4refc	oc5refc	oc6refc	oc7refc	PWM mode(1)
Combined PWM mode 1	01100	oc1ref OR oc2ref		oc3ref OR oc4ref		oc5ref OR oc6ref		-	1
Combined PWM mode 2	01101	oc1ref AND oc2ref		oc3ref AND oc4ref		oc5ref AND oc6ref		-	2
Combined PWM mode 3	10000	oc1ref OR oc5ref	oc2ref OR oc6ref	oc3ref OR oc5ref	oc4ref OR oc6ref	-	-	-	1
Combined PWM mode 4	10001	oc1ref AND oc5ref	oc2ref AND oc6ref	oc3ref AND oc5ref	oc4ref AND oc6ref	-	-	-	2

1. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value). PWM mode 2: channel active when the counter is above the TIM_CCRx value.

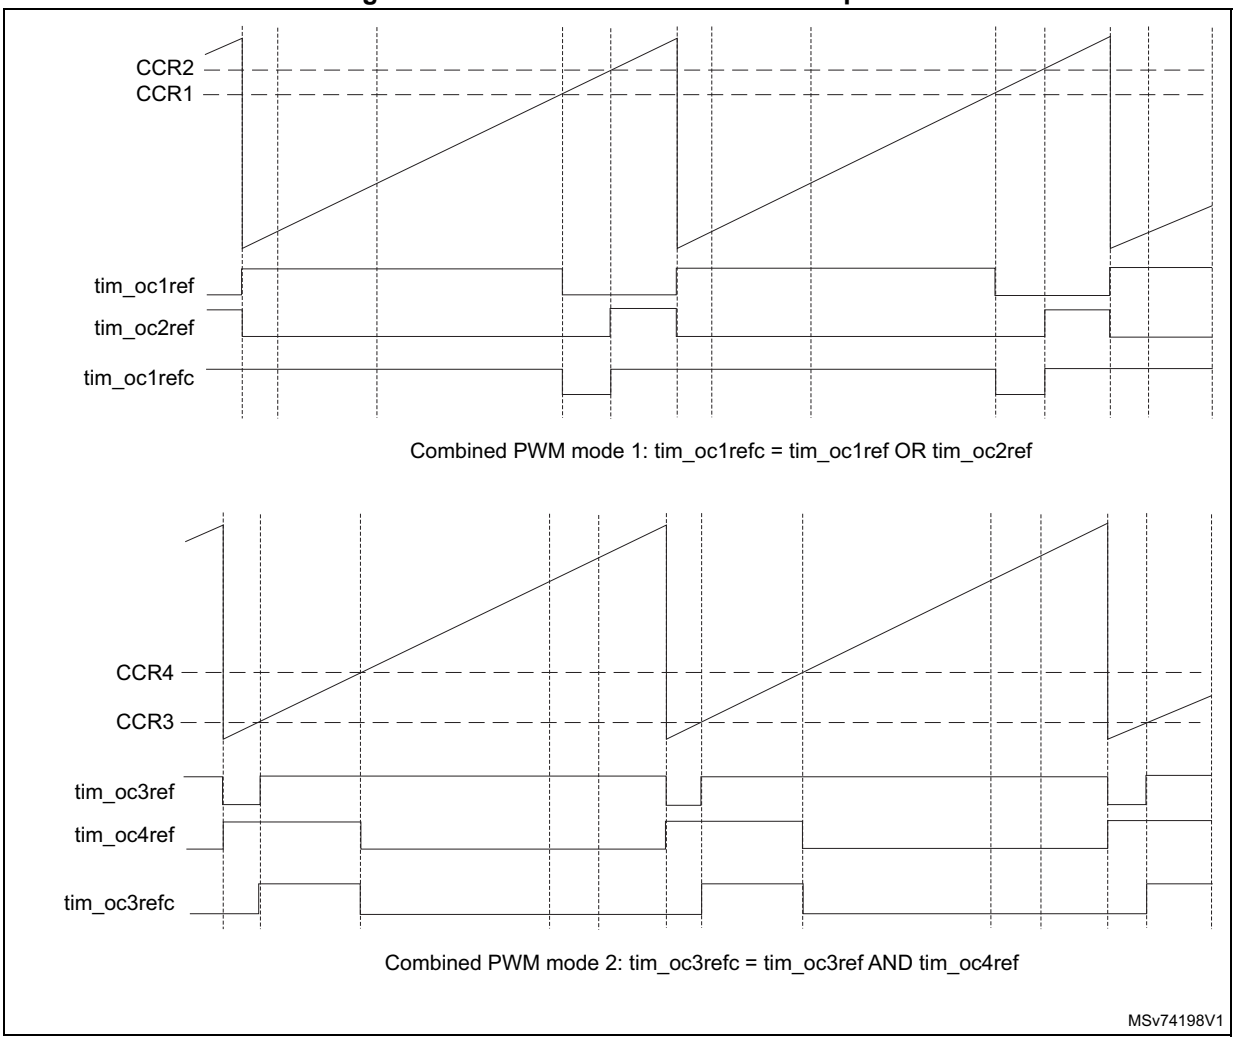
When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in PWM mode 1 and the other in PWM mode 2).

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

Figure 261 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
- Channel 3 is configured in Combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.

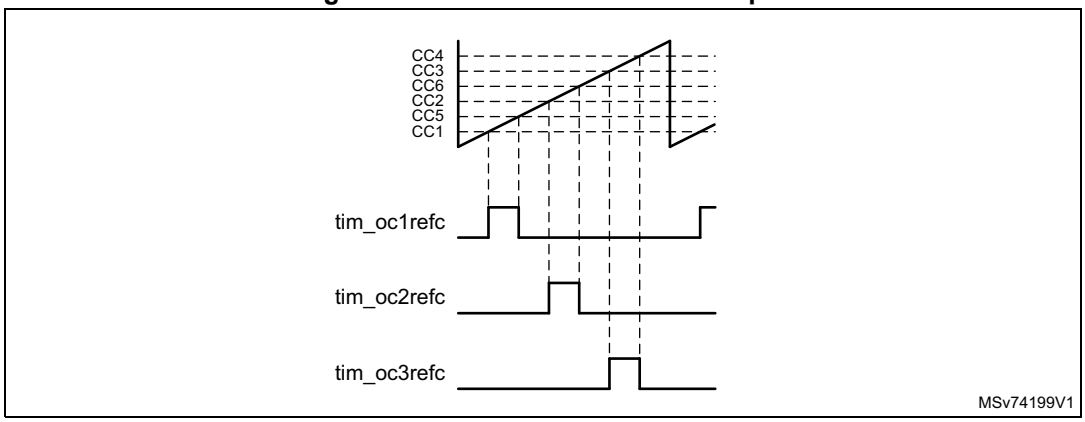
Figure 261. Combined PWM mode examples



The *Figure 262* represents an example suitable for a 3-phase interleaved converter requiring independent control of duty cycle and phase-shift. This is done using Combined PWM mode 2 and 4:

- Channel 1 is configured in Combined PWM mode 4
- Channel 2 is configured in Combined PWM mode 4
- Channel 3 is configured in Combined PWM mode 2

Figure 262. Combined PWM 3 example



31.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal.

The 4 bits GC5C[4:1] in the TIM_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is the logical AND of tim_oc1ref and tim_oc5ref
- If GC5C2 is set, tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref
- If GC5C3 is set, tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref
- If GC5C4 is set, tim_oc4refc is the logical AND of tim_oc4ref and tim_oc5ref

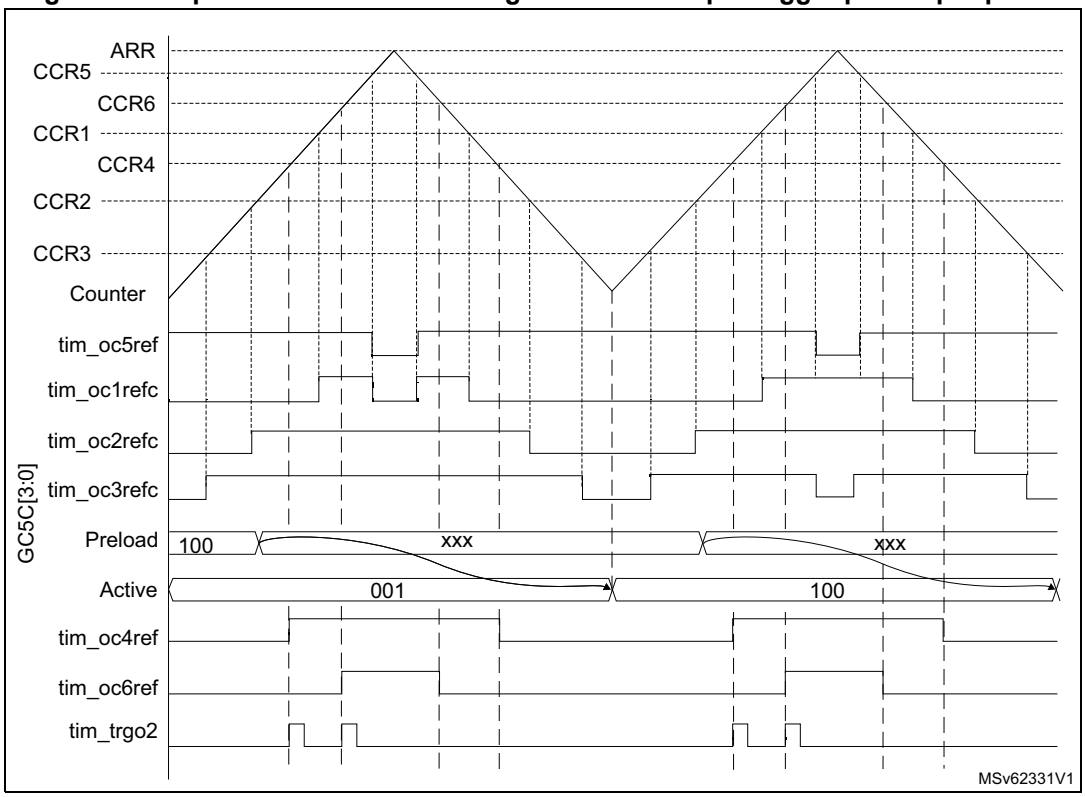
It is possible also to select an OR fonction with GC5C1O, GC5C2O, GC5C3O and GC5C4O bits, as following:

- If GC5C1O is set, tim_oc1refc is the logical OR of tim_oc1ref and tim_oc5ref
- If GC5C2O is set, tim_oc2refc is the logical OR of tim_oc2ref and tim_oc5ref
- If GC5C3O is set, tim_oc3refc is the logical OR of tim_oc3ref and tim_oc5ref
- If GC5C4O is set, tim_oc4refc is the logical OR of tim_oc4ref and tim_oc5ref

If both GC5Cx and GC5CxO bits are set, GC5Cx bit overrides GC5CxO programming and tim_ocxrefc is equal to tim_ocxref AND tim_oc5ref.

Combined 3-phase PWM mode can be selected independently on channels 1 to 4 by setting at least one of the bits GC5C[4:1] or GC5CO[4:1].

Figure 263. 3-phase combined PWM signals with multiple trigger pulses per period



The tim_trgo2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to *Section 31.3.36: ADC triggers* for more details.

31.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (such as intrinsic delays of level-shifters, or delays due to power switches).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIM_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIM_CCER register and the MOE, OISx, OISxN, OSSI, and OSSR bits in the TIM_BDTR and TIM_CR2 registers. Refer to *Table 304: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature* for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a

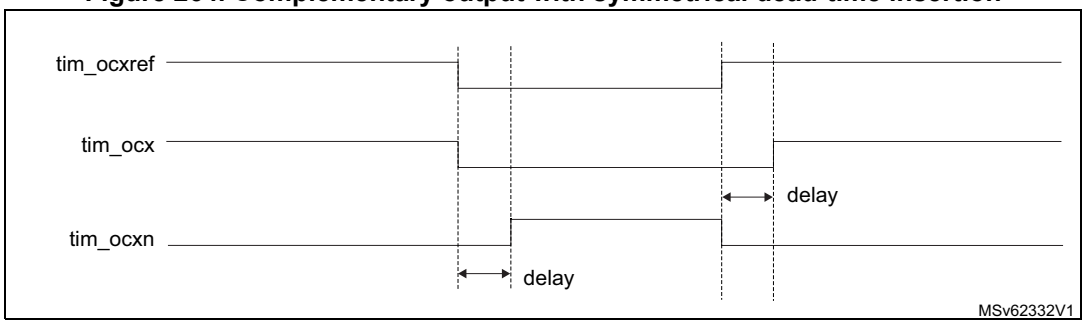
reference waveform tim_ocxref, it generates two outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref considering CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1 in these examples.

Figure 264. Complementary output with symmetrical dead-time insertion



The DTAE bit in the TIM_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on *Figure 265*.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIM_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIM_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIM_DTR2 register. The preload value is loaded in the active register on the next update event.

Note: If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.

Figure 265. Asymmetrical deadtime

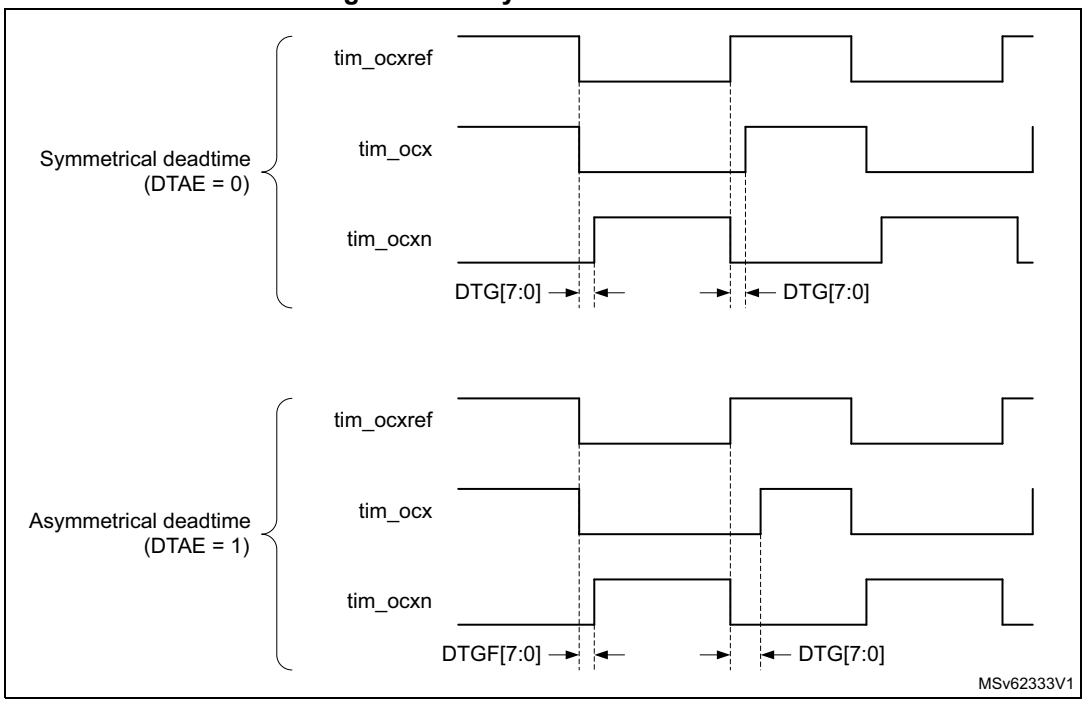


Figure 266. Dead-time waveforms with delay greater than the negative pulse

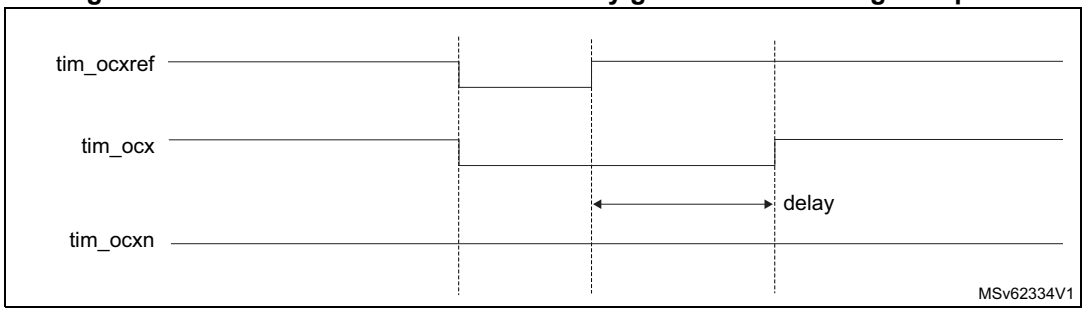

Figure 267. Dead-time waveforms with delay greater than the positive pulse

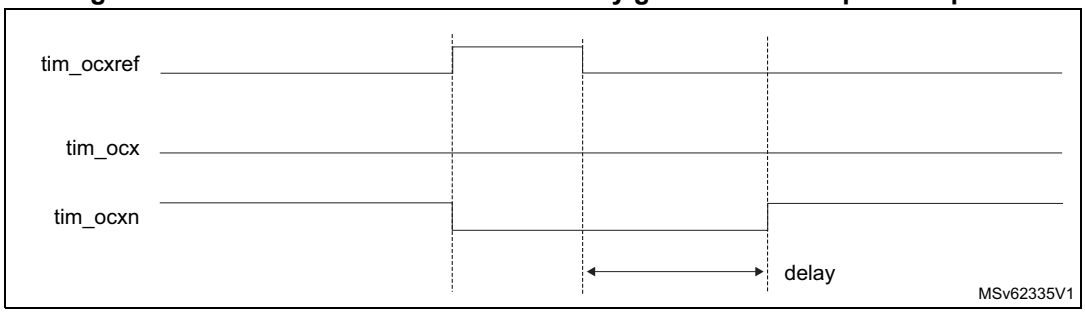


The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIM_BDTR register. Refer to *Section 31.6.20: TIM break and dead-time register (TIM_BDTR)* for delay calculation.

Redirecting tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be redirected to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIM_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

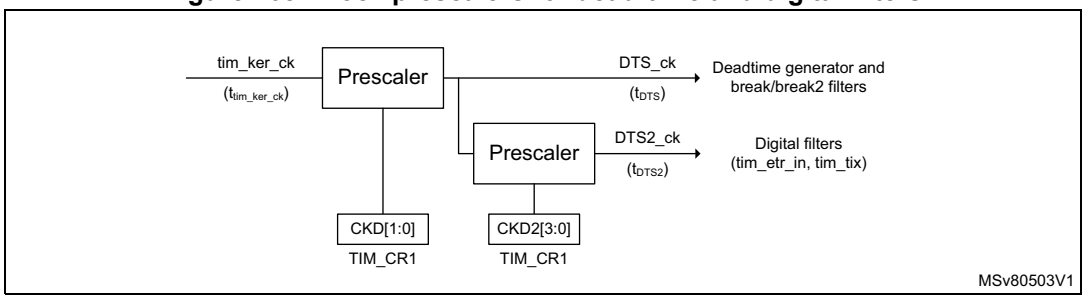
Note: When only tim_ocxn is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP = 0 then tim_ocxn = tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE = CCxNE = 1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

31.3.18 Clock dividers for dead-time generators and digital filters

The dead-time generators and the digital filters (for tim_etr_in, tim_tix) are using a DTS_ck clock (with a t_{DTS} period), derived from the tim_ker_ck clock.

A prescaler can decrease the frequency to extend the deadtime period programmed with the CKD[1:0] bitfield in the TIM_CR1 register. A second prescaler can decrease the resulting DTS_ck clock to extend solely the digital filters range, with the CKD2[3:0] bitfield in the TIM_CR1 register.

Figure 268. Clock prescalers for dead-time and digital filters



31.3.19 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC/parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- The MOE bit in TIM_BDTR register is used to enable/disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIM_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- The OISx and OISxN bits in the TIM_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to *Table 304: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature* for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIM_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of one APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait one APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIM_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)
  - coming from a system break request (refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)

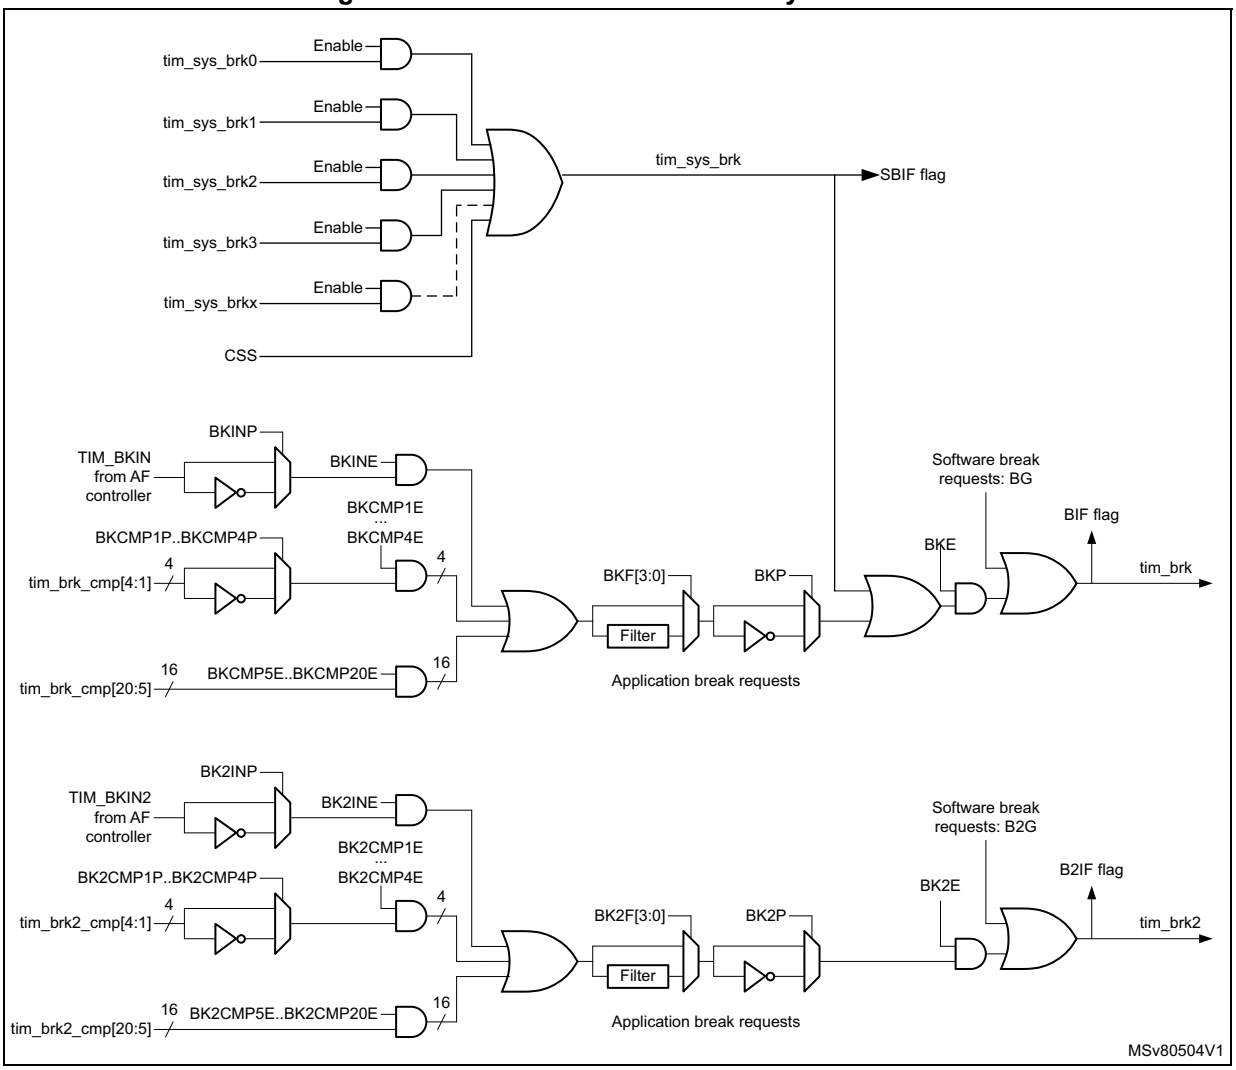
The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIM_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIM_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per *Figure 269* below.

