- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CAN-FD module, 2-channel version, 16 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Table 34.21 Mapping between pages and AFL entries (1 of 2)

Page 0	Entry 0 – 15
Page 1	Entry 16 – 31
Page 2	Entry 32 – 47

Page 13	Entry 208 – 223

Table 34.21 Mapping between pages and AFL entries (2 of 2)

Page 14	Entry 224 – 239
Page 15	Entry 240 – 255

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (see Figure 34.26). This register has the following fields:

- 4 bits to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL

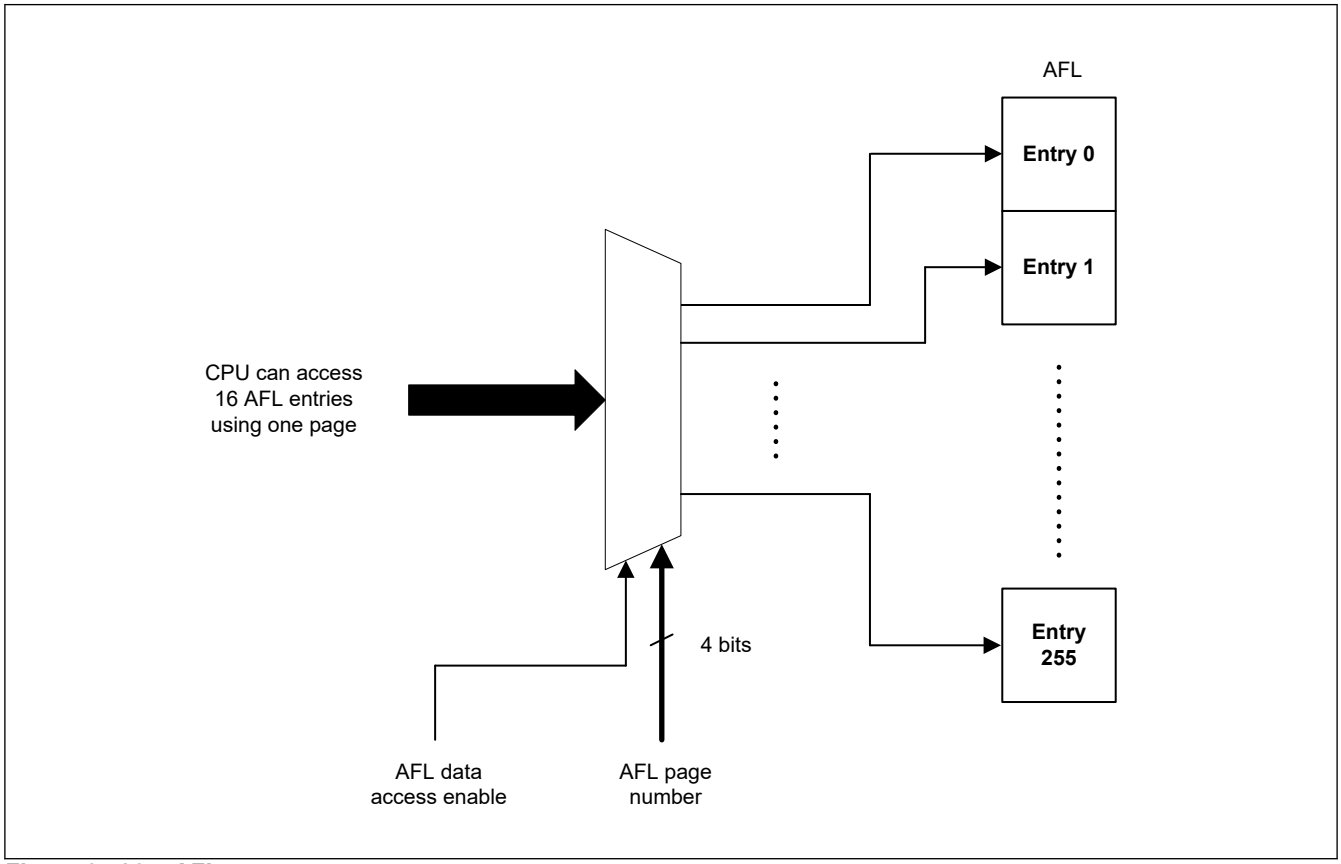

Figure 34.26 AFL page access

Application software should not write numbers higher than 0xF for the AFL page number.

Follow the configuration shown in Figure 34.27 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

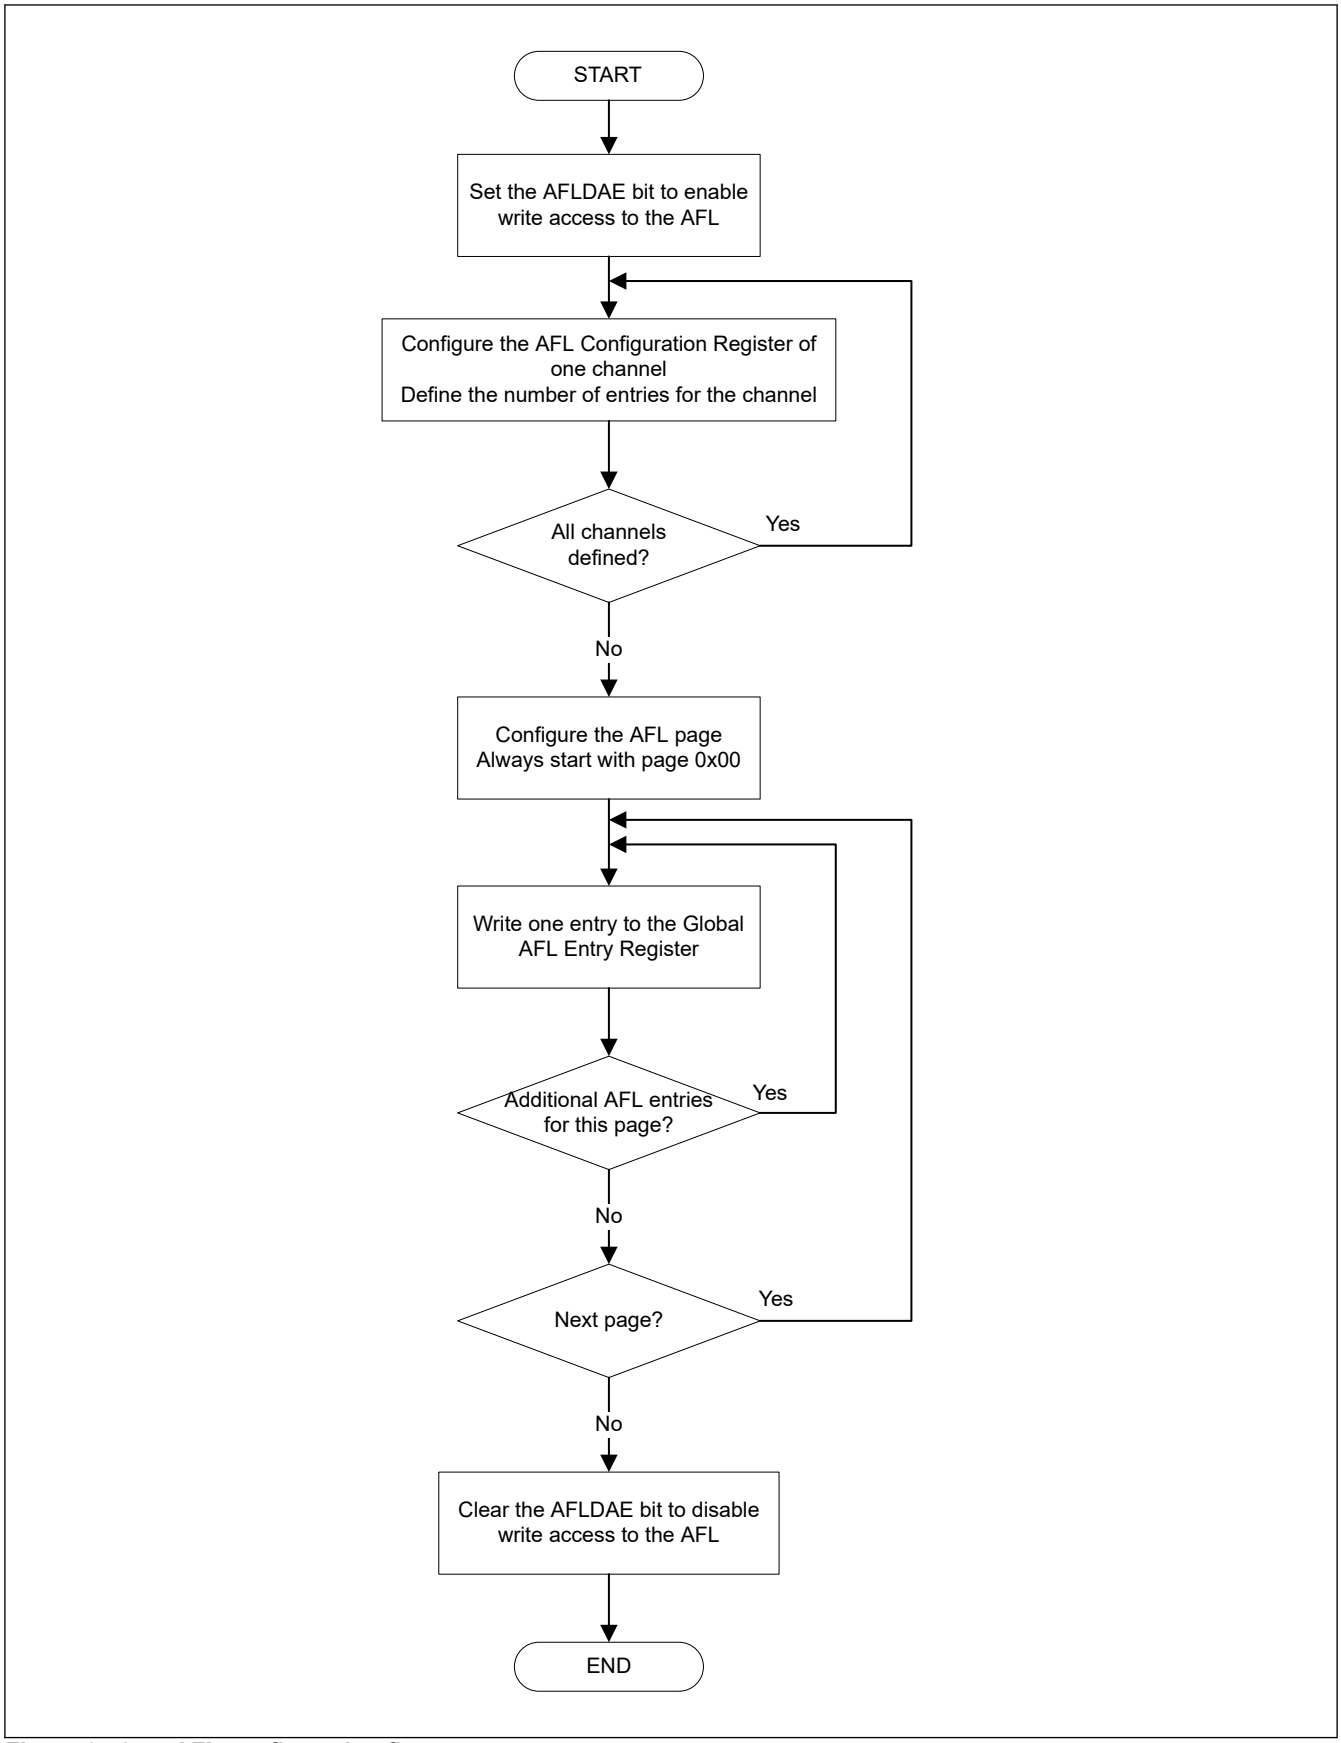

Figure 34.27 AFL configuration flow

34.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in loopback test mode (Self test mode 0 or Self test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If mirror mode and loopback test mode are configured at the same time, the loopback test mode behavior applies.

Table 34.22 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 34.22 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror mode enable (MME Configuration bit)	Loopback in Test mode (Self test mode 0 or Self test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

34.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x0553A20
  - CFDGAFLMn = 0x0000FFFF → IDEM = 0, RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF
- The comparison result for the four different received IDs with AFL entry x is described as follows:

– If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
– If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
– If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
– If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

34.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CAN-FD module. The message buffers are mapped as shown in Figure 34.28.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode, TX mode, or GW mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in GW mode or RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

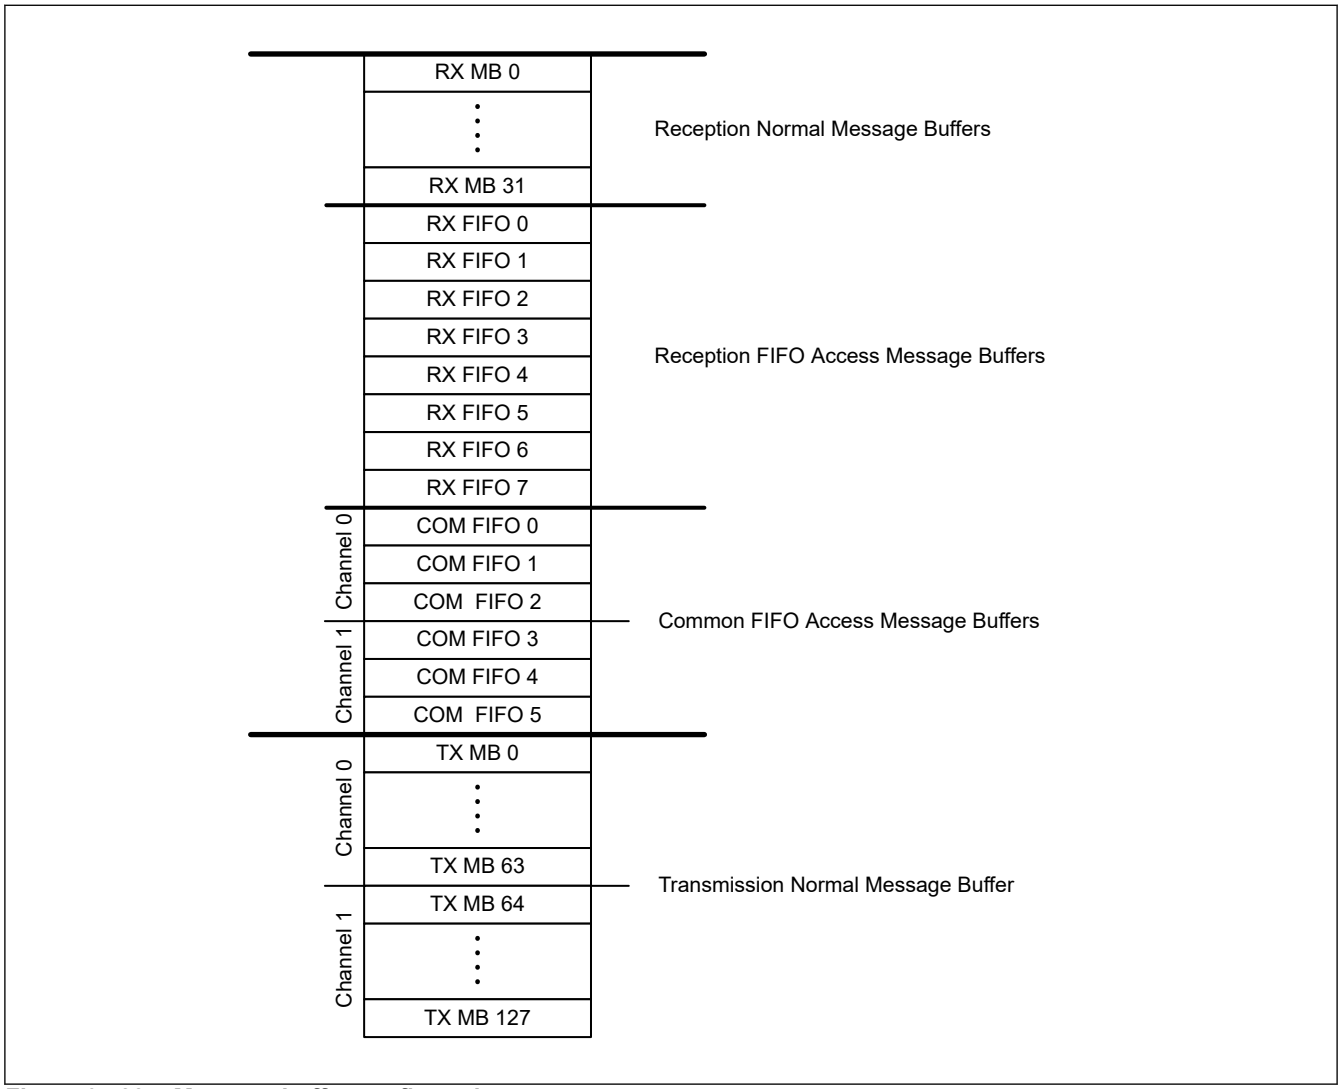

Figure 34.28 Message buffer configuration

34.6.1 Normal RX Message Buffers

In CAN-FD module, the frames received by various channels can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

34.6.1.1 Normal RX Message Buffer Configuration

In CAN-FD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = (16 × number of CAN channels) = 16 × 2 = 32 = 0x20 (32 flat RX MBs for 2 channels)

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CAN-FD module against incorrect configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS[2:0] bits. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

34.6.2 FIFO Buffer

The CAN-FD module provides a fixed number of FIFO buffers to support storage of frames for reception, transmission and gateway functions for various CAN channels.

The number of reception-only FIFO buffers is fixed to 8. However, 3 common FIFO buffers per channel can be configured to store messages for transmission, reception, or gateway function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO or GW FIFO

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

34.6.2.1 FIFO Buffers Configuration

In CAN-FD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 8 RX FIFO buffers + 6 common FIFO buffers = 14 FIFO buffers for 2 channels and message overwrite mechanism.

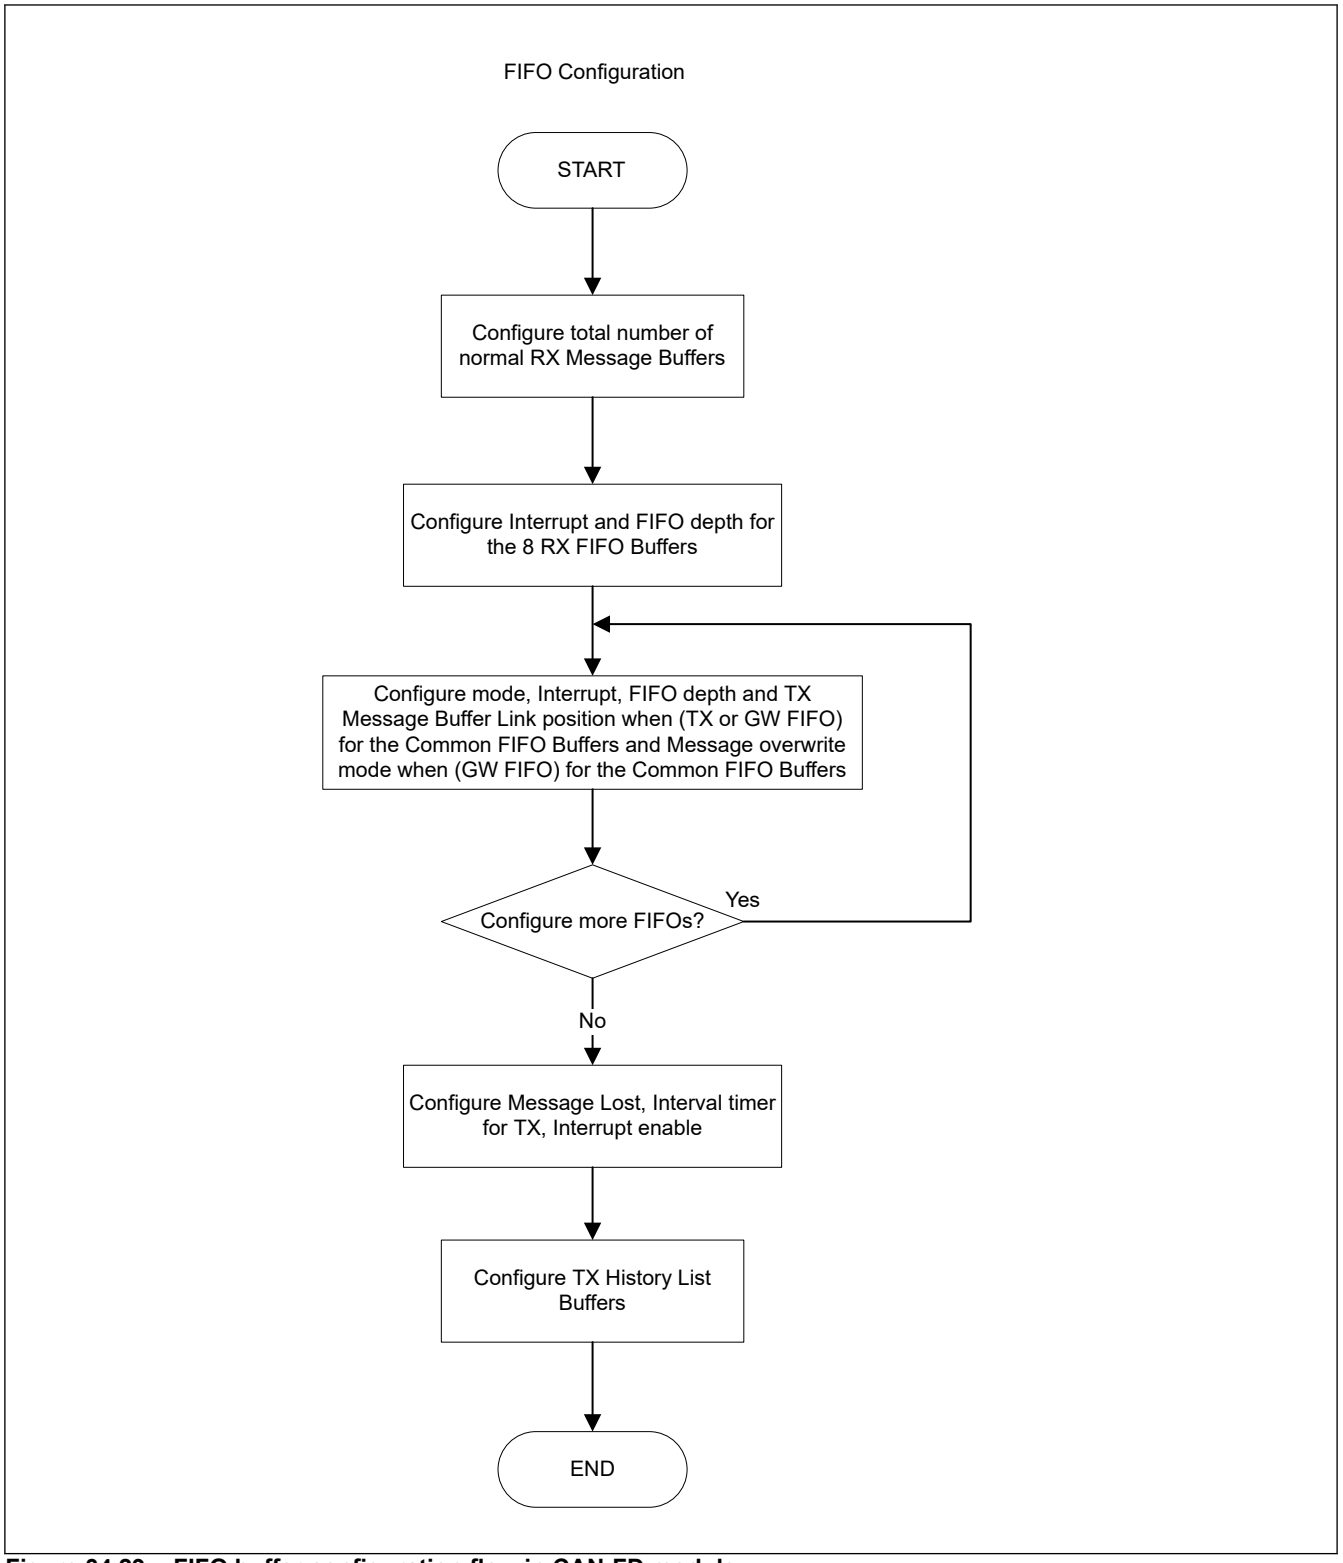

Figure 34.29 FIFO buffer configuration flow in CAN-FD module

As shown in Figure 34.29, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 8 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size

For the common FIFO buffers, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position

(1) FIFO Mode Configuration of Common FIFO Buffers

The mode of the common FIFO buffers can be configured by writing to the CFDCFCCn.CFM[1:0] bits in the Common FIFO Configuration/Control Registers. The possible modes of configuration for Common FIFO buffers are:

- 00b: RX mode (default mode after hardware reset)
- 01b: TX mode
- 10b: GW mode
- 11b: Reserved (do not write this value to the register bits)

Messages can only be read from the RX FIFO buffers and the Common FIFO buffers configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffers configured in TX mode. These messages are transmitted on the appropriate CAN channel.

Messages can only be read from the Common FIFO buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers. The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CAN-FD module.

After a hardware reset, all the Common FIFO buffers are configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded, and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message. The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message. The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point is then moves to the next message automatically. Do not write to this bit when the CFDCFCCn.CFE bit is 1.

(2) FIFO TX Message Buffer Link Configuration

When the common FIFO is configured as TX or GW FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan of a CAN channel.

The link to a normal TX message buffer must be unique, for example the same TX message buffer cannot be shared between 2 or more common FIFO buffers.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 32
- 0x01: TX Message Buffer 33
  ⋮

- 0x1F: TX Message Buffer 63

(3) FIFO Depth Configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCn.RFDC[2:0] bits and CFDCFCCn.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The 8 available options for depth configuration are:

- 000b: 0 Messages (FIFO buffer cannot be enabled)
- 001b: 4 Messages
- 010b: 8 Messages
- 011b: 16 Messages
- 100b: 32 Messages
- 101b: 48 Messages
- 110b: 64 Messages
- 111b: 128 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CAN-FD module logic does not check the validity of the configuration.

Note:
- If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCCn.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.
- If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) **FIFO Payload Size Configuration**

The data size of each FIFO buffer can be configured by writing to the CFDRFCCn.RFPLS[2:0] bits and CFDCFCCn.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

(5) FIFO Interrupt Configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCn.RFIM bit and the CFDCFCCn.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCn.RFIGCV/ CFDCFCCn.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
  - GW FIFO mode
    Frame RX: Interrupt generated when message counter increments and reaches the interrupt threshold value
    Frame TX: Interrupt generated when the last message is transmitted successfully from FIFO
- 1:

– RX FIFO mode: Interrupt generated at the end of storage of every received message
– TX FIFO mode: Interrupt generated for every successfully transmitted message
– GW FIFO mode
Frame RX: Interrupt generated when message is stored in the FIFO
Frame TX: Interrupt generated when message is successfully transmitted from the FIFO

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCn.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCCn.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCn.RFIGCV[2:0] and CFDCFCCn.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 34.23.

Table 34.23 FIFO interrupt generation counter and FIFO depth configuration

RFDC[2:0] (FDC[2:0])	RFIGCV[2:0] (CFGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

Common FIFO buffer can set an interrupt output at the completion time of transmitting one frame, or the completion of reception. In addition, Common FIFO and RX FIFO can set an interrupt output, when stored to the setup number (CFDC/RFDC) of FIFO stages.