Figure 269. Break and Break2 circuitry overview



Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state, or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIM_CR2 register as soon as MOE = 0. If OSSI = 0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to

their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

  - If OSSI = 0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flags (B2GF, BGF, SBIF, BIF, and B2IF bits in the TIM_SR register) are set. An interrupt is generated if the BIE bit in the TIM_DIER register is set.
- An output disable status flag (ODS in the TIM_SR register) indicates the status of the outputs:
  - ODS = 0: Idle state. Break was triggered (or MOE was written to 0) and OIS states are forced on tim_ocx and tim_ocxn outputs
  - ODS = 1: Disabled state. Break2 was triggered, tim_ocx and tim_ocxn outputs are inactive
- If the AOE bit in the TIM_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors, or any security components.

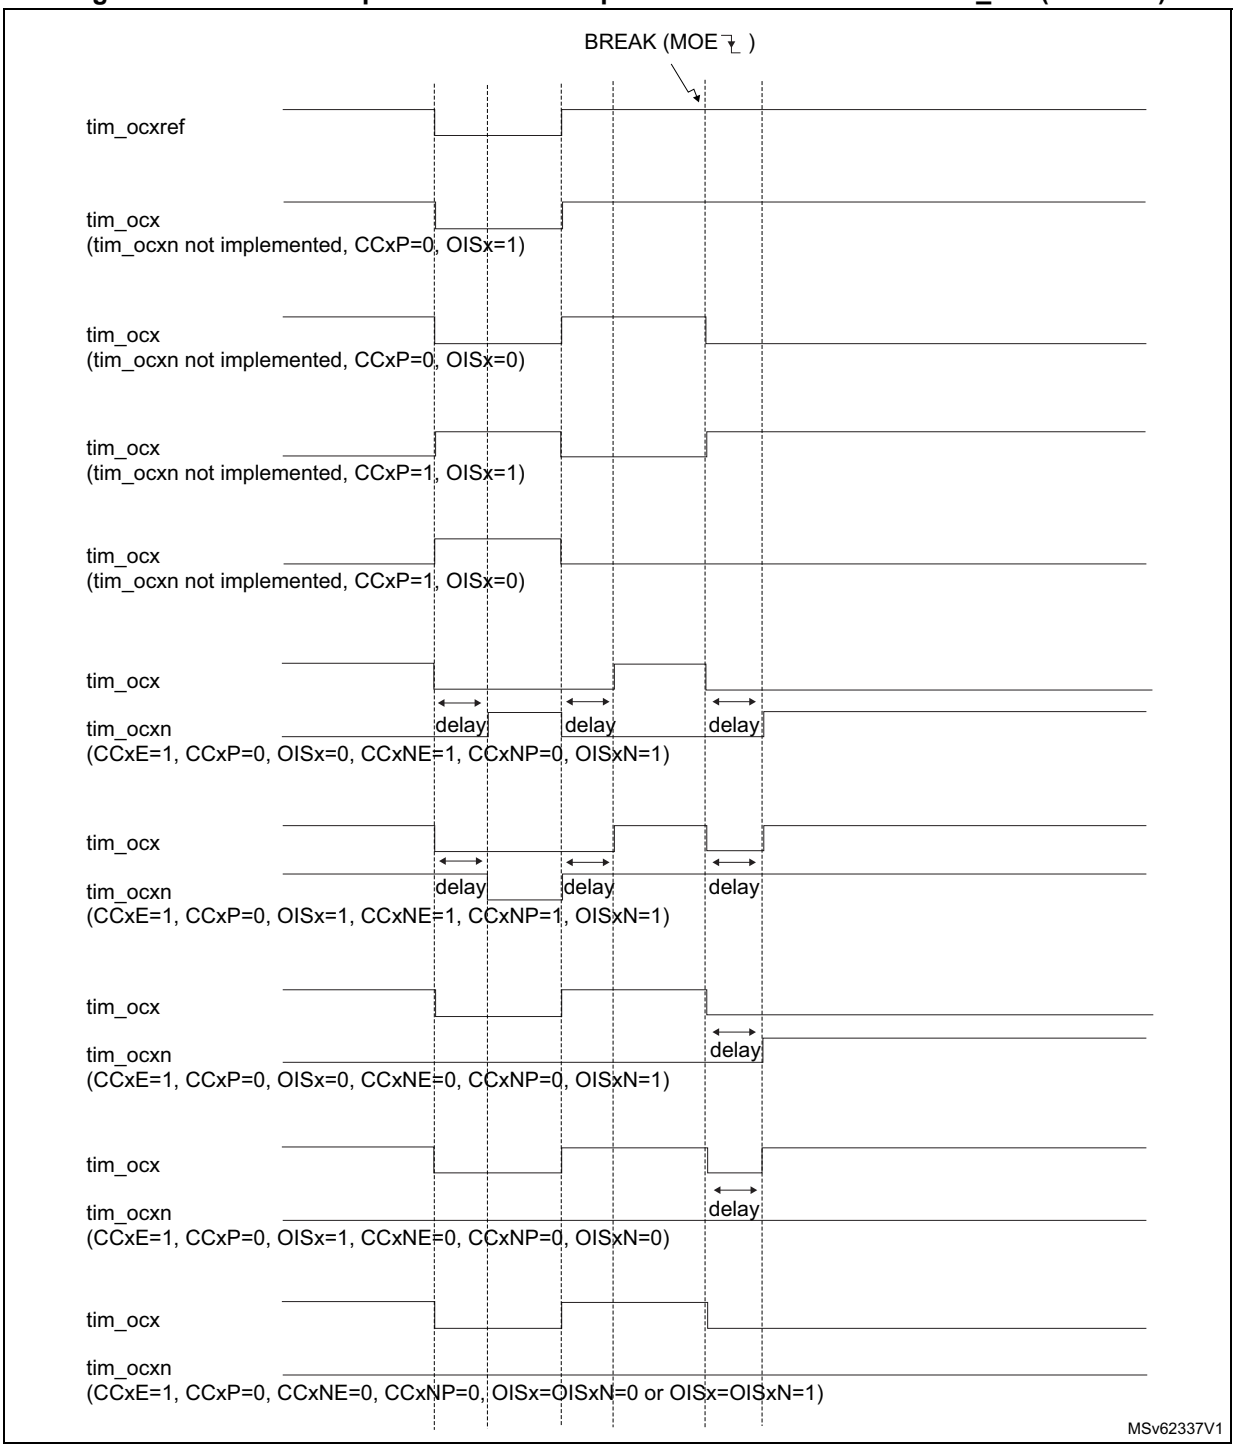
Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIM_CR2 register.

The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable, and polarity). The application can choose from three levels of protection selected by the LOCK bits in the TIM_BDTR register. Refer to *Section 31.6.20: TIM break and dead-time register (TIM_BDTR)*. The LOCK bits can be written only once after an MCU reset.

Figure 270 shows an example of behavior of the outputs in response to a break.

Figure 270. Various output behavior in response to a break event on tim_brk (OSSI = 1)



The two break inputs have different behaviors on timer outputs:

- The tim_brk input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- tim_brk2 can only disable (inactive state) the PWM outputs.

The tim_brk has a higher priority than tim_brk2 input, as described in *Table 297*.

The output disable status flag (ODS in the TIM_SR register) indicates the status of the outputs after a break event and is useful to distinguish break and break2 safe states.

Note: tim_brk2 must only be used with OSSR = OSSI = 1.

Table 297. Behavior of timer outputs versus tim_brk/tim_brk2 inputs

tim_brk	tim_brk2	Timer outputs state	Typical use case	
			tim_ocxn output (low side switches)	tim_ocx output (high side switches)
Active	X	– Inactive then forced output state (after a deadtime) – Outputs disabled if OSSI = 0 (control taken over by GPIO logic)	ON after deadtime insertion	OFF
Inactive	Active	Inactive	OFF	OFF

Figure 271 gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIM_CCER register).

Figure 271. PWM output state following tim_brk and tim_brk2 assertion (OSSI = 1)

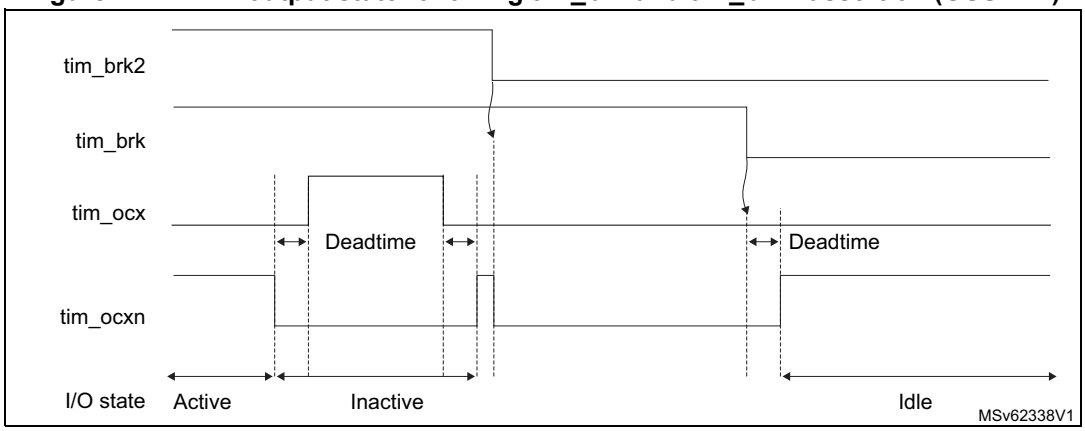


Figure 272. PWM output state following tim_brk assertion (OSSI = 0)

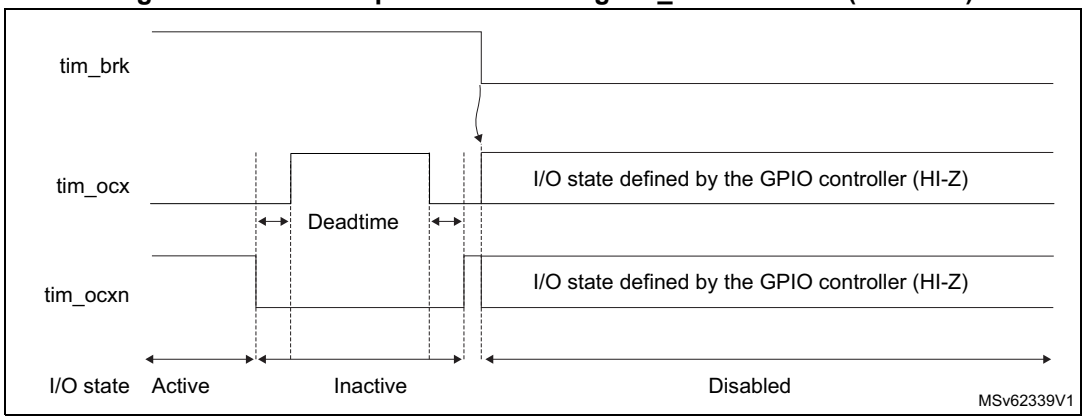


31.3.20 Delayed break

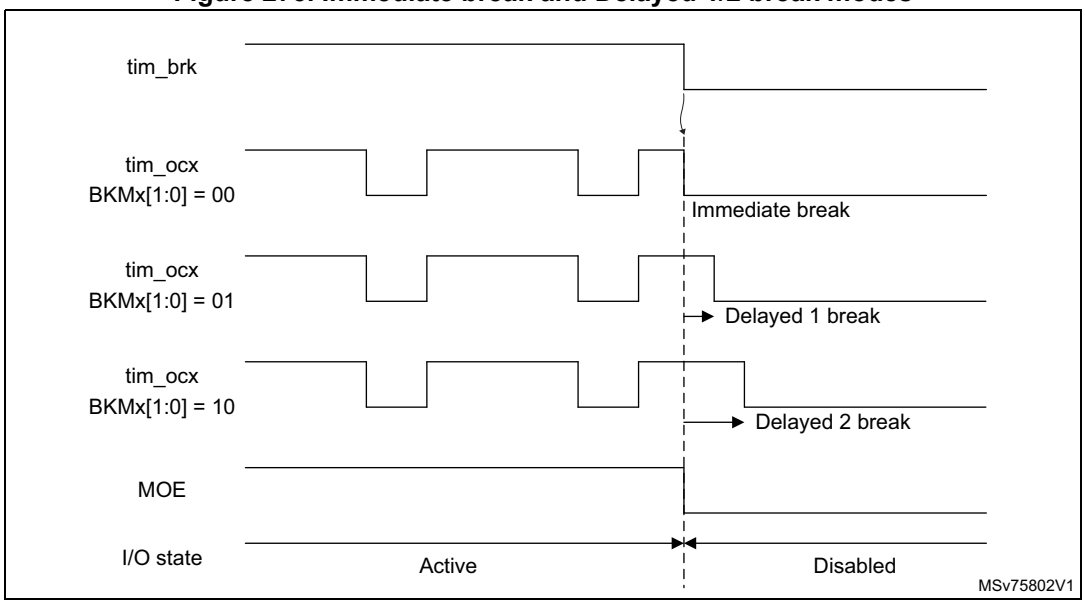
In Neutral-Point Clamped (NPC) multilevel converter topology, a break strategy with immediate outputs shut-down is not suitable, as it may damage the power switches with excessive voltage levels.

The delayed break features provide 2 options delaying the response to a break event, and implement a safe shut-down sequence.

BKMx[1:0] and BKMxN[1:0] bitfields in TIM_MPR1 provides 3 options for each complementary outputs (tim_oc1/tim_oc1n to tim_oc4/tim_oc4n), as show on *Figure 273* below:

- BKM[1:0] = 00: the break response is immediate
- BKM[1:0] = 01: Delayed 1 break. The break response is delayed with a delay defined in the DBK1[7:0] bitfield of the TIM_MPR2 register
- BKM[1:0] = 10: Delayed 2 break. The break response is delayed with a delay defined in the DBK2[7:0] bitfield of the TIM_MPR2 register

Figure 273. Immediate break and Delayed 1/2 break modes



The delayed break mode is triggered when:

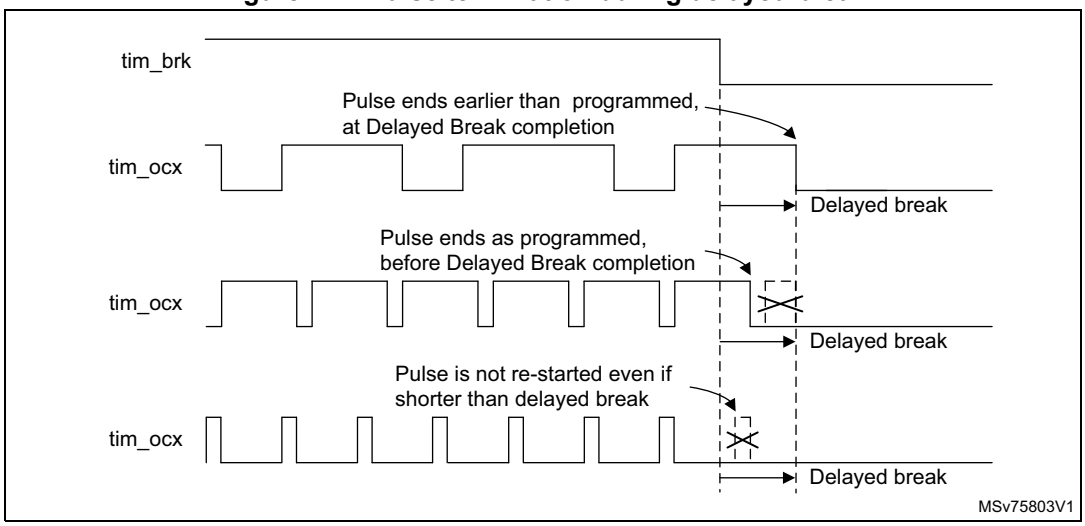
- A break event occurs
- The MOE bit is reset
- When the microcontroller enters debug mode with DBG_TIM_STOP=1

Warning: The break2 feature must be disabled when the delayed mode is enabled.

When delayed break mode is triggered, the MOE bit is immediately cleared, and cannot be set during the delayed break duration. In bidirectional break mode, the break output is reset immediately to indicate the delayed break start to external components. Once the longest of the 2 delays is over, the deadtime generator is enabled to prevent any deadtime violation if OISx/OISxN bits are set.

If the tim_ocx/tim_ocxn signal is reset before the end of the delayed break (due to a compare match in PWM mode, typically), the signal is not maintained during the full delayed break period, to maintain the duty cycle, as shown on *Figure 274* below. Still, the Delayed break circuitry guarantees that the tim_ocx/tim_ocxn signals cannot be set again once the break event occurred.

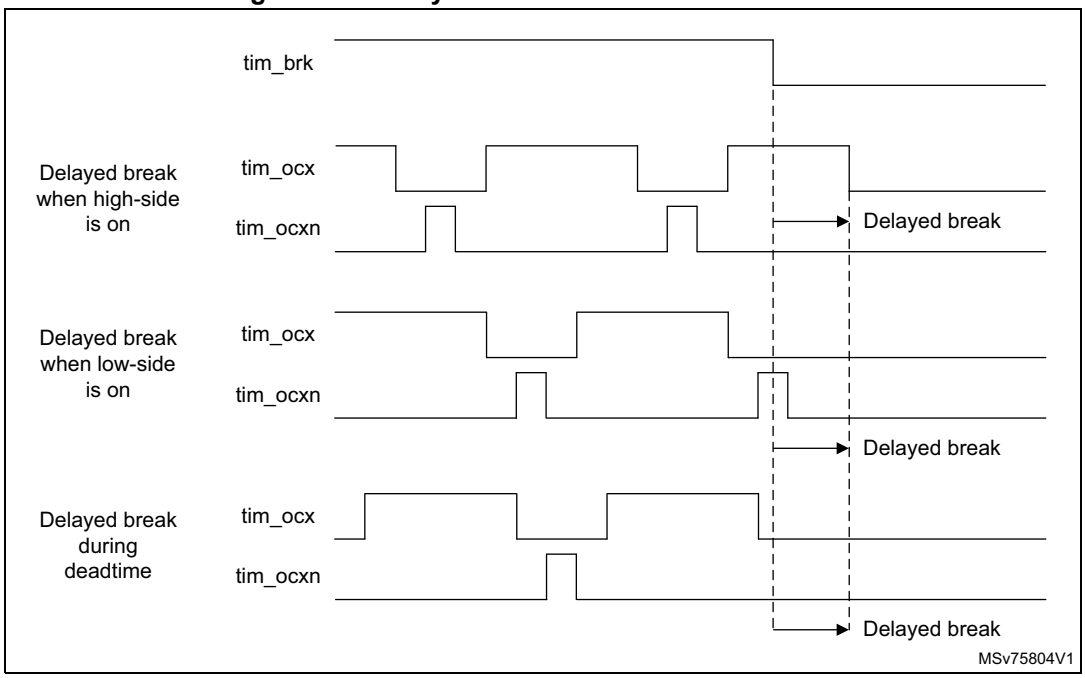
Figure 274. Pulse termination during delayed break



The Figure 563 depicts the behavior when the deadtime generator is enabled, for the 3 cases:

– Delayed break triggered when tim_ocx is set
– Delayed break triggered when tim_ocxn is set
– Delayed break triggered during deadtime interval

Figure 275. Delayed break with deadtime insertion



The delay programming is identical to deadtime generator's, with 2 user-programmable durations in the TIM_MPR2 register: DBK1[7:0] bitfield for the Delayed 1 break and DBK2[7:0] bitfield for the Delayed 2 break.

DBK1[7:0] and DBK2[7:0] bitfields are preloaded: they can be changed during timer operation, and the new value is transferred to the active register when an update event occurs.

DBK1[7:0] and DBK2[7:0] bitfields are partially preloaded: they can be changed during timer operation, and the new value is transferred to the active register when an update event occurs.

The bits coding for t_{DTG} selection are not preloaded.

It is thus recommended to update only the least significant bits to have the expected duration value:

- DBKx[6:0] if DBKx[7] = 0
- DBKx[5:0] if DBKx[7:6] = 10
- DBKx[4:0] if DBKx[7:5] = 110 or 111

The BKMx[1:0] and BKMxN[1:0] bits are static, they can only be modified when the counter is stopped (CEN=0 in TIM_CR1).

The content of the TIM_MPR1 and TIM_MPR2 register can be write protected using the LOCK[1:0] bits in the TIM_BDTR register.

31.3.21 Bidirectional break inputs

The TIM1/TIM8 feature bidirectional break I/Os, as represented on *Figure 276*.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIM_BDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIM_BDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals, or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to 0 to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN and TIM_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be restarted as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see *Table 298*).

Table 298. Break protection disarming conditions

MOE	BKBID (BK2BID)	BKDSRM (BK2DSRM)	Break protection state
0	0	X	Armed
0	1	0	Armed
0	1	1	Disarmed
1	X	X	Armed

Arming and rearming break circuitry

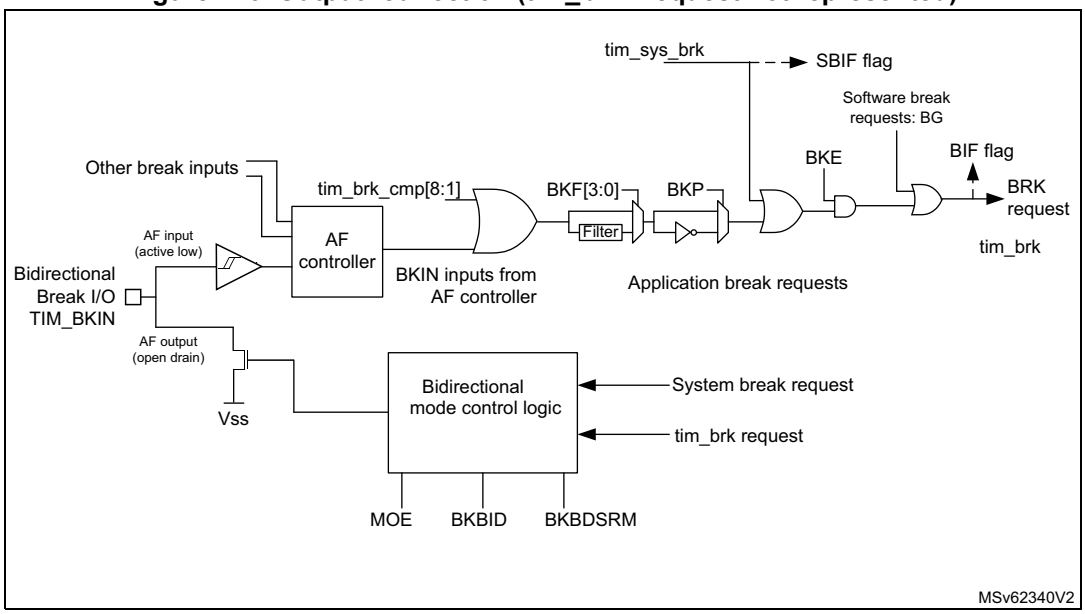
The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control.
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before rearming).
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears).