34.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCn.RFIE
- CFDRFCCn.RFFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Registers:

- CFDCFCCn.CFRXIE

- CFDCFCCn.CFTXIE
- CFDCFCCEn.CFFIE
- CFDCFCCEn.CFOFRXIE
- CFDCFCCEn.CFOFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCn.RFE and CFDCFCCn.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers to allow transmission and reception of messages.

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in the Common FIFO, and transmission is stopped. Transmission starts when CFDCFCCEn.CFBME = 0.

Do not write 1 from 0 for this bit when the CFDCFCCn.CFE bit is 1.

34.7 Interrupt and DMA

34.7.1 Interrupts

The CAN-FD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional Status Flag register. These status bits are only set when the corresponding interrupt enables are set.

The Status Flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CAN-FD module can be classified into 2 groups, global interrupts and channel interrupts:

- Global interrupts:
  The CAN-FD module can generate 2 global interrupts:
  1. One Global interrupt for successful reception into the 8 RX FIFO buffers
  2. One Global error interrupt
- Channel interrupts:
  Each channel of the CAN-FD module can generate 3 channel interrupts:
  1. Channel transmission
     Transmission completion from channel
     Transmission abort from channel
     Transmission from TX Queue for a channel
     Channel THL Interrupt
     Successful transmission from a Common FIFO in TX or GW mode for a channel
  2. Channel error interrupt
  3. Successful reception in a Common FIFO in RX or GW mode for a channel or successful routing in a TXQ

The interrupts are cleared when the corresponding flag bits are cleared or interrupt enable bits are cleared.

Table 34.24 provides an overview of interrupt.

Table 34.24 Overview of interrupt source

Parameter	Interrupt	Interrupt source	Interrupt clearing
Global Interrupts	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	FIFO full into at least one RX FIFO	FIFO Full Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO Full Interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	Global error	Any of the following: • DLC Error flag • Message Lost Status bit • Message Overwrite Status bit • TXQ Message Lost Status bit • TXQ Message Overwrite Status bit • TX History Entry Lost Status bit • CAN-FD Message Payload overflow flag	Clear all of: • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • Message Overwrite flags in all of the Common FIFO Status Registers • Message Lost flags in all of the TXQ Status Registers • Message Overwrite Flags in all of the TXQ Status Registers • TX History List Entry Lost flag • CAN-FD Message Payload Overflow flag
Channel Transmission Interrupts	Channel n successful transmission	Any channel related TX MB Successful flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled
	Channel n abort	Any channel related TX MB Abort flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled globally
	Channel n transmission from TX Queue	Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel n THL Interrupt	Channel n THL Interrupt Status flag	Clear the relevant THL Interrupt Status flag
	Channel n COM FIFO TX Interrupt	Interrupt flag for Common FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame TX Interrupt	One Frame Transmission Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of Common FIFOs belonging to the related channel
	Channel n TXQ One Frame TX Interrupt	One Frame Transmission Interrupt flag for TXQs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of TXQs belonging to the related channel
Channel COM RX FIFO Interrupt	Channel n COM FIFO RX Interrupt	Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame RX Interrupt	One Frame Reception Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Reception Interrupt flags of Common FIFOs belonging to the related channel
	Channel n COM FIFO Full Interrupt	FIFO Full Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n TXQ One Frame Routing Interrupt	One Frame Routing Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the One Frame Routing Interrupt flags of TXQs in GW mode belonging to the related channel
	Channel n TXQ Full Interrupt	TXQ Full Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of TXQs in GW mode belonging to the related channel
Channel Error Interrupt	Channel n Error	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.

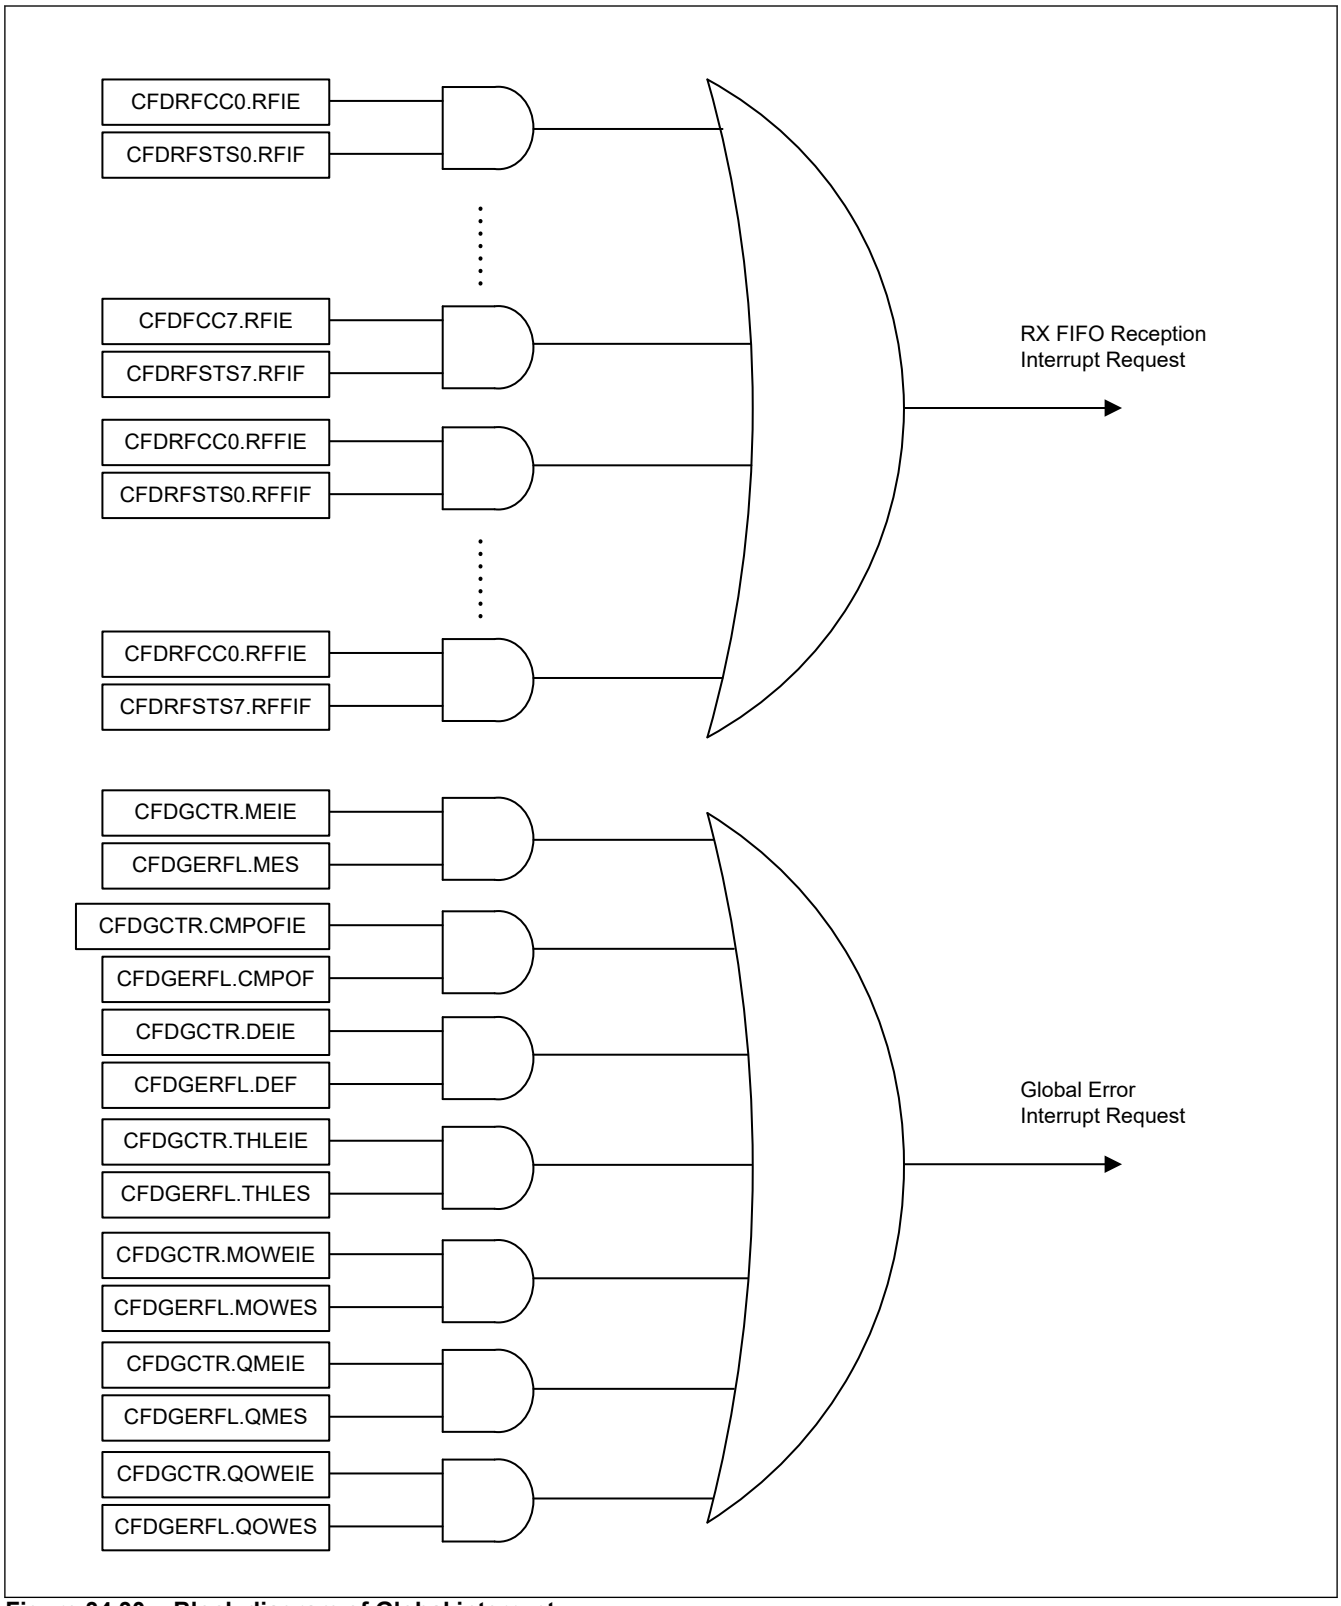

Figure 34.30 Block diagram of Global interrupt

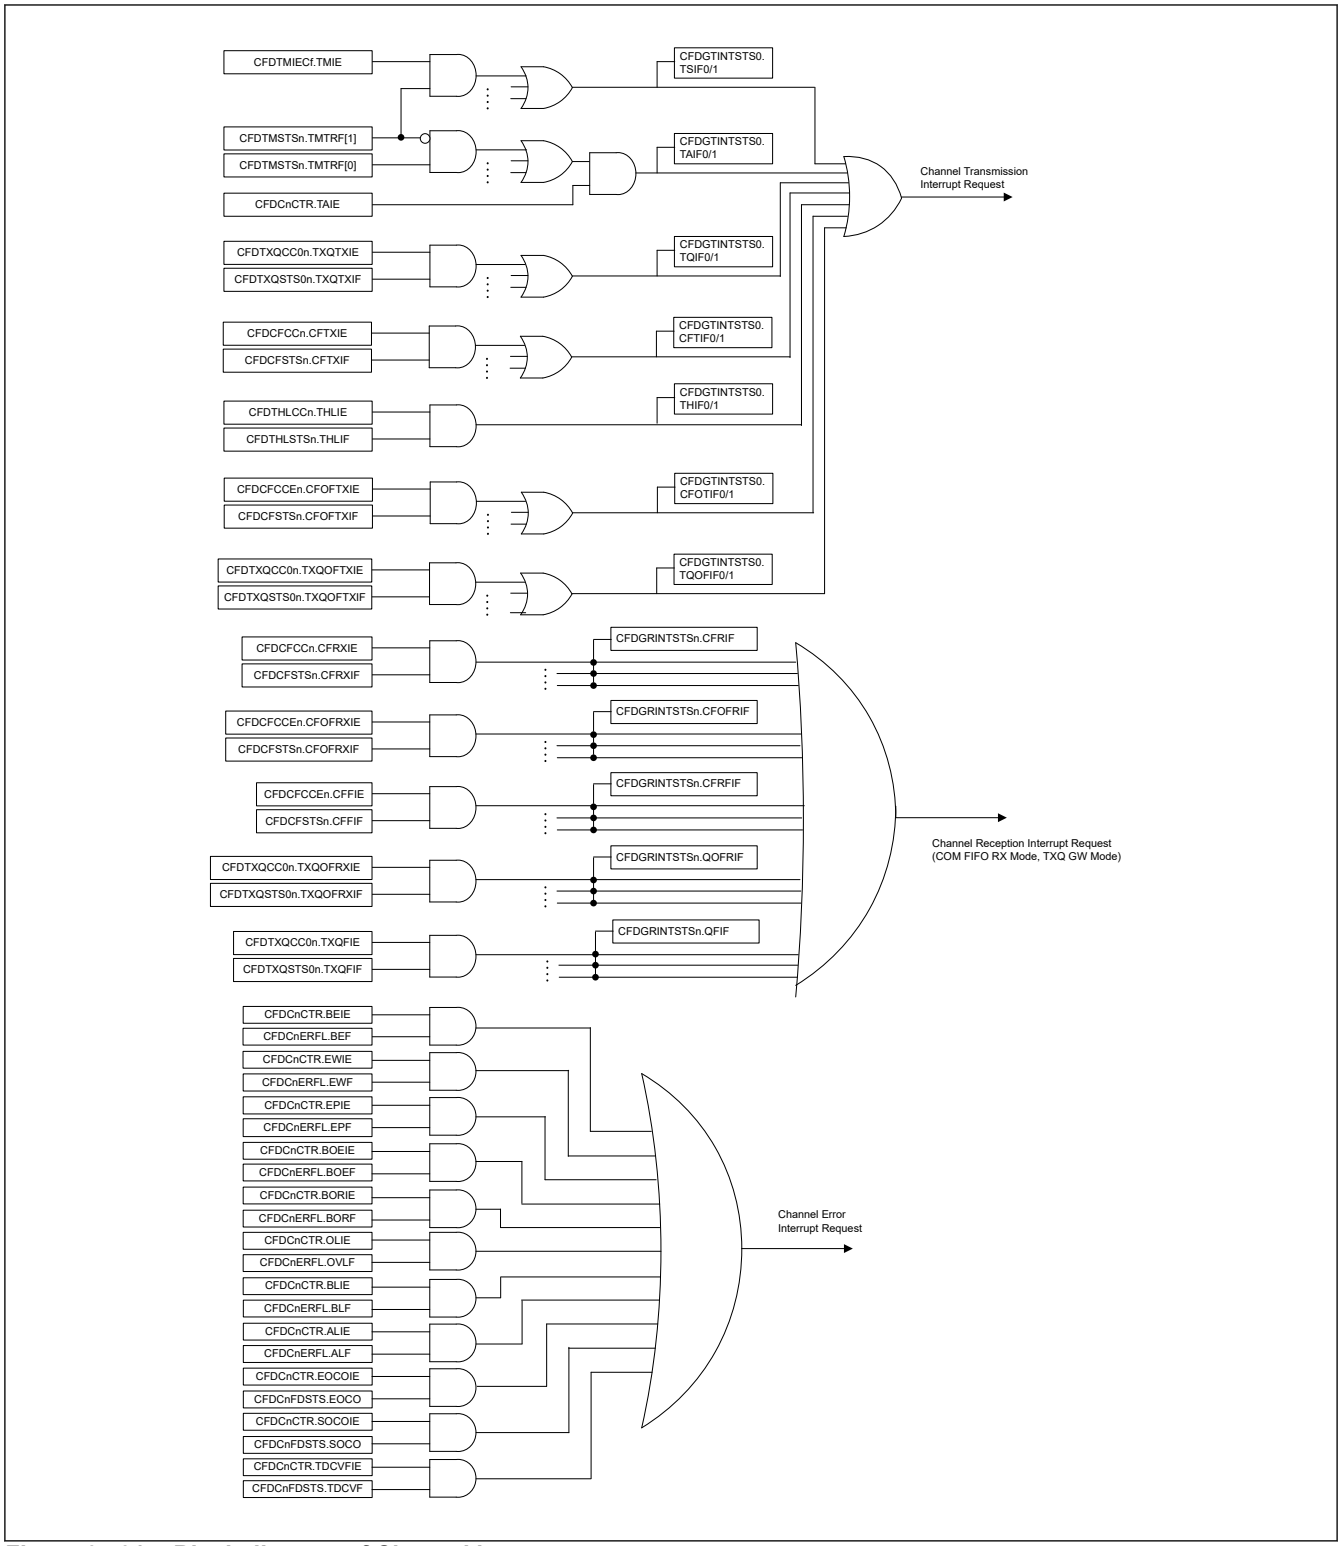

Figure 34.31 Block diagram of Channel interrupt

34.7.2 DMA Transfer

The CAN-FD module has some message buffer which can be associated with a DMA channel:

- Reception DMA
  - 8 RX FIFO Message Buffers
  - 2 Common FIFO Message Buffers
- Transmission DMA

– 16 TXQ Message Buffers (TXQ0, TXQ3)
– 2 Common FIFO Message Buffer

Figure 34.32 shows the potential DMA channels.

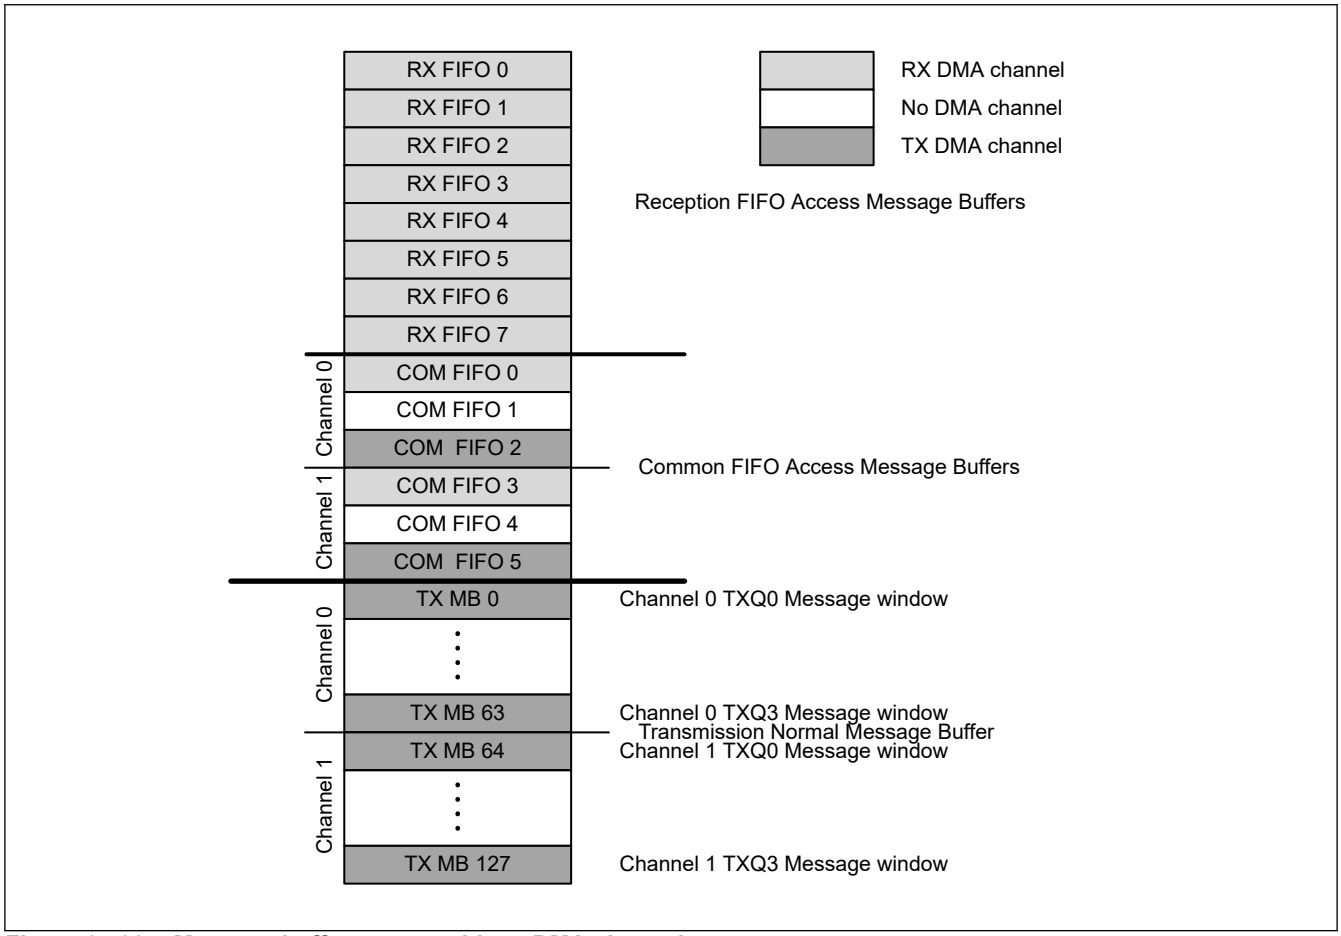

Figure 34.32 Message buffer connectable to DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO interrupt should be disabled for this particular FIFO (CFDRFCCn.RFIE or CFDCFCCn.CFRXIE).

Use the regular start address for the DMA access window address and add 0x8000 to the regular start address for the debugger access window. See Table 34.25.

Table 34.25 DMA channel access window address

b = Message buffer component.index	MBCP	Register	p	Start address n = 0, 1
0 to number_of_RFMBCPs - 1	RFMBCPb	RFID	x	0x6000 + b × 0x0080
		RFPTR	x	0x6004 + b × 0x0080
		RFFDSTS	x	0x6008 + b × 0x0080
		RFDFp	0 to 15	0x600C + p × 0x0004 + b × 0x0080
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb	CFID	x	0x6400 + b × 0x0080 + n × 0x0180
		CFPTR	x	0x6404 + b × 0x0080 + n × 0x0180
		CFFDCSTS	x	0x6408 + b × 0x0080 + n × 0x0180
		CFDFp	0 to 15	0x640C + p × 0x0004 + b × 0x0080 + n × 0x0180

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

The software debugger must access outside of the regular SFR address range from 0xE000 to 0xEFFF.

Do not write to the FIFO and TXQ control registers when DMA is enabled.

The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time, the procedure in this section is a configuration flow for an initial setup.

When CFDCDTTCT.TQ0DMAE or CFDCDTTCT.TQ3DMAE or CFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Common FIFO can be handled by DMA controller.

Use the following procedure when the TXQ or the Common FIFO can be handled by DMA controller.

1. CPU checks the TXQ or the Common FIFO is not full.
2. When transmit data can be used, CPU sets this data to Common FIFO or TXQ.
   When using Common FIFO, transmit data is write in CFDCFID, CFDCFPTR, CFDCFFDCSTS, and CFDTMBCPb[i] registers.
   When using TXQ, transmit data is write in CFDTMID, CFDTMPTR, CFDTMFDCTR, and CFDTMDFp registers.
3. For Common FIFO, the common FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by CFDCFCCn.CFPLS.
   For TXQ, if the data of 64 data payload is written, a TXQ pointer increases automatically. When payload data is less than 64 bytes, dummy data must be written in and 64 data payload size must be done.

   Note: Only 32-bit write-access can be possible on the DMA message handling.

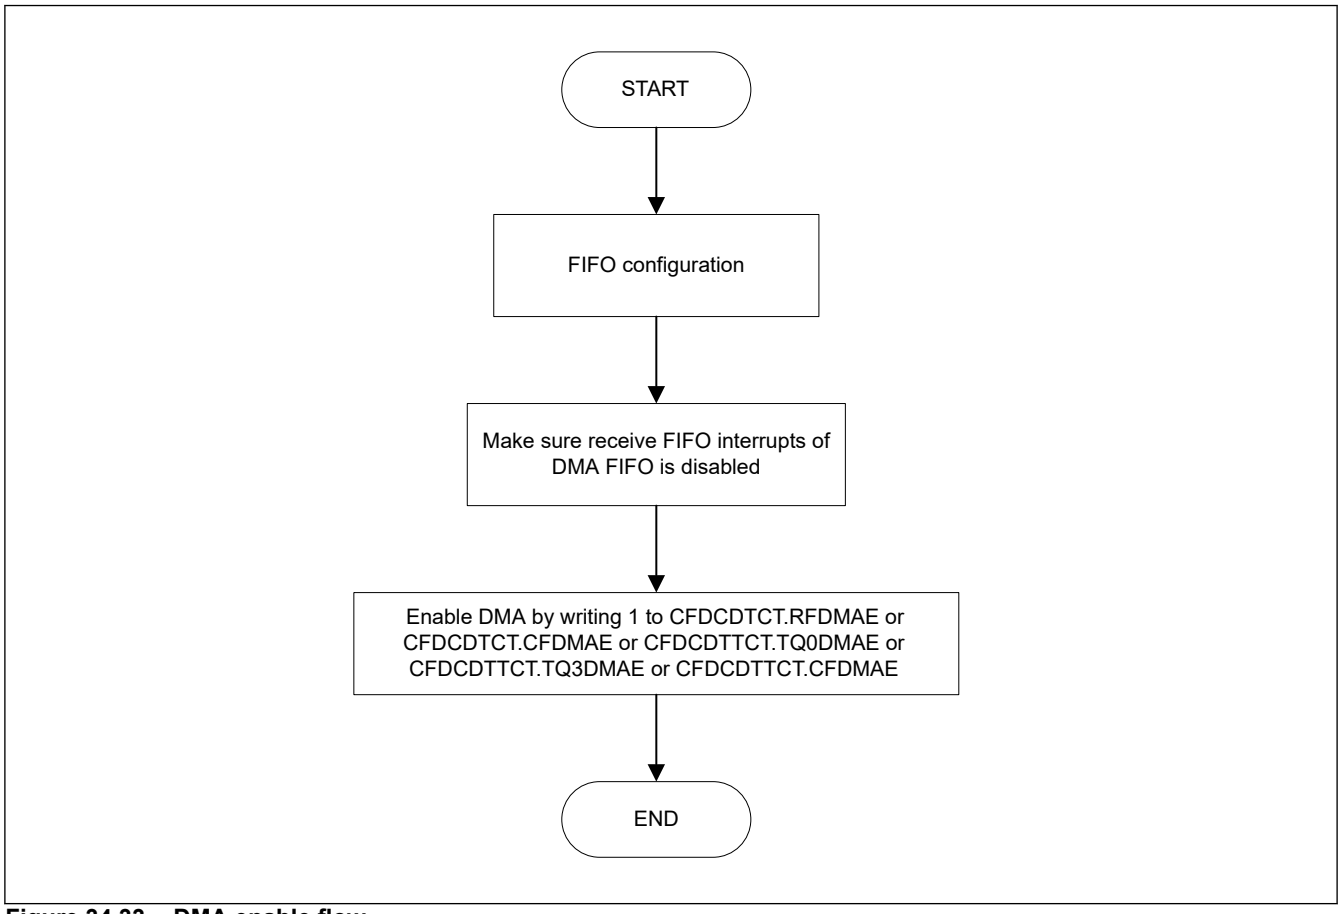

Figure 34.33 DMA enable flow

To disable a DMA transfer requested, disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then this must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS. For reference, see the flow in Figure 34.34. When the DMA is disabled, then consider what to do with the remaining or new incoming messages to this particular FIFO reception.

When the FIFO is not disabled, reception to the FIFO continues.

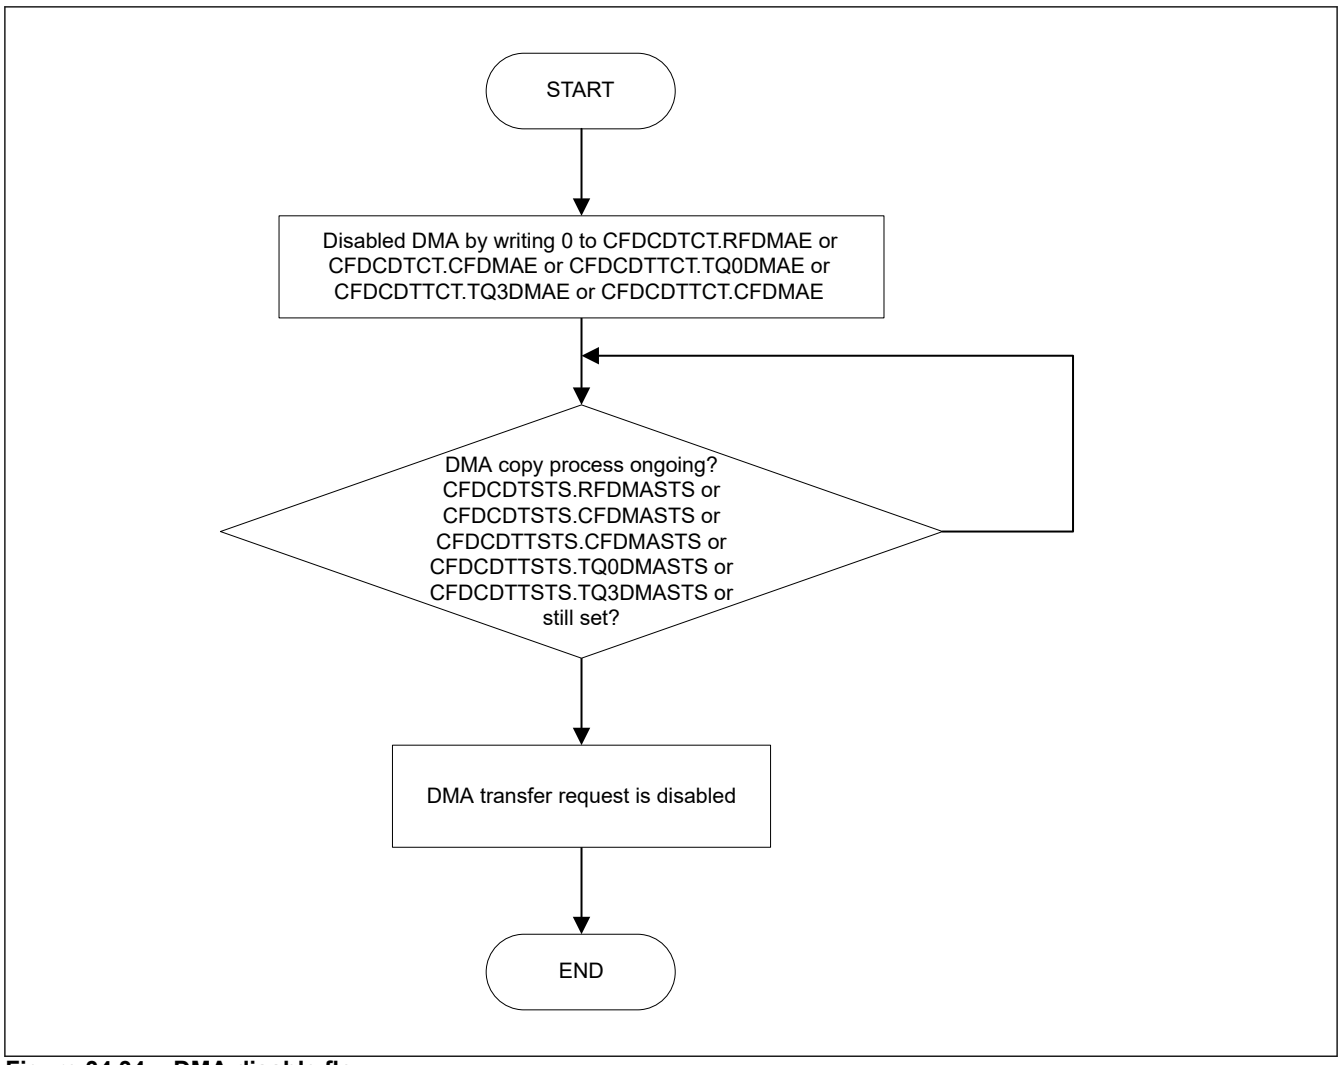

Figure 34.34 DMA disable flow

34.8 Reception and Transmission

34.8.1 Reception

FIFO buffers or Common FIFO buffers configured in RX mode or GW mode depending on the Acceptance Filter List entries are as follows:

- Up to 32 RX Message Buffers can be configured
- 8 RX FIFO buffers available
- Up to 6 Common FIFO buffers can be configured in RX mode or GW mode
- Up to 4 TX Queues can be configured in GW mode

34.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX Message Buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX Message Buffer.

If a new message is stored into a RX Message Buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX Message Buffer. If such a loss of messages is not acceptable, then RX FIFO should be used to store related messages.

Note:
- Interrupts are not provided for the RX Message Buffers in the CAN-FD module and so the RX Message Buffer New Data Register should be accessed periodically to check if a new message has been stored in the RX Message Buffers.
- Unused data bytes are filled with 0x00 depending on the DLC value.

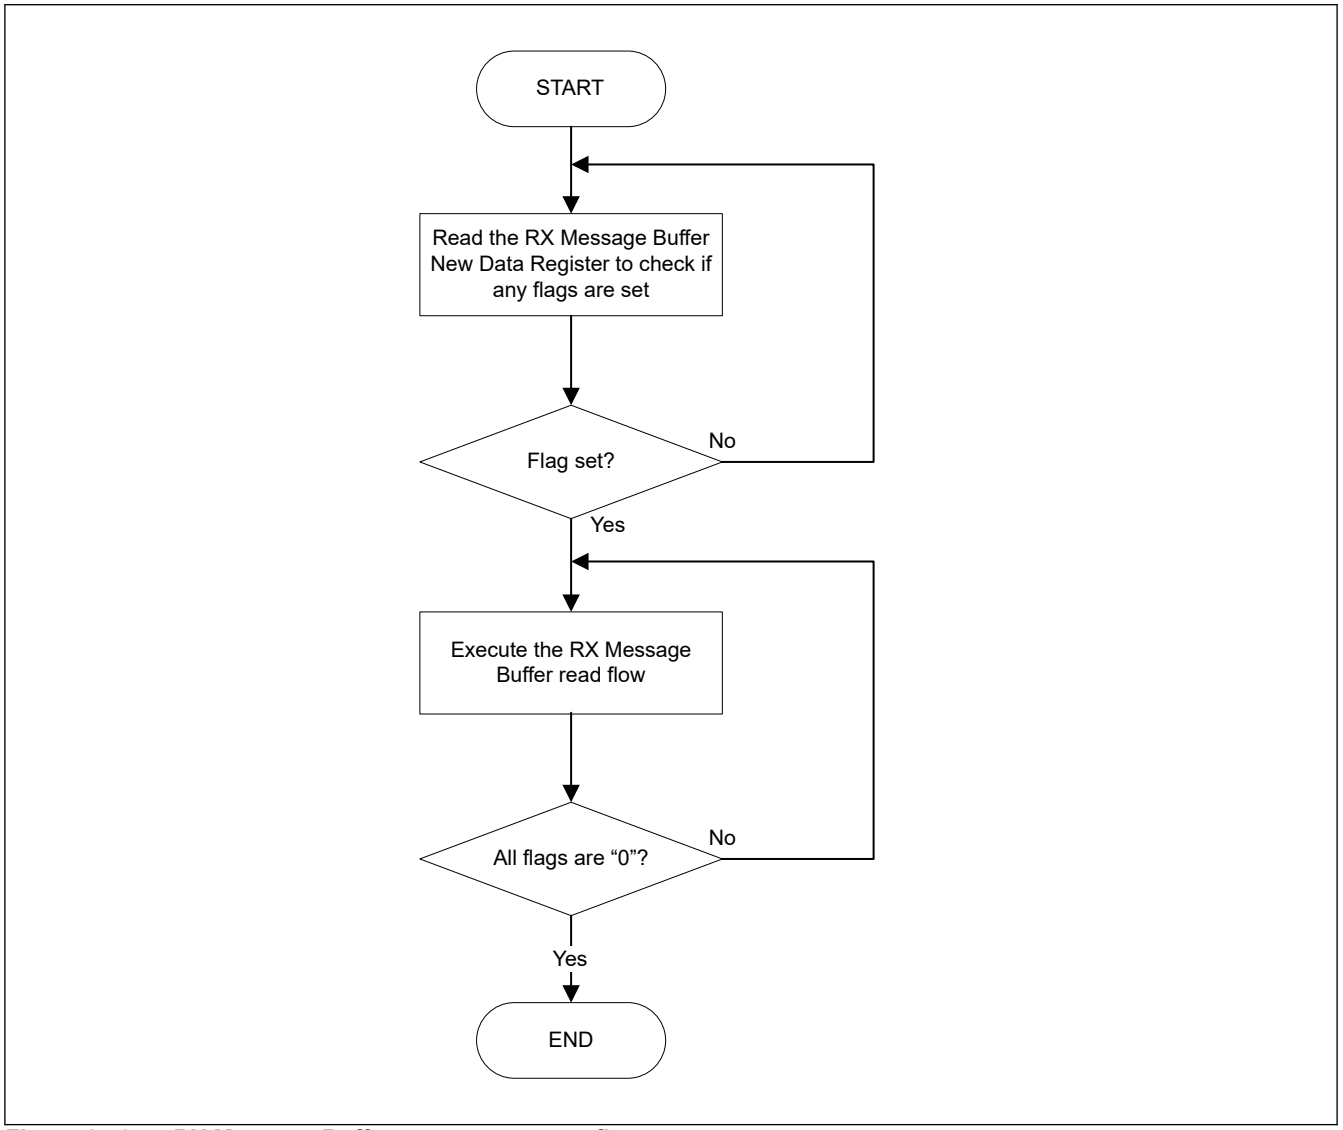

Figure 34.35 RX Message Buffer message access flow

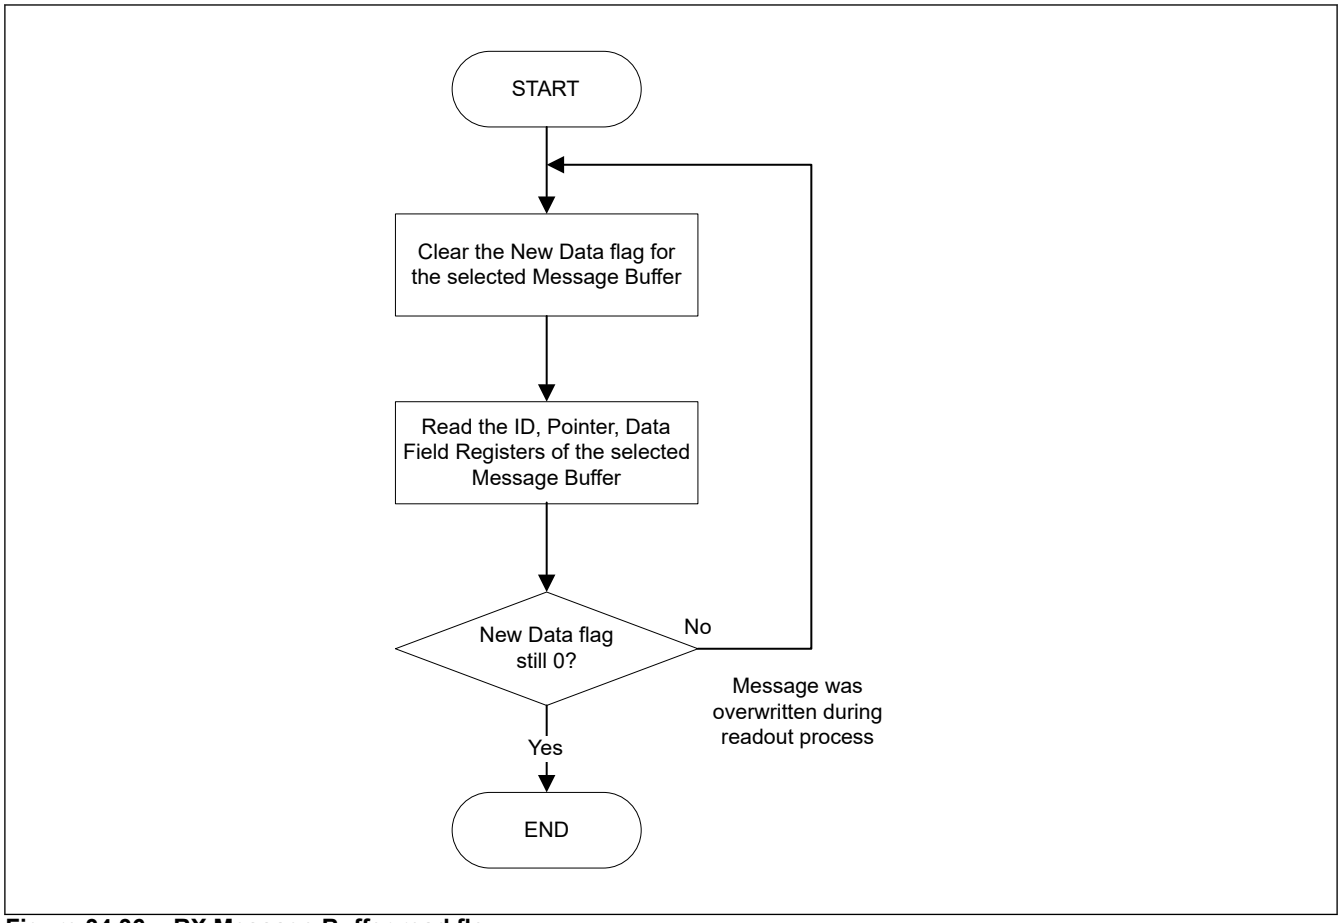

Figure 34.36 RX Message Buffer read flow

34.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffers configured in RX or GW mode should be configured based on system requirements.

The CFDGAFLP1n.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffers configured in RX mode or GW mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Registers.

Depending on the configuration of the FIFO buffers, an interrupt may also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to overrun condition.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, if a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission of the message is not performed. The read point moves to the next message automatically.

Do not write change for this bit when the CFDCFCCn.CFE bit is 1.

Common FIFO can set interrupt when:

- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

Note:
- The message lost can be set only in RX or GW mode by CAN, the flag is not set when the CPU is overloading the FIFO buffers.
- When CFDGAFLP0n.GAFLSRDi (i = 0 to 2) is set and CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO Buffers and the Common FIFO Buffers configured in RX or GW mode can be disabled at any time by clearing the CFDRFCCn.RFE or CFDCFCCn.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCn.RFE or CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO Buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO Buffers or Common FIFO Buffers configured in RX mode are assigned as DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTRn.CFPC or CFDRFPCTRn.RFPC), because this could lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO Buffer and then the FIFO is disabled, the interrupt flag is not automatically cleared. The interrupt flag should be cleared before disabling the FIFO.

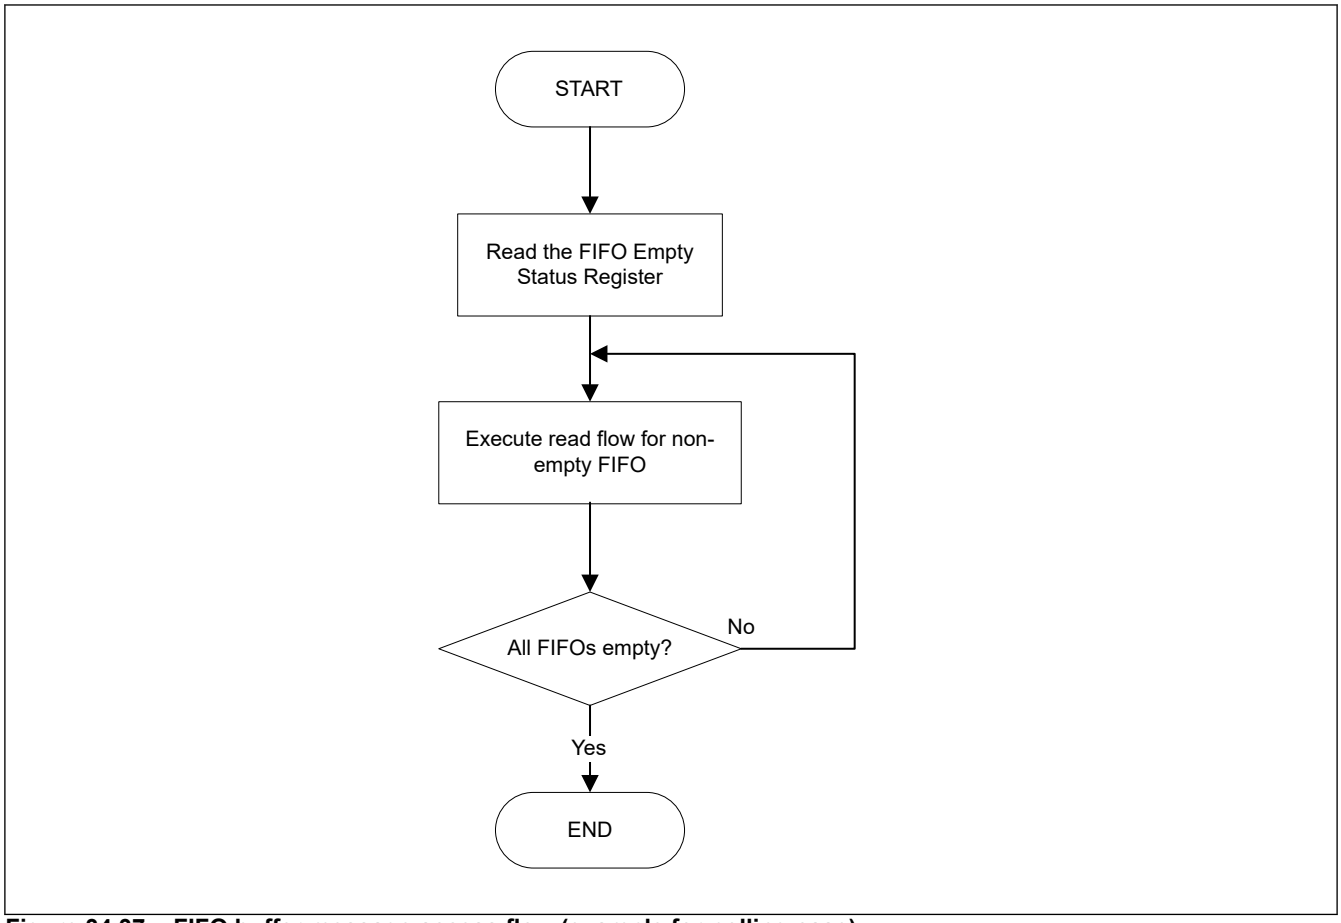

Figure 34.37 FIFO buffer message access flow (example for polling case)

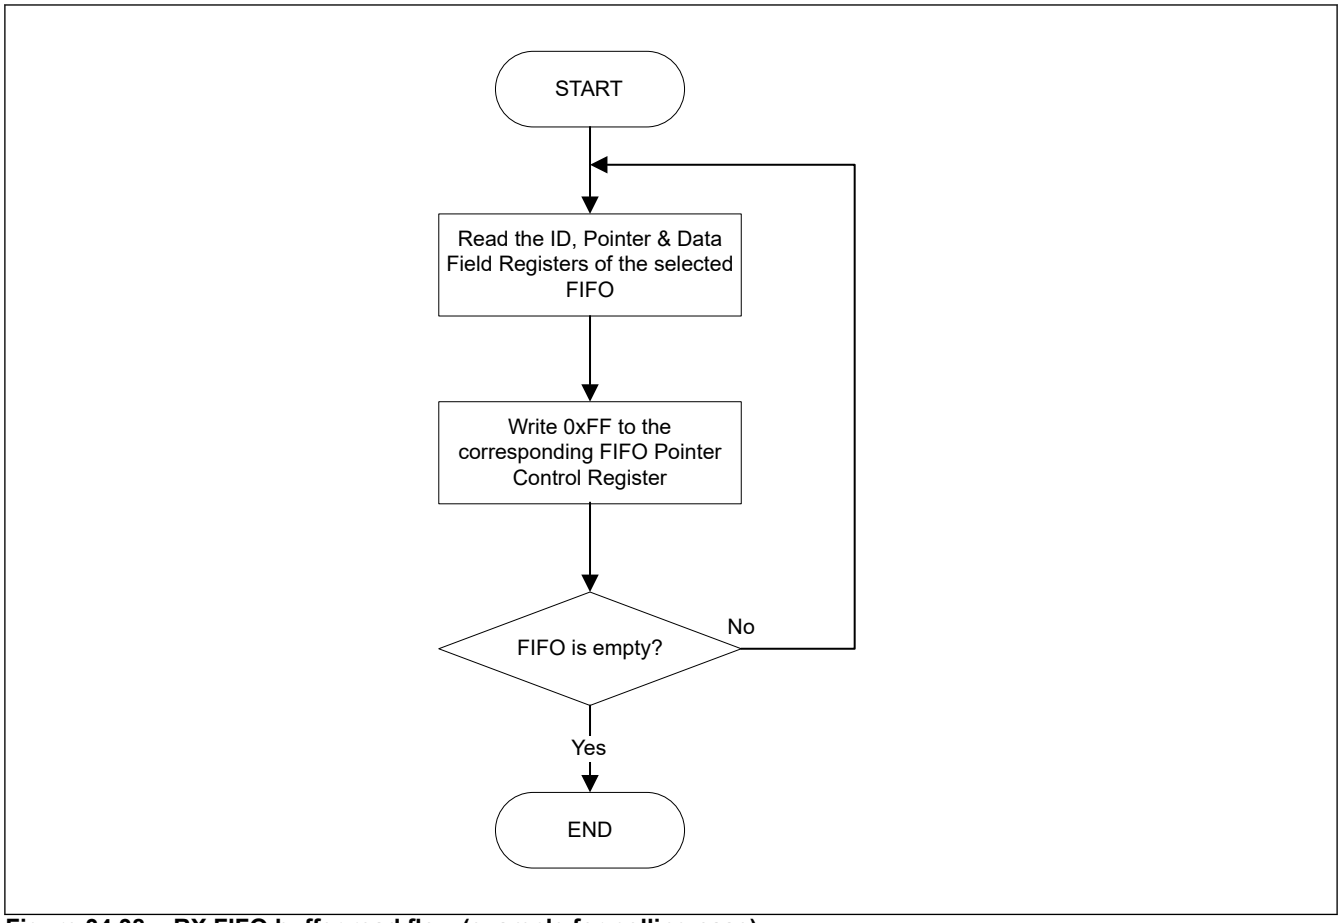

Figure 34.38 RX FIFO buffer read flow (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even if it clears an interruption flag after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the deadline, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

34.8.1.3 Timestamp

The Timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CAN-FD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and Data into the target RX Message Buffer or RX/GW FIFO.

For transmit message, the Timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If it is 0, the peripheral clock is used. If it is 1, the selected CAN channel bit time clock is used.

The channel selection is done with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset mode for this channel, the Timestamp counter is stopped. Therefore, for other CAN channels, the Timestamp counter value is also not updated.

If peripheral clock is selected as the Timestamp counter clock source, Channel modes do not influence the Timestamp counter function.

The source clock for the Timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (Timestamp Prescaler) in the Global Configuration Register.

The Timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (Timestamp Reset).

34.8.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission message buffers (64 TX message buffers) are dedicated for each channel. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue and/or Common FIFO in TX or GW mode can be configured in the following way (see Figure 34.39):
  - TX Queue: Up to 32 transmission message buffers for one channel can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ1 or TXQ3.
    Lower transmission message buffers are used to form the TXQ0 or TXQ2.
    Transmission control and status registers of these transmission message buffers should not be used.
    One channel has four TX Queues. Each TXQ has an access window:
    - TXQ0 is transmission Message Buffer 0 of each channel
    - TXQ1 is transmission Message Buffer 31 of each channel
    - TXQ2 is transmission Message Buffer 32 of each channel
    - TXQ3 is transmission Message Buffer 63 of each channel

    When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0 should not exceed 32.
    When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2 should not exceed 32.
- Common FIFO (TX/GW mode): Each Common FIFO in TX or GW mode is linked to a dedicated channel.
  Each channel has a fixed number of three Common FIFOs assigned to it. Within the channel, a Common FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 39 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission control and status registers of these transmission message buffers should not be used.

See Figure 34.28 for information on Common FIFO buffer assignment to related channels.

Note: Common FIFO buffers should not be linked to TX message buffers that are already part of a TX Queue.