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

Figure 276. Output redirection (tim_brk2 request not represented)



31.3.22 Output idle state override

It is possible to override the outputs states when they are disabled (ie MOE bit reset in TIM_BDTR). This feature can be used to apply specific patterns prior to start PWM operations, for instance to refresh bootstrap capacitors of power switch gate drivers.

The OOC control bit in the TIM_OOR register acts as following:

- OOC= 0: 0: tim_ocx and tim_ocxn outputs are in the default idle state
- OOC=1: tim_ocx and tim_ocxn outputs are forced in an idle state defined with OOSx/OOSxN bits in the TIM_OOR register

The OOC bit can only be modified when the outputs are in idle state (MOE = 0). It is cleared by hardware when the MOE bit is set, and the deadtime generator ensures there's no deadtime violation on complementary outputs.

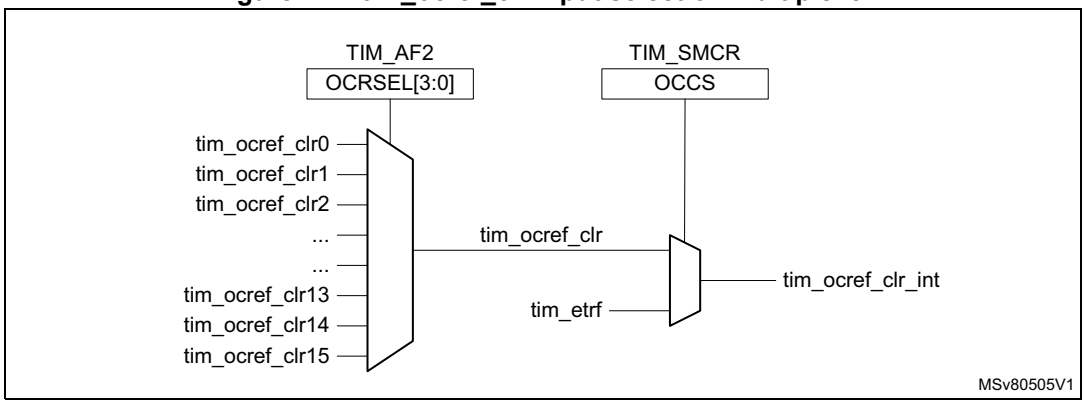
The OOSx/OOSxN bits in the TIM_OOR register cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

31.3.23 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIM_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It must not be used in Forced mode. tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etr_in after the filter) by configuring the OCCS bit in the TIM_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[3:0] bitfield in the TIM_AF2 register, as shown on the *Figure 277* below. Refer to *Section 31.3.2: TIM1/TIM8 pins and internal signals* for a list of sources available in the product.

Figure 277. tim_ocref_clr input selection multiplexer

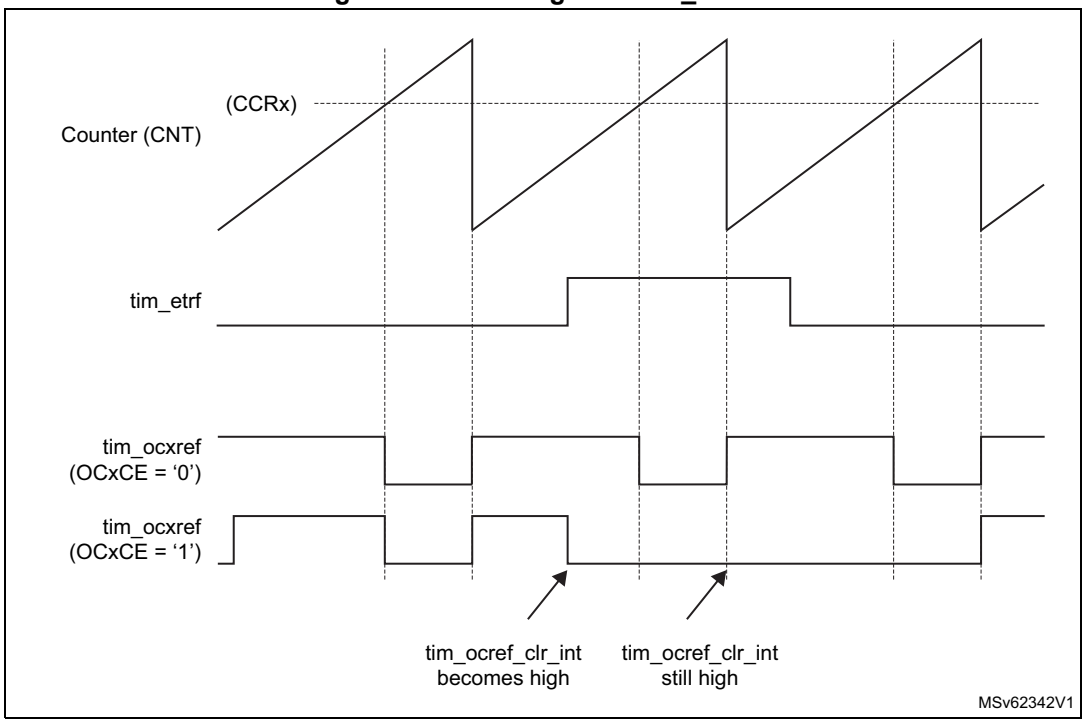


When tim_etrf is chosen, tim_etr_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] of the TIM_SMCR register set to 00.
2. The external clock mode 2 must be disabled: bit ECE of the TIM_SMCR register set to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

Figure 278 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 278. Clearing TIMx tim_ocxref



Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.

This feature is also supported in combined and asymmetric modes. In this case, it is mandatory to have the OCxCE bit enabled for the channel, the OCxCE bit of the complementary channel (e.g. OC2CE = X for oc2ref in *Figure 279*) is ignored in this case.

Figure 279 to *Figure 282* are describing the output waveforms for some use cases, when the ocref_clr_int signal is asserted.

Figure 279. Asymmetric PWM mode 1

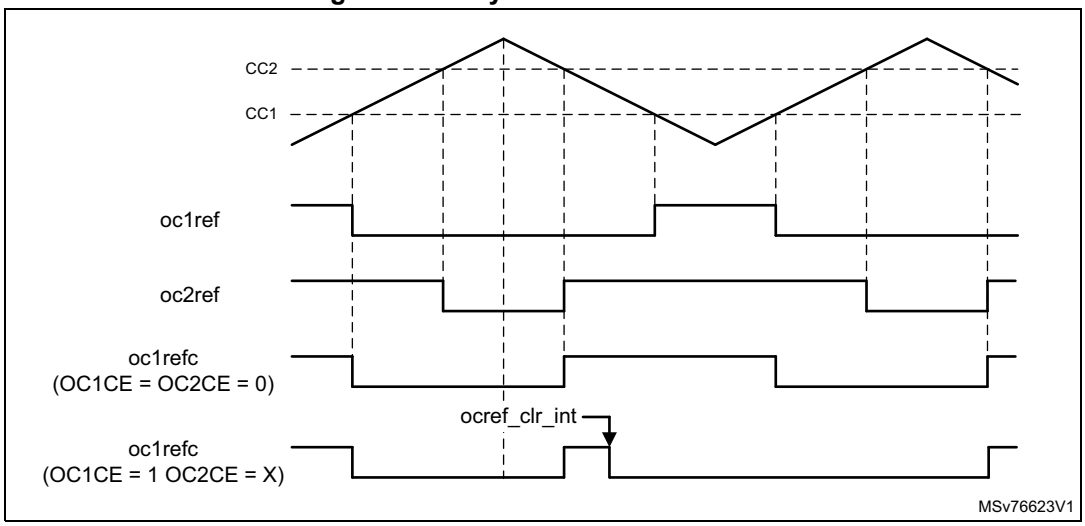


Figure 280. Asymmetric PWM mode 2

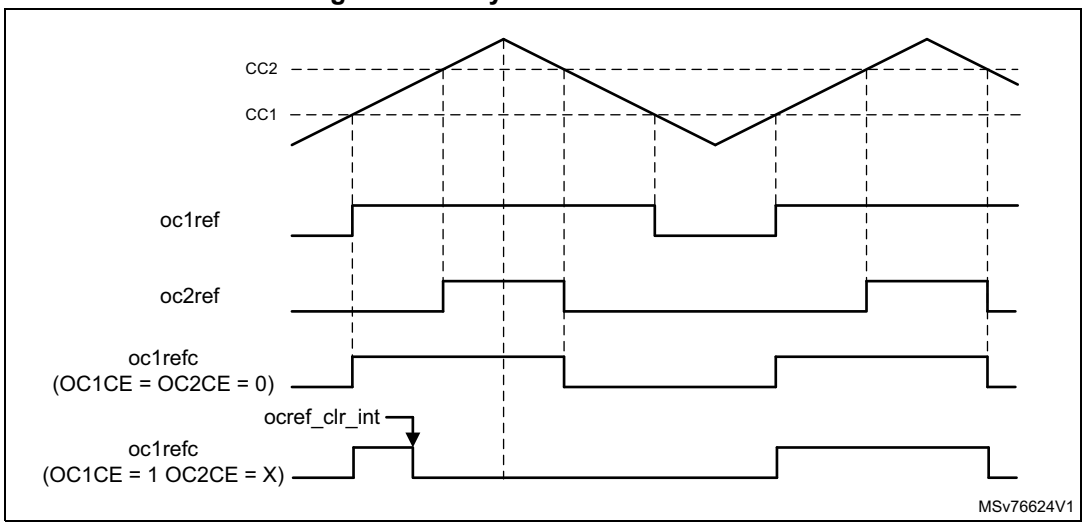

Figure 281. Asymmetric PWM mode 7 (OC1refc = oc1ref OR oc5ref)

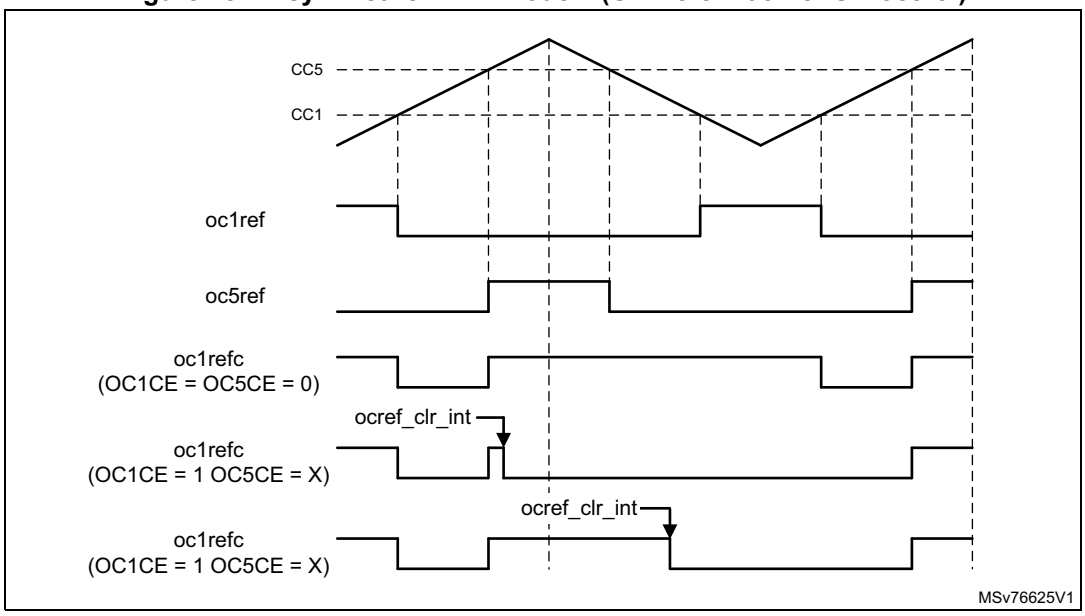

Figure 282. Combined PWM mode 1

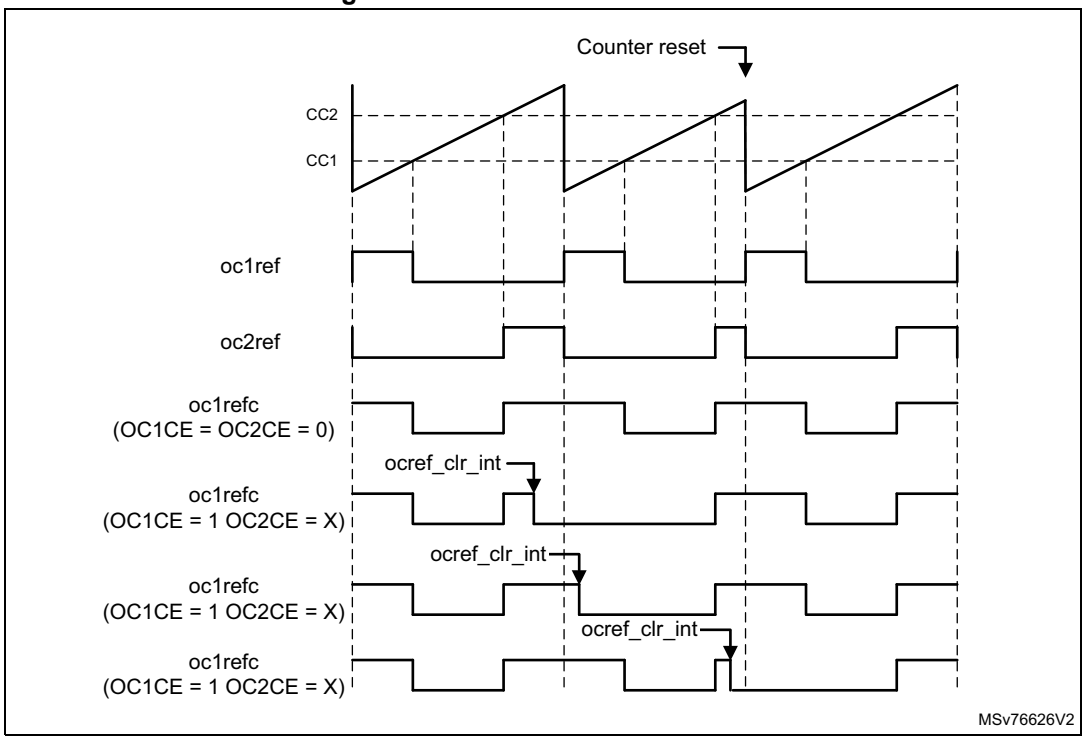


Conditions of use

This feature is intended to support cycle-by-cycle current control loops, typically with a comparator shortening the PWM on-time when a current threshold is exceeded.

It cannot be used for the following modes, where the OCxCE bit must be cleared:

- PWM toggle mode (OCxM[4:0] = 0x03)
- One pulse mode with PWM active on match (OPM=1 and OCxM[4:0] = 0x06, 0x08, 0x0C, 0x0E, 0x10, 0x12, 0x14, 0x16, 0x18)
- Combined 3-phase modes (GC5Cx or GC5CxO = 1)
- Combined PWM mode 1 or 3 in center aligned mode (CMS[1:0] = 1,2,3 and OCxM[4:0] = 0x0C or 0x10)

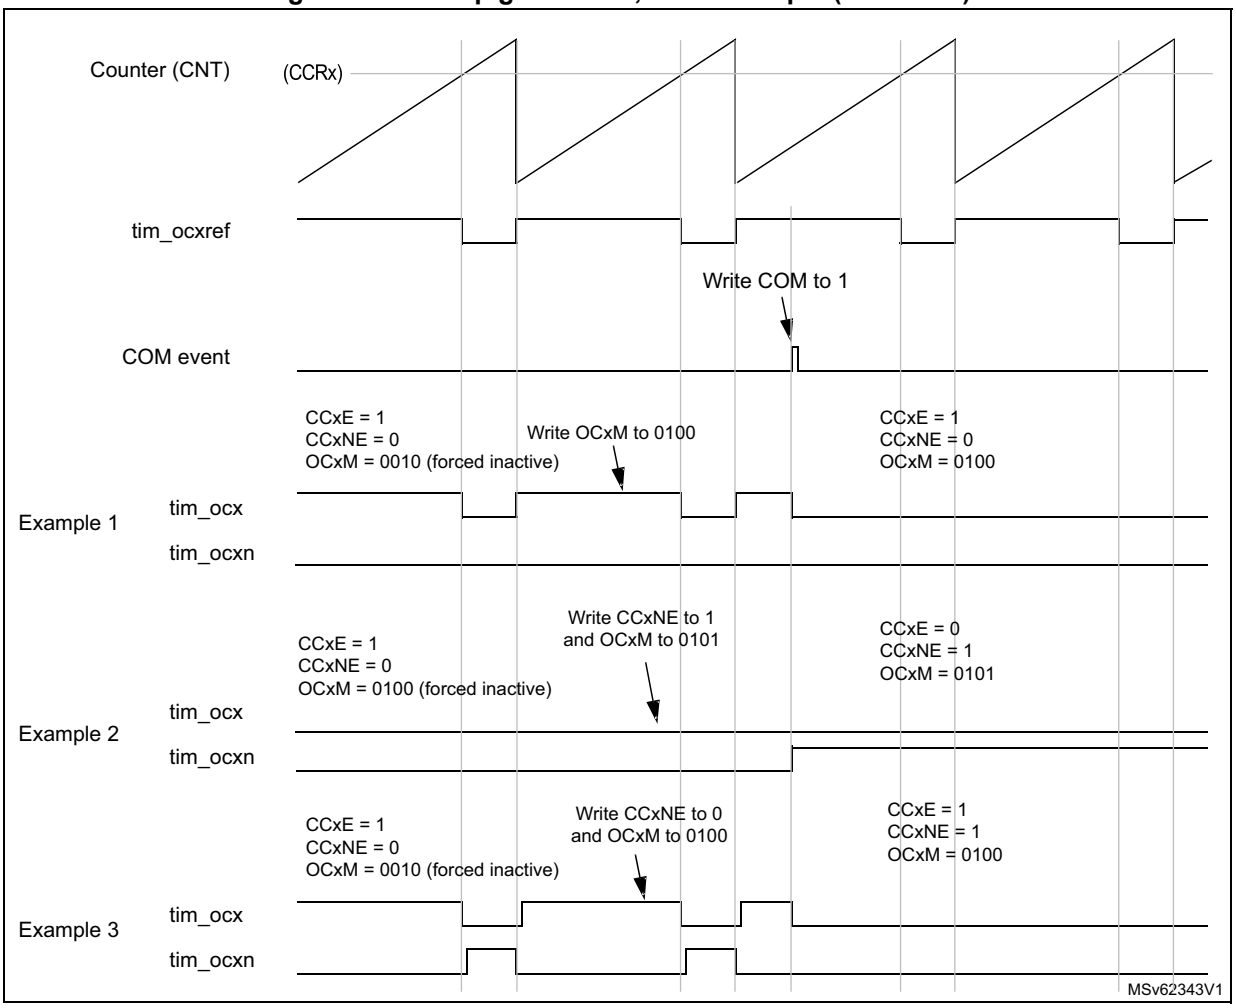
31.3.24 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE, and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIM_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIM_SR register), which can generate an interrupt (if the COMIE bit is set in the TIM_DIER register) or a DMA request (if the COMDE bit is set in the TIM_DIER register).

Figure 283 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in three different examples of programmed configurations.

Figure 283. 6-step generation, COM example (OSSR = 1)



31.3.25 One-pulse mode

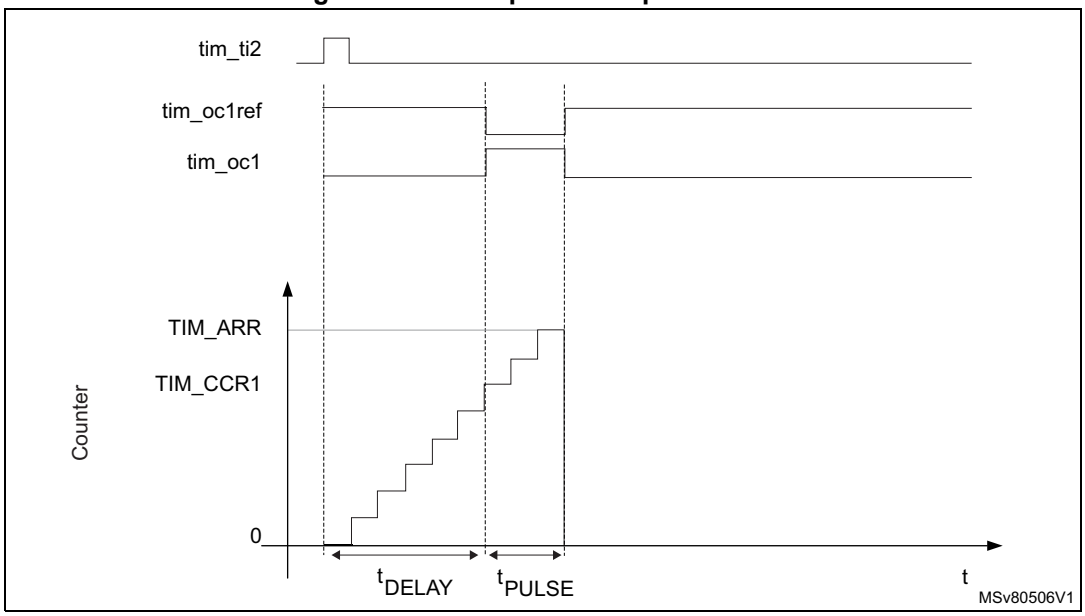
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIM_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

Figure 284. Example of one pulse mode.



In the following example, the user wants to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:

- Map tim_ti2fp2 to tim_ti2 by writing CC2S = 01 in the TIM_CCMR1 register.
- tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
- Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIM_SMCR register.
- tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIM_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIM_CCR1 register.
- The t_{PULSE} is defined by the difference between the autoreload value and the compare value (TIM_ARR - TIM_CCR1).
- Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the auto-reload value. This is achieved by enabling PWM mode 2 (OC1M = 00111 in TIM_CCMR1). Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIM_CCMR1 register and ARPE in the TIM_CR1 register. In this case one has to write the compare value in the TIM_CCR1 register, the autoreload value in the TIM_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIM_CR1 register must be low.

Since only one pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIM_CR1 register to stop the counter at the next update event (when the counter rolls over

from the autoreload value back to 0). When OPM bit in the TIM_CR1 register is set to 0, so the Repetitive mode is selected.

Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min that can be achieved.

To output a waveform with the minimum delay, the OCxFE bit can be set in the TIM_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

31.3.26 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with nonretriggerable one-pulse mode described in *Section 31.3.25*:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.

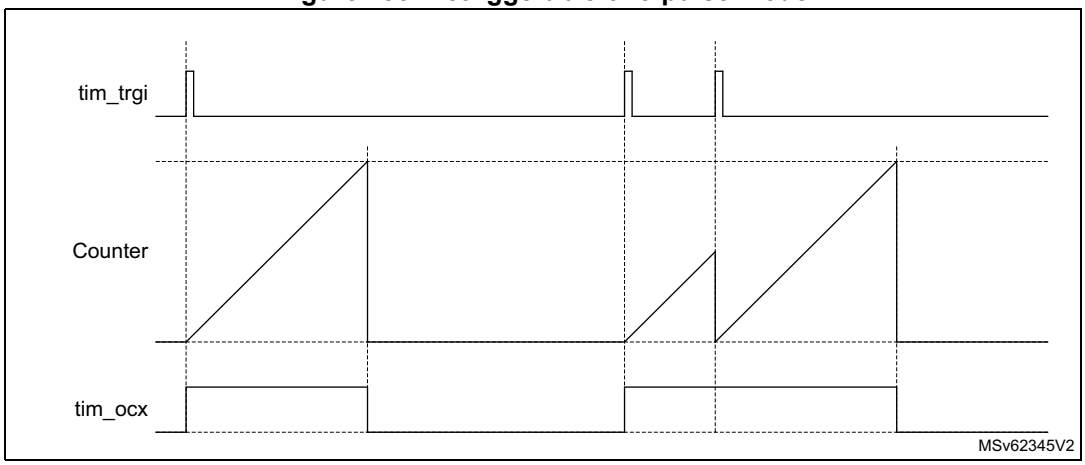
The timer must be in Slave mode, with the bits SMS[4:0] = 01000 (Combined Reset + trigger mode) in the TIM_SMCR register, and the OCxM[4:0] bits set to 01000 or 01001 for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[4:0] and SMS[4:0] bitfields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the three least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIM_CR1.

Figure 285. Retriggerable one-pulse mode



31.3.27 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on *Figure 286*.

Figure 286. Pulse generator circuitry

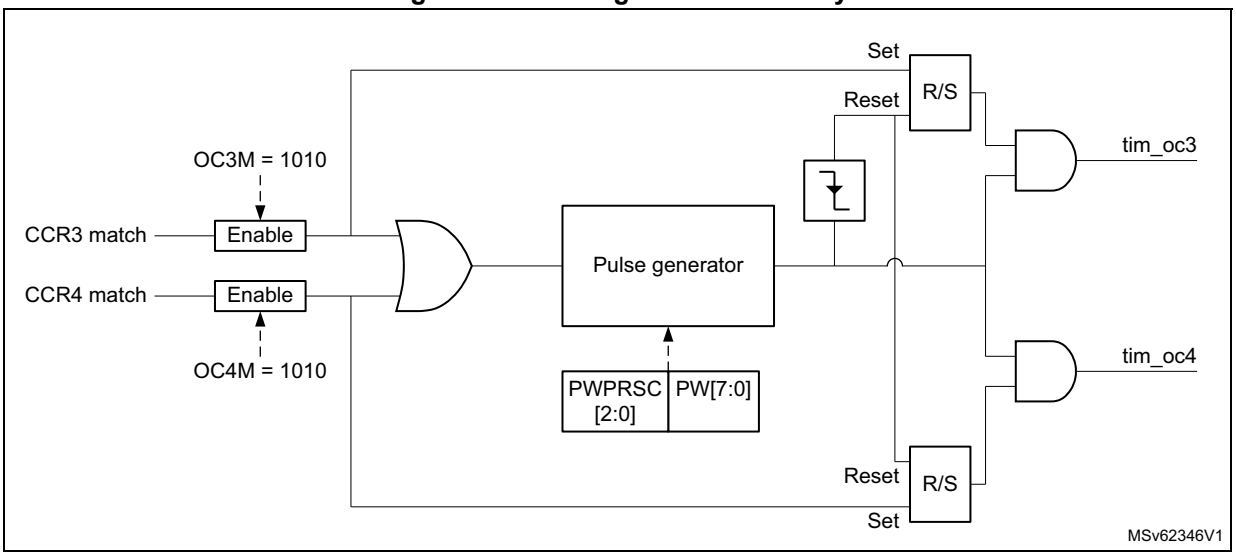


Figure 287 shows how the pulse is generated for edge-aligned and encoder operating modes.

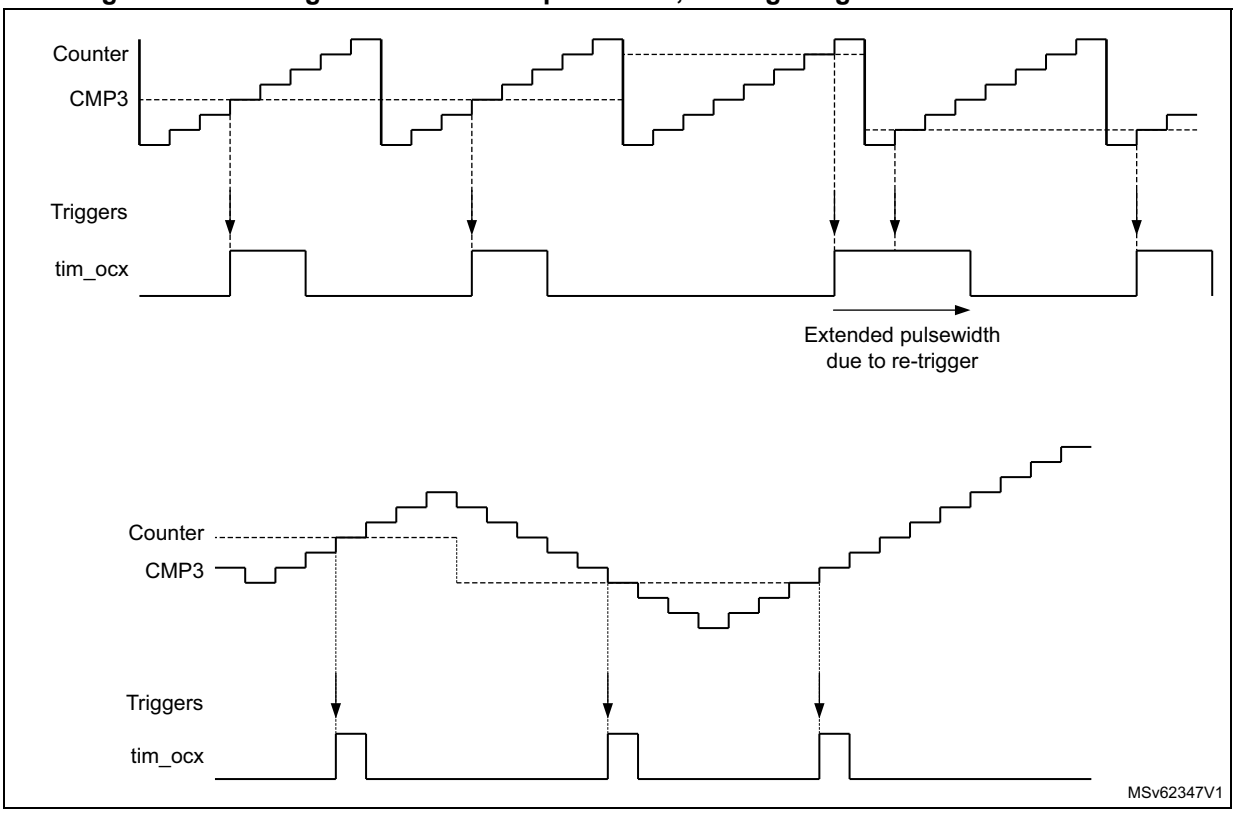
Figure 287. Pulse generation on compare event, for edge-aligned and encoder modes



This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIM_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

t_{PW} = PW[7:0] x t_{PWG}

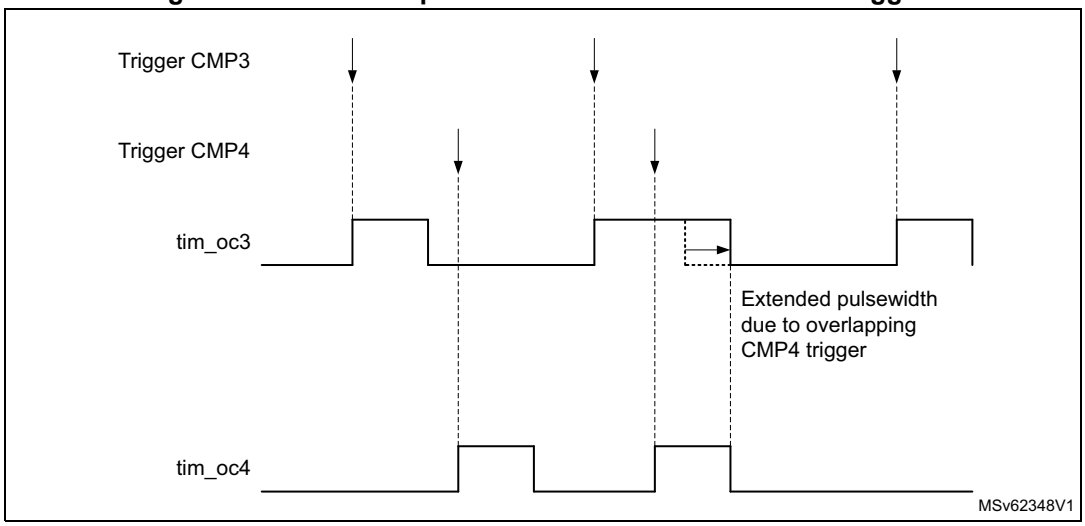
where $t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim_ker_ck}$

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the first arriving trigger is extended (because of the retrigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 288).

Figure 288. Extended pulsewidth in case of concurrent triggers



31.3.28 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS = 0001 in the TIM_SMCR register if the counter is counting on tim_ti1 edges only, SMS = 0010 if it is counting on tim_ti2 edges only and SMS = 0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIM_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_ti1 and tim_ti2 are used to interface to an quadrature encoder. Refer to *Table 299*. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1 = tim_ti1 if not filtered and not inverted, tim_ti2fp2 = tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIM_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIM_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the autoreload value in the TIM_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIM_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.

Table 299. Counting direction versus encoder signals (CC1P = CC2P = 0)

Active edge	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
Counting on tim_ti1 only x1 mode	01110	High	Down	Up	No count	No count
		Low	No count	No count	No count	No count
Counting on tim_ti2 only x1 mode	01111	High	No count	No count	Up	Down
		Low	No count	No count	No count	No count
Counting on tim_ti1 only x2 mode	00001	High	Down	Up	No count	No count
		Low	Up	Down	No count	No count
Counting on tim_ti2 only x2 mode	00010	High	No count	No count	Up	Down
		Low	No count	No count	Down	Up
Counting on tim_ti1 and tim_ti2 x4 mode	00011	High	Down	Up	Up	Down
		Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 289 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example the configuration is the following:

- CC1S = 01 (TIM_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIM_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P = 0 and CC1NP = 0 (TIM_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1).
- CC2P = 0 and CC2NP = 0 (TIM_CCER register, tim_ti1fp2 noninverted, tim_ti1fp2= tim_ti2).
- SMS = 0011 (TIM_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIM_CR1 register, Counter enabled).

Figure 289. Example of counter operation in encoder interface mode.

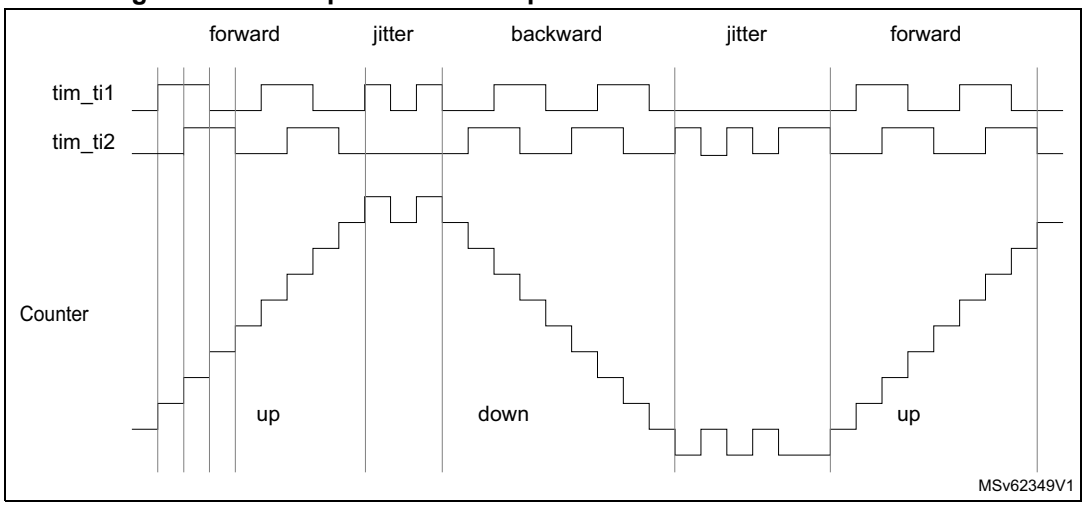


Figure 290 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P = 1).

Figure 290. Example of encoder interface mode with tim_ti1fp1 polarity inverted.

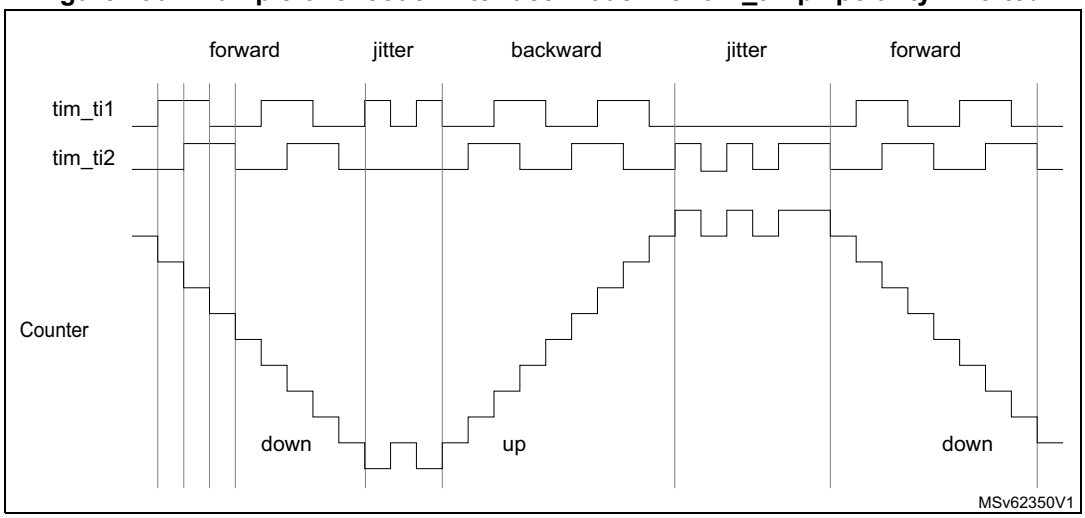

Figure 291 shows the timer counter value during a speed reversal, for various counting modes.

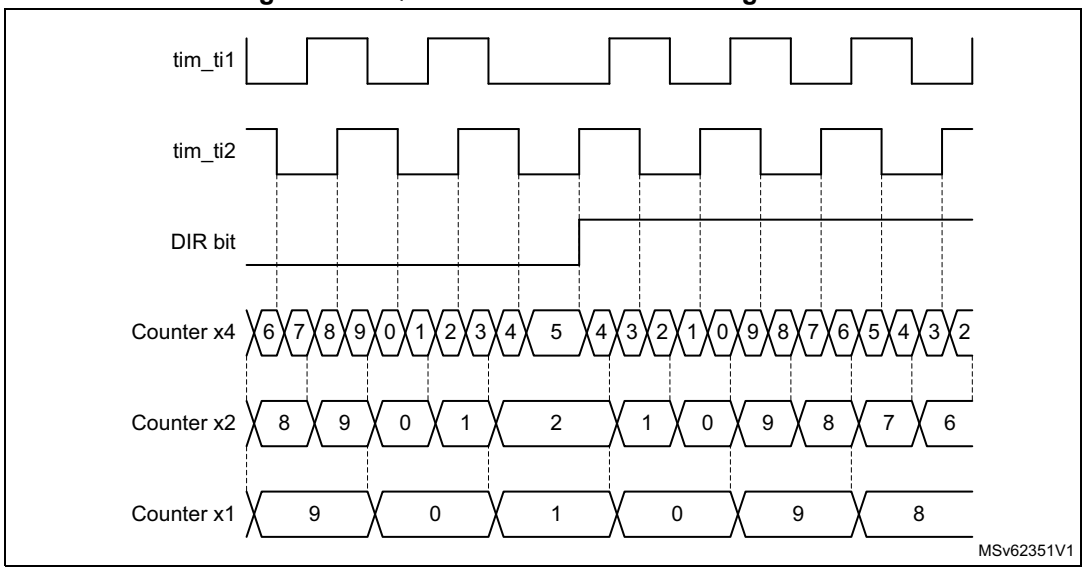
Figure 291. Quadrature encoder counting modes



The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIM_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support for other types of encoders.

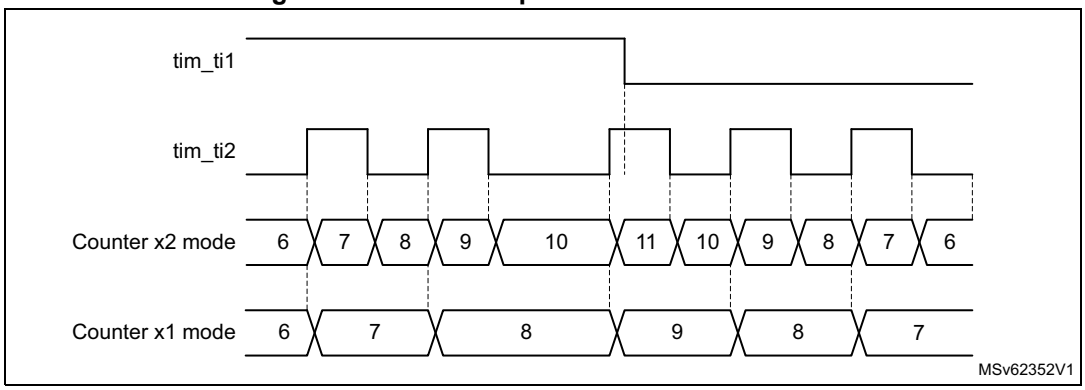
In the clock plus direction mode shown on *Figure 292*, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 01011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

Figure 292. Direction plus clock encoder mode



Directional clock encoder mode

In the directional clock mode on *Figure 293*, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to *Figure 293*) and CCxP = 1 corresponds to low-level idle state (refer to *Figure 294*).
- 01101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to *Figure 293*), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to *Figure 294*).

Figure 293. Directional clock encoder mode (CC1P = CC2P = 0)

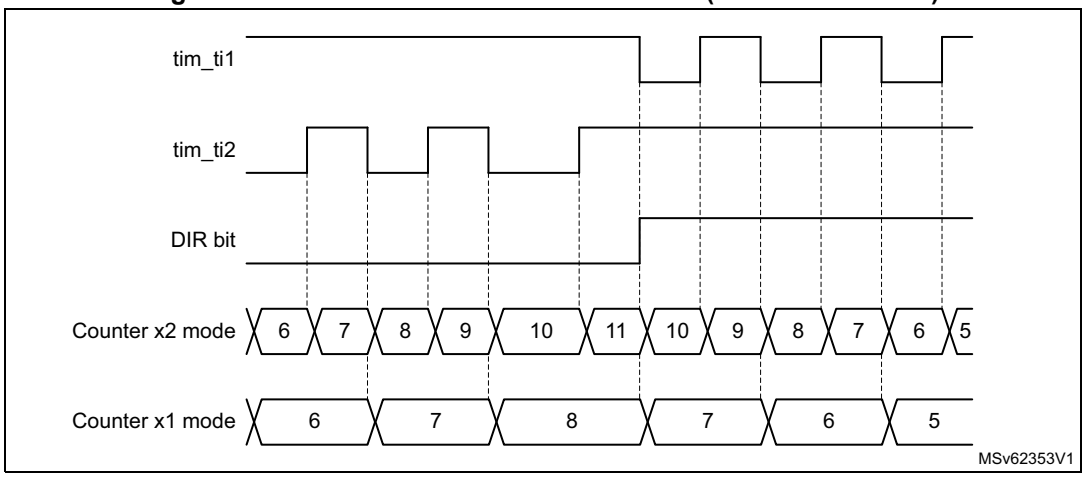


Figure 294. Directional clock encoder mode (CC1P = CC2P = 1)

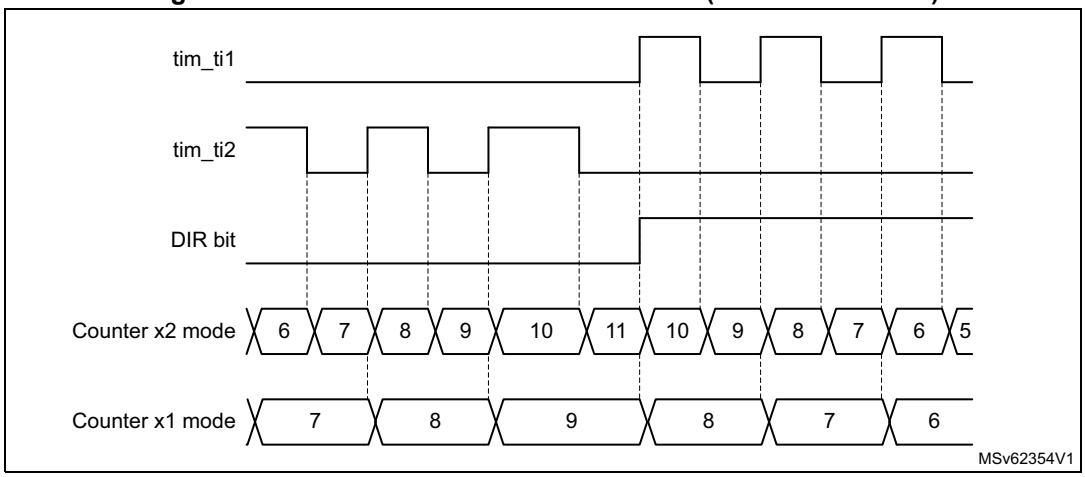

Table 300 here-below details how the directional clock mode operates, for any input transition.

Table 300. Counting direction versus encoder signals and polarity settings

Directional clock mode	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
x2 mode CCxP = 0	01100	High	Down	Down	Up	Up
		Low	No count	No count	No count	No count
x2 mode CCxP = 1	01100	High	No count	No count	No count	No count
		Low	Down	Down	Up	Up
x1 mode CCxP = 0	01101	High	No count	Down	No count	Up
		Low	No count	No count	No count	No count
x1 mode CCxP = 1	01101	High	No count	No count	No count	No count
		Low	Down	No count	Up	No count

Index input

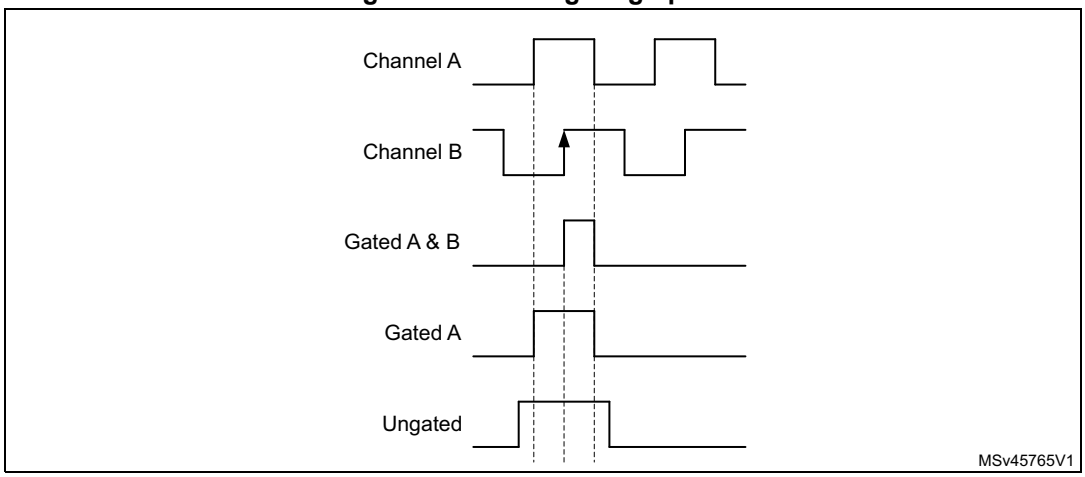
The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIM_ECR register. The IE bit must be set only in encoder mode, when the SMS[4:0] bitfield has the following values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111.