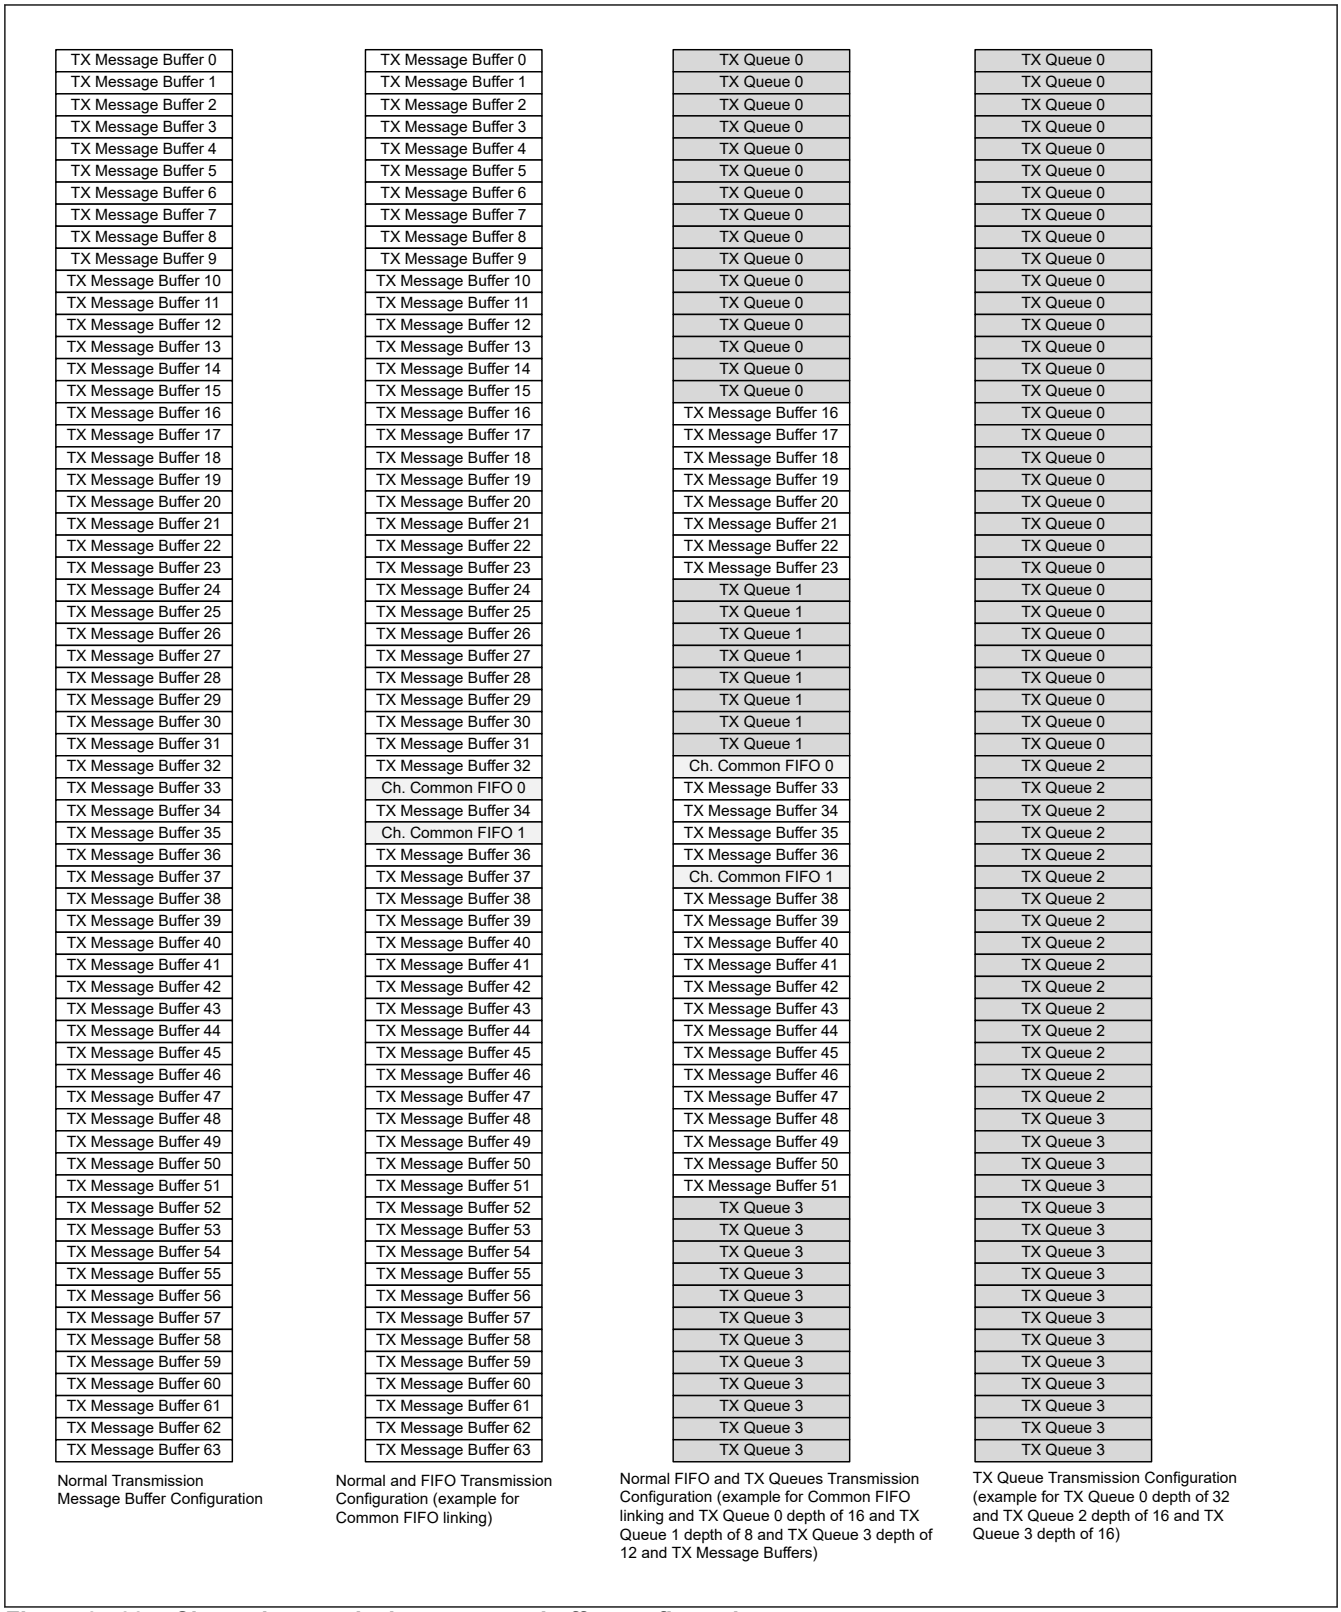

Figure 34.39 Channel transmission message buffer configuration

34.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, the transmission priority in the CAN-FD module can be selected from the following two modes:

- CAN ID priority

- Message buffer number priority

The transmission priority mode is common for all message buffers and all CAN channels. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, the next pending message within the same FIFO will be considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 34.40 shows the transmission configuration flow.

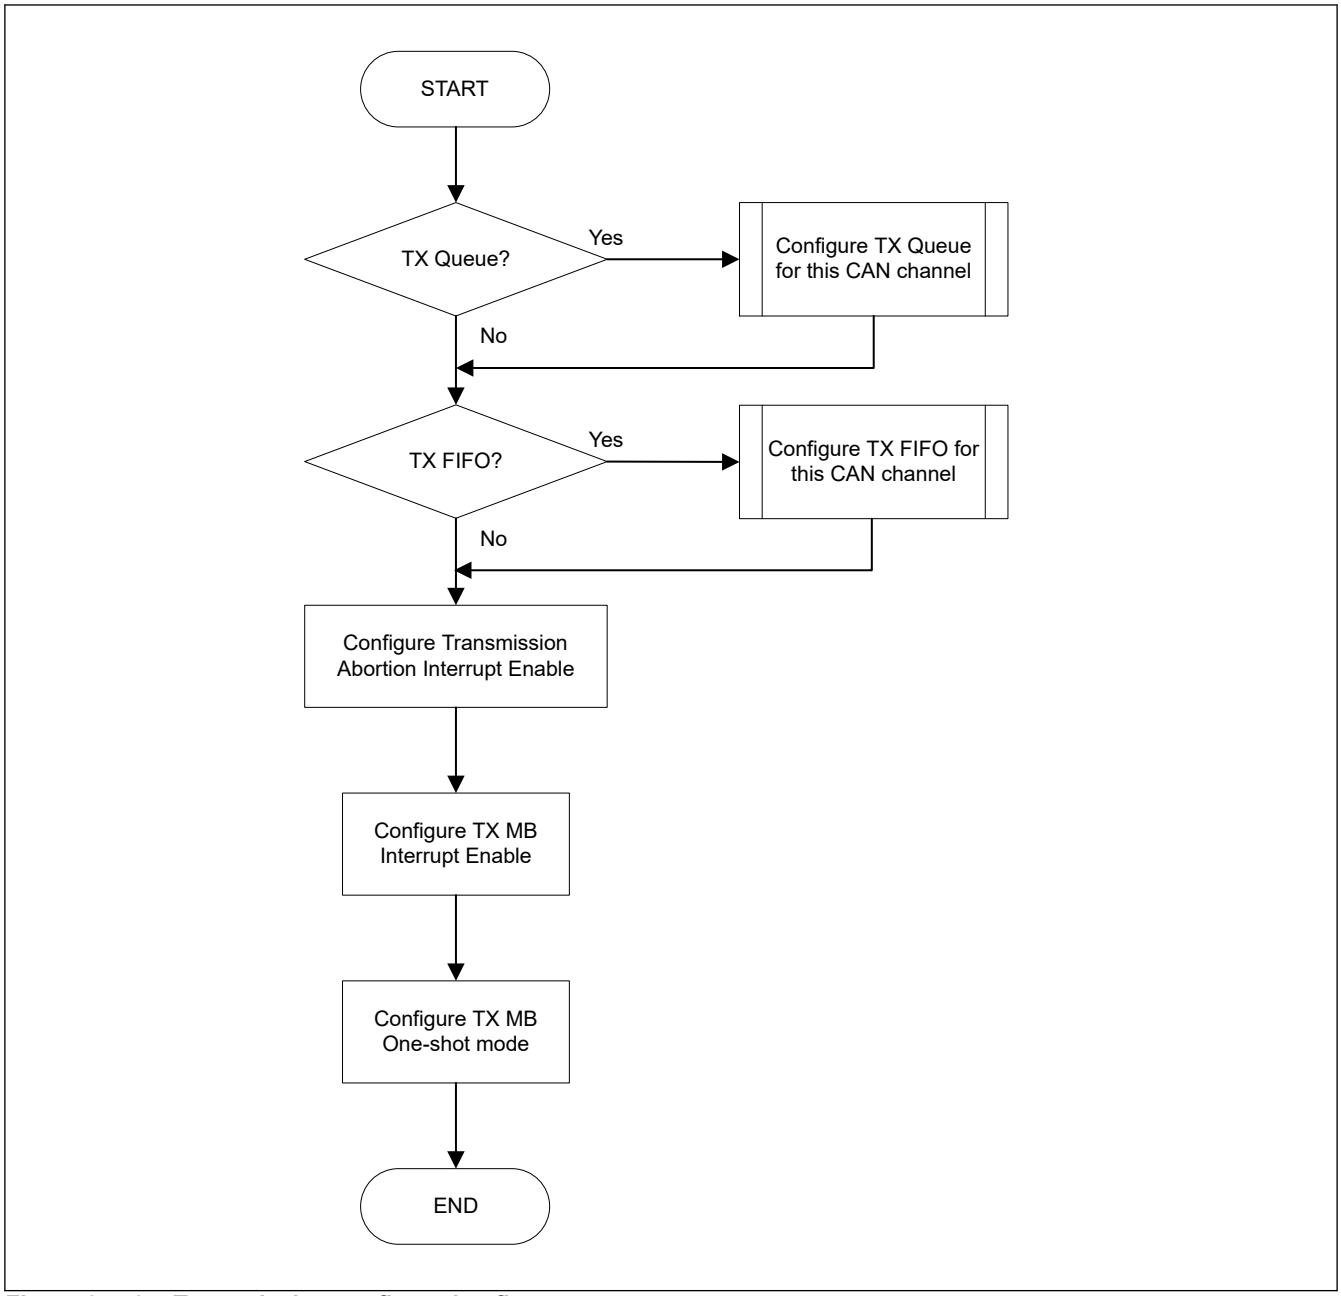

Figure 34.40 Transmission configuration flow

34.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

- Regular transmission mode
  If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
  Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.
  When arbitration is lost or an error occurs, message transmission will be attempted further if no transmission abort request is set for this transmission message buffer.
  New internal transmission arbitration for this channel is performed for all message buffers with transmission request.
- One-shot transmission mode
  When the CFDTMCn.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, then the message buffer is placed in one-shot transmission mode and attempts to transmit a message only once.

Completion of one-shot transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. The CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b when the one-shot transmission is successful.
The CFDTMSTSn.TMTRF[1:0] bits are set to 01b when arbitration is lost or an error occurs during the transmission of the related message buffer.
Additional message transmission will not be attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 34.41.

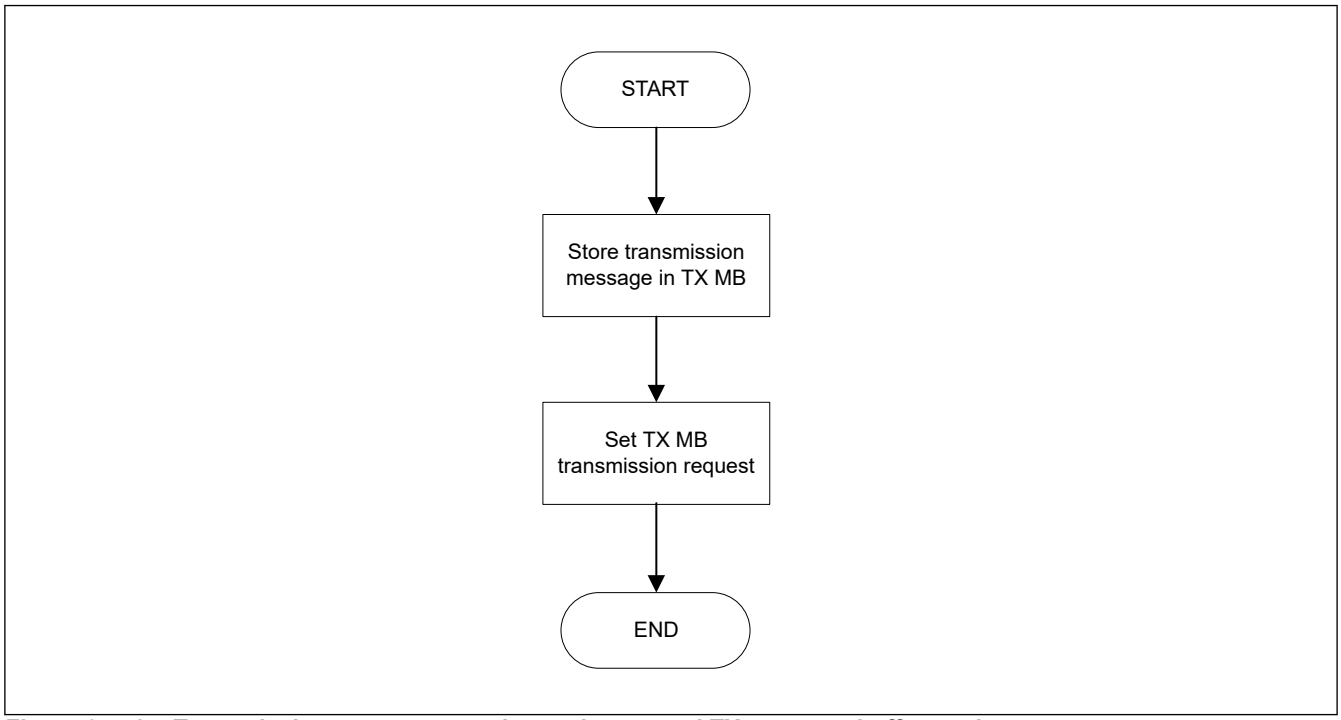

Figure 34.41 Transmission request procedure using normal TX message buffer mode

(1) TX Message Buffer Control Register Setting

Table 34.26 shows configuration of the normal CAN transmission mode.

Table 34.26 Configuration of CAN transmission mode

Transmission request CFDTMCn.TMTR	Transmission abortion request CFDTMCn.TMTAR	One Shot Enable CFDTMCn.TMOM	Communication activity
0	0	0	Message buffer is disabled
0	0	1	Message buffer is disabled
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abortion is requested
1	1	1	One shot transmission abortion is requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 34.42 shows timings for successful transmission for two message buffers of one channel.

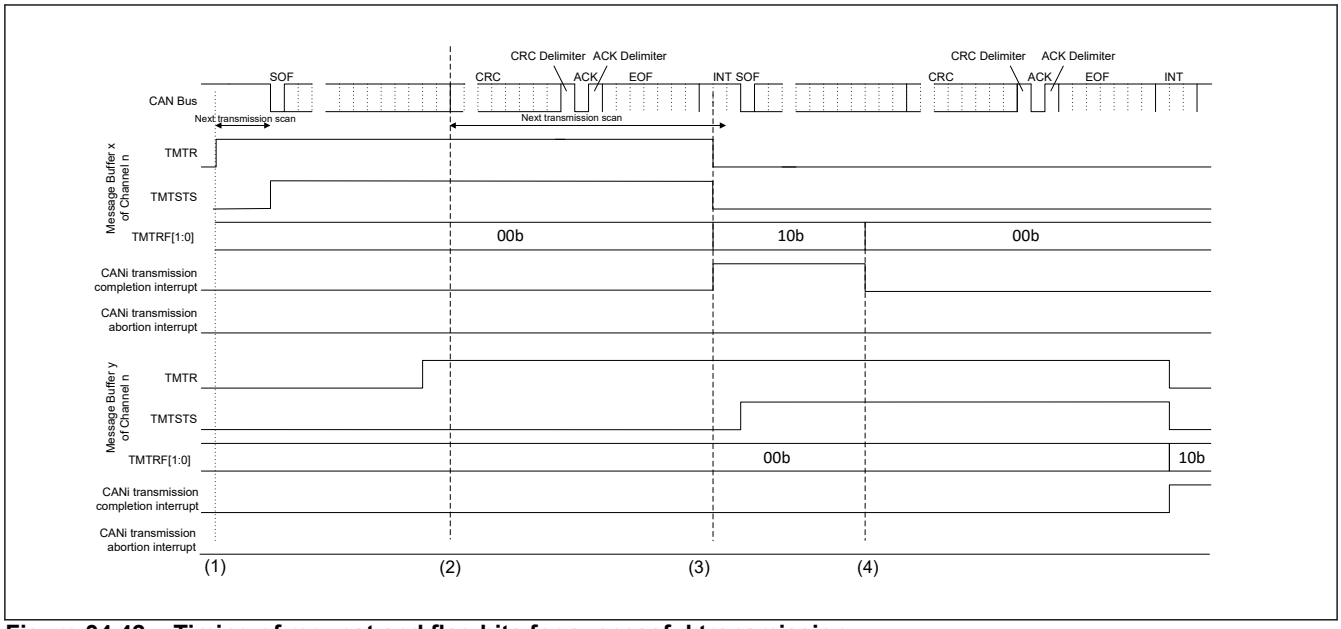

Figure 34.42 Timing of request and flag bits for successful transmission

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the related TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission[*1].
2. On the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
3. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line the CFDTMSTSn.TMTRF flag bits must be cleared.
4. Before starting the next transmission, clear the CFDTMSTSn.TMTRF[1:0] bits. Load the next message in the transmission message buffer and set the CFDTMCn.TMTR bit again. CFDTMCn.TMTR bit cannot be set again before CFDTMSTSn.TMTRF[1:0] bits are cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during the transmission or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSn.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 34.43 shows timings for transmission abort for two message buffers of one channel.

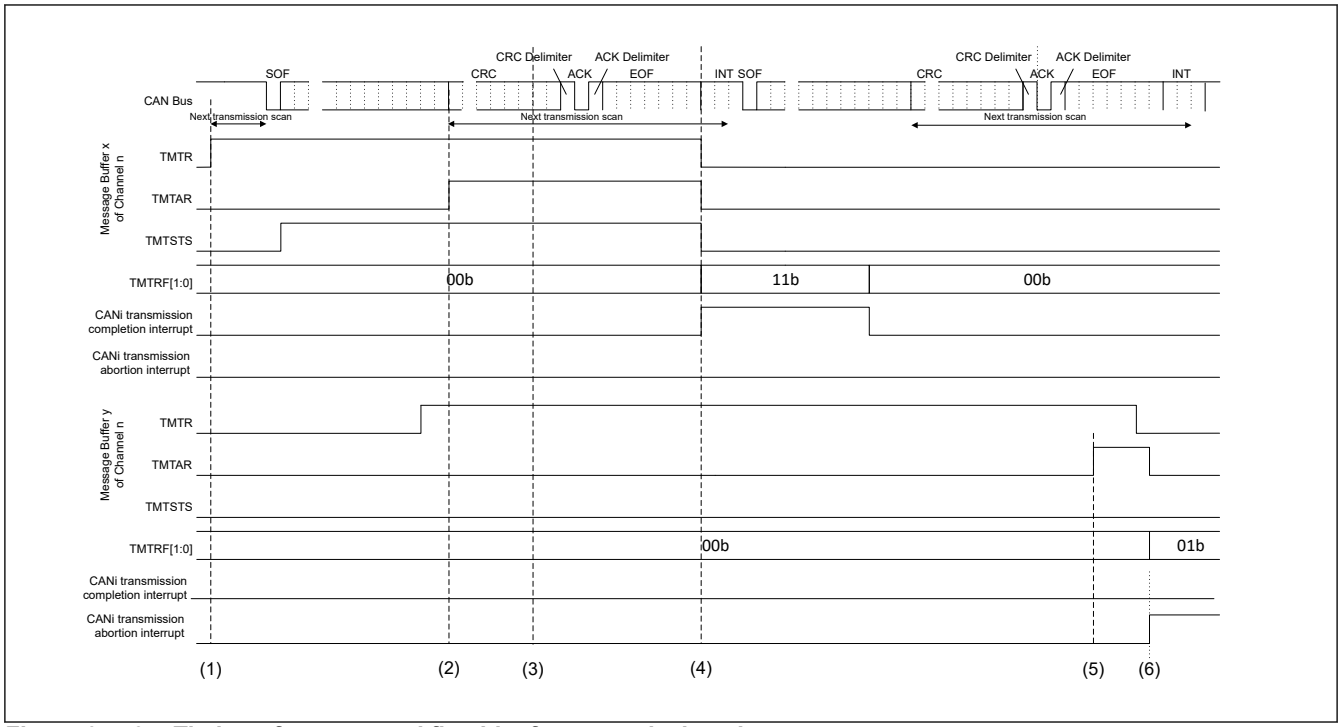

Figure 34.43 Timing of request and flag bits for transmission abort

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission[*1].
2. If the CFDTMCn.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. On the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example timing diagram, message buffer y is not selected as the next transmission message buffer.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
4. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSn.TMTSTS not set). If the CFDTMCn.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSn.TMTRF[1:0] bits are set to 01b. If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCn.TMTR, and CFDTMCn.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set, an interrupt is generated for successful transmission abort.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS is cleared. The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit. If an error occurs, either during the transmission, or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

34.8.2.3 TX FIFO or GW FIFO Transmission

Three common FIFO buffers are assigned to each channel. The three FIFO buffers can be linked to any normal TX Message Buffer position for this channel by the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX Message Buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX Message Buffer linked to a FIFO buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers.

If the message count matches the FIFO Depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, an interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCCn.CFIM bit is 1, an interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

Common FIFO can set interrupt, when CAN frame transmitted is completed.

The Common FIFO buffers configured in TX mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Registers. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCCn.CFE bit only when the Empty flag is set for the corresponding Common FIFO Buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCCn.CFE is set again, ensure that CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the TX FIFO.

When the CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 34.44.

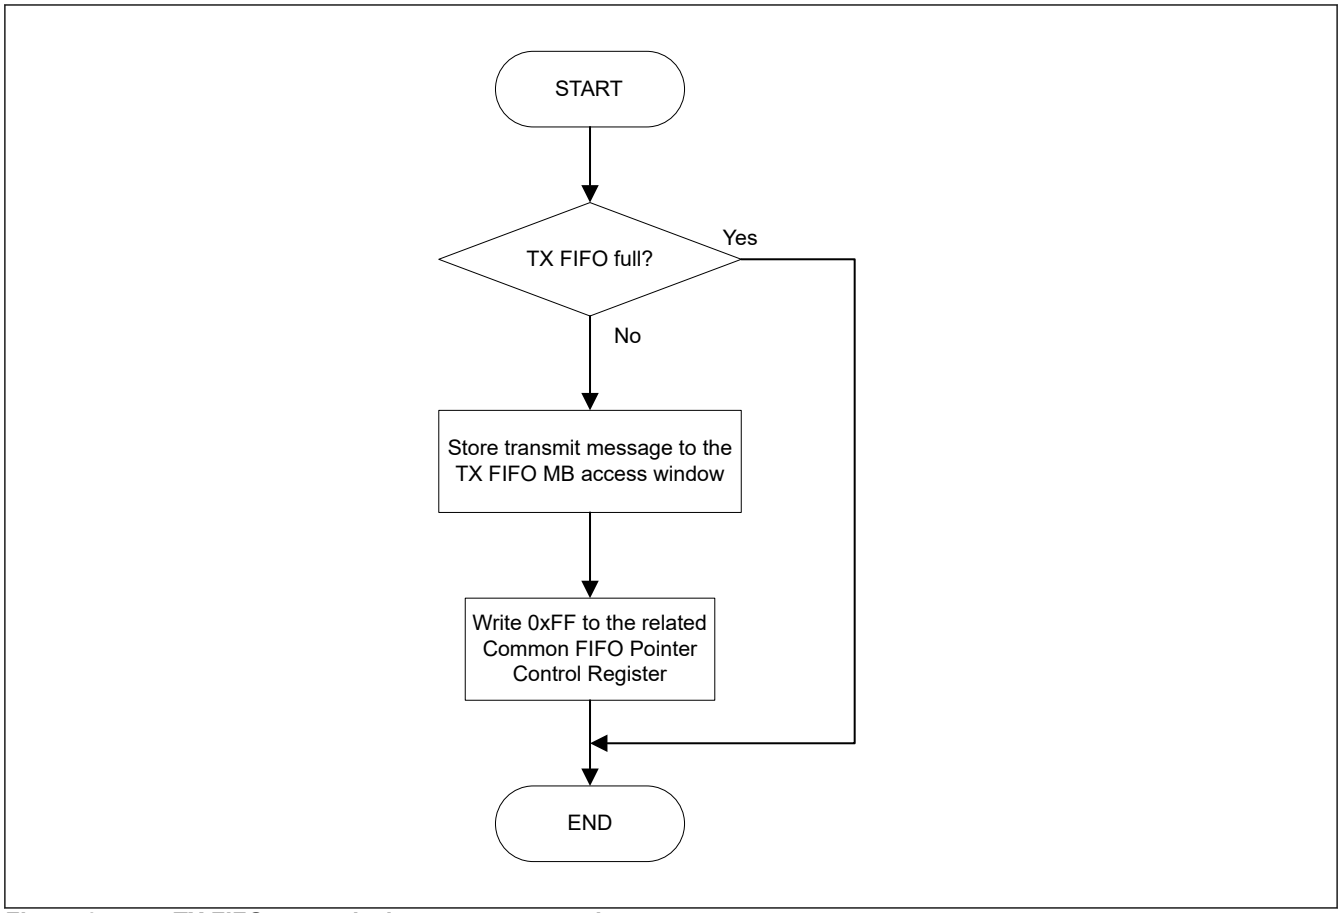

Figure 34.44 TX FIFO transmission request procedure

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the requirements of the system. The matching AFL entry selects the GW FIFO buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO buffer, the FIFO message count in the corresponding FIFO Status Register is incremented by 1.

If the message count matches the FIFO depth, then the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the GW FIFO, the message count value is decremented by 1. When all the messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive.
  FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.

The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message is overwritten with the received message.
In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point moves to the next message automatically.

The interrupt generation conditions for the GW FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, then RX interrupt flag is set when FIFO counter increments and reaches value configured by CFDCFCCn.CFIGCV and the TX interrupt flag is set when FIFO transmits the last message successfully.

If CFDCFCCn.CFIM bit is 1, then RX interrupt flag is set at the end of storage of every received message and TX interrupt flag is set if a message is successfully transmitted from the FIFO.

Common FIFO can set interrupt when:

- CAN frame transmitted is completed
- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in Common FIFO, and transmission is stopped. Transmission will be started if it is set as CFDCFCCEn.CFBME = 0.

The Common FIFO buffers configured in GW mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared, the GW FIFO becomes empty as follows:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission

Other possible messages pending from the GW FIFO are lost.

Before CFDCFCCn.CFE is set again, ensure that the CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the GW FIFO.

When the CFDCFCCn.CFE bit is cleared and the CFDCFSTSn.CFEMP bit is set, the message read and write pointers of the GW FIFO are cleared and are no longer active. Therefore, all messages in the GW FIFO buffers are lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways, it is useful if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node Error State Indication. For this, each channel has the control function register CFDCnFDCFG.ESIC to replace their own ESI information by the routing ESI information.

Note: If the sending node is error passive, the ESI bit is sent anyway as error passive (ESI = 1).

(3) Interval Timer for FIFO Transmission

For each Common FIFO in TX or GW mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCCn.CFE bit is set.