Available encoders are proposed with several options for index pulse conditioning, as per *Figure 295*:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

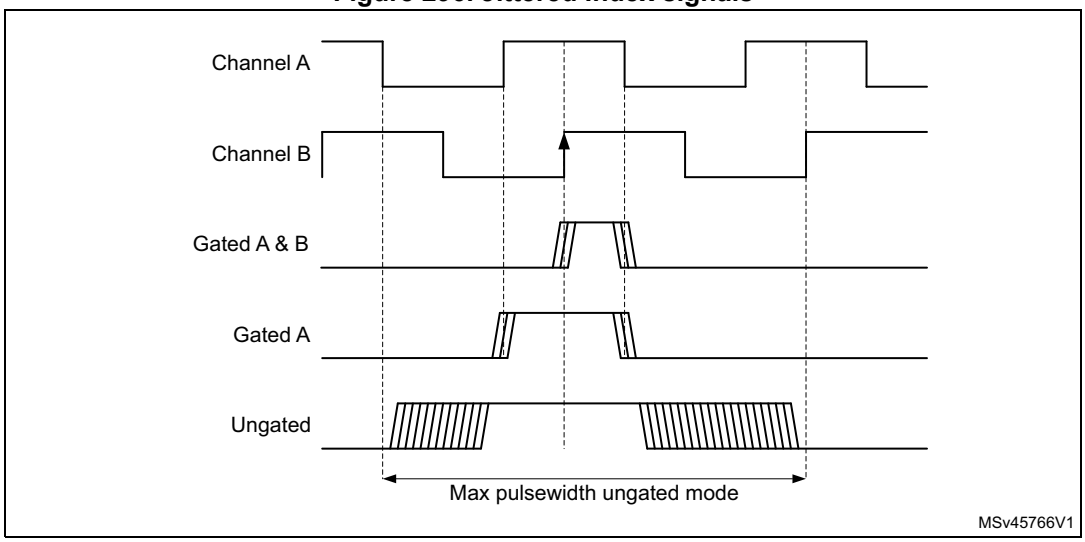
Figure 295. Index gating options



The circuitry tolerates jitter on index signal, whatever the gating mode, as show on *Figure 296*.

In ungated mode, the signal must be strictly below two encoder periods. If the pulsewidth is greater or equal to two encoder period, the counter is reset multiple times.

Figure 296. Jittered Index signals



The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and

channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIM_ECR register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIM_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. *Figure 297* shows at which position is the index generated, for a simplistic example (an encoder providing four edges par mechanical rotation).

Figure 297. Index generation for IPOS[1:0] = 11

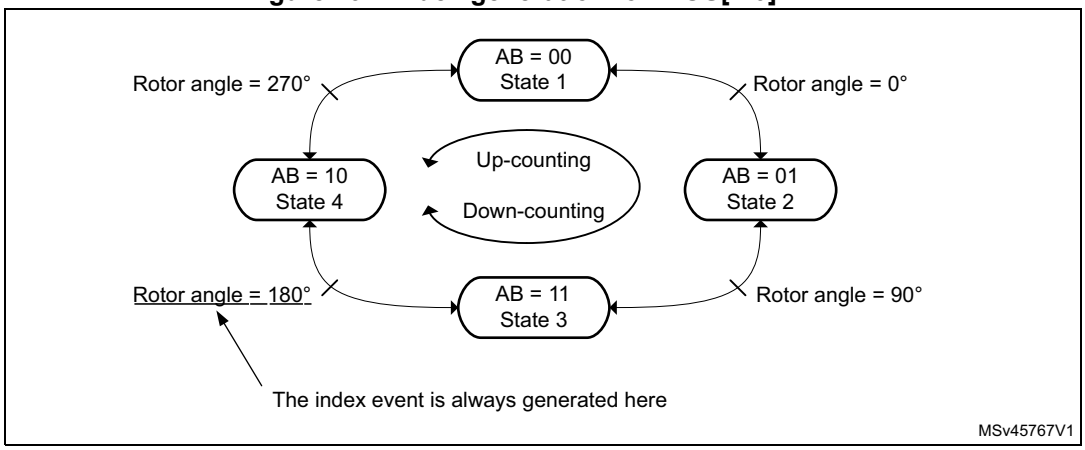


Figure 298 presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is 11 (ChA = 1, ChB = 1), when up-counting (DIR bit = 0).
- Counter set to TIM_ARR when exiting the 11 state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

Figure 298. Counter reading with index gated on channel A (IPOS[1:0] = 11)

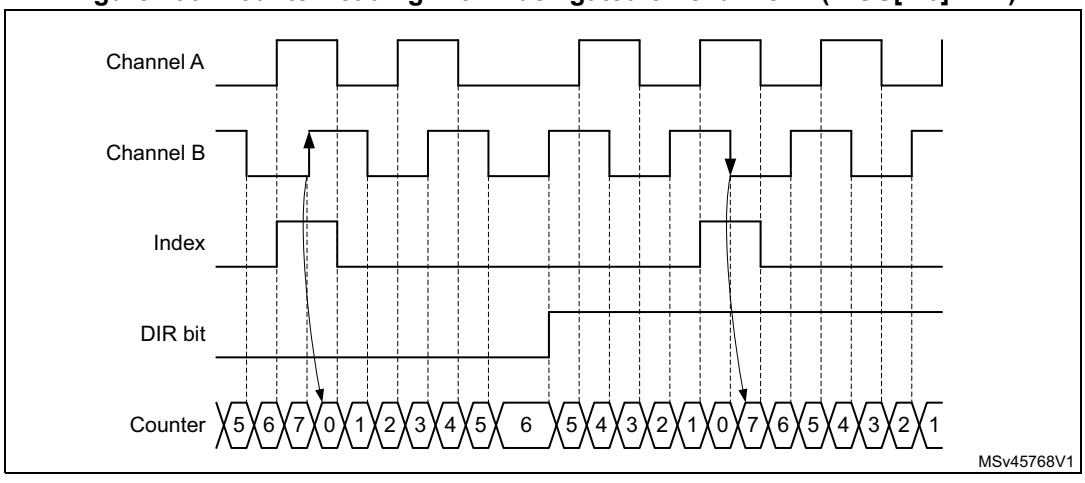

Figure 299. presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 299. Counter reading with index ungated (IPOS[1:0] = 00)

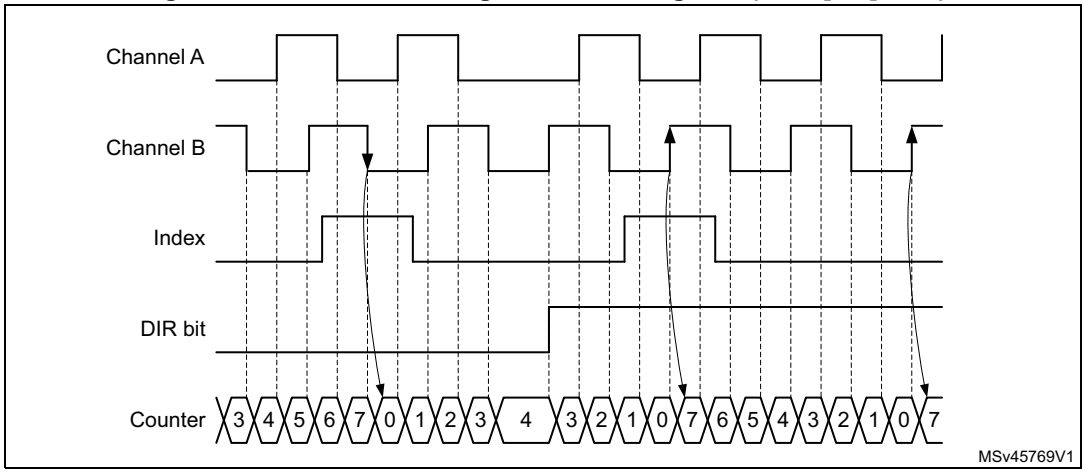

Figure 300. shows how the 'gated on A & B' mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

Figure 300. Counter reading with index gated on channel A and B

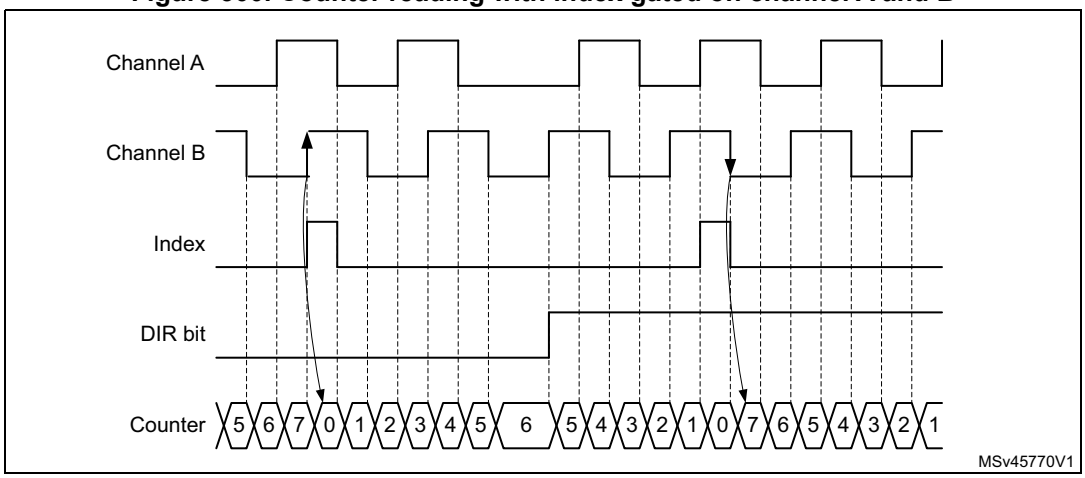

Figure 301 and *Figure 302* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 301. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

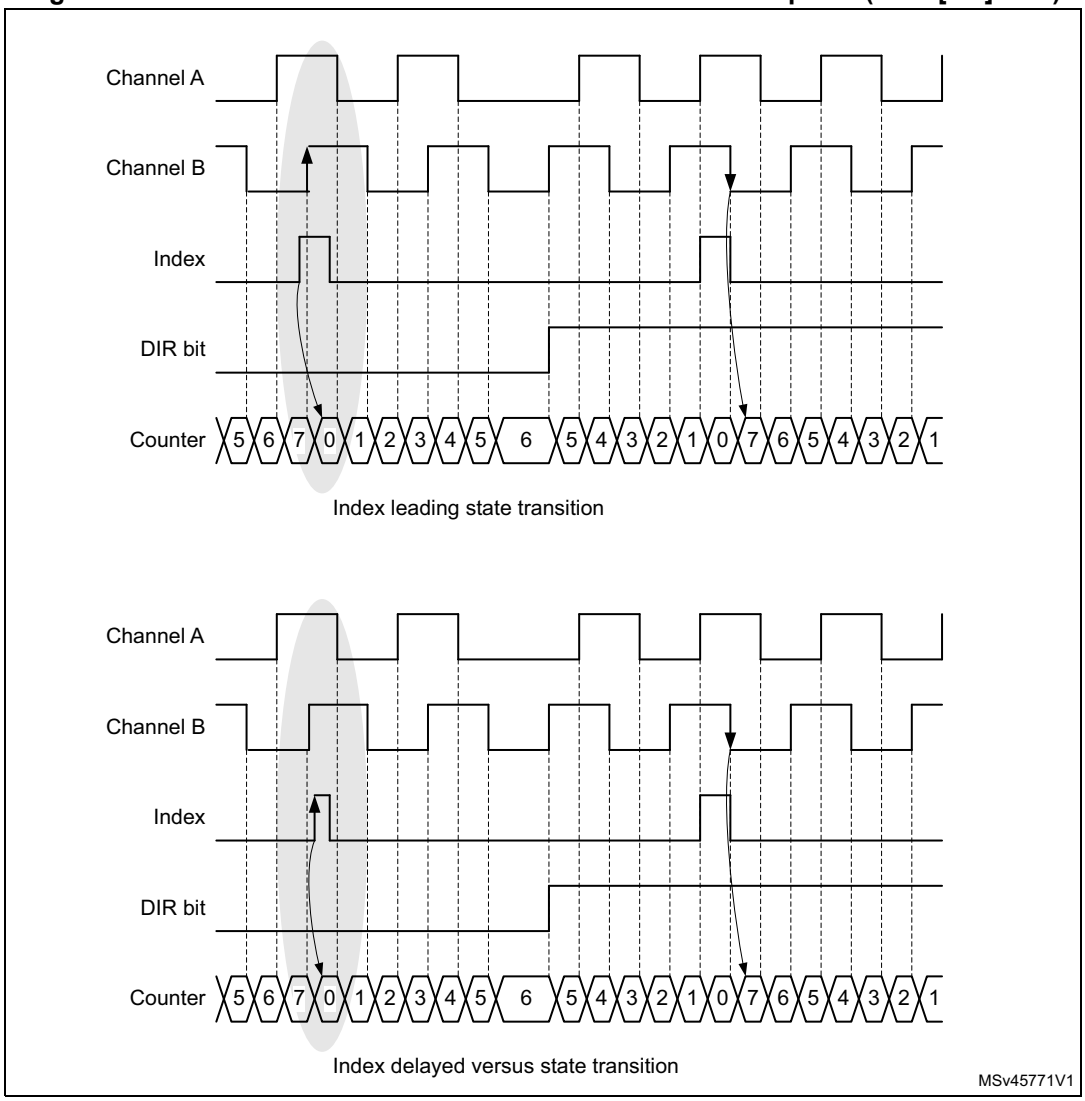

Figure 302. Counter reset Narrow index pulse (closer view, ARR = 0x07)

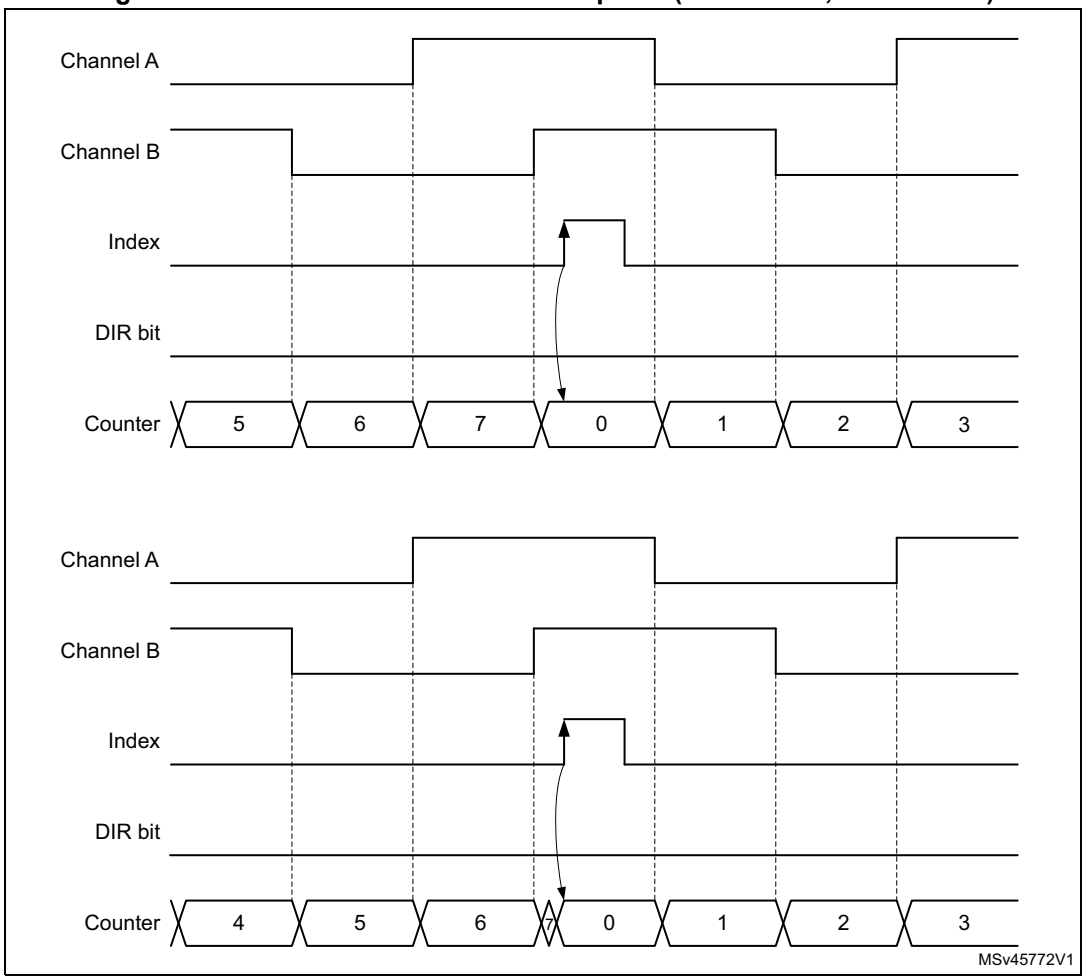

Figure 303 shows how the index is managed in x1 and x2 modes.

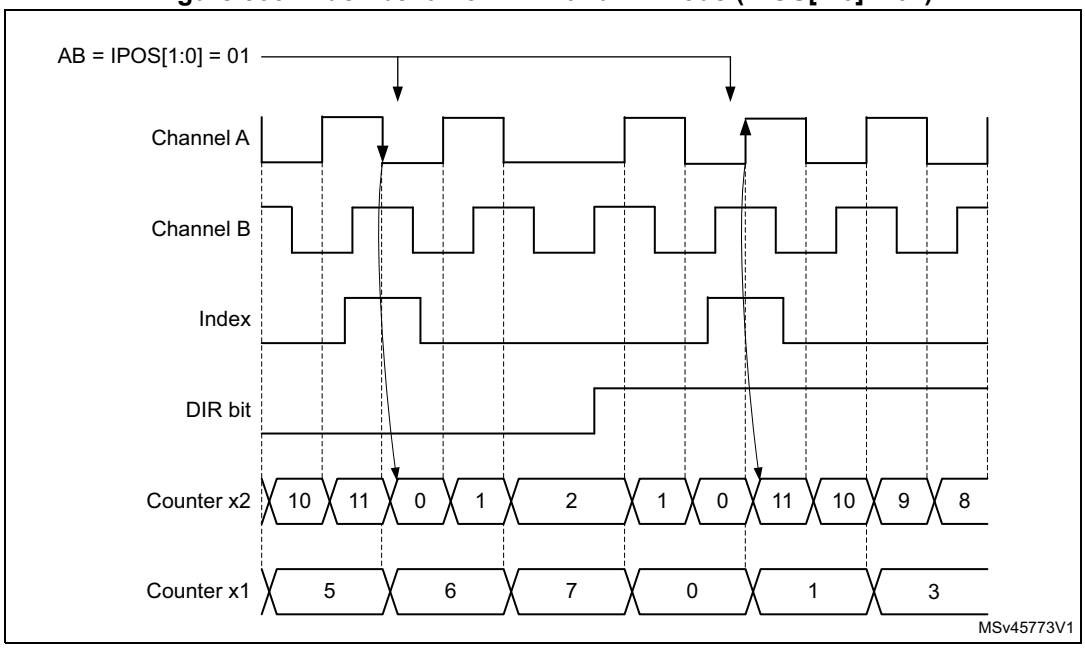
Figure 303. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

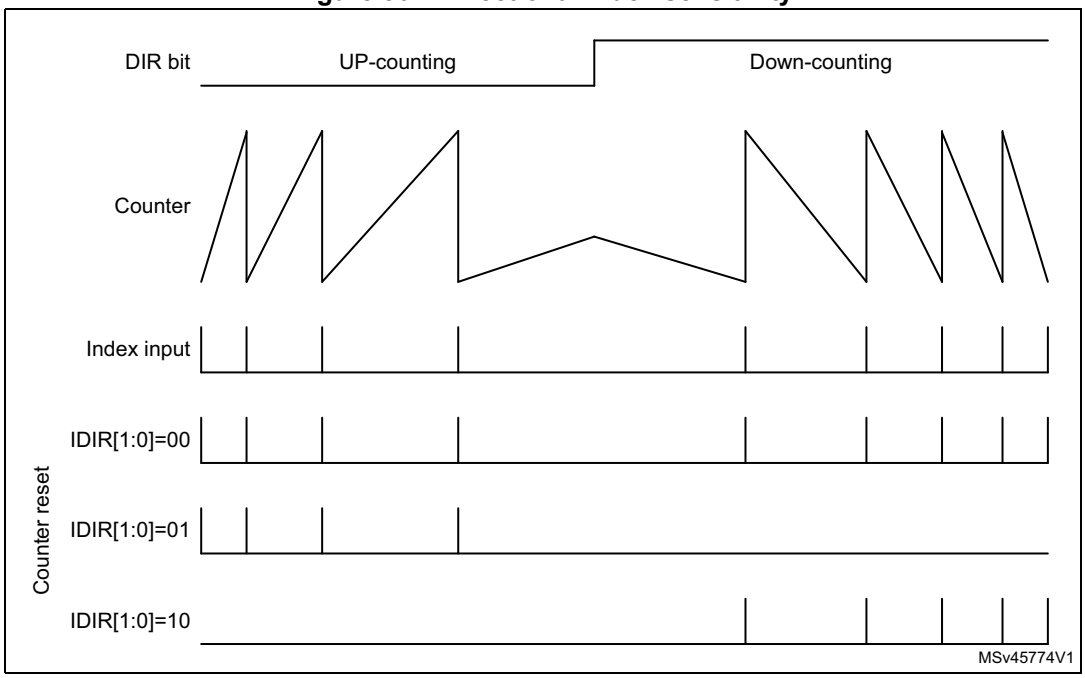


Directional index sensitivity

The IDIR[1:0] bitfield in the TIM_ECR register allows the index to be active only in a selected counting direction.

Figure 304 shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

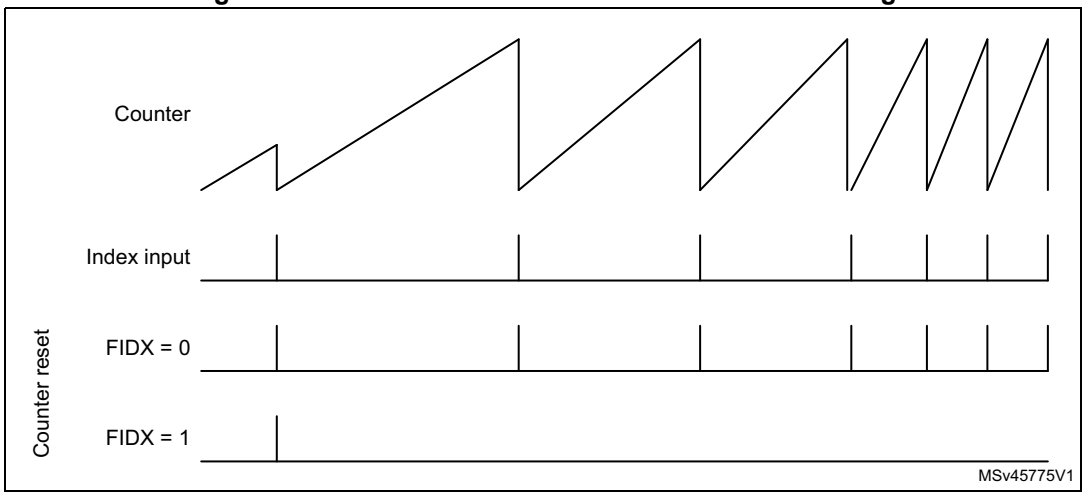
Figure 304. Directional index sensitivity



Special first index event management

The FIDX bit in the TIM_ECR register allows the index to be taken only once, as shown on *Figure 305*. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be rearmed by writing the FIDX bit to 0 and setting it again to 1.

Figure 305. Counter reset as function of FIDX bit setting



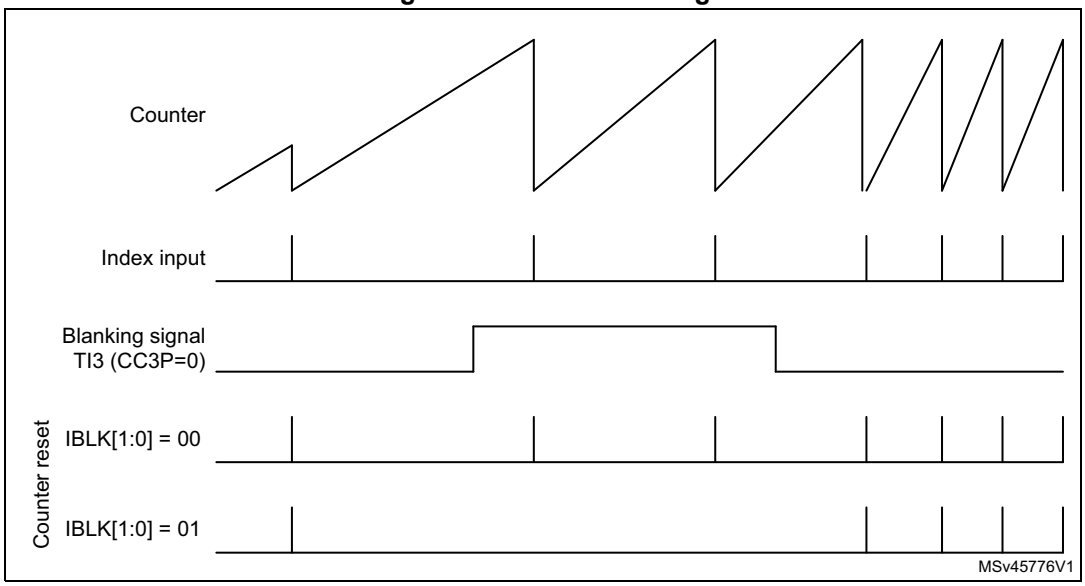
Index blanking

The index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the *Figure 306* below.

This mode is enabled using the IBLK[1:0] bitfield in the TIM_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 306. Index blanking



Index management in nonquadrature mode

Figure 307 and *Figure 308* detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[4:0] bitfield is equal to 01010, 01011, 01100, 01101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Figure 307. Index behavior in clock + direction mode, IPOS[0] = 1

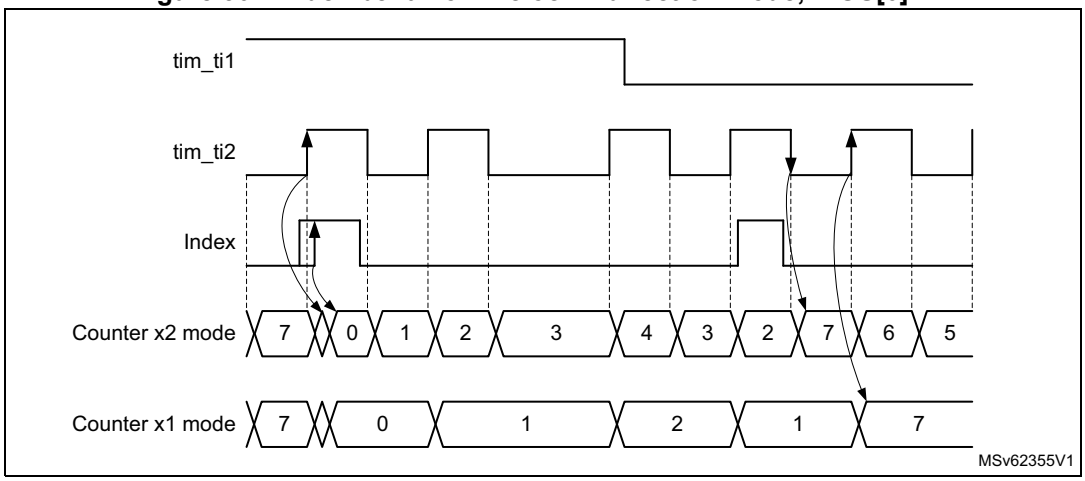


Figure 308. Index behavior in directional clock mode, IPOS[0] = 1

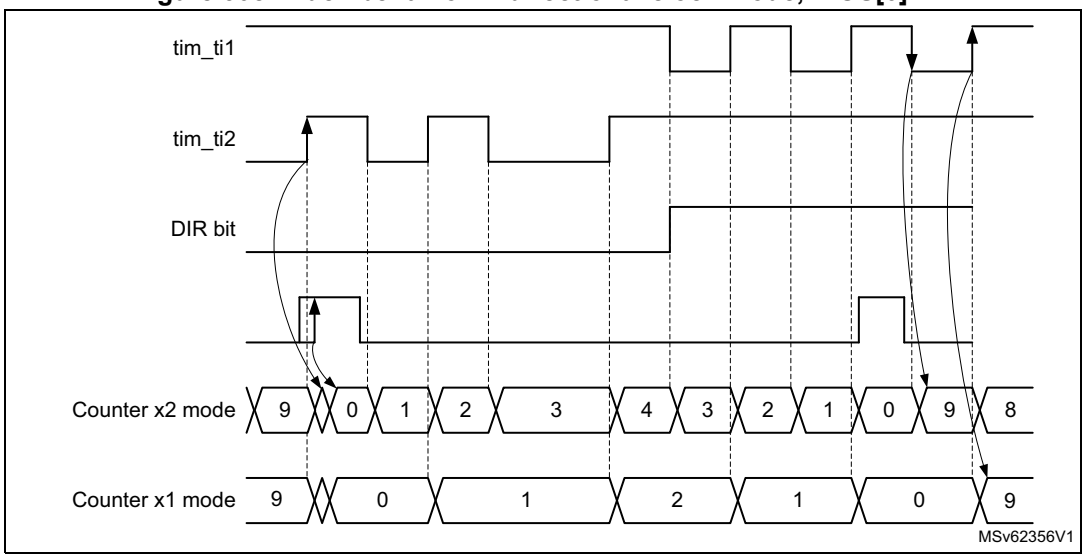
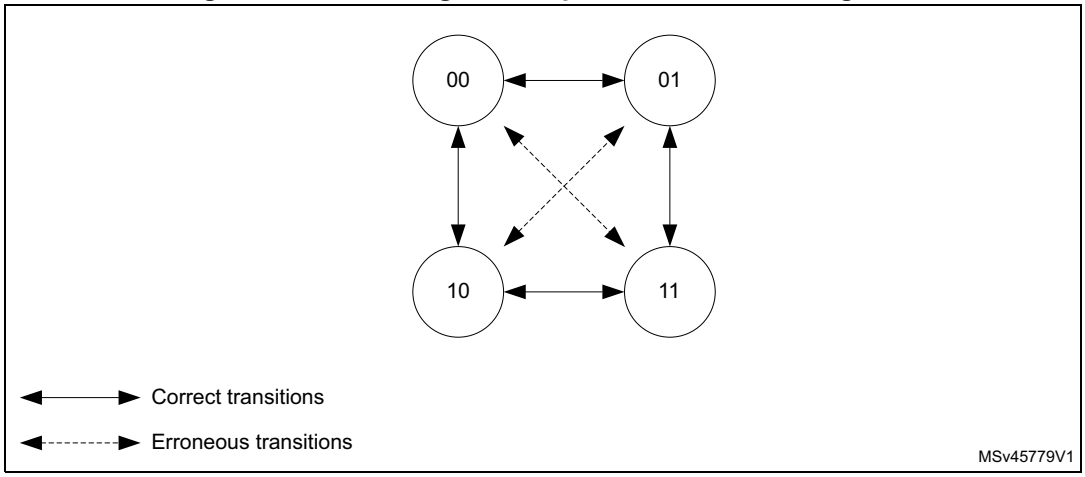


Encoder error management

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on *Figure 309.*. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIM_SR status

register. A transition error interrupt is generated if the TERRIE bit is set in the TIM_DIER register.

Figure 309. State diagram for quadrature encoded signals



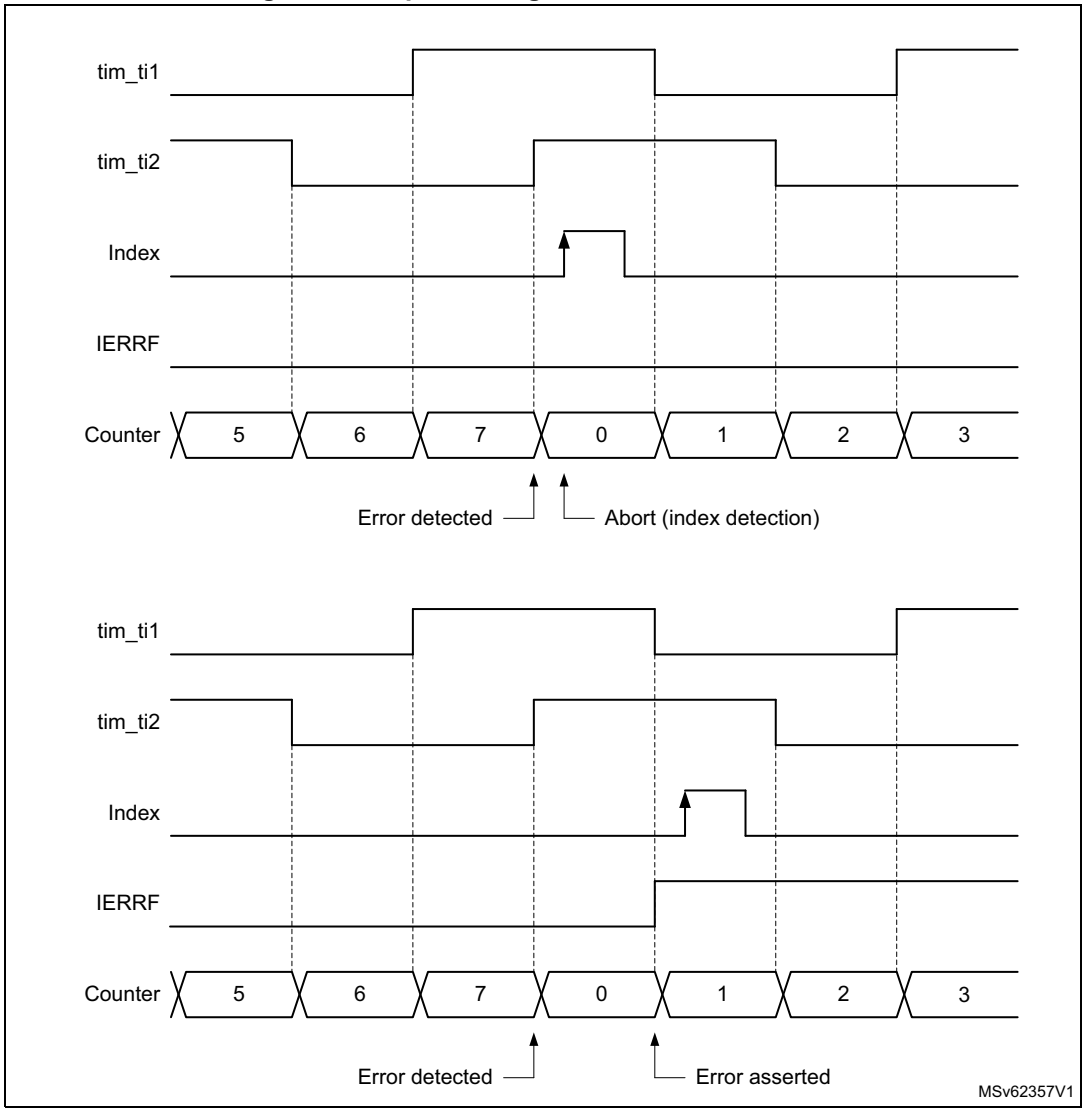
For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIM_ARR to 0 or decremented from 0 to TIM_ARR value without any index event, this is reported as an index position error.

The overflow threshold is programmed using the TIM_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIM_ARR = 3999 + 1 = 4000.

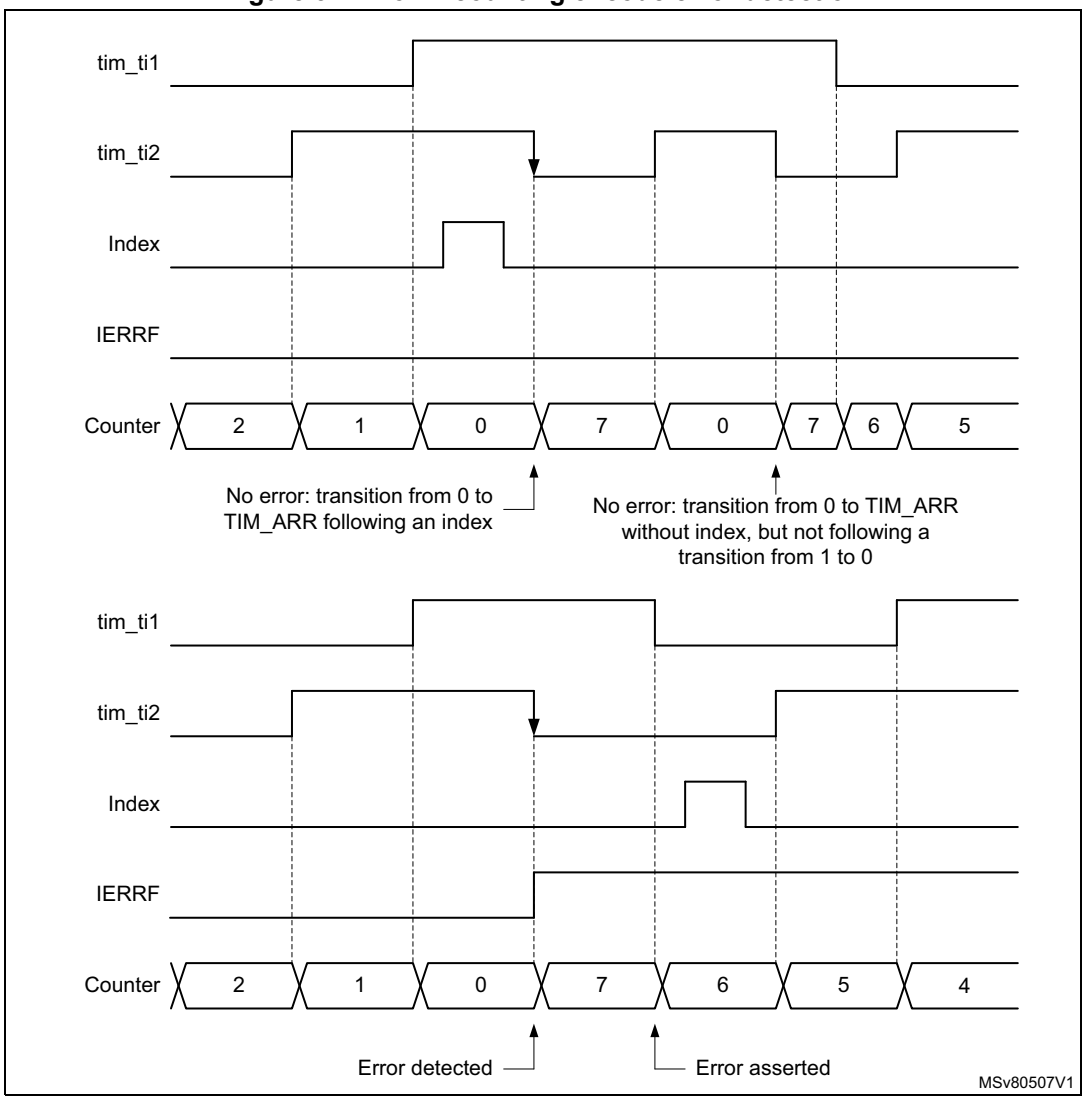
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on *Figure 310*.

Figure 310. Up-counting encoder error detection



In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 311*, to avoid any false error detection in case the encoder dithers between TIM_ARR and 0 immediately after the index detection.

Figure 311. Down-counting encode error detection



An index error sets the IERRF interrupt flag in the TIM_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIM_DIER register.

Functional encoder interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIM_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIM_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIM_DIER register.
- Index event: the index event sets the IDXF interrupt flag in the TIM_SR status register. An index interrupt is generated if the IDXIE bit is set in the TIM_DIER register.

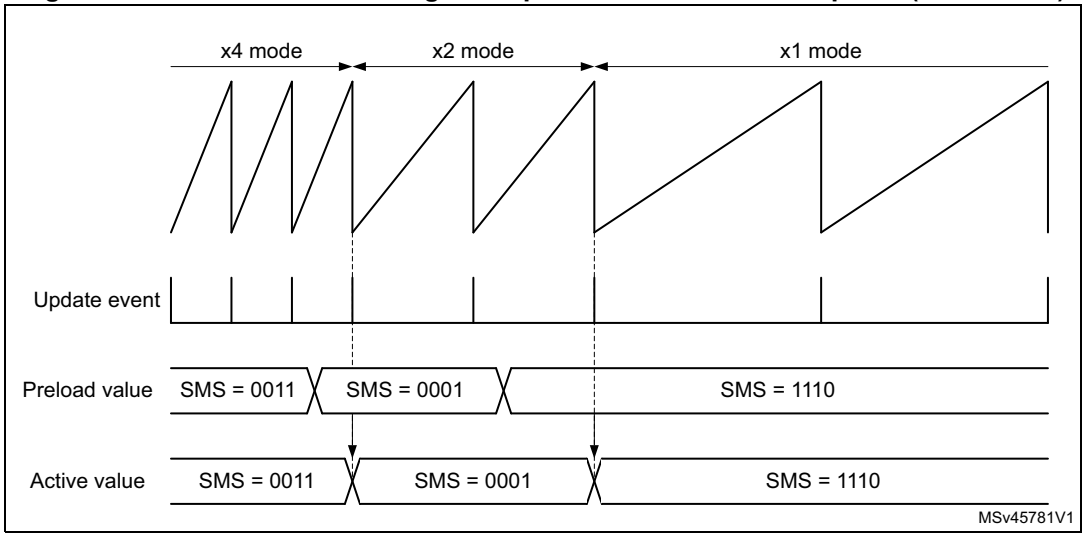
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on *Figure 312*.

For this purpose, the SMS[4:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIM_SMCR register. The trigger for the transfer from SMS[4:0] preload to active value can be selected with the SMSPS bit in the TIM_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the index event.

Figure 312. Encoder mode change with preload transferred on update (SMSPS = 0)



Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIM_CR2 register.It is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

31.3.29 Encoder with built-in debouncer

This mode is intended to support noisy digital potentiometers and knobs, providing quadrature encoded signals with potentially long bouncing periods after each transition.

The operating principle consists of working on the first valid transition and discard any other until a second valid transition is detected on the alternate encoder signal.

The *Figure 313* below represents the x2 operating mode. It must be noticed that a transition on input 1 is ignored during direction reversal, if there's no edge on input 2.

The *Figure 314* below represents the x4 operating mode. In this case, a transition is always ignored during a direction reversal or when the encoder dithers between 2 positions.

These 2 modes are enabled by writing SMS[4:0] = 10000 or 10001 in TIM_SMCR register.

The encoder with built-in debouncer modes are not suitable for tracking a position or an angle in motor control applications. The transitions ignored during direction reversal will lead to a position/angle error that will build-up over time.

Figure 313. Encoder with built-in debouncer, x2 mode

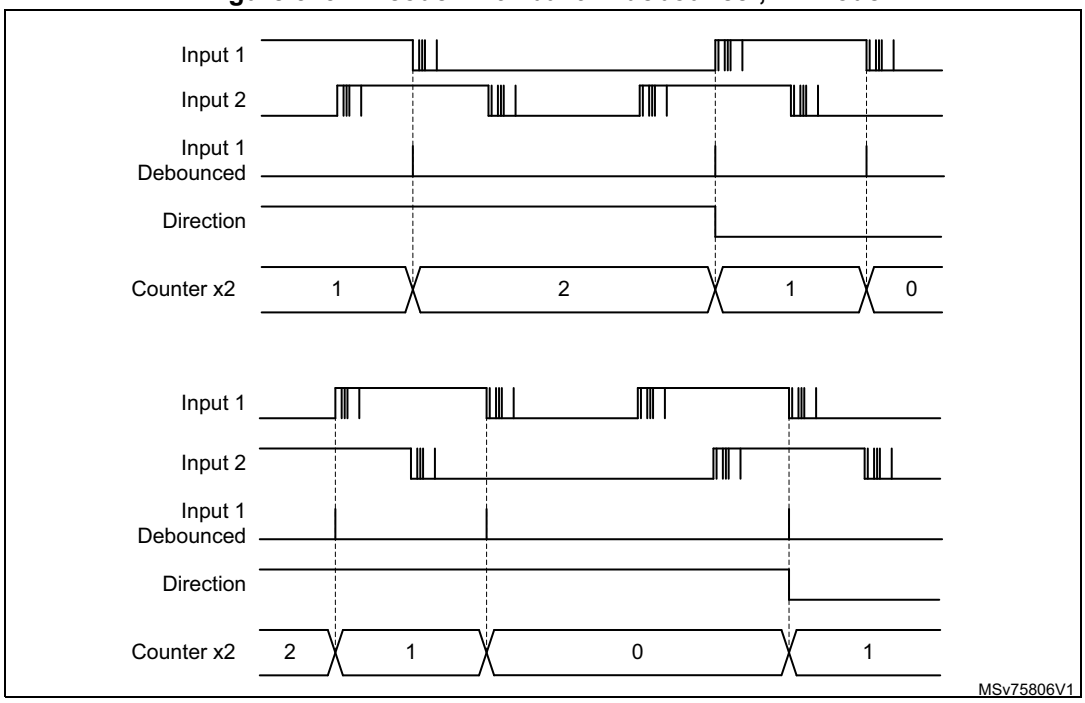


Figure 314. Encoder with built-in debouncer, x4 mode

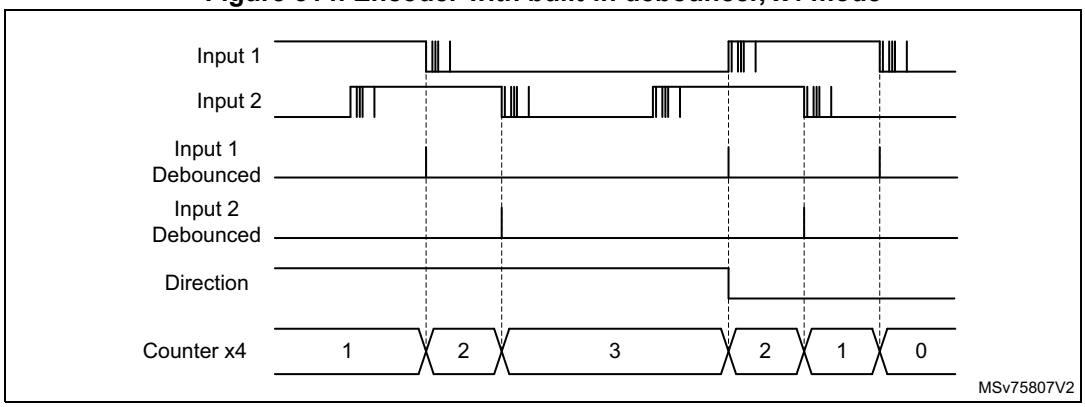


31.3.30 Direction bit output

Its is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIM_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIM_CCMR2 register.