When the Common FIFO in TX or GW mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCCn.CFE bit
- CAN channel is in CH_RESET mode

The interval time is specified by the CFDCFCCn.CFITT value in the Common FIFO Configuration/Control Register and can be specified from 0 to 255 timer units.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, a value of 0 should be selected.

The timer source can be selected by the configuration bit CFITSS in the Common FIFO Configuration/Control Register. For the timer source the CAN bit timing clock of the FIFO related channel or a global reference clock can be selected.

If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT or CH_RESET or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 34.27 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency/period.

Table 34.27 Configuration example for the FIFO interval timer reference clock

Peripheral clock (PCLKM)	Reference clock		
	1 µs	100 µs	500 µs
75 MHz / 13.33 ns	75	7500	37500
100 MHz / 10 ns	100	10000	50000

Additionally, the reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCCn.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (× 1 or × 10).

The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time.

Figure 34.45 shows an example timing of the internal processing.

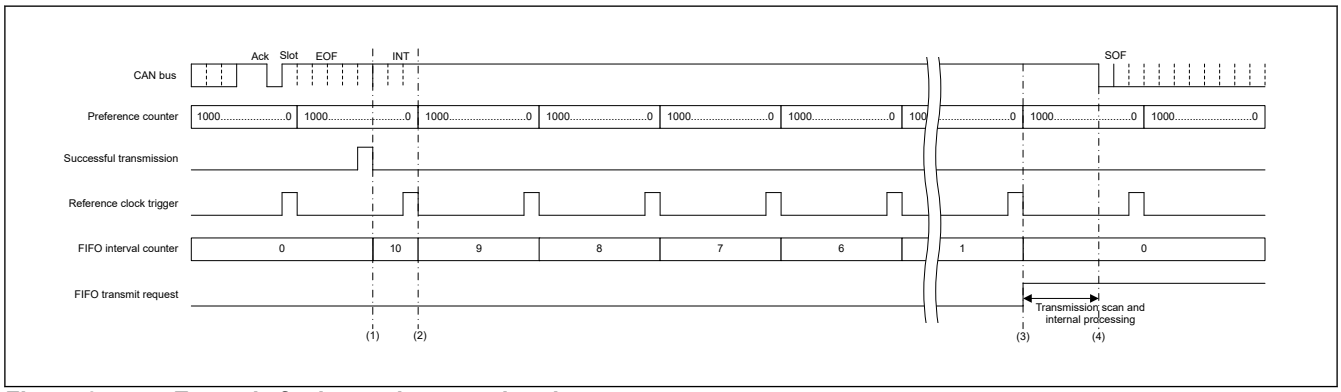

Figure 34.45 Example for interval processing time

The configuration for the above timing is as follows:

- Peripheral clock frequency = 100 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 1000 times
- Reference clock due to the above settings = 10 µs
- Common FIFO interval timer source selection (CFDCFCCn.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCCn.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCCn.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to one reference clock interval.
2. With the next reference clock trigger, the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0 the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing this usually takes less than 3 CAN bit time, between internal FIFO transmit request set 3 and actual transmission.

In the worst case when multi events such as reception scan, internal message routing, transmit scan on all channels occur, then it can take up to 432 peripheral clock cycles.

As shown in Figure 34.45, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCCn.CFITT to the required minimum value + 1.

If additional TX message buffers or TX/GW FIFOs are configured for transmission for the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time due to higher priority message transmission from these TX message buffers or TX/GW FIFOs.

Figure 34.46 shows a block diagram of the FIFO interval time generation circuit.

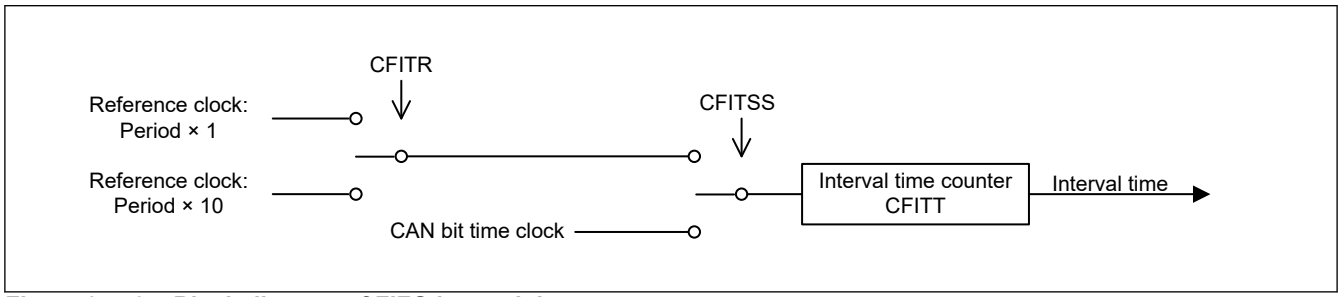

Figure 34.46 Block diagram of FIFO interval timer

34.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 32 TX message buffers, which are accessed by one access window. One channel has 4 TX Queues. One TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 0 as access window (referred to as TXQ0). The second TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 31 as access window (referred to as TXQ1). The third TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 32 as access window (referred to as TXQ2). The fourth TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 63 as access window (referred to as TXQ3).

All TXQ0, TXQ1, TXQ2, and TXQ3 messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ0 are CFDTXQCC0n, CFDTXQSTS0n, and CFDTXQPCTR0n.

The registers for TXQ1 are CFDTXQCC1n, CFDTXQSTS1n, and CFDTXQPCTR1n.

The registers for TXQ2 are CFDTXQCC2n, CFDTXQSTS2n, and CFDTXQPCTR2n.

The registers for TXQ3 are CFDTXQCC3n, CFDTXQSTS3n, and CFDTXQPCTR3n.

When access window TX Message Buffer No.63 (TXQ3) or TX Message Buffer No.32 (TXQ2) or TX Message Buffer No.31 (TXQ1) or TX Message Buffer No.0 (TXQ0) is used, refer to the related access registers TX Message Buffer ID Registers (CFDTMIDn), TX Message Buffer Pointer Registers (CFDTMPTRn), TX Message Buffer Data Field 0 Registers (CFDTMDF0_n), and TX Message Buffer Data Field 1 Registers (CFDTMDF1_n).

The depth of each TXQ0 buffer can be configured by writing to the CFDTXQCC0n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ0 can set from TXMB0 to TXMB31 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled

- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ1 buffer can be configured by writing to the CFDTXQCC1n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ1 can set from TXMB31 to TXMB0 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ2 buffer can be configured by writing to the CFDTXQCC2n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ2 can set from TXMB32 to TXMB63 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ3 buffer can be configured by writing to the CFDTXQCC3n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ3 can set from TXMB63 to TXMB32 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 32 or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 32 or less in total.

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 63, TX Message Buffer No. 32, TX Message Buffer No. 31 and TX Message Buffer No. 0, which acts as TX Queue access window).

When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

When CFDTXQCCn.TXQOWE bit is 1, the TX Queue is in TX Queue overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message is overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When using the function in GW mode and TX Queue overwrite mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3. If it accesses by routing in gateway mode when a TXQ buffer is full, CFDTXQSTS.TXQMLT is set and send data is thrown away.

The function is valid for the standard ID frame and is invalid for the extended ID frame.

Explanation of operation of the TX Queue with same ID over-writing function in GW mode is shown in Figure 34.47.

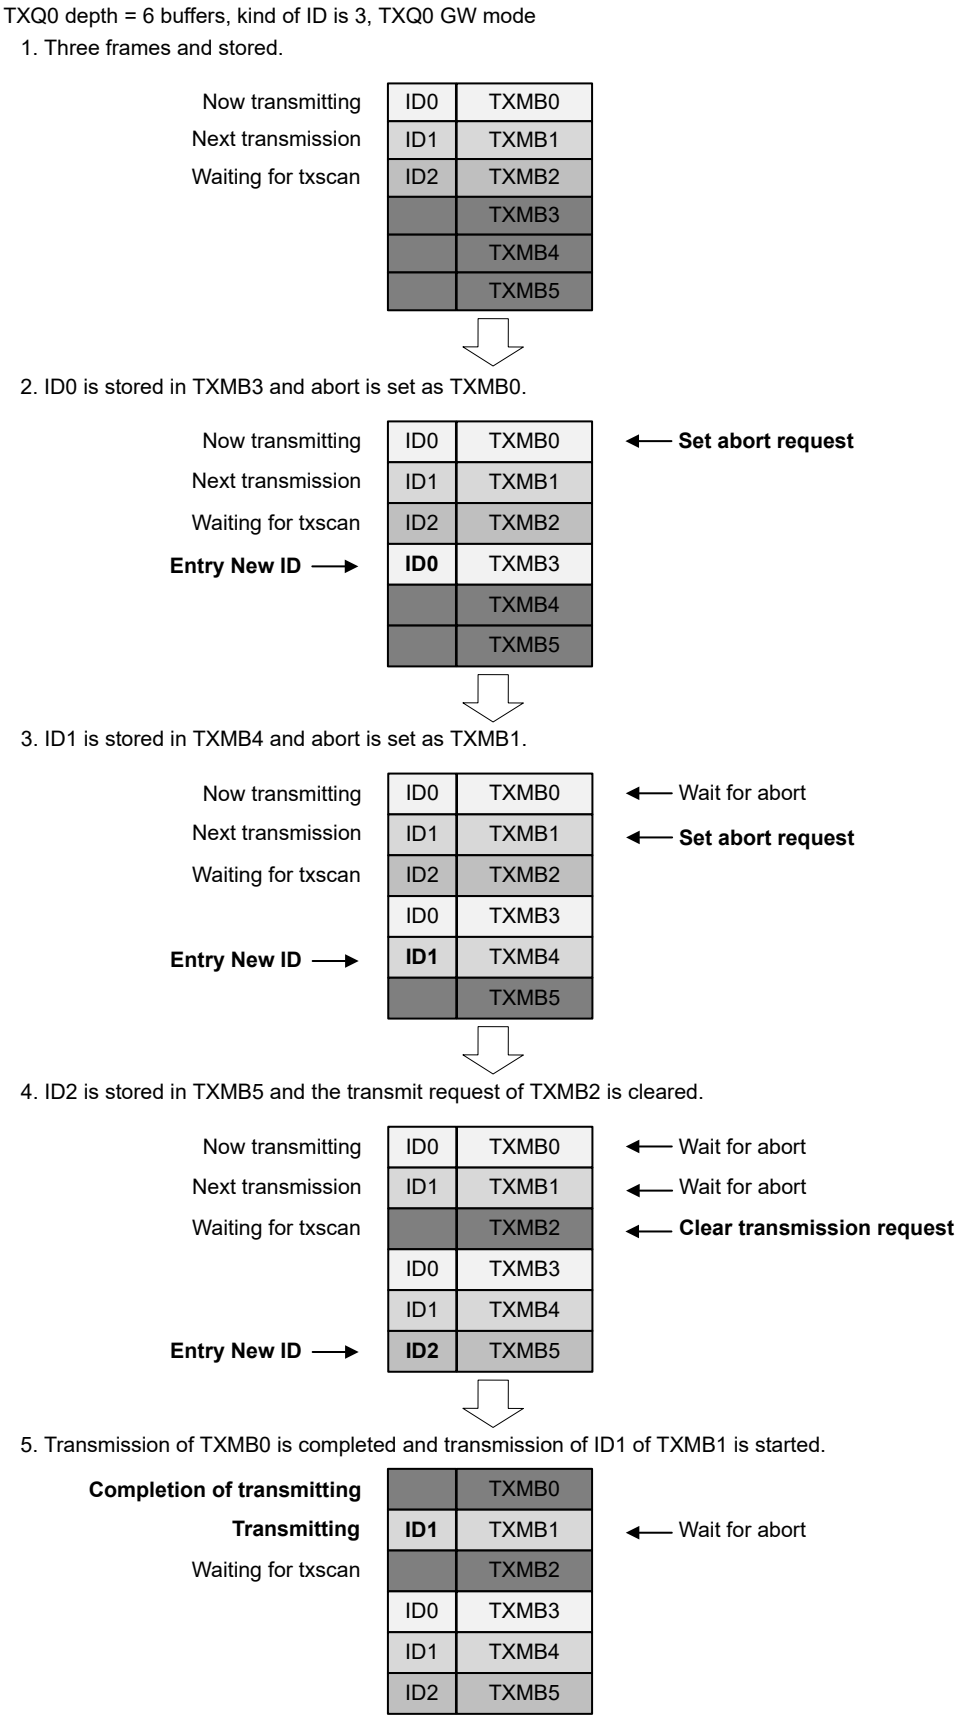

Figure 34.47 Operation of TXQ0 in Gateway mode

When a system writes in TXQ, a system should write in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full then no further access should be done to the queue, until it is no longer full. If it accesses by software writing in when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTSn.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored into the TX Queue.

When a message has been stored to the TX Queue, 0xFF must be written into the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same identifier are stored in the TX Queue, then the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same identifier is stored in the TX Queue. Or if TX queue overwrite mode is used, the frame of the same ID is rewritten on a new frame.

For the TX Queue a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 34.48.

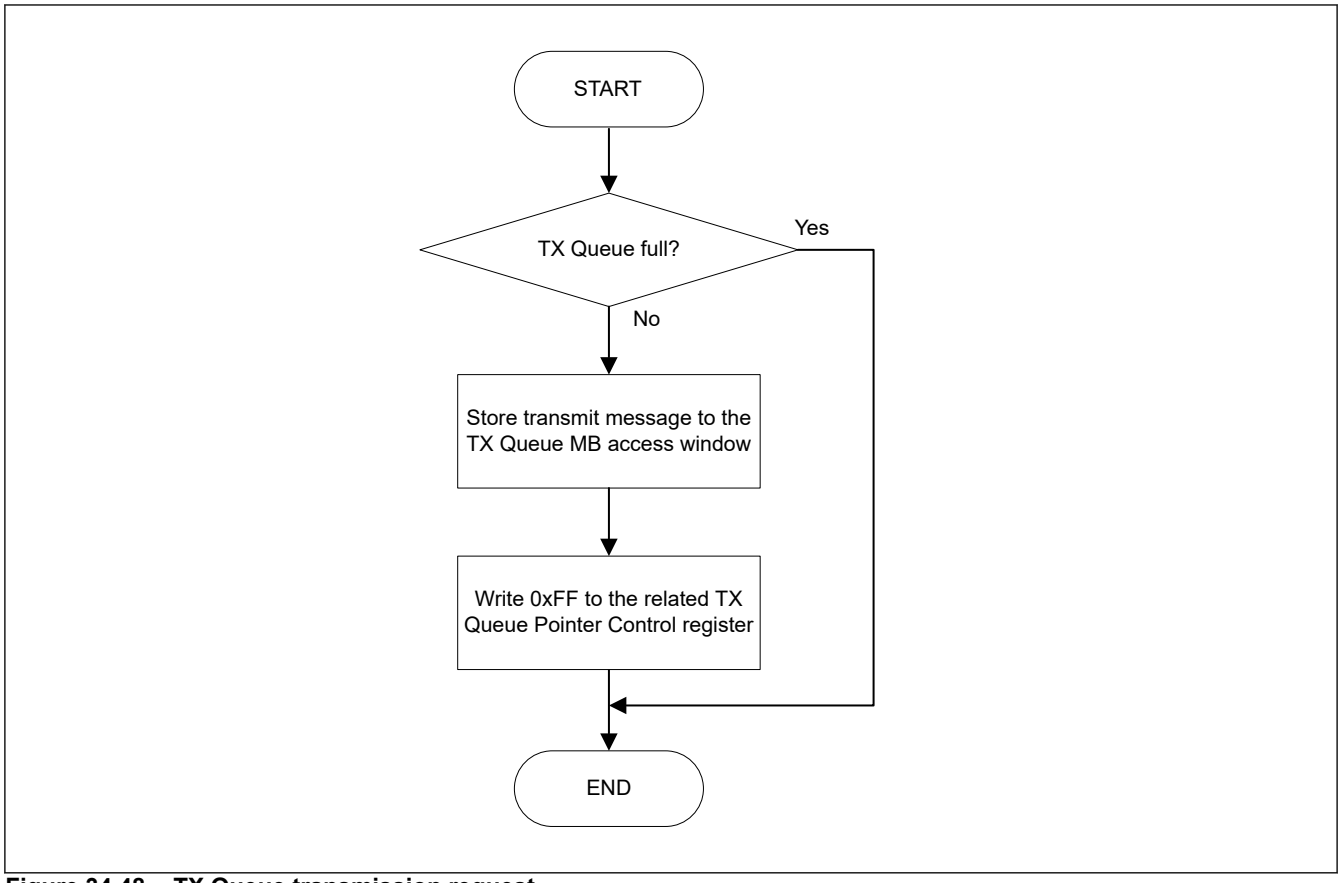

Figure 34.48 TX Queue transmission request

TXQ name	Access window	Range width	Direction	Hardware routing access point	CPU access point	DMA access point	Note
TXQ0	TXMB0	0, 3-32	TXMB0 → TXMB31	Yes	Yes	Yes	When using both TXQ0/1, the total number of stages is 32 or less
TXQ1	TXMB31	0, 3-32	TXMB31 → TXMB0	Yes	Yes	No	
TXQ2	TXMB32	0, 3-32	TXMB32 → TXMB63	Yes	Yes	No	When using both TXQ2/3, the total number of stages is 32 or less
TXQ3	TXMB63	0, 3-32	TXMB63 → TXMB32	No	Yes	Yes	

TXQ0 can use hardware routing, CPU access, and DMA access.

Hardware routing access, CPU access, and DMA access should not be used simultaneously. Choose one access method.

34.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List buffers for each CAN channel. Two TX History List buffers are provided for each CAN channel and each TX History List buffer can store up to 16 TX History List entries for a CAN channel.

The CFDTHLCCn.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFOs/TX Queue is stored or if all transmit message information from TX Queue, TX FIFO or normal TX message buffers should be stored in the TX History List for a CAN channel.

When a CFDTHLCCn.THLDGE bit is set up, the information on all the frames transmitted in GW mode is stored in TX History List.

Each transmit message can be individually configured for acceptance to the TX History List by the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the List is not synchronized with the status of CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the List can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF bit is set to 1 when the THLIE is configured to 1 or when the TX History List counter CFDTHLSTSn.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

- Maximum delay time from setting the CFDTMSTSn.TMTRF to storing the TX History List data is 224 peripheral bus clock cycles.

The History list records the following information of the transmitted message:

- Buffer type:
  - 001b: TX Message Buffer
  - 010b: TX FIFO
  - 100b: TX Queue
- Buffer number:
  TX Message Buffer, TX Queue Message Buffer or TX Message Buffer Link for the Common FIFO Buffer from which the transmission occurred. The number depends on the buffer type, see Table 34.28.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at the capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.
- Transmit gateway buffer indication:
  For data transmitted from the gateway, CFDTHLACC0n.TGW bit is set to 1.

Table 34.28 TX History List buffer number entry

CFDTHLACC0n.BT[2:0] buffer type		
001b	**101b**	**100b**
TX Message Buffer	**TX FIFO**	**TX Queue**
TXMB0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO Configuration	Number shown corresponds to the message buffer belonging to the TX Queue for which the frame was transmitted.
TXMB1		
TXMB2		
TXMB3

TXMB30		
TXMB31		
TXMB32		
TXMB33		
TXMB34		
⋮		
TXMB61		
TXMB62		
TXMB63		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTSn.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, the identification number is then stored together with the other message related information to the TX History List and can be read with the Transmission ID (TID) of the TX History List Access Register.

Also for normal TX message buffers, the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List. Information label is the same.

Figure 34.49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 34.50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCCn.THLIM bit of the corresponding TX History List Configuration/Control Registers and enabled with the CFDTHLCCn.THLIE bit of the same registers, either to generate an interrupt when the history list reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTSn.THLELT bit in the TX History List Status Register.

Status of this bit is also shown by the THLES bit in the Global Error Flag Register.

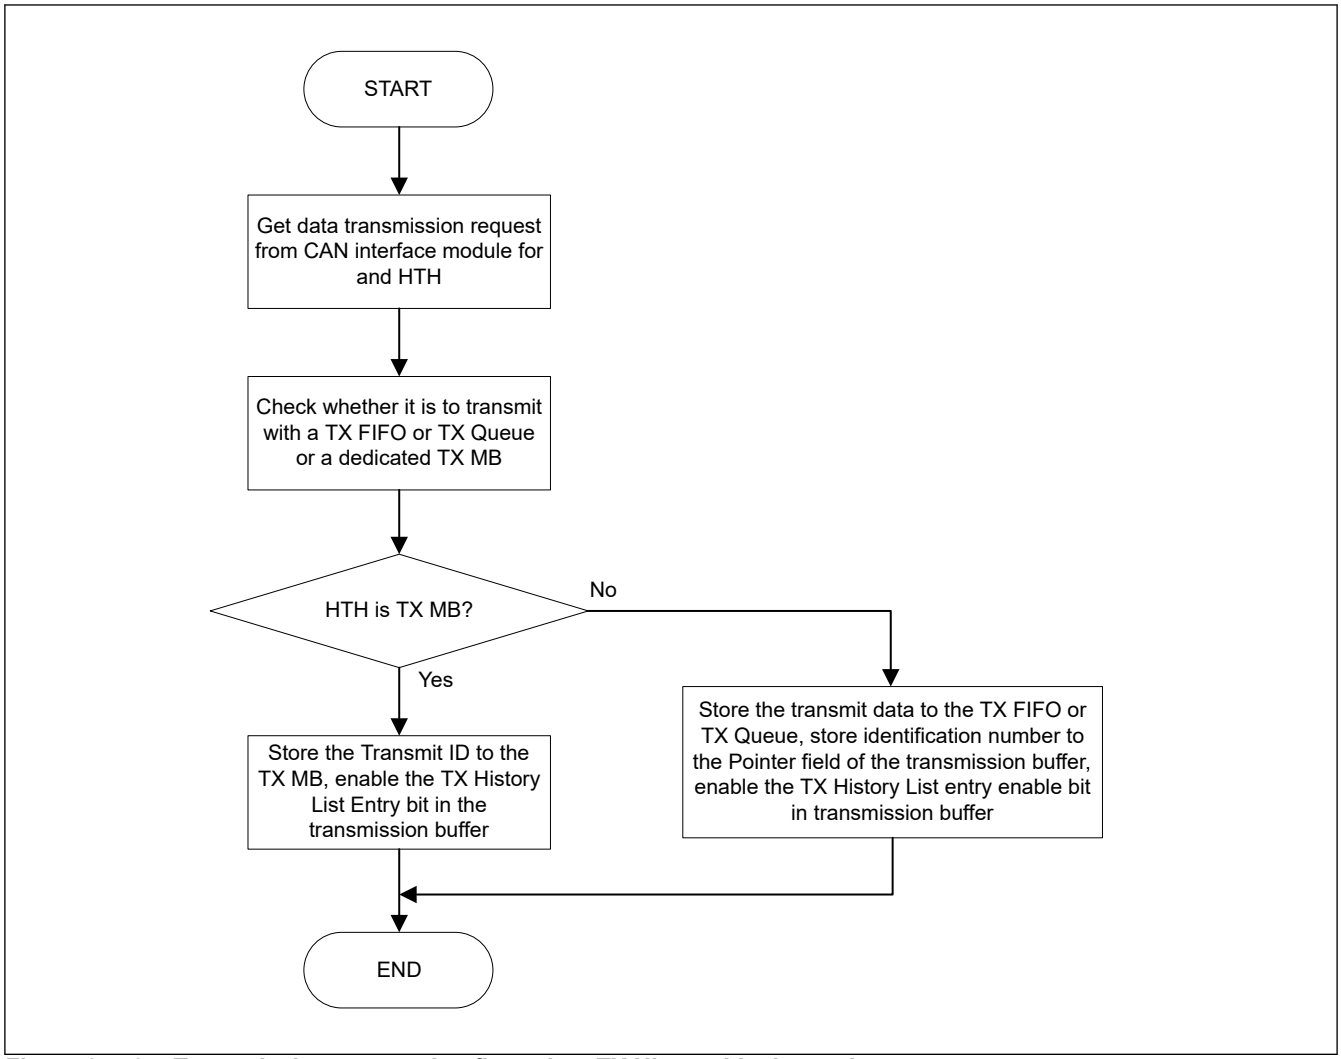

Figure 34.49 Transmission preparation flow when TX History List is used

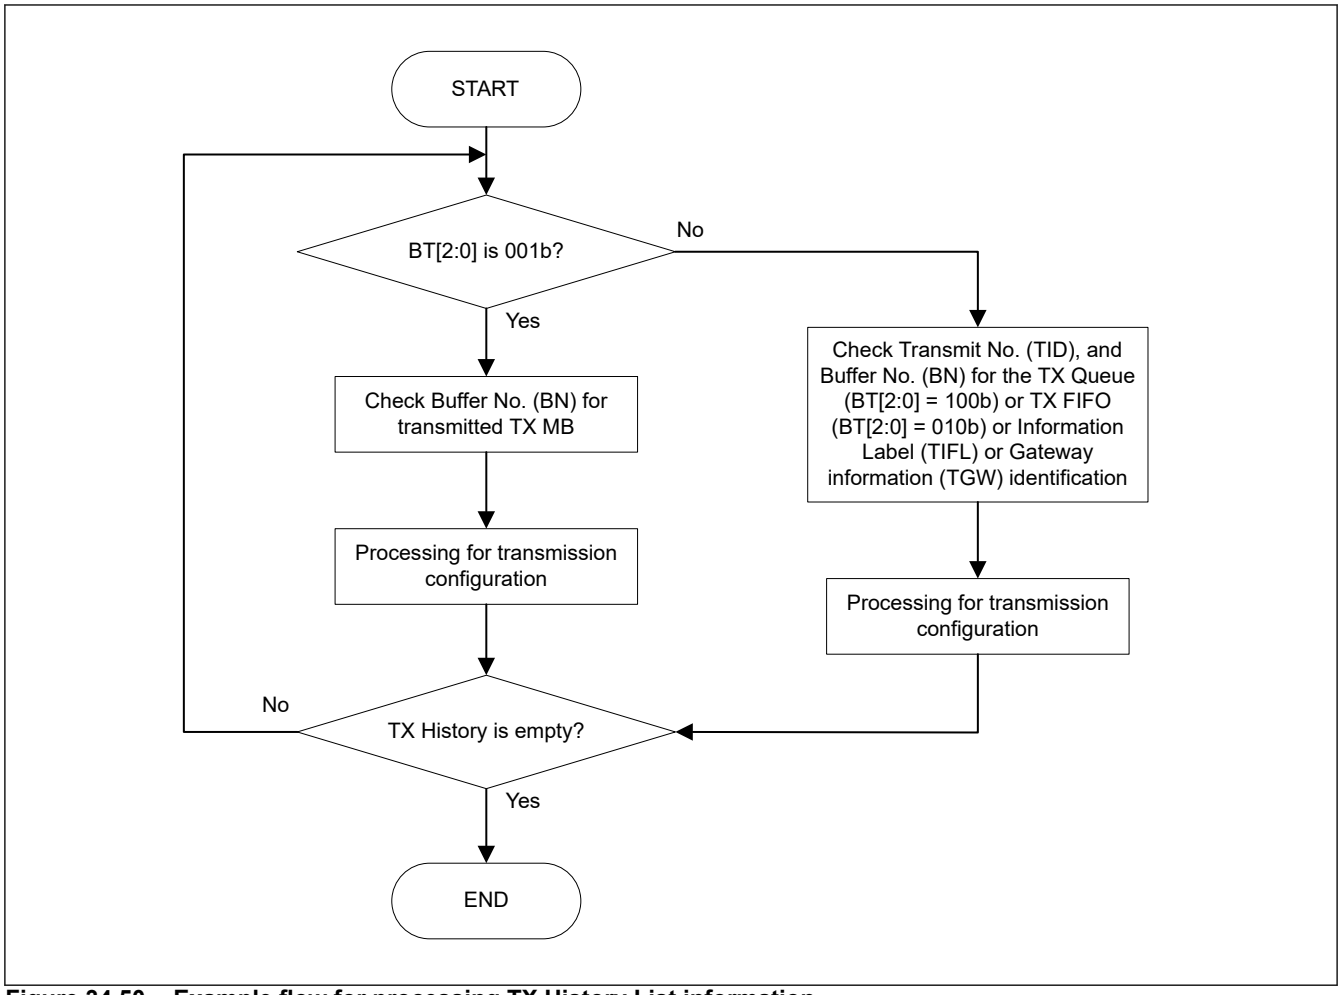

Figure 34.50 Example flow for processing TX History List information

34.8.2.6 TX Data Padding

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, then the data bytes beyond the restricted range are replaced by bytes with the value of CC HEX.

This can happen for Common FIFOs configured as (TX or GW) when the transmit message DLC is higher than CFDCFCCn.CFPLS.

This can also happen in FD-only mode, if a Classical Frame is configured with a DLC larger than 8.

34.9 Test Mode

The CAN-FD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CAN-FD module in test modes.

All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes

34.9.1 Channel Specific Test Modes

Each CAN channel can be configured into the following test modes:

- Basic test mode

- Listen-only mode
- Self-test mode 0 (External Loop Back mode)
- Self-test mode 1 (Internal Loop Back mode)
- Restricted operation mode

34.9.1.1 Basic Test Mode

The Basic test mode should be used when a particular test setting must be enabled other than when in Listen-Only and Self-test modes.

34.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional Bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, Overload flag, Active Error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX Message Buffer or TX-/GW-FIFO of this channel.

Note: If a message is stored in GW FIFO or Routing TXQ, ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or Routing TXQ.

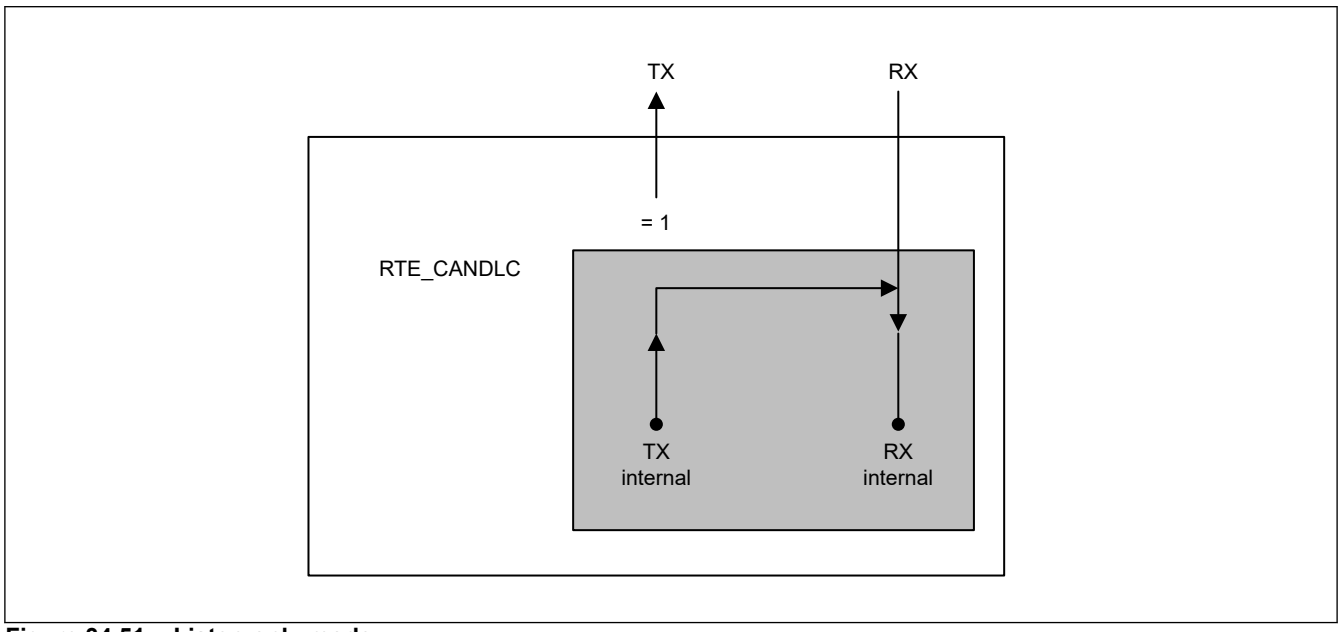

Figure 34.51 Listen-only mode

34.9.1.3 Self-Test Mode 0 (External Loop Back Mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and can store them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests.

The RX/TX pins should be connected to the transceiver.

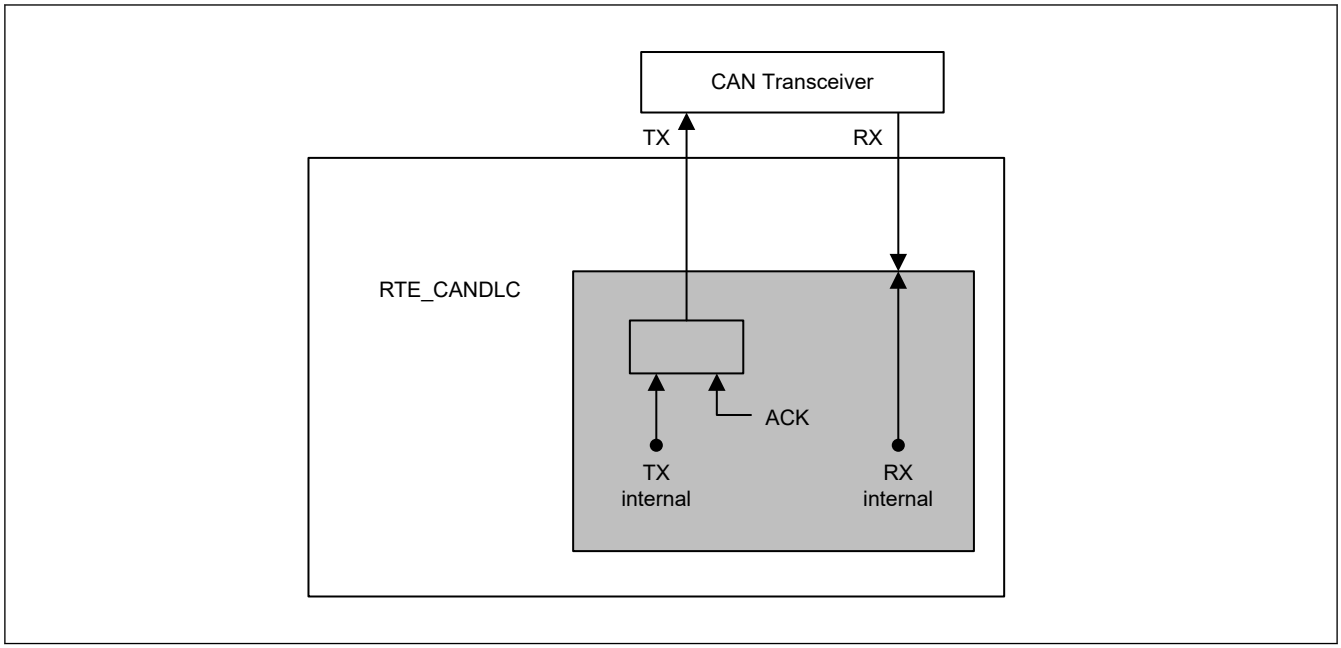

Figure 34.52 Self-test mode 0 (External Loop Back mode)

34.9.1.4 Self-Test Mode 1 (Internal Loop Back Mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits.

The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

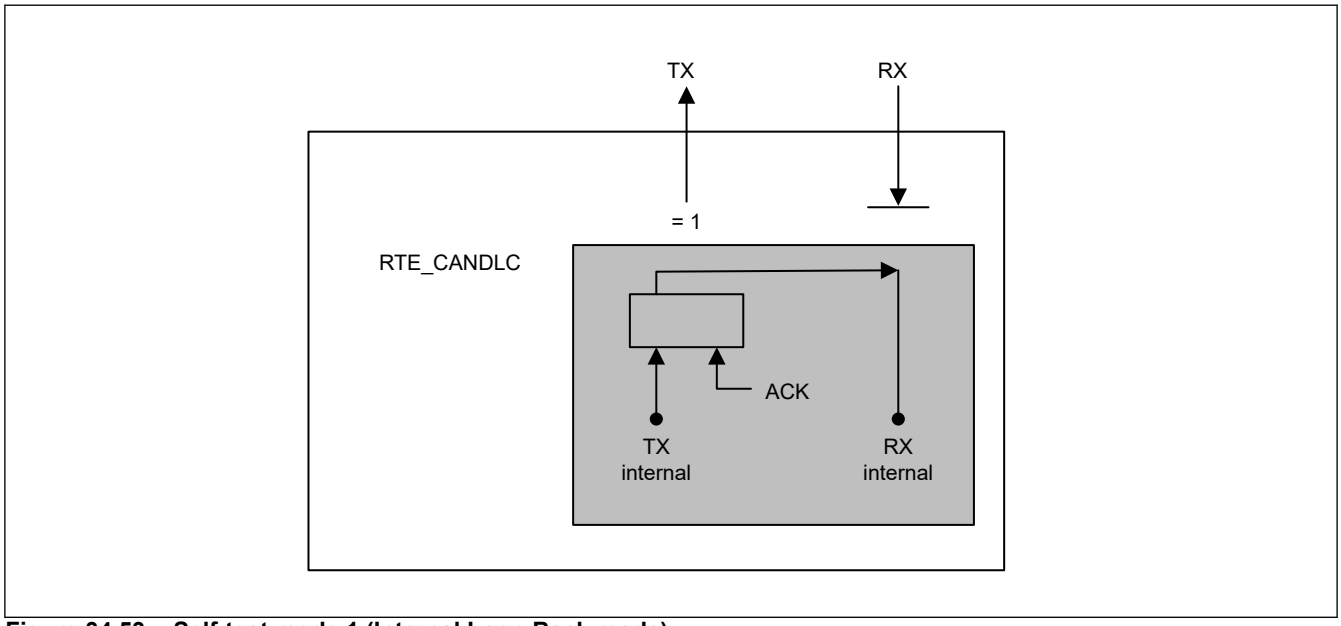

Figure 34.53 Self-test mode 1 (Internal Loop Back mode)

34.9.1.5 Restricted Operation Mode

In Restricted operation mode, the CAN node is able to receive valid data and remote frames that generates the Acknowledge bit.

Active error and overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors.

The mode is specified as in ISO 11898-1. However, it is permitted to set any requested transmit.

34.9.2 Global Test Modes

The CAN-FD module can be configured into the following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

These test modes are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key, the related unlock key can be seen in the following table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word accesses) is interrupted by any other write access to the SFR or if incorrect data is written to the Global Unlock Key Register then the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding Test Mode Enable bit. If this is not followed, the unlock mechanism resets and the Test Mode Enable bit cannot be set. At this time, the unlock sequence must be restarted.

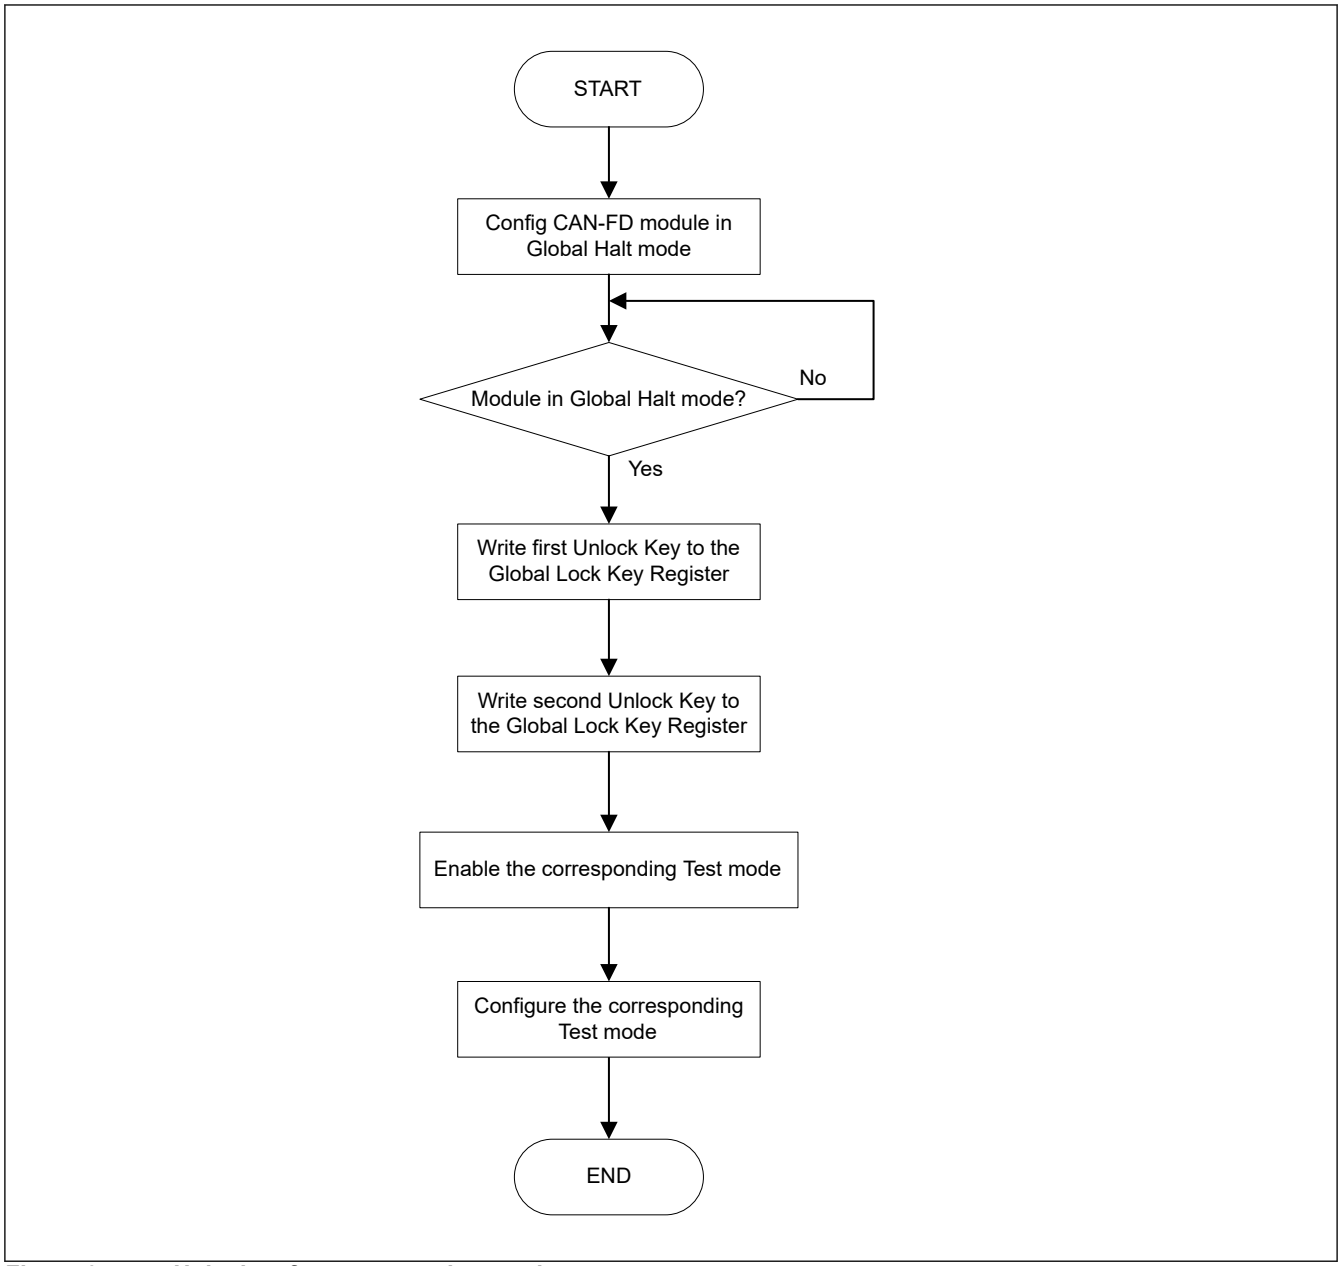

Figure 34.54 Unlock software protection routine

34.9.2.1 RAM Test Mode

The CAN-FD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes each. Which can be accessed with the CFDRPGACCn register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Data can then be read from or written into the RAM Test Page Access Registers.

Figure 34.55 shows the structure of the pages in the RAM when performing a RAM test mode.

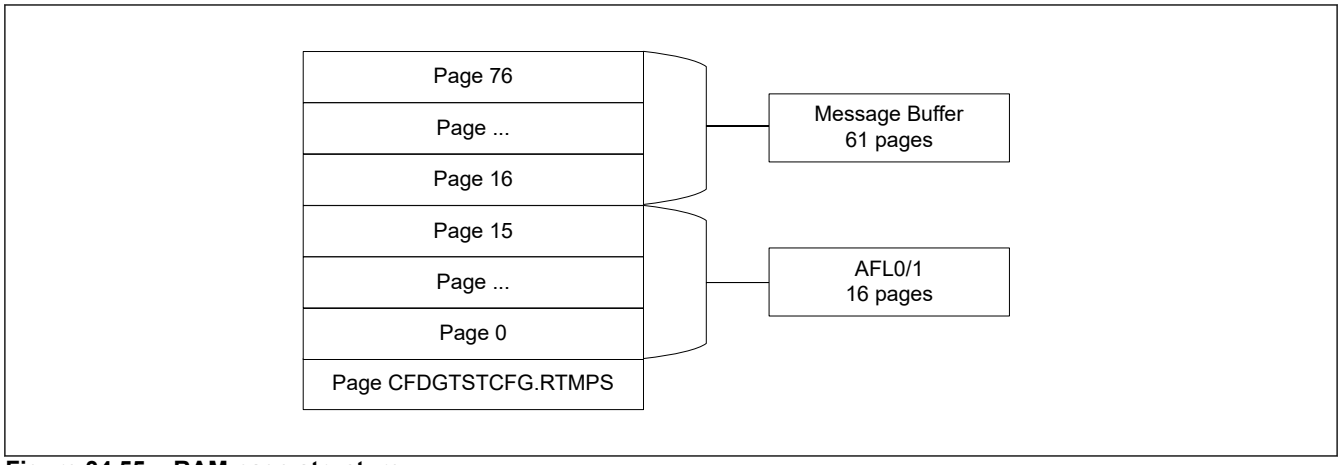

Figure 34.55 RAM page structure

The total available RAM size for a 2-CAN channel version is 4096 bytes for the AFL RAM and 15488 bytes for the Message Buffer RAM.

AFL RAM0/1 can treat RAM test mode as one RAM.

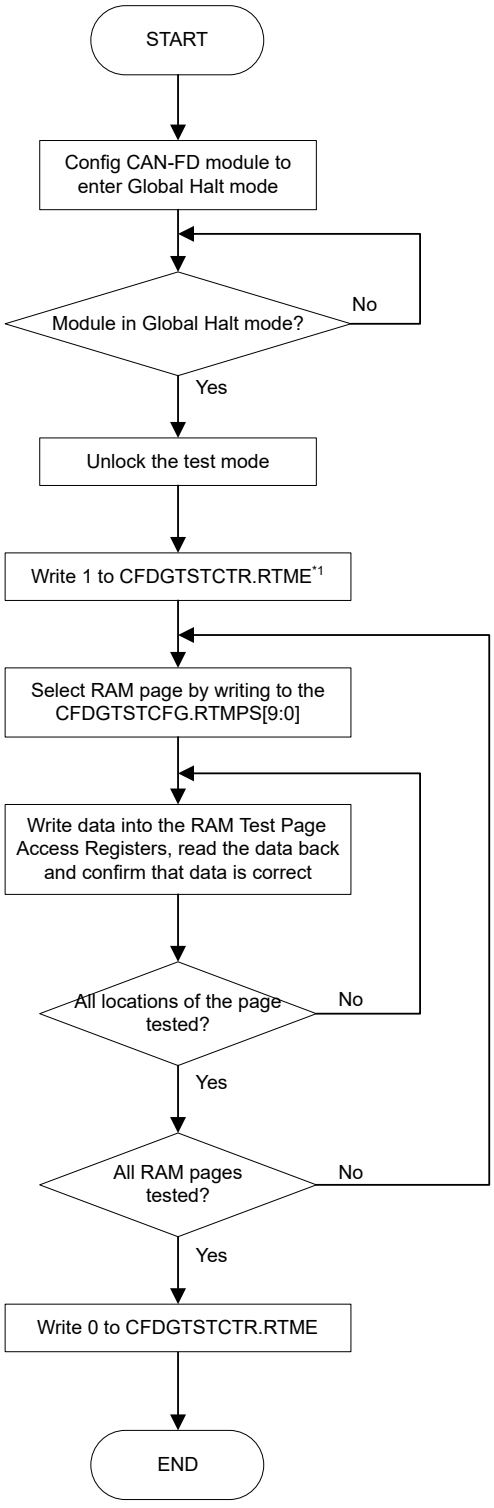
The number of pages (pn) and CFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- AFL RAM:
  pn = ceil (4096 / 256) = 16 pages
  CFDGTSTCFG.RTMPS[9:0] = 0 to 15 (0x00F) inclusive
- MB RAM:
  pn = ceil (15488 / 256) = 61 pages
  CFDGTSTCFG.RTMPS[9:0] = 16 to 76 (0x04C) inclusive

Do not access more than 128 bytes of RAM on the last page (RTMPS[9:0] = 0x04C).

Figure 34.56 shows the software flow for RAM test mode.



Note 1: Change into the following status before changing to RAMTEST.

- Cancel of a request of transmission
- Disable of all the FIFO and TXQ
- Clear of the receiving flag of a receiving buffer

Figure 34.56 Software flow of RAM test mode

To exit this test mode, clear the CFDGTSTCTR.RTME bit. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CAN-FD module enters Global Reset mode from the test mode.

34.9.2.2 Internal CAN Bus Communication Mode

The CAN-FD module can be configured in Internal CAN bus communication test mode by setting the CFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the CAN-FD module.

Only use the following sequence to enter Internal CAN bus communication test mode:

1. Configure all channels in Halt mode and check that all channels have entered Global Halt mode.
2. Write data into the Global Test Configuration Register to select the channels participating in the Internal CAN bus communication test.
3. Set the CFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that CFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TXD outputs of the channels participating (configured) in Internal CAN bus communication mode are connected together using AND gate. The output of the AND gate is connected to the RXD inputs of all participating channels to create a CAN cluster within the CAN-FD module. The channels are isolated from the external CAN bus while the CAN-FD module is in this test mode.

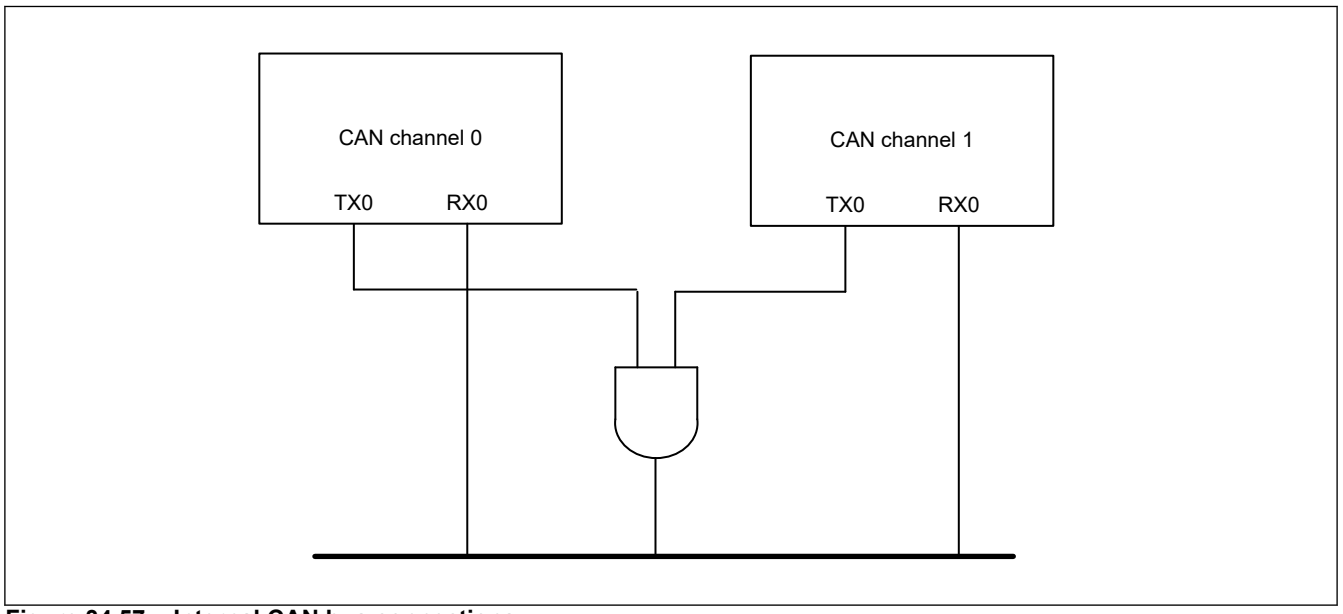


Figure 34.57 Internal CAN bus connections

The AFL, Flat RX message buffers, FIFO buffers, Flat TX message buffers, and various registers can now be configured as normal to start communication between channels.

The channels not participating in Internal CAN bus should only be configured in Halt mode.

34.9.2.3 CRC Error Test

After the CAN-FD module has been configured in Internal CAN bus communication test mode, use the following sequence to perform CRC error testing. In the following sequence, channel x is the reference transmitter CAN-FD module and channel y is the receiver CAN-FD module where (x, y = [0,…, n] and $x \neq y$):

1. Configure channel x node to transmit one reference message.
2. Set the CFDCyCTR.CRCT bit to 1, in order to invert the first bit of the incoming bit stream from channel x.
3. Set the CFDTMCx.TMTR.
4. Read either CFDCyERFL.CRCREG or CFDCyFDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.

5. Check that CFDCyERFL.CERR is 1.

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC error test.

34.10 Bus Traffic Measurement

The idle time of the CAN bus can be measured using PCLKM or PCLKCAN. Bus traffic can be calculated based on the measurement results.

34.10.1 How to count the CAN Bus Idle Time

Figure 34.58 shows the concept of measuring the idle time of the CAN bus.