This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

31.3.31 Clock drift measurement

It is possible to measure the drift between two clock sources using the directional clock encoder mode. This is useful for audio applications typically, when one need to compute the drift between two streams.

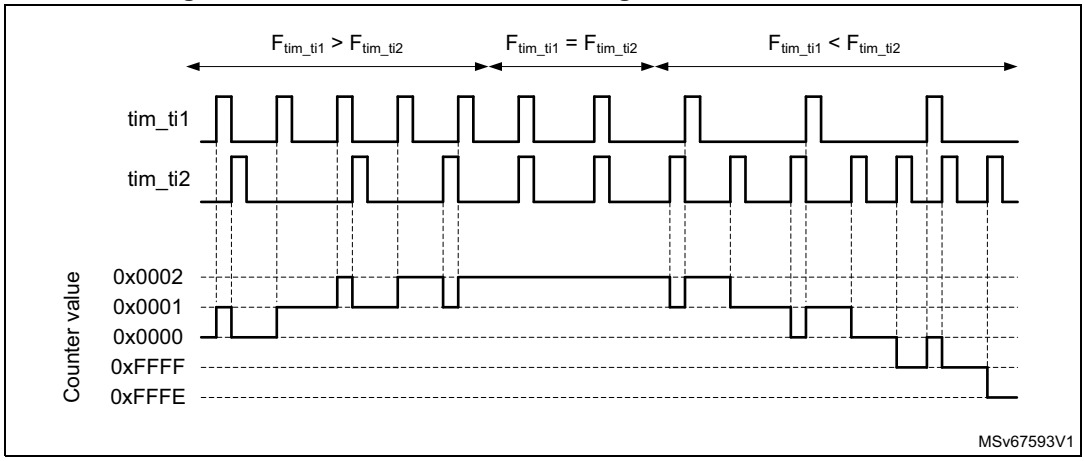
To do so, a signal representing the rate of a first audio stream must be connected to tim_ti1 and a signal representing the rate of a second audio stream must be connected to tim_ti2. The signals representing the audio rates are generally the SAIx_FS_A, SAIx_FS_B, SPIx_WS or spdifrx_frame_sync (this list of signals is provided as example and depends on the audio peripheral availability for a given product line, as detailed on the product datasheet).

In this case, the clocks are present on both tim_ti1 and tim2 simultaneously, as shown on *Figure 315*, and the counter value indicates the drift.

Let's define F_{tim_ti1} and F_{tim_ti2} the frequencies of the signals on tim_ti1 and tim_ti2. The counter value changes as following:

- If $F_{tim_ti1} > F_{tim_ti2}$ the counter value increases
- If $F_{tim_ti1} < F_{tim_ti2}$ the counter value decreases
- If $F_{tim_ti1} = F_{tim_ti2}$ the counter value dithers between two consecutive values, from one clock edge to the other. If the two clocks are perfectly synchronized (clock edges occuring simultaneously on the two inputs), the counter value does not change (as shown on *Figure 315* below).

Figure 315. Clock drift measure using directional clock mode



31.3.32 UIF bit remapping

The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register's bit 31 (TIM_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

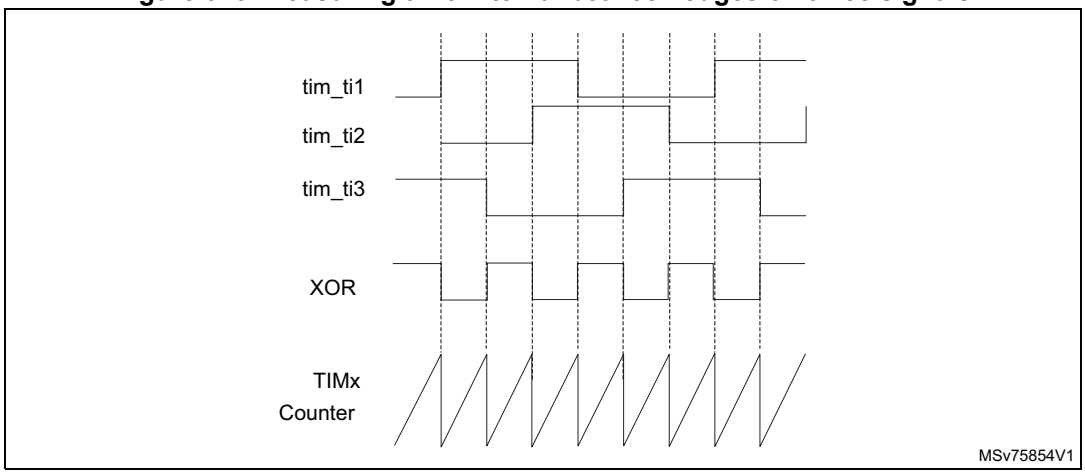
There is no latency between the UIF and UIFCPY flags assertion.

31.3.33 Timer input XOR function

The TI1S bit in the TIM_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per *Figure 316*.

Figure 316. Measuring time interval between edges on three signals



The XORPS control bit selects the position of the XOR gate, as shown on the *Figure 317* and *Figure 318* below, when the TI1S bit is set.

Figure 317. XOR gate connection with TI1S = 1 and XORPS = 0

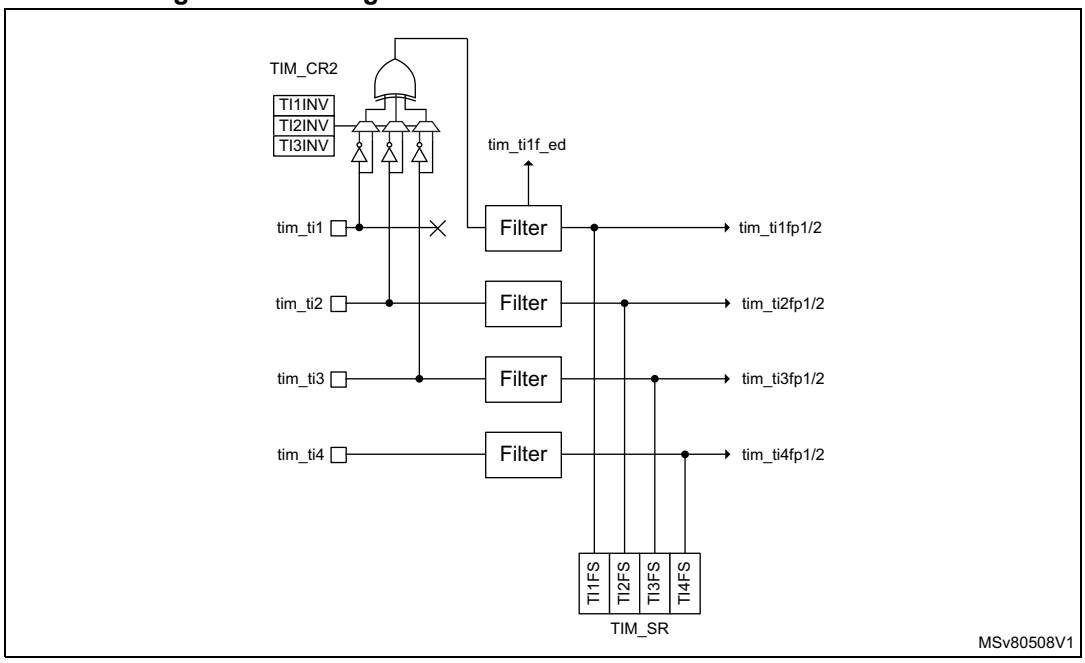


Figure 318. XOR gate connection with TI1S = 1 and XORPS = 1

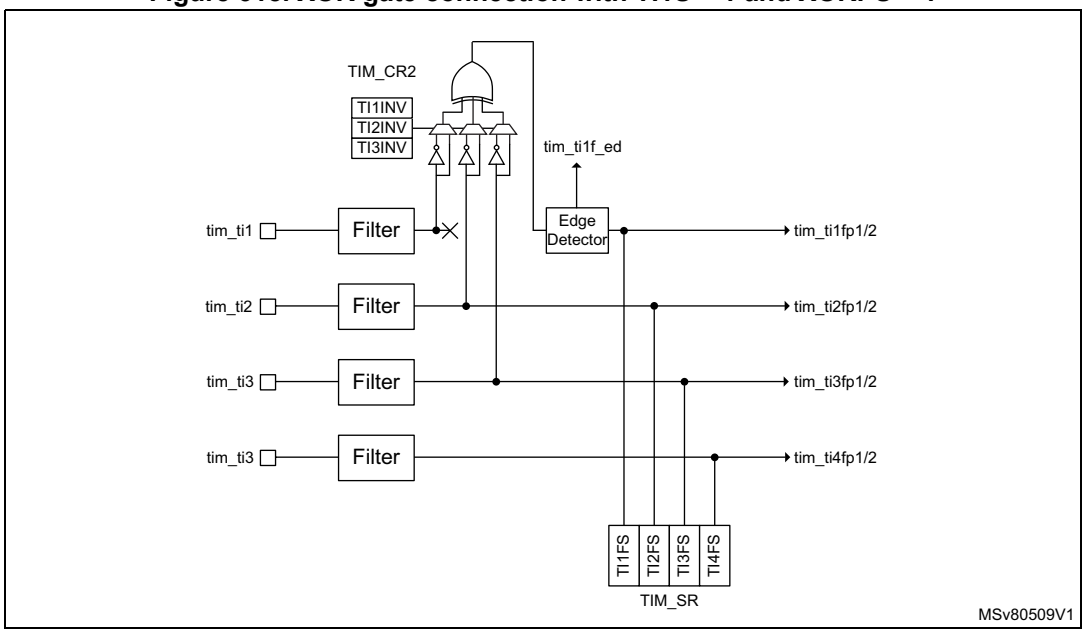


Three control bits T1INV, T2INV and T3INV in the TIM_CR2 register can invert the tim_in1, tim_in2 and tim_in3 signals prior entering the XOR gate.

The status of the tim_in1, tim_in2, tim_in3 and tim_in4 signals can be software polled using the TI1FS, TI2FS, TI3FS and TI4FS bits in the TIM_SR register (tim_ti4 is not represented on figures above and do not enter into the XOR gate).

31.3.34 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in *Figure 319*. The “interfacing timer” captures the three timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIM_CR2 register, with XORPS bit = 0).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the three inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See *Figure 245*). The captured value, which corresponds to the time elapsed between two changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

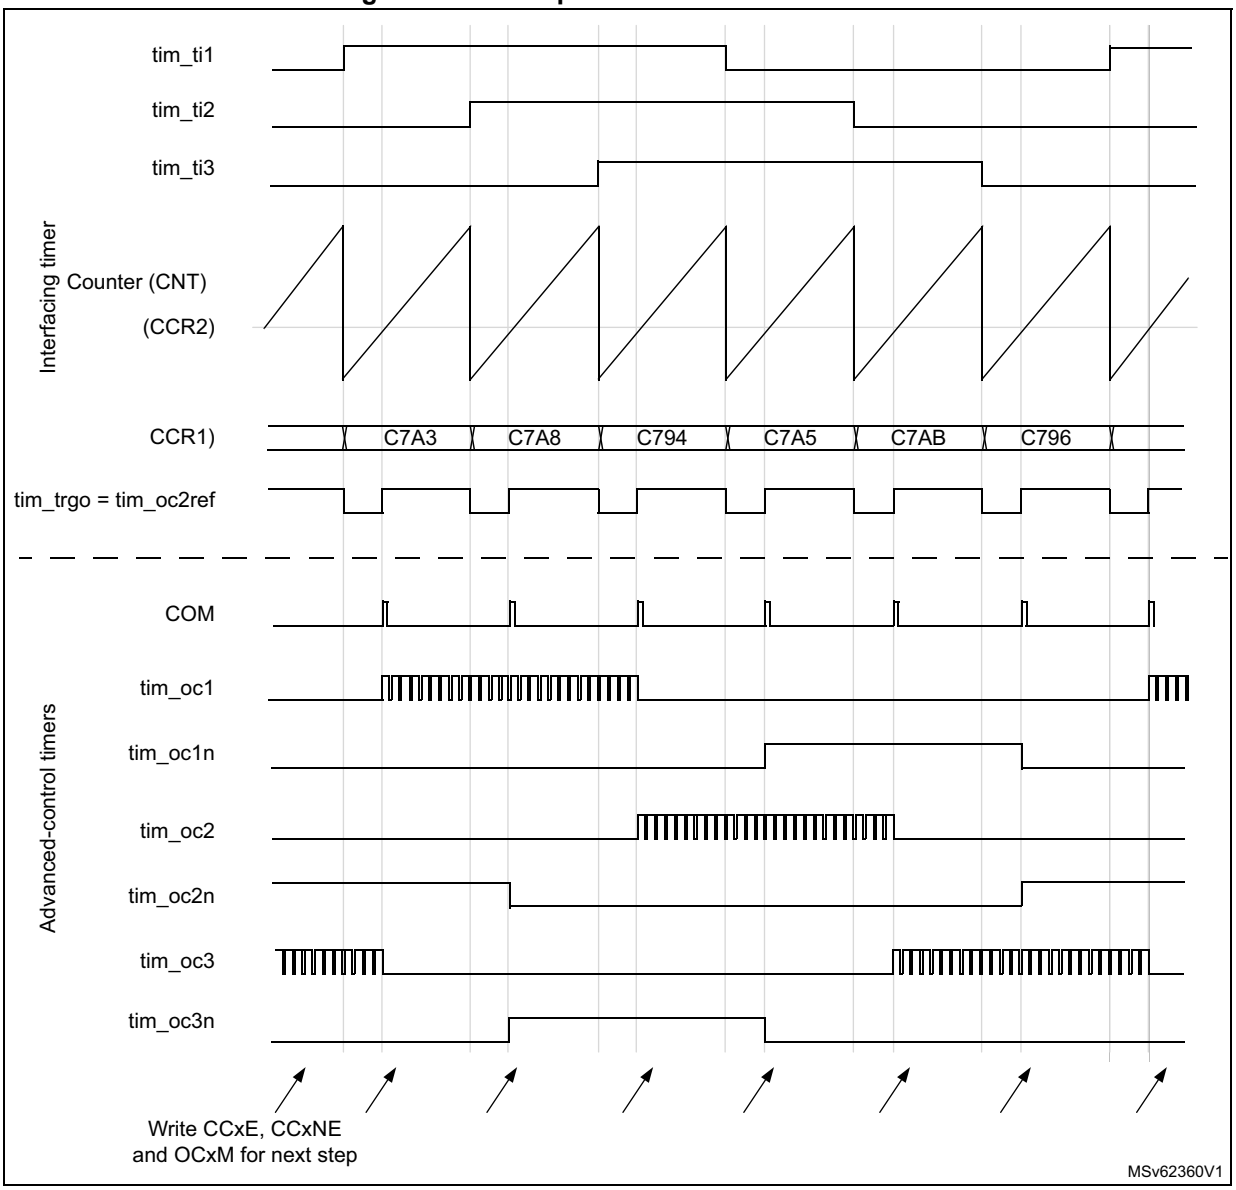
In this example the user wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure three timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIM_CR2 register to 1.
- Program the time base: write the TIM_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between two changes on the sensors.
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIM_CCMR1 register to 01. The digital filter can also be programmed if needed.
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to 111 and the CC2S bits to 00 in the TIM_CCMR1 register.
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIM_CR2 register to 101.

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC = 1 in the TIM_CR2 register) and the COM event is controlled by the trigger input (CCUS = 1 in the TIM_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

Figure 319 describes this example.

Figure 319. Example of Hall sensor interface



31.3.35 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to *Section 32.4.27: Timer synchronization* for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger, and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIM_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIM_ARR, TIM_CCRx) are updated.

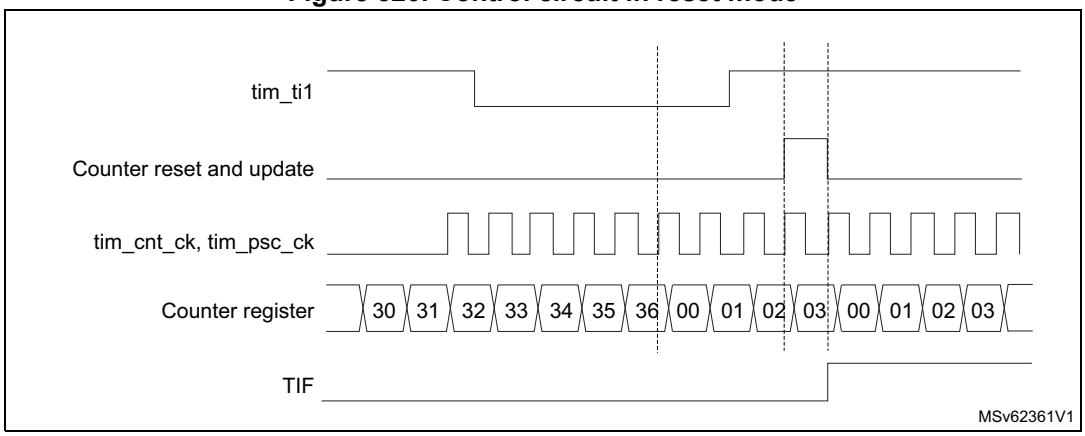
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIM_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS = 100 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
- Start the counter by writing CEN = 1 in the TIM_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIM_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIM_DIER register).

The following figure shows this behavior when the autoreload register TIM_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 320. Control circuit in reset mode



Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

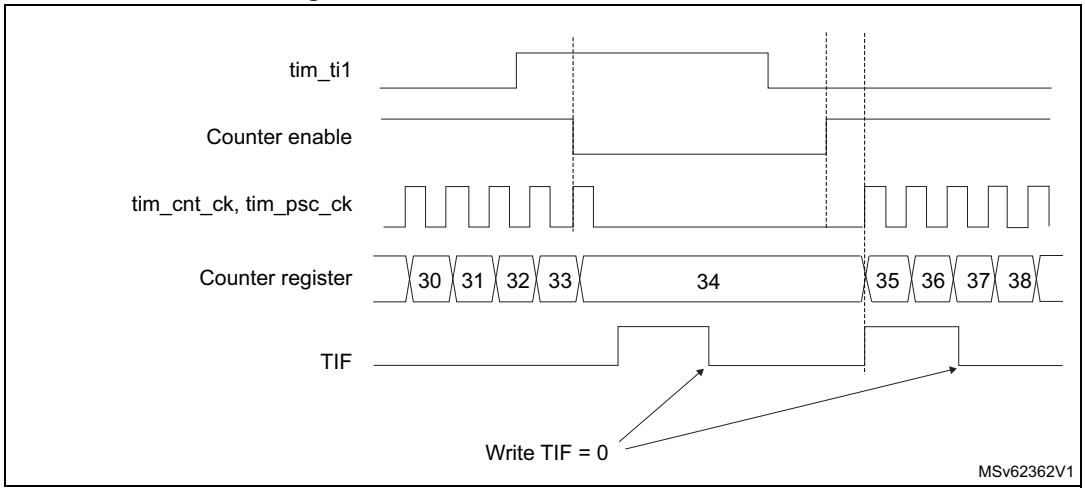
In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIM_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS = 101 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
- Enable the counter by writing CEN = 1 in the TIM_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIM_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 321. Control circuit in Gated mode



Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

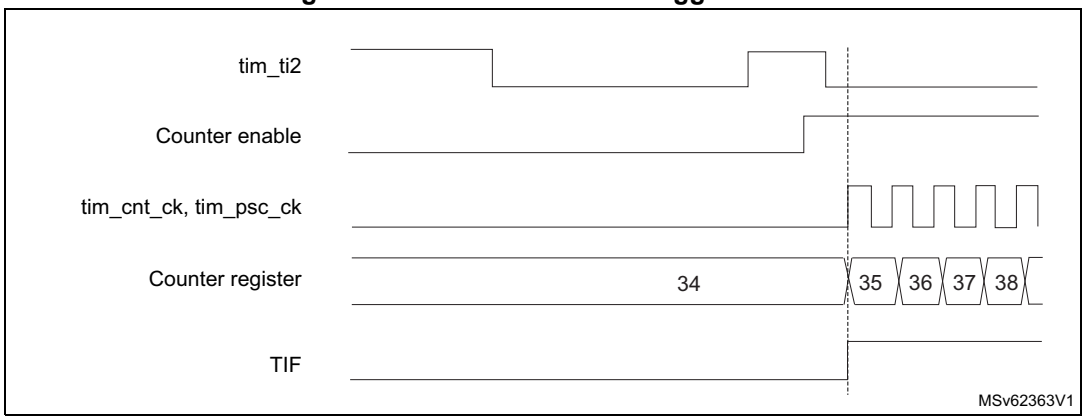
In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S = 01 in TIM_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti2 as the input source by writing TS = 00110 in TIM_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 322. Control circuit in trigger mode



Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIM_SMCR register.

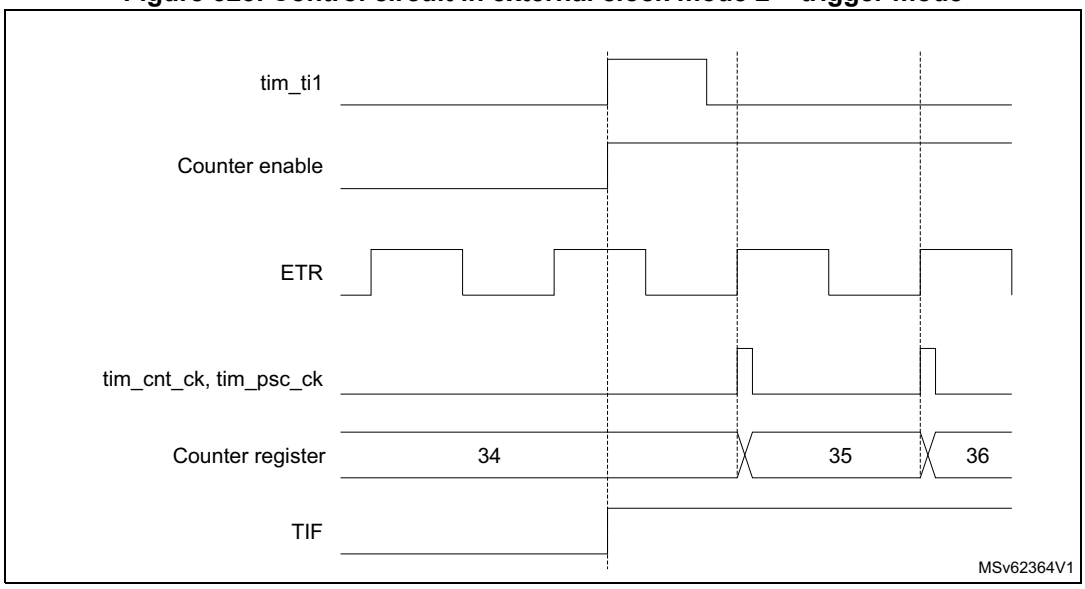
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIM_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01in TIM_CCMR1 register to select only the input capture source
   - CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

Figure 323. Control circuit in external clock mode 2 + trigger mode



Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

31.3.36 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

Refer to MMS2[4:0] bitfield description in TIM_CR2 for the complete list of triggering options.

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 24 possible events, which can be selected using the MMS2[4:0] bits in the TIM_CR2 register.