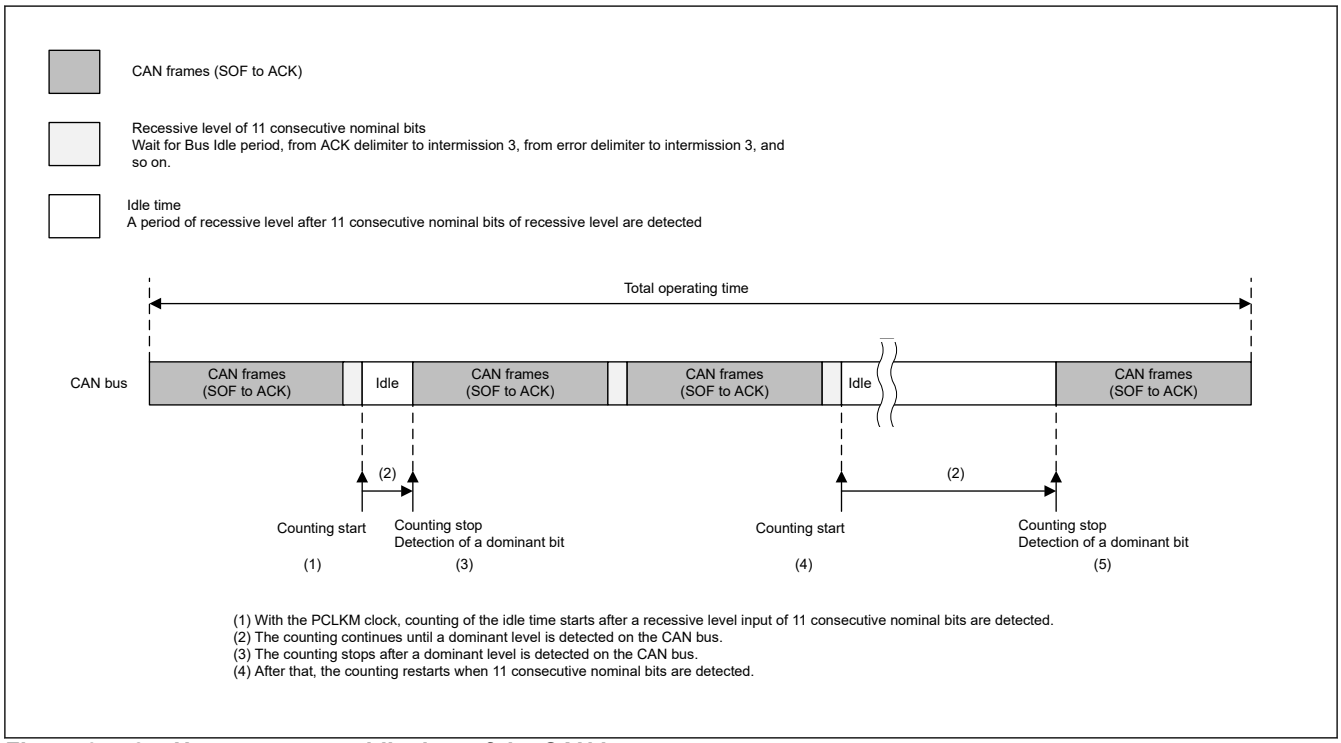

Figure 34.58 How to measure idle time of the CAN bus

34.10.2 Operations and Measurement Procedure

The following procedure is for measuring the idle time of the CAN bus.

1. The channel to be measured transits to operation mode.
2. Write 1 to CFDCnBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register.
4. Detect a recessive level input of 11 consecutive nominal bits.
5. Start counting the bus idle time.
6. Detect a dominant level.
7. The counting stops.
8. Detect a recessive level input of 11 consecutive nominal bits.
9. The counting starts.
10. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to CFDCnBLSTS.
11. Read the value of CFDCnBLSTS.

To stop the measurement counter, write 0 to CFDCnBLCT.BLCE bit.

To initialize the counter, write 1 to CFDCnBLCT.BLCLD bit.

This measurement is enabled when the channel to be measured is in Operation mode.

When the relevant channels are in reset mode, the counter does not operate.

Also, accurate measurements are not available in test mode.

Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to CFDCnBLSTS.

The lower 3 bits of CFDCnBLSTS are fixed to 0.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas:

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{\text{Bus operating time}}{\text{Total operating time}} = \text{Bus usage ratio}$$

- Total idle time: a value read from CFDCnBLSTS × a clock cycle of PCLKM
- Total operating time: a setting interval of CFDCnBLCT.BLCLD bit

Example: Below is a calculation example under the following conditions:

- Conditions: nominal bit rate = 1 Mbps
- PCLKCAN clock = 40 MHz (= 25 ns)
- A setting interval of CFDCnBLCT.BLCLD bit = cycle of 1 ms
- A read value of CFDCnBLSTS register = 0x4E20

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{(1000000\ \text{ns} - 20000 \times 25\ \text{ns})}{1000000\ \text{ns}} = 50\%$$

35. Serial Peripheral Interface (SPI)

35.1 Overview

The SPI supports serial communications for transmit-receive, transmit only, and receive only. The SPI is provided with a function for high-speed serial communication with multiple processors and peripheral devices.

35.1.1 Features

Table 35.1 lists the specifications of the SPI, and Figure 35.1 shows a block diagram of the SPI.

Table 35.1 SPI specifications (1 of 2)

Item	Description
Number of channels	4 channels (ch0 to ch2 in NON-SAFETY and ch3 in SAFETY)
Transfer functions	• SPI serial communication (4-wire) and clock synchronous (3-wire) serial communication are possible by using the MOSI (Master Out Slave In), MISO (Master In Slave Out), SSL (Slave Select), and RSPCK (SPI Clock) signals. • Transmit-only operation is available • Receive-only operation is available • Serial communication is possible in master mode and slave mode • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB first or LSB first selectable. • Transfer bit length selectable from 4 to 32 bits • 32 bit x 4 stage FIFO transmit and receive buffers • Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function • Transmit/receive data inversion
Bit rate	• In master mode, the on-chip baud rate generator divides the PCLKSPIn to generate RSPCK. A division ratio of 2 to 4096 is settable. • In slave mode, an external input clock is used as a serial clock. The maximum frequency = PCLKSPIn/2 (High width: 1 PCLKSPIn cycles, low width: 1 PCLKSPIn cycles)
Buffer configuration	• Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection

Table 35.1 SPI specifications (2 of 2)

Item	Description
SSL control function	[Motorola SPI mode] ● Four SSL pins (SSLn0 to SSLn3) each channel ● In single master mode, SSLn0 to SSLn3 pins are output. ● In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused ● In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused ● Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Configurable delay between frames in burst transfer ● Function for changing SSL polarity [TI SSP mode] ● Four SSL pins (SSL0 to SSL3) each channel ● In single master mode, SSLn0 to SSLn3 pins are output. ● In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused ● In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused ● Controllable delay from SSL output assertion to SSL output negation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable delay from RSPCK stop to Output disable (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Configurable delay between frames in burst transfer ● Function for changing SSL polarity
Communication Protocol	● Motorola SPI ● TI SSP (Synchronous Serial Protocol)
Synchronization bypass function	● Synchronization circuit can be bypassed using bus clock (PCLKM) as operation clock (PCLKSPIn)
Control in master transfer	[Motorola SPI mode] ● Transfers of up to eight commands each can be executed sequentially in looped execution ● For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay, next-access delay ● Transfers can be initiated by writing to the transmit buffer ● MOSI signal value specifiable in SSL negation ● RSPCK auto-stop function [TI SSP mode] ● Transfers of up to eight commands each can be executed sequentially in looped execution ● For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay (Output disable delay), next-access delay ● Transfers can be initiated by writing to the transmit buffer ● MOSI signal value specifiable in SSL negation ● RSPCK auto-stop function
Interrupt sources	● Maskable Interrupt sources SPI receive buffer full / Receive data ready interrupt SPI transmit buffer empty interrupt SPI communication end interrupt SPI error interrupt (mode fault, overrun, parity error, receive data ready) SPI idle interrupt (SPI idle)
Others	● Switching between CMOS output and open-drain output ● SPI disable (initialization) function ● Loopback mode function
Module-stop function	Module-stop state can be set to reduce power consumption*1

Note 1. Module stop condition: It depends on the setting higher than this module. This module is not reset, and the clock stops on module stop condition. It contributes to low power consumption, because the clock stops.

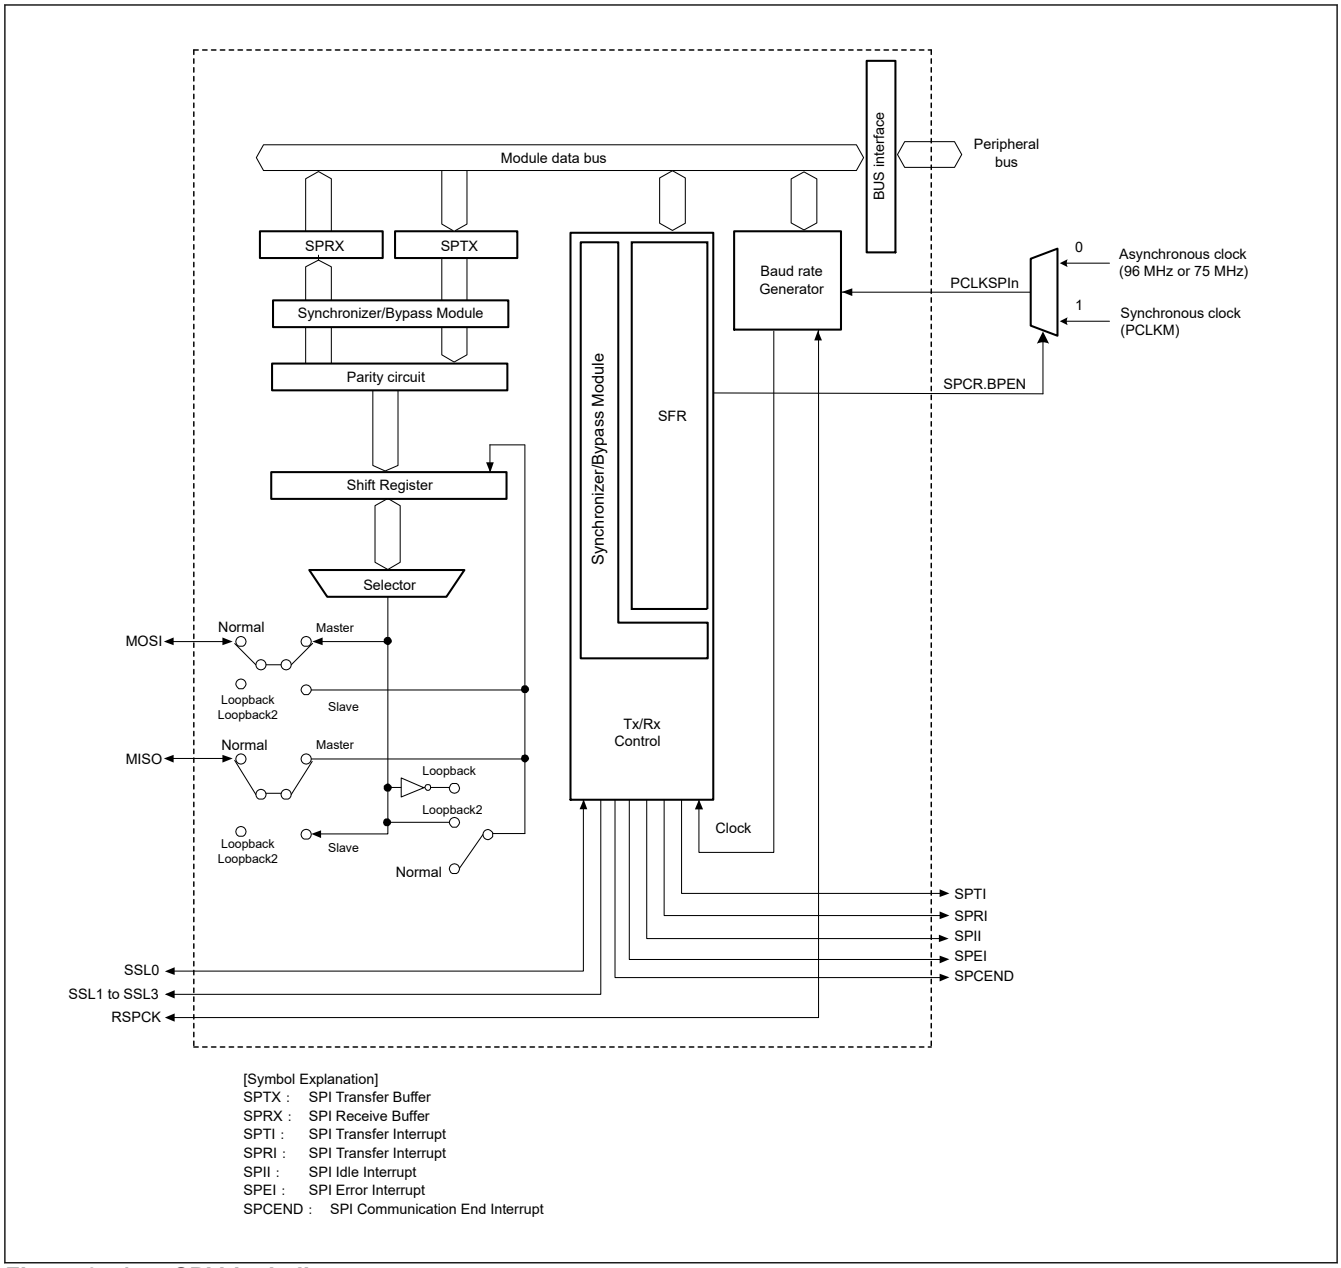

Figure 35.1 SPI block diagram

The SPI automatically switches the SSL0 pin input and output directions. The SSL0 pin is switched to output when single master is set, and it is switched to input when multi-master or slave is set. Furthermore, the SPI automatically switches the input and output directions of pins RSPCK, MOSI, MISO, SSL1 to SSL3 according to the master/slave setting and SPI operation (4-wire)/clock synchronous operation (3-wire) SSL0 input level. (See section 35.3.2. SPI Pin Control.)

Table 35.2 lists the I/O pins used in the SPI.

Table 35.2 SPI pin configuration

Channel	Pin name	I/O	Function
SPIn (n = 0 to 3)	SPI_RSPCKn	I/O	Clock I/O
	SPI_MOSIn	I/O	Master transmit data I/O
	SPI_MISOn	I/O	Slave transmit data I/O
	SPI_SSLn0	I/O	Slave selection signal I/O
	SPI_SSLn1	Output	Slave selection signal output
	SPI_SSLn2	Output	Slave selection signal output
	SPI_SSLn3	Output	Slave selection signal output

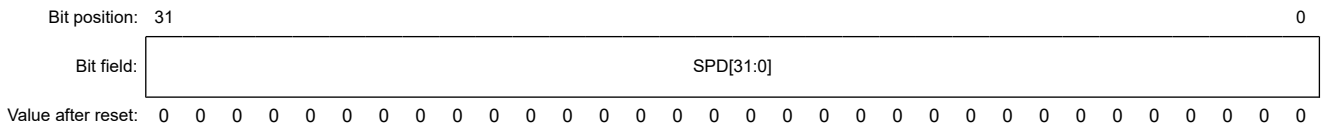
Note: For convention, pin names within this chapter are written without "SPI_" notation except this table.

35.2 Register Descriptions

35.2.1 SPDR/SPDR_HA/SPDR_BY : SPI Data Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

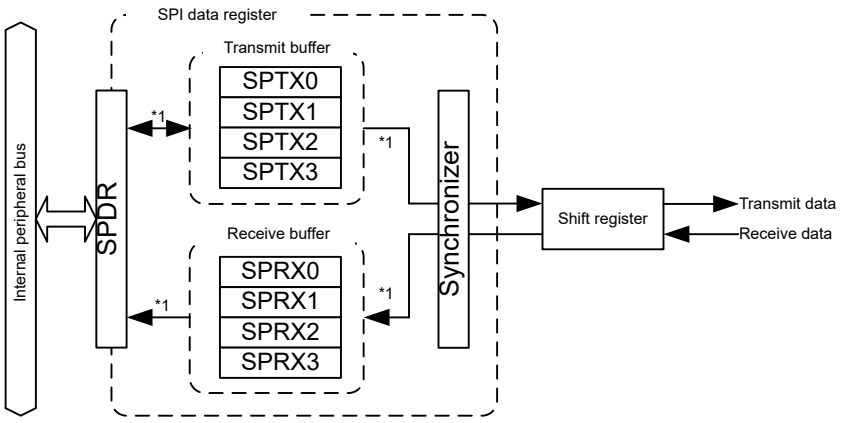
Offset address: 0x00



Bit	Symbol	Function	R/W
31:0	SPD[31:0]	The SPI data register (SPDR) is used to store SPI's transmit data and receive data. Transmit buffers and receive buffers independently function.	R/W

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI.

Figure 35.2 shows the structure of SPDR.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 35.2 Structure of SPDR

32 bit × 4 stage transmit FIFO and 32 bit × 4 receive FIFO are provided. These 8 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 3) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

Bus Interface

The SPI data register has 32 bit × 4 stage transmit FIFO and 32 bit × 4 receive FIFO (32 bytes in total). These 32 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

(a) Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

Figure 35.3 shows the configuration of the bus interface with the transmission buffer in the case of writing to SPDR.

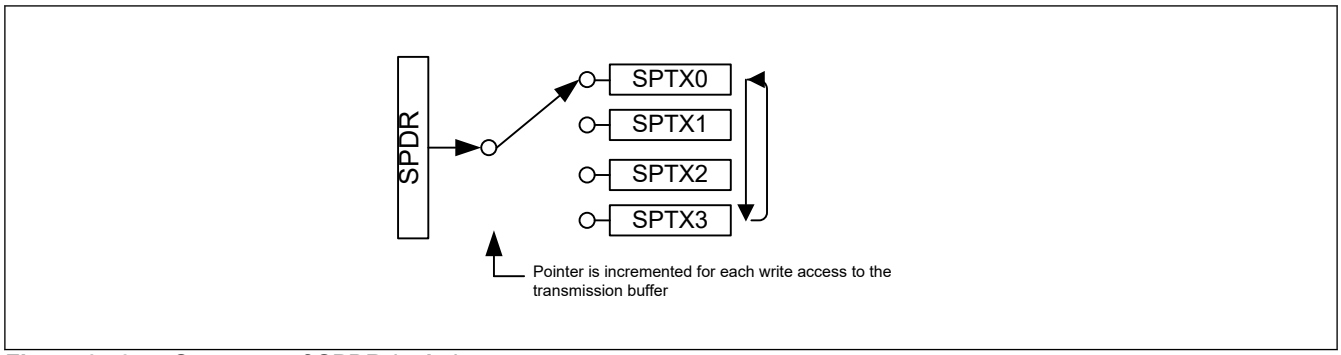


Figure 35.3 Structure of SPDR (write)

The transmit buffer (SPTX0 to SPTX3) switching order:

SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→…

When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

(b) Read

Values can be read from receive buffers (SPRXn, n = 0 to 3) or transmit buffers (SPTXn, n = 0 to 3) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD).

The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer.

The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

Figure 35.4 shows the configuration of the bus interface with the receive and transmission buffers in the case of reading from SPDR.

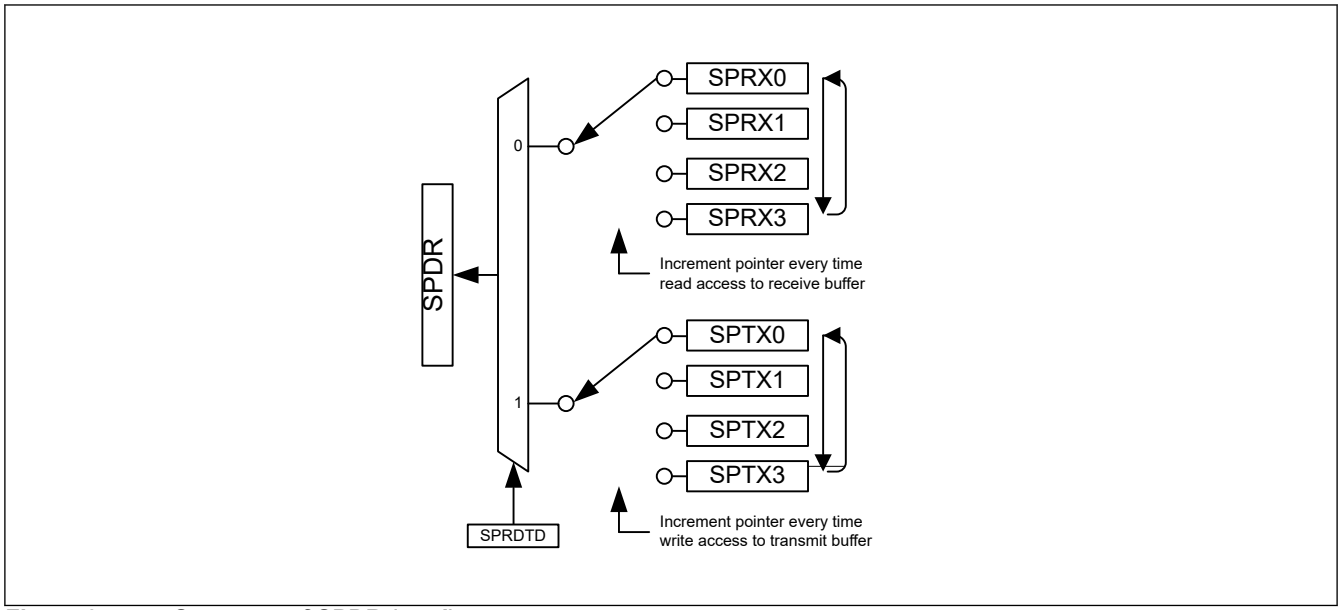

Figure 35.4 Structure of SPDR (read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.

The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

35.2.2 SPCKD : SPI Clock Delay Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SCKDL[2:0]	RSPCK Delay Setting 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

[In the Motorola-SPI case]

The SPCKD register is used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while SPCMD.SCKDEN = 1. If SPCKD is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SPCKD register is used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while SPCMD.SCKDEN = 1. Also that is used to set the period until the SSL signal is negated. If SPCKD is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

SCKDL[2:0] bits (RSPCK Delay Setting)

These bits are used to set the RSPCK delay value when SPCMD.SCKDEN = 1.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

35.2.3 SSLND : SPI Slave Select Negation Delay Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SLNDL[2:0]	SSL Negation Delay Bits This is the synchronization delay for replacing the RSPCK input with PCLKSPIn. RSPCK Delay Setting 0 0 0: 1 RSPCK [Master mode] 1 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 0 1: 2 RSPCK [Master mode] 2 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 1 0: 3 RSPCK [Master mode] 3 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 1 1: 4 RSPCK [Master mode] 4 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 0 0: 5 RSPCK [Master mode] 5 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 0 1: 6 RSPCK [Master mode] 6 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 1 0: 7 RSPCK [Master mode] 7 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 1 1: 8 RSPCK [Master mode] 8 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode]	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

[In the Motorola-SPI case]

The SSLND register is used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while SPCMD.SCKDEN = 1. If SSLND is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SSLND register is used to set the period (Output disable delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the Output enable signal while SPCMD.SCKDEN = 1. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the Output enable signal is negated. If SSLND is modified while the SPE bit in SPCR.SPE = 1, subsequent operation is not guaranteed.

SLNDL[2:0] bits (SSL Negation Delay Bits)

[In the Motorola-SPI case]

These bits are used to set the SSL negation delay value when SPCMD.SLNDEN = 1.

To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 000b.

[In the TI-SSP case]

These bits are used to set the Output disable delay value when SPCMD.SLNDEN = 1.

35.2.4 SPND : SPI Next-Access Delay Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPNDL[2:0]	SPI Next-Access Delay Bits RSPCK Delay Setting 0 0 0: 1 RSPCK + 5 PCLKSPIn 0 0 1: 2 RSPCK + 5 PCLKSPIn 0 1 0: 3 RSPCK + 5 PCLKSPIn 0 1 1: 4 RSPCK + 5 PCLKSPIn 1 0 0: 5 RSPCK + 5 PCLKSPIn 1 0 1: 6 RSPCK+ 5 PCLKSPIn 1 1 0: 7 RSPCK + 5 PCLKSPIn 1 1 1: 8 RSPCK + 5 PCLKSPIn	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPND register is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while SPCMD.SCKDEN = 1. If SPND is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

SPNDL[2:0] bits (SPI Next-Access Delay Bits)

These bits are used to set the next-access delay value when SPCMD.SCKDEN = 1. To use the SPI in slave mode, set SPNDL[2:0] bits to 000b.

35.2.5 MRCKD : SPI ClocK Digital control Register for Master Receive

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ARST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ARST[2:0]	Receive Sampling Timing Adjustment Bits The sampling of the serial data (MISO) input in master mode can be adjusted by delaying 0 to 7 PCLKSPIn from the center of the bit. 0 0 0: 0 PCLKSPIn delay 0 0 1: 1 PCLKSPIn delay 0 1 0: 2 PCLKSPIn delay 0 1 1: 3 PCLKSPIn delay 1 0 0: 4 PCLKSPIn delay 1 0 1: 5 PCLKSPIn delay 1 1 0: 6 PCLKSPIn delay 1 1 1: 7 PCLKSPIn delay	R/W

Bit	Symbol	Function	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The MRCKD register is a register for adjusting the reception sampling timing in master mode. If the ARST[2:0] bits are rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

ARST[2:0] bits (Receive Sampling Timing Adjustment Bits)

These bits are used to select the amount of reception sampling timing adjustment. The sampling timing can be adjusted by delaying 0 to 7 PCLKSPIn from the center of the bit.

Delay setting exceeding the dividing ratio is prohibited.

This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0, when MRCLK is selected (SPCR.SPSCKSEL = 1), and SPPCR.SPLP2 = 0) and in master mode. For details, see SPSCKSEL bit of section 35.2.6. SPCR : SPI Control Register.