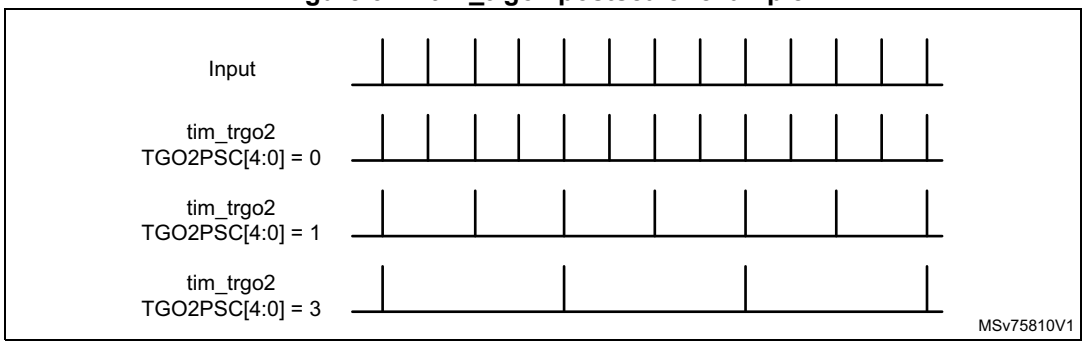
An example of an application for 3-phase motor drives is given in *Figure 263*.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

It is possible to reduce the ADC triggering rate with the tim_tro2 post scaler. This is done by periodically discarding tim_trgo2 events, as per the value programmed in TGO2PSC[4:0] bitfield in TIM_CR1, as shown on *Figure 324* below.

Figure 324. tim_trgo2 postscaler example



The post scaler is able to operate with:

– pulses as shown on *Figure 324* above, when selecting for instance MMS2[4:0] = 10001 to have a trigger on tim_oc7refc rising rising or falling edges

– the tim_ocxrefc signal itself (ie with user-defined duty cycle), when selecting for instance MMS2[4:0] = 10000 to have a trigger on tim_oc7refc

31.3.37 ADC synchronization

The timer operation can be synchronized to the ADC clock to trigger jitter-free ADC sampling. This function is enabled using the ADSYNC bit in the TIM_CR2 register.

This feature is useful when the timers and the ADCs are operating with semisynchronous clocks (clocks derived from a same source with integer ratio tim_ker_ck/adc_ker_ck), for instance adc_ker_ck = 75 MHz and tim_ker_ck = 150 MHz or 300 MHz.

ADSYNC must also be set when both peripherals are operating at the same frequency from the same clock source, when jitter-free operation is needed.

ADSYNC must not be set and jitter-free operation is not supported in the following cases:

- when the clock ratio is not an integer (for example adc_ker_ck = 75 MHz and tim_ker_ck = 100 MHz): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum
- when the ADC is operating in asynchronous mode (adc_ker_ck uncorrelated with tim_ker_ck): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.

When ADSYNC = 1, the timer operation is slightly changed: the counter enable and counter reset events are aligned to the adc_ker_ck ADC clock, to avoid any phase shift due to clocks enable in the RCC.

Jitter-free operation is guaranteed only when one of the two requirements below is met (depending on the selected trigger source).

1. The counter period must be a multiple of the ADC clock period:

$$(\text{TIM_PSC} + 1) \times (\text{TIM_ARR} + 1) \times T_{\text{tim_ker_ck}} = n \times T_{\text{adc_ker_ck}}$$

2. The compare value must be a multiple of the ADC clock period:

$$(\text{TIM_PSC} + 1) \times \text{TIM_CMPy} \times T_{\text{tim_ker_ck}} = m \times T_{\text{adc_ker_ck}}$$

Note: If none of the two above requirements are met, the trigger is still generated, but the latency is not constant and varies with the timer and ADC clocks phase shift.

Programming guidelines

The ADC synchronization feature must not be modified during run-time, once the counter is enabled and once the ADC has been configured for receiving triggers from the timer.

It is mandatory to follow the procedure below to use the ADC synchronization:

1. Enable the destination ADC clock.
2. Configure the timer and set the ADSYNC bit.
3. Configure the ADC and enable it (using ADSTART and/or JADSTART bits).
4. Start the timer (with the CEN counter enable bit).

31.3.38 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to reprogram part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIM_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIM_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIM_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address), i.e. the number of transfers (in words).

The DBA[4:0] bits in the TIM_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIM_DMAR address). DBA is defined as an offset starting from the address of the TIM_CR1 register:

Example:

00000: TIM_CR1

00001: TIM_CR2

00010: TIM_SMCR

The DBSS[3:0] bits in the TIM_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 31.6.34: TIM DMA control register (TIM_DCR)* for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (see note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bitfields as follows: DBL = 2, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5, and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3, and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

31.3.39 TIM1/TIM8 DMA requests

The TIM1/TIM8 can generate a DMA request, as shown in the table below.

Table 301. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_cc2_dma	Capture/compare 2	CC2DE
tim_cc3_dma	Capture/compare 3	CC3DE

Table 301. DMA request (continued)

DMA request signal	DMA request	Enable control bit
tim_cc4_dma	Capture/compare 4	CC4DE
tim_com_dma	Commutation (COM)	COMDE
tim_trgi_dma	Trigger	TDE

31.3.40 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIM_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).

31.4 TIM1/TIM8 low-power modes

Table 302. Effect of low-power modes on TIM1/TIM8

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

31.5 TIM1/TIM8 interrupts

The TIM1/TIM8 can generate multiple interrupts, as shown in *Table 303*.

Table 303. Interrupt requests

Interrupt acronym		Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM_UPD		Update	UIF	UIE	write 0 in UIF	Yes	No
TIM_CC		Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
		Capture/compare 2	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
		Capture/compare 3	CC3IF	CC3IE	write 0 in CC3IF	Yes	No
		Capture/compare 4	CC4IF	CC4IE	write 0 in CC4IF	Yes	No
TIM_TRGI_COM_DIR_IDX	TIM_COM	Commutation (COM)	COMIF	COMIE	write 0 in COMIF	Yes	No
	TIM_TRGI	Trigger	TIF	TIE	write 0 in TIF	Yes	No
	TIM_IDX	Index	IDXF	IDXIE	write 0 in IDXF	Yes	No
	TIM_DIR	Direction	DIRF	DIRIE	write 0 in DIRF	Yes	No
TIM_BRK_TERR_IERR	TIM_BRK	Break	BIF	BIE	write 0 in BIF	Yes	No
		Break2	B2IF		write 0 in B2IF	Yes	No
		System Break	SBIF		write 0 in SBIF	Yes	No
	TIM_IERR	Index Error	IERRF	IERRIE	write 0 in IERRF	Yes	No
	TIM_TERR	Transition Error	TERRF	TERRIE	write 0 in TERRF	Yes	No

31.6 TIM1/TIM8 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

31.6.1 TIM control register 1 (TIM_CR1)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CKD2[3:0]				Res.	Res.	Res.	TGO2PSC[4:0]				
				rw	rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **CKD2[3:0]**: Clock division 2

This bit field indicates the division between sampling clock (t_{DTS}) used by the dead-time generators and the digital filters (tim_etr_in, tim_tix).

0000: No Division
0001: $t_{DTS2} = 4*t_{DTS}$
0010: $t_{DTS2} = 16*t_{DTS}$
0011: $t_{DTS2} = 64*t_{DTS}$
0100: $t_{DTS2} = 256*t_{DTS}$
0101: $t_{DTS2} = 1024*t_{DTS}$
0110: $t_{DTS2} = 4096*t_{DTS}$
0111: $t_{DTS2} = 16384*t_{DTS}$
1000: $t_{DTS2} = 65536*t_{DTS}$
1001: $t_{DTS2} = 262144*t_{DTS}$
Others: Reserved, do not program this value

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **TGO2PSC[4:0]**: Trigger output 2 postcaler

The postscaler discards periodically events sent on the tim_trgo2 output, to reduce the ADC triggering rate.
The number of events on tim_trgo2 is divided by (TGO2PSC[4:0] + 1).
When TGO2PSC[4:0] = 0x0, the tim_trgo2 event rate is not affected.
With TGO2PSC[4:0] = 0x1, one event out of 2 is sent on tim_trgo2, with TGO2PSC[4:0] = 0x2, one event out of 3 is sent on tim_trgo2, up to 1 event out of 31 when TGO2PSC[4:0] = 0x1F,...

Note: The postscaler is only applicable when tim_trgo2 transfers a pulse (reset, update, compare pulse). When the tim_trgo2 outputs a level-based information (compare signal or enable bit for gated mode), the postscaler must be set set to 0

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIM_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIM_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (t_{DTS})used by the dead-time generators and the digital filters (tim_etr_in, tim_tix),
00: $t_{DTS} = t_{tim_ker_ck}$
01: $t_{DTS} = 2*t_{tim_ker_ck}$
10: $t_{DTS} = 4*t_{tim_ker_ck}$
11: $t_{DTS} = 8*t_{tim_ker_ck}$

Bit 7 **ARPE**: Autoreload preload enable
0: TIM_ARR register is not buffered
1: TIM_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection
00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set both when the counter is counting up or down.
Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)

Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter
Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

31.6.2 TIM control register 2 (TIM_CR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TI3INV	TI2INV	TI1INV	ADSYNC	XORPS	Res.	MMS[3]	MMS2[4:0]					OIS7	OIS6	Res.	OIS5
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bit 31 **TI3INV**: tim_ti3 signal inversion on XOR gate input

0: tim_ti3 non-inverted

1: tim_ti3 inverted

Bit 30 **TI2INV**: tim_ti2 signal inversion on XOR gate input

0: tim_ti2 non-inverted

1: tim_ti2 inverted

Bit 29 **TI1INV**: tim_ti1 signal inversion on XOR gate input

0: tim_ti1 non-inverted

1: tim_ti1 inverted

Bit 28 **ADSYNC**: ADC synchronization

0: The timer operates independently from the ADC

1: The timer operation is synchronized with the ADC clock to provide jitter-free sampling point. This mode can be enabled only with specific ADC / timer clock relationship. Refer to *Section 31.3.37* for requirements.

The ADSYNC must not modified when the counter is enabled (CEN bit is set).

Bit 27 **XORPS**: XOR gate position selection

This bit defines the position of the XOR gate with respect to input filters.

0: XOR gate placed before TI1 filter

1: XOR gate placed after TI1, TI2 and TI3 filters

Bit 26 Reserved, must be kept at reset value.

Bits 24:20 **MMS2[4:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

00000:**Reset** - the UG bit from the TIM_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

00001:**Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIM_SMCR register).

00010:**Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

00011:**Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

00100:**Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

00101:**Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

00110:**Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

00111:**Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

01000:**Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

01001:**Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

01010:**Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

01011:**Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

01100:**Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

01101:**Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

01110:**Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

01111:**Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

10000: **Compare** - tim_oc7refc signal is used as trigger output (tim_trgo2)

10001: **Compare Pulse** - tim_oc7refc rising or falling edges generate pulses on tim_trgo2

10010: **Compare Pulse** tim_oc4refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10011: **Compare Pulse** - tim_oc4refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

10100: **Compare Pulse** -tim_oc5refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10101: **Compare Pulse** - tim_oc5refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

10110: **Compare Pulse** - tim_oc6refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10111: **Compare Pulse** - tim_oc6refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19 **OIS7**: Output idle state 7 (tim_oc7 output)

Refer to OIS1 bit

Bit 18 **OIS6**: Output idle state 6 (tim_oc6 output)
Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output idle state 5 (tim_oc5 output)
Refer to OIS1 bit

Bit 15 **OIS4N**: Output idle state 4 (tim_oc4n output)
Refer to OIS1N bit

Bit 14 **OIS4**: Output idle state 4 (tim_oc4 output)
Refer to OIS1 bit

Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n = 0 after a dead-time when MOE = 0
1: tim_oc1n = 1 after a dead-time when MOE = 0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1 = 0 (after a dead-time) when MOE = 0
1: tim_oc1 = 1 (after a dead-time) when MOE = 0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection
This bit enables the insertion of a XOR gate to combine tim_ti1_in[15:0], tim_ti2_in[15:0], and tim_ti3_in[15:0] inputs into tim_ti1.
The position of the XOR gate, with respect to input filters, is defined with the XORPS bit.
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input

Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIM_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

Note: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE, CCxP, CCxNP and OCxM bits are not preloaded

1: CCxE, CCxNE, CCxP, CCxNP and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

Note: This bit acts only on channels that have a complementary output.

31.6.3 TIM slave mode control register (TIM_SMCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SETPS[3:0]				SMSPS	SMSPE	Res.	Res.	TS[4:3]		Res.	Res.	SMS[4:3]	
		rw	rw	rw	rw	rw	rw			rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:26 **SETPS[3:0]**: Synchronous external trigger prescaler

The linear synchronous prescaler divides the frequency of the tim_etrf signal, by a factor (SETPS[3:0] + 1).

Bit 25 **SMSPS**: SMS preload source

This bit selects whether the events that triggers the SMS[4:0] bitfield transfer from preload to active

0: The transfer is triggered by the Timer's Update event

1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded

0: SMS[4:0] bitfield is not preloaded

1: SMS[4:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **TS[4:3]**: Trigger selection - bit 4:3

Refer to TS[2:0] description - bits 6:4

Bits 19:18 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether tim_etr_in or $\overline{\text{tim_etr_in}}$ is used for trigger operations

0: tim_etr_in is non-inverted, active at high level or rising edge.

1: tim_etr_in is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111).

It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).

If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF
01: tim_etr_in frequency divided by 2
10: tim_etr_in frequency divided by 4
11: tim_etr_in frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bit 7 **MSM:** Master/slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]:** Trigger selection

This bitfield is combined with TS[4:3] bits.

This bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal trigger 0 (tim_itr0)
00001: Internal trigger 1 (tim_itr1)
00010: Internal trigger 2 (tim_itr2)
00011: Internal trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
00111: External trigger input (tim_etrf)
01000: Internal trigger 4 (tim_itr4)
01001: Internal trigger 5 (tim_itr5)
01010: Internal trigger 6 (tim_itr6)
01011: Internal trigger 7 (tim_itr7)
01100: Internal trigger 8 (tim_itr8)
01101: Internal trigger 9 (tim_itr9)
01110: Internal trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
10100: Internal trigger 16 (tim_itr16)
10101: Internal trigger 17 (tim_itr17)
10110: Internal trigger 18 (tim_itr18)
10111: Internal trigger 19 (tim_itr19)
11000: Internal trigger 20 (tim_itr20)
11001: Internal trigger 21 (tim_itr21)
11010: Internal trigger 22 (tim_itr22)
11011: Internal trigger 23 (tim_itr23)
11100: Internal trigger 24 (tim_itr24)
11101: Internal trigger 25 (tim_itr25)
11110: Internal trigger 26 (tim_itr26)
11111: Internal trigger 27 (tim_itr27)

See *Section 31.3.2: TIM1/TIM8 pins and internal signals* for more details on tim_itrx meaning for each Timer.

Note: These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS:** OCREF clear selection

This bit is used to select the OCREF clear source.

0: tim_ocref_clr_int is connected to the tim_ocref_clr input
1: tim_ocref_clr_int is connected to tim_etrf

Bits 17:16, 2:0 **SMS[4:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIM_SMCR for tim_etr_in and CCxP/CCxNP bits in TIM_CCER register for tim_ti1fp1 and tim_ti2fp2).

00000:Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.

00001:Quadrature encoder mode 1, x2 mode- Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

00010:Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

00011:Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

00100:Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

00101:Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

00110:Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

00111:External Clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

01000:Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

01001:Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

01010:Encoder mode: Clock plus direction, x2 mode.

01011:Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

01100:Encoder mode: Directional Clock, x2 mode.

01101:Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

01110:Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

01111:Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

10000:Quadrature encoder with built-in debouncer: x2 mode.

10001:Quadrature encoder with built-in debouncer: x4 mode.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

31.6.4 TIM DMA/interrupt enable register (TIM_DIER)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **TI4FS**: tim_ti4f status

This flag indicates the value of the tim_ti4f signal (after the digital filtering stage), for polling purpose.
0: tim_ti4f signal is low
1: tim_ti4f signal is high

Bit 30 **TI3FS**: tim_ti3f status

This flag indicates the value of the tim_ti3f signal (after the digital filtering stage), for polling purpose.
0: tim_ti3f signal is low
1: tim_ti3f signal is high

Bit 29 **TI2FS**: tim_ti2f status

This flag indicates the value of the tim_ti2f signal (after the digital filtering stage), for polling purpose.
0: tim_ti2f signal is low
1: tim_ti2f signal is high

Bit 28 **TI1FS**: tim_ti1f status

This flag indicates the value of the tim_ti1f signal (after the digital filtering stage), for polling purpose.
0: tim_ti1f signal is low
1: tim_ti1f signal is high

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **ODS**: Output disable status

This bit indicates the global output state when a break or break2 event occured, to discriminate the source.
0: Idle state: break was triggered (or MOE was written to 0), and OIS states are forced on tim_ocx and tim_ocxn outputs
1: Disabled state: break2 was triggered, tim_ocx and tim_ocxn outputs are inactive

Bit 24 **UIOVRF**: Update Interrupt Overrun flag

This flag is set by hardware when an update request occurs while an update interrupt is pending (update interrupt flag set). It is cleared by software by writing it to '0'.
0: No Update Interrupt Overrun
1: Update Interrupt Overrun

Bit 23 **TERRF**: Transition error interrupt flag

This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 **IERRF**: Index error interrupt flag

This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.
0: No index error has been detected.
1: An index error has been detected

Bit 21 **DIRF**: Direction change interrupt flag

This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIM_CR is changing). It is cleared by software by writing it to 0.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
0: No index event occurred.
1: An index event has occurred

Bit 19 Reserved, must be kept at reset value.

Bit 18 **CC7IF**: Compare 7 interrupt flag
Refer to CC1IF description
Note: Channel 7 can only be configured as output.

Bit 17 **CC6IF**: Compare 6 interrupt flag
Refer to CC1IF description
Note: Channel 6 can only be configured as output.

Bit 16 **CC5IF**: Compare 5 interrupt flag
Refer to CC1IF description
Note: Channel 5 can only be configured as output.

Bit 15 **B2GF**: Break 2 generation flag
This flag is set by hardware as soon as a break 2 event is forced by software, using the B2G bit. It is useful to distinguish hardware-triggered from software-triggered break events. It is cleared by software by writing it to 0.
0: No break 2 event occurred.
1: A break 2 event was forced with the B2G bit

Bit 14 **BGF**: Break generation flag
This flag is set by hardware as soon as a break event is forced by software, using the BG bit. It is useful to distinguish hardware-triggered from software-triggered break events. It is cleared by software by writing it to 0.
0: No break event occurred.
1: A break event was forced with the BG bit

Bit 13 **SBIF**: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 12 **CC4OF**: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
0: No overcapture has been detected.
1: The counter value has been captured in TIM_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.

1: An active level has been detected on the break 2 input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.

1: An active level has been detected on the break input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.

1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIM_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred
If channel CC1 is configured as output: this flag is set when the content of the counter TIM_CNT matches the content of the TIM_CCR1 register. When the content of TIM_CCR1 is greater than the content of TIM_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIM_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIM_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIM_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
–At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS = 0 in the TIM_CR1 register.
–When CNT is reinitialized by software using the UG bit in TIM_EGR register, if URS = 0 and UDIS = 0 in the TIM_CR1 register.
–When CNT is reinitialized by a trigger event (refer to *Section 31.6.3: TIM slave mode control register (TIM_SMCR)*), if URS = 0 and UDIS = 0 in the TIM_CR1 register.

31.6.6 TIM event generation register (TIM_EGR)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	B2G	BG	TG	COMG	CC4G	CC3G	CC2G	CC1G	UG
							w	w	w	w	w	w	w	w	w

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **B2G**: Break 2 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIM_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 **COMG**: Capture/compare control update generation

This bit can be set by software, it is automatically cleared by hardware

0: No action

1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)

Note: This bit acts only on channels having a complementary output.

Bit 4 **CC4G**: Capture/compare 4 generation

Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation

Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

If channel CC1 is configured as output:

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

If channel CC1 is configured as input:

The current value of the counter is captured in TIM_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR = 0 (upcounting), else it takes the autoreload value (TIM_ARR) if DIR = 1 (downcounting).

31.6.7 TIM capture/compare mode register 1 (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode:

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter
Refer to IC1F[3:0] bit description

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler
Refer to IC1PSC[1:0] bit description

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIM_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 Selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

31.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

OC2CE	OC2M[2:0]			OC2PE	OC2FE	CC2S[1:0]		OC1CE	OC1M[2:0]			OC1PE	OC1FE	CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC2CE:** Output compare 2 clear enable

0: tim_oc2ref is not affected by the tim_ocref_clr_int signal

1: tim_oc2ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 31.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC2M[4:0]**: Output compare 2 mode

Refer to OC1M[4:0] bit description

Bit 11 **OC2PE**: Output compare 2 preload enable

0: Preload register on TIM_CCR2 disabled. TIM_CCR2 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR2 enabled. Read/Write operations access the preload register. TIM_CCR2 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 10 **OC2FE**: Output compare 2 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC2 behaves normally depending on counter and CCR2 values even when the trigger is ON. The minimum delay to activate CC2 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC2 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC2 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bit 7 **OC1CE:** Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 31.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC1M[4:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

00000:Frozen - The comparison between the output compare register TIM_CCR1 and the counter TIM_CNT has no effect on the outputs.This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

00001:Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00010:Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00011:Toggle - tim_oc1ref toggles when TIM_CNT = TIM_CCR1.

00100:Force inactive level - tim_oc1ref is forced low.

00101:Force active level - tim_oc1ref is forced high.

00110:PWM mode 1 - In upcounting, channel 1 is active as long as TIM_CNT<TIM_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref = 0) as long as TIM_CNT>TIM_CCR1 else active (tim_oc1ref = 1).

00111:PWM mode 2 - In upcounting, channel 1 is inactive as long as TIM_CNT<TIM_CCR1 else active. In downcounting, channel 1 is active as long as TIM_CNT>TIM_CCR1 else inactive.

01000:Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001:Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01100-01101:Combined PWM mode 1 and 2. Refer to *Table 296* for details.

01110-01111:Asymmetric PWM mode 1 and 2. Refer to *Table 295* for details.

10000-10001:Combined PWM mode 3 and 4. Refer to *Table 296* for details.

10010-11001: Asymmetric PWM mode 3 to 10. Refer to *Table 295* for details.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Note: On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIM_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIM_CCR1 disabled. TIM_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR1 enabled. Read/Write operations access the preload register. TIM_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

31.6.9 TIM capture/compare mode register 2 (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter
Refer to IC3F[3:0] bit description

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler
Refer to IC3PSC[1:0] bit description

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIM_CCER).

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter
This bitfield defines the frequency used to sample tim_ti3 input and the length of the digital filter applied to tim_ti3. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler
This bitfield defines the ratio of the prescaler acting on CC3 input (tim_ic3). The prescaler is reset as soon as CC3E = 0 (TIM_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIM_CCER).

31.6.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Output compare mode

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

0: tim_oc4ref is not affected by the tim_ocref_clr_int signal

1: tim_oc4ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 31.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC4M[4:0]**: Output compare 4 mode

Refer to OC3M[4:0] bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

0: Preload register on TIM_CCR4 disabled. TIM_CCR4 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR4 enabled. Read/Write operations access the preload register. TIM_CCR4 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 10 **OC4FE**: Output compare 4 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC4 behaves normally depending on counter and CCR4 values even when the trigger is ON. The minimum delay to activate CC4 output when an edge occurs on the trigger input is 5 clock cycles.