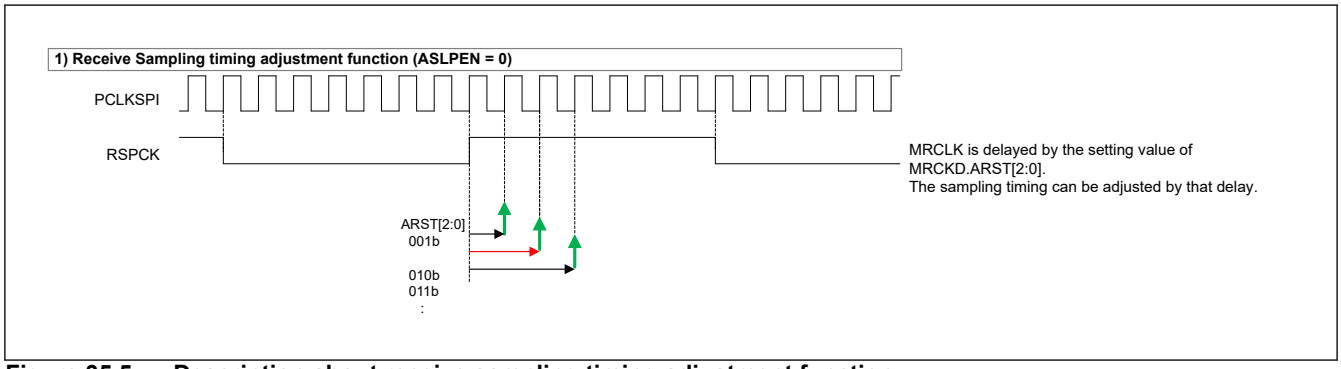

Figure 35.5 Description about receive sampling timing adjustment function

35.2.6 SPCR : SPI Control Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BPEN	MSTR	TXMD[1:0]		—	—	SPFRF	SPMS	—	—	CENDIE	SPTIE	SPDRES	SPIIE	SPRIE	SPEIE

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPE	SPI Function Enable 0: SPI function is disabled. 1: SPI function is enabled.	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	SPSCKSEL	SPI Master Receive Clock Select 0: MRIOCLK (Adjust with Analog Delay (SPCR2.SPSCKDL)) 1: MRCLK (Adjust with Digital Delay (MRCKD.ARST))	R/W
8	SPPE	Parity Enable 0: A parity bit is not added to transmit data. Received-data parity check is not performed. 1: A parity bit is added to transmit data. Received-data parity check is performed.	R/W

Bit	Symbol	Function	R/W
9	SPOE	Parity Mode 0: Even parity is used for transmission and reception. 1: Odd parity is used for transmission and reception.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PTE	Parity Self-Diagnosis Enable 0: Parity circuit self-diagnosis function is disabled. 1: Parity circuit self-diagnosis function is enabled.	R/W
12	SCKASE	RSPCK Auto-Stop Function Enable 0: RSPCK auto-stop function is disabled. 1: RSPCK auto-stop function is enabled.	R/W
13	BFDS	Between Burst Transfer Frames Delay Select 0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer. 1: Delay between frames is not inserted in burst transfer.	R/W
14	MODFEN	Mode Fault Error Detection Enable 0: Mode fault error detection is disabled. 1: Mode fault error detection is enabled.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
16	SPEIE	SPI Error Interrupt Enable 0: SPI error interrupt request is disabled. 1: SPI error interrupt request is enabled.	R/W
17	SPRIE	SPI Receive Buffer Full Interrupt Enable 0: SPI receive buffer full interrupt request is disabled. 1: SPI receive buffer full interrupt request is enabled.	R/W
18	SPIIE	SPI Idle Interrupt Enable 0: Idle interrupt request is disabled. 1: Idle interrupt request is enabled.	R/W
19	SPDRES	SPI Receive Data Ready Error Select 0: Receive data full interrupt 1: Error interrupt	R/W
20	SPTIE	SPI Transmit Buffer Empty Interrupt Enable 0: SPI transmit buffer empty interrupt request is disabled. 1: SPI transmit buffer empty interrupt request is enabled.	R/W
21	CENDIE	SPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SPMS	SPI Function Enable 0: SPI operation (4-wire) 1: Clock synchronous operation (3-wire)	R/W
25	SPFRF	SPI Frame Format Select When SPMS = 1 (clock synchronous operation (3-wire)), this bit setting is invalid. 0: Motorola-SPI 1: TI-SSP	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
29:28	TXMD[1:0]	Communication Mode Select 0 0: Transmit-Receive 0 1: Transmit only 1 x: Receive only	R/W
30	MSTR	SPI Master/Slave Mode Select 0: Slave mode 1: Master mode	R/W
31	BPEN	Synchronization Circuit Bypass Enable 0: Non-Bypass 1: Bypass	R/W

The SPCR register is used to set operating mode of the SPI. If the set MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE, SPSCKSEL, and BPEN bit value is modified while SPCR.SPE = 1, subsequent operation is not guaranteed.

SPE bit (SPI Function Enable)

The SPE bit is used to enable or disable SPI functions. Setting this bit to 1 enables SPI functions. When SPSR.MODF = 1, the SPCR.SPE bit is cleared to 0 and the SPCR.SPE bit cannot be set to 1 until the MODF flag is cleared to 0. (See section 35.3.10. Error Detection.) Setting the SPE bit to 0 disables SPI functions and initializes a part of module functions. (See section 35.3.12. SPI Initialization.)

SPSCKSEL bit (SPI Master Receive Clock Select)

The SPSCKSEL bit selects the clock used to sample the received data in master mode. By setting this bit, the sampling timing of the MISO can be adjusted. This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0 and SPPCR.SPLP2 = 0) and in master mode.

Figure 35.6 shows a Master Receive Clock Delay configuration. By selecting this bit, you can select MRIOCLK (adjust with analog delay (SPCR2.SPSCKDL)) or MRCLK (adjust with digital delay (MRCKD.ARST)).

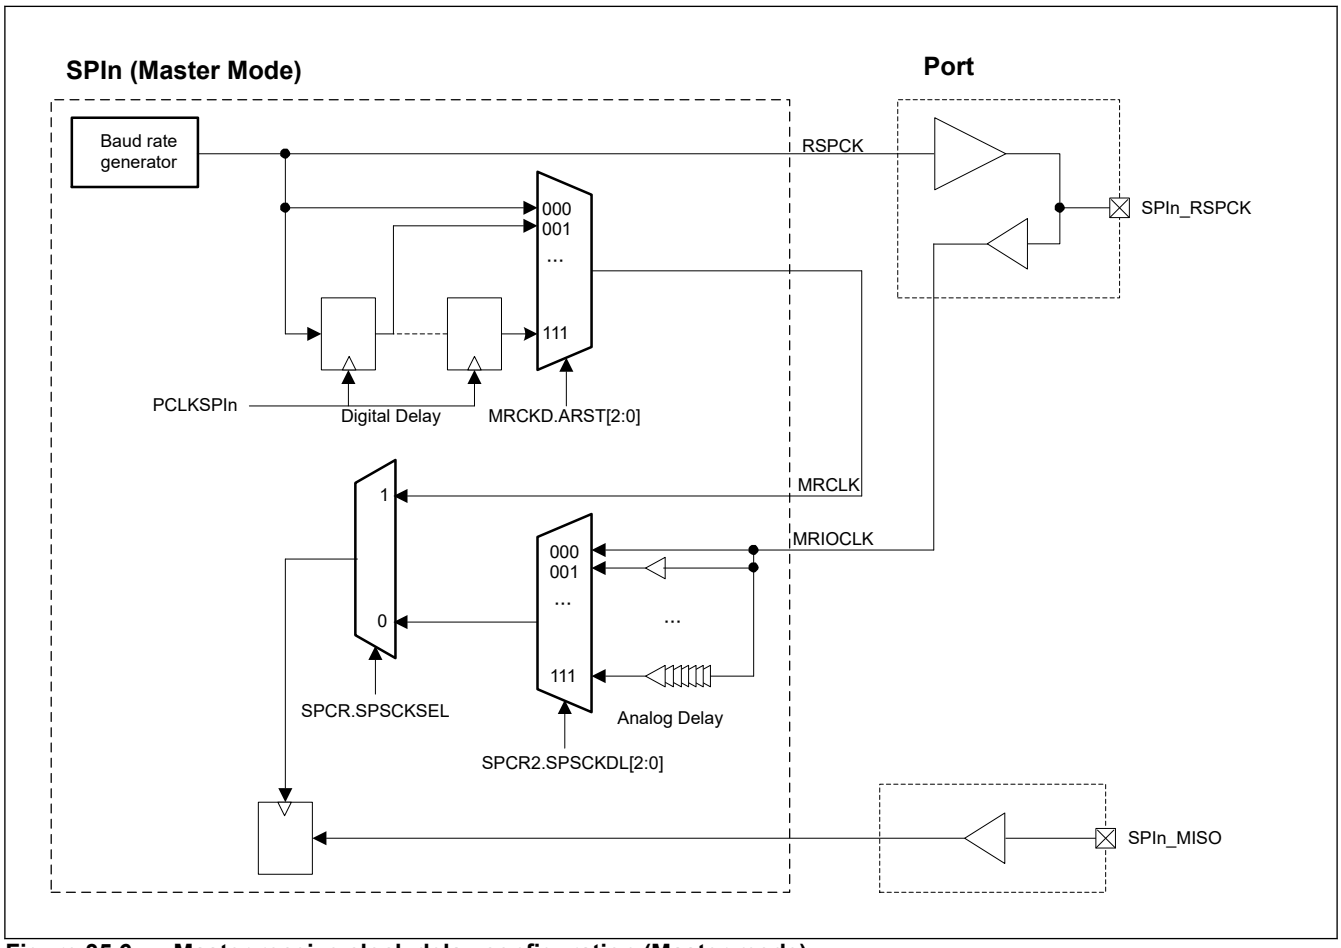

Figure 35.6 Master receive clock delay configuration (Master mode)

SPPE bit (Parity Enable)

The SPPE bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

The SPOE bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit +

transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPCR.SPPE is set to 1.

PTE bit (Parity Self-Diagnosis Enable)

The PTE bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see section 35.3.10.1. Overrun Error.

BFDS bit (Between Burst Transfer Frames Delay Select)

The BFDS bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDm.SSLKP bit set to 1.

This bit shold be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below.

For details, see (4)Burst Transfer in section 35.3.13.2. Slave Mode Operation.

(1) Non-burst transmits

(2) Burst transmit with delay between frames

(2-1) From the 1st frame to the last previous frame

(2-2) The last frame

(3) Burst transmit with no delay between frames

(3-1) From the 1st frame to the last previous frame

(3-2) The last frame

Table 35.3 Usage of SSL delay control between transfer frames (master mode)

	SPCMDm SSLKP bit	SPCR BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
(1)	0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay, and next access delay.
(2-1)	1	0	
(2-2)	0	0	
(3-1)	1	1	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
(3-2)	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See section 35.2.14. SPCMDm : SPI Command Register m (m = 0 to 7).)
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

< Setting / operation example > (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1 → Burst transfer / no interframe delay between 0 and 1 (SSL keep active)

SPCMD1.SSLKP = 1 → Burst transfer / no interframe delay between 1 and 2 (SSL keep active)

SPCMD2.SSLKP = 1 → Burst transfer / no interframe delay between 2 and 3 (SSL keep active)

SPCMD3.SSLKP = 1 → Burst transfer / no interframe delay between 3 and 4 (SSL keep active)

SPCMD4.SSLKP = 0 → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1 → Burst transfer / no interframe delay between 5 and 6 (SSL keep active)

SPCMD6.SSLKP = 1 → Burst transfer / no interframe delay between 6 and 7 (SSL keep active)

SPCMD7.SSLKP = 0 → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit is used to enable or disable detection of a mode fault error. (See section 35.3.10. Error Detection.) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See section 35.3.2. SPI Pin Control.)

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1. (See section 35.3.10. Error Detection.)

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0.

SPDRES bit (SPI Receive Data Ready Error Select)

When a receive data ready is detected (SPSR.SPDRF = 1), select whether to use SPRI interrupt request or SPEI interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

The SPTIE bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1 simultaneously when or after the SPTIE bit is set to 1. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1 even though SPI functions are disabled (SPE bit = 0).

CENDIE bit (SPI Communication End Interrupt Enable)

The CENDIE bit controls generation of a communication end interrupt request.

SPMS bit (SPI Function Enable)

The SPMS bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1), the SPCMD.CPHA bit can be set to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

The communication status according to the settings of SPCR.MSTR, SPCR.TXMD[1:0], SPCR.SPFRF, and SPCR.SPMS as follows.

Table 35.4 SPI communication status (1 of 2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master / Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)
1	0	1	—	1	Transmit only Master / Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)

Table 35.4 SPI communication status (2 of 2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master / Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave / Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave / Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave / Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

The SPFRF bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0 to 3) can be set according to the set communication protocol.

When SPMS = 1 (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bits (Communication Mode Select)

The TXMD[1:0] bits are used to select the transmit-receive, transmit-only, and receive-only serial communication.

TXMD[1:0] = 01b

→ Transmit-only is performed without reception.

→ Receive buffer full interrupt request cannot be used.

TXMD[1] = 1b

→ Receive-only is performed without transmission.

→ Transmit buffer empty interrupt request cannot be used.

For details, see section 35.3.6. Communications Operating Mode.

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

When BPEN = 1, bus clock (PCLKM) is used as operation clock (PCLKSPIn) and synchronization circuit is bypassed.

35.2.7 SPCRRM : SPI Control Register for Master Receive only

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RMSTTG	RMEDTG	—	RMFM[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RMFM[4:0]	Frame processing count setting in Master Receive only 0x00: This function is not used.*1 0x01: Automatically stop communication after processing 1 received frame. ⋮ 0x1F: Automatically stop communication after processing 31 received frames.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	RMEDTG	1: Receive End (writable only when in Master Receive) Reading value is always 0.	W
7	RMSTTG	1: Receive Start (writable only when in Master Receive) Reading value is always 0.	W

Note 1. See (9)Software Processing Flow in section 35.3.13.1. Master Mode Operation.

The SPCRRM register controls the start and completion of communication for master mode reception only operation. If the RMFM[4:0] bits are rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

RMFM[4:0] bits (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication operation mode select bits (SPCR.TXMD[1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after "starts frame processing according to the value set in this bit" after reception starts.

RMEDTG bit (1: Receive End (writable only when in Master Receive))

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

RMSTTG bit (1: Receive Start (writable only when in Master Receive))

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

35.2.8 SPDRCR : SPI Control Register for Received Data Ready Detection

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPDRC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SPDRC[7:0]	SPI Receive Data Ready Detect Adjustment 0x00: Disable receive data ready detection function 0x01: Performs reception data ready judgment after 1 PCLKSPIn ⋮ 0xFF: Performs reception data ready judgment after 255 PCLKSPIn	R/W

The SPDRCR register is used to set the SPI receive data ready detection function. If the set value is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

SPDRC[7:0] bits (SPI Receive Data Ready Detect Adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 PCLKSPIn.

The value set in the SPDRC[7:0] bits is used to 1 set the SPDRF flag. For details, see the description of SPDRF in section 35.2.18. SPSR : SPI Status Register.

35.2.9 SPPCR : SPI Pin Control Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x0E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MOIFE	MOIFV	—	SPOM	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPLP	SPI Loopback 0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
1	SPLP2	SPI Loopback 2 0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
2	SPOM	SPI Output Pin Mode 0: CMOS output 1: Open-drain output	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	MOIFV	MOSI Idle Fixed Value 0: The fixed value of MOSI idle = 0. 1: The fixed value of MOSI idle = 1.	R/W
5	MOIFE	MOSI Idle Value Fixing Enable 0: The MOSI output value is the last data of previous transfer. 1: The MOSI output value is the set MOIFV bit value.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

The SPPCR register is used to set pin mode of the SPI. If SPPCR is modified with the SPCR.SPE bit = 1, subsequent operation is not guaranteed.

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when SPCR.MSTR = 0) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when SPCR.MSTR = 0) (loopback mode). If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

SPOM bit (SPI Output Pin Mode)

This bit is used to select CMOS output pin or open drain output pin as SPI's output pins.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when SPCR.MOIFE = 1 in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When SPCR.MOIFE = 0, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When SPCR.MOIFE = 1, the SPI outputs the fixed MOIFV bit value to MOSI.

35.2.10 SPCR2 : SPI Control Register 2

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPSCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPSCKDL[2:0]	SPI Master Receive Clock Analog Delay Valid only in master mode 0 0 0: No delay 0 0 1: 1.1 ns (max) 0 1 0: 2.2 ns (max) 0 1 1: 3.3 ns (max) 1 0 0: 4.4 ns (max) 1 0 1: 5.5 ns (max) 1 1 0: 6.6 ns (max) 1 1 1: 7.7 ns (max)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPCR2 register is used to set the analog delay of the master receive clock. If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

SPSCKDL[2:0] bits (SPI Master Receive Clock Analog Delay)

These bits set the analog delay for MRIOCLK input to SPI in master mode. By setting these bits, the sampling timing of the received data can be adjusted. For details, see the SPSCKSEL bit of section 35.2.6. SPCR : SPI Control Register.

35.2.11 SSLP : SPI Slave Select Polarity Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SSL0P	SSL0 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL0 signal is active low (0). In the TI-SSP case, the SSL0 signal is active high (1). 1: In the Motorola-SPI case, the SSL0 signal is active high (1). In the TI-SSP case, the SSL0 signal is active low (0).	R/W
1	SSL1P	SSL1 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL1 signal is active low (0). In the TI-SSP case, the SSL1 signal is active high (1). 1: In the Motorola-SPI case, the SSL1 signal is active high (1). In the TI-SSP case, the SSL1 signal is active low (0).	R/W

Bit	Symbol	Function	R/W
2	SSL2P	SSL2 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL2 signal is active low (0). In the TI-SSP case, the SSL2 signal is active high (1). 1: In the Motorola-SPI case, the SSL2 signal is active high (1). In the TI-SSP case, the SSL2 signal is active low (0).	R/W
3	SSL3P	SSL3 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL3 signal is active low (0). In the TI-SSP case, the SSL3 signal is active high (1). 1: In the Motorola-SPI case, the SSL3 signal is active high (1). In the TI-SSP case, the SSL3 signal is active low (0).	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

The SSLP register is used to set the polarity of SSL0 to SSL3 signals of the SPI. If any of these SSLP bits is modified with the SPCR.SPE bit = 1, subsequent operation is not guaranteed.

SSLnP bits (SSLn Signal Polarity Setting)

These bits are used to specify the polarity of SSL signals. The set SSLnP bit (n = 3 to 0) values indicate the active polarity of SSLn signals.

SSL0 is different from SSL1, SSL2, and SSL3. In slave or multi-master mode, it functions as an input.

For details, see section 35.3.3.2. Single Master/Single Slave (This LSI = Slave) and section 35.3.3.5. Multi-Master/Multi-Slave (with This LSI Acting as Master) .

35.2.12 SPBR : SPI Bit Rate Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPR[7:0]							
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	SPR[7:0]	The SPBR register is used to set the bit rate in master mode. If SPBR is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.	R/W

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPBR.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR and BRDV[1:0] in the SPCMDm register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where "n" is the set SPBR value (0 to 255) and "N" is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{f(\text{PCLKSPIn})}{2 \times (n+1) \times 2^{N}}$$

Table 35.5 shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 35.5 Corresponding between bit rates and set values (examples) (1 of 2)

SPBR (n)	BRDV[1:0] bits (N)	Division ratio	Bit rate		
			PCLKSPIn = 75 MHz	PCLKSPIn = 96 MHz	PCLKSPIn = 100 MHz
0	0	2	37.50 Mbps	48.0 Mbps	50.0 Mbps
1	0	4	18.75 Mbps	24.0 Mbps	25.0 Mbps
2	0	6	12.50 Mbps	16.0 Mbps	16.7 Mbps

Table 35.5 Corresponding between bit rates and set values (examples) (2 of 2)

SPBR (n)	BRDV[1:0] bits (N)	Division ratio	Bit rate		
			PCLKSPIn = 75 MHz	PCLKSPIn = 96 MHz	PCLKSPIn = 100 MHz
3	0	8	9.38 Mbps	12.0 Mbps	12.5 Mbps
4	0	10	7.50 Mbps	9.6 Mbps	10.0 Mbps
5	0	12	6.25 Mbps	8.0 Mbps	8.33 Mbps
5	1	24	3.13 Mbps	4.0 Mbps	4.17 Mbps
5	2	48	1.56 Mbps	2.0 Mbps	2.08 Mbps
5	3	96	781 kbps	1.0 Mbps	1.04 Mbps
255	3	4096	18.3 kbps	23.4 kbps	24.4 kbps

35.2.13 SPSCR : SPI Sequence Control Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPSLN[2:0]	SPI Sequence Length Specification The order in which the SPCMD0 to SPCMD07 registers are to be referenced is changed in accordance with the sequence length that is set in these bits. The relationship among the setting of these bits, the sequence length, and the SPCMD0 to SPCMD7 register numbers referenced by SPI is as follows. However, the SPI in slave mode always refers to SPCMD0. 0 0 0: Sequence Length = 1 (0→0→⋯) 0 0 1: Sequence Length = 2 (0→1→0→⋯) 0 1 0: Sequence Length = 3 (0→1→2→0→⋯) 0 1 1: Sequence Length = 4 (0→1→2→3→0→⋯) 1 0 0: Sequence Length = 5 (0→1→2→3→4→0→⋯) 1 0 1: Sequence Length = 6 (0→1→2→3→4→5→0→⋯) 1 1 0: Sequence Length = 7 (0→1→2→3→4→5→6→0→⋯) 1 1 1: Sequence Length = 8 (0→1→2→3→4→5→6→7→0→⋯)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPSCR register is used to set the sequence length for the SPI to perform master operation.

Before modifying the SPSLN[2:0] bits in SPSCR while SPCR.MSTR = 1 and SPCR.SPE = 1, confirm that SPSR.IDLNF = 0.

SPSLN[2:0] bits (SPI Sequence Length Specification)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation.

According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes the SPCMDm registers (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see (3)Sequence Control.

The SPI in slave mode always references SPCMD0.

35.2.14 SPCMDm : SPI Command Register m (m = 0 to 7)

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x14 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	SSLA[1:0]		—	—	—	SPB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SCKDEN	SLNDEN	SPNDEN	LSBF	—	—	—	—	SSLKP	—	—	—	BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPHA	RSPCK Phase This register is valid only for Motorola-SPI cases. (In the TI-SSP case, it is fixed at 1). 0: Data is sampled at an odd edge and changes at an even edge. 1: Data changes at an odd edge and is sampled at an even edge.	R/W
1	CPOL	RSPCK Polarity 0: RSPCK in idle state is 0. 1: RSPCK in idle state is 1.	R/W
3:2	BRDV[1:0]	Bit Rate Division 0 0: The base bit rate is selected. 0 1: Two-divided base bit rate is selected. 1 0: Four-divided base bit rate is selected. 1 1: Eight-divided base bit rate is selected.	R/W
6:4	—	These bits are read as 0. The write value should be 0.	R/W
7	SSLKP	SSL Signal Level Hold 0: All SSL signals are negated at the end of transfer. 1: SSL signal level is held after the transfer ends until the next access starts.	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	LSBF	SPI LSB First 0: MSB first 1: LSB first	R/W
13	SPNDEN	SPI Next-Access Delay Enable 0: Next-access delay is 1 RSPCK + 5 PCLKSPIn 1: Next-access delay is the set value of the SPI next-access delay register (SPND).	R/W
14	SLNDEN	SSL Negation Delay Setting Enable 0: [Master] SSL negation delay is 1 RSPCK. [Slave in the TI-SSP] SSL negation delay is 1 PCLKSPIn + 2~3 PCLKSPIn (Synchronization delay) 1: SSL negation delay is the set value of the slave select negation delay register (SSLND).	R/W
15	SCKDEN	RSPCK Delay Setting Enable 0: RSPCK delay is 1 RSPCK. [In the Motorola-SPI case] RSPCK delay is 0 RSPCK. [In the TI-SSP case] 1: RSPCK delay is the set value of the RSPCK delay register (SPCKD).	R/W

Bit	Symbol	Function	R/W
20:16	SPB[4:0]	SPI Data Length 0x00: Setting prohibited 0x01: Setting prohibited 0x02: Setting prohibited 0x03: 4 bits 0x04: 5 bits 0x05: 6 bits ⋮ 0x1E: 31 bits 0x1F: 32 bits	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
25:24	SSLA[1:0]	SSL Signal Assertion 0 0: SSL0 0 1: SSL1 1 0: SSL2 1 1: SSL3	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode.

The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of SPSCR.SPSLN[2:0], and then performs serial transfer specified in the referenced SPCMD.

SPCMD should be set while the transmit buffer is empty (next-transfer data is not set) and data which refers to SPCMD has not been written.

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPSSR register. If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0 and SPCR.SPFRF = 1 (in TI SSP mode), setting CPHA = 0 is invalid.

This register is valid only for Motorola-SPI cases.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bits (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPBR register. The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1 enables burst transfer in SPI operation master mode. For details, see (4)Burst Transfer in section 35.3.13.1. Master Mode Operation.

To use the SPI in slave mode, set SSLKP bit to 0.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period from SSL negation to SSL assertion in SPI master mode. When SPNDEN = 0, the SPI sets the next-access delay to 1 RSPCK + 5 PCLKSPIn. When SPNDEN = 1, the SPI inserts the next-access delay in accordance with the SPND register setting.

To use the SPI in slave mode, set SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period from RSPCK oscillation stop to SSL negation in SPI master mode. When SLNDEN = 0, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.

To use the SPI in slave mode, set SLNDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from RSPCK oscillation stop to output disable in SPI master mode, or last edge of RSPCK to output disable in slave mode. When the SLNDEN bit is 0, the SSL negate delay is 1 RSPCK in master mode and 1 PCLKSPIn + 2~3 PCLKSPIn (Synchronization delay) in slave mode. When SLNDEN = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.

When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN = 0, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN = 0, the SPI does not sets the RSPCK delay. When SCKDEN = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

SPB[4:0] bits (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[1:0] bits (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[1:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SSLP register. When SSLA[1:0] bits are set to 00b in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the SPI in slave mode, set SSLA[1:0] bits to 00b.

35.2.15 SPDCR : SPI Data Control Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPFC[1:0]		—	—	—	SINV	SPRDTD	SLSEL[1:0]		BYSW
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte swap is disabled 1: Byte swap is enabled	R/W
2:1	SLSEL[1:0]	SSL Pin Output Select See Table 35.6.	R/W
3	SPRDTD	SPI Receive Data or Transmit Data Selection 0: The SPDR reads the receive buffer 1: The SPDR reads the transmit buffer	R/W
4	SINV	Serial data invert 0: Not invert serial data 1: Invert serial data	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	SPFC[1:0]	Frame Count Number of Frames Specification 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

The SPDCR register controls the data format.

If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32 bits or 16 bits. Other case of data length (for example, 4 to 15, 17 to 31 bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see section 35.3.4. Data Format and section 35.3.4.5. Byte swap reception.

When the parity function set to valid, the behavior is not guaranteed.

SLSEL[1:0] bits (SSL Pin Output Select)

The SLSEL[1:0] bits are used to select SSL output or I/O as an SSL pin function in master mode.

Table 35.6 SSL pin output selection

SSLn pin	SLSEL[1:0] = 00b	SLSEL[1:0] = 01b	SLSEL[1:0] = 10b	SLSEL[1:0] = 11b
SSL0	Output/Input	Output/Input	Output/Input	Setting prohibited
SSL1	Output	I/O	Output	
SSL2, SSL3	Output	I/O	I/O	

Note: Input or output of SSL0 is determined by the SPCR.MODFEN bit. For details, see Table 35.7.

SPRDTD bit (SPI Receive Data or Transmit Data Selection)

The SPRDTD bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value written to SPDR the last time is read.

SINV bit (Serial data invert)

The SINV bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] bits (Frame Count)

The SPFC[1:0] bits are used for the condition to set the CENDF flag in slave receive only mode. For details on the CENDF flag setting conditions, see section 35.2.18. SPSR : SPI Status Register.

The SPFC[1:0] bits are invalid except in the slave receive only mode.

35.2.16 SPDCR2 : SPI Data Control Register 2

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x44

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TTRG[1:0]		—	—	—	—	—	—	RTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTRG[1:0]	Receive FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0 0: Threshold 0 0 1: Threshold 1 1 0: Threshold 2 1 1: Threshold 3	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
9:8	TTRG[1:0]	Transmission FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0 0: Threshold 0 0 1: Threshold 1 1 0: Threshold 2 1 1: Threshold 3	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

The SPDCR2 register controls the FIFO threshold. If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

RTRG[1:0] bits (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] bits (Transmission FIFO threshold setting)

Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[1:0], the transmit buffer empty flag is set.

35.2.17 SPSSR : SPI Sequence Status Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x51

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPCP[2:0]	SPI Command Pointer 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
3	—	This bit is read as 0.	R
6:4	SPECM[2:0]	SPI Error Command 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
7	—	This bit is read as 0.	R

The SPSSR register indicates the sequence control status when the SPI performs master operation. Write access to SPSSR is ignored.

SPCP[2:0] bits (SPI Command Pointer)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see section 35.3.13.1. Master Mode Operation.

SPECM[2:0] bits (SPI Error Command)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (SPSR.OVRF = 0, SPSR.MODF = 0, SPSR.PERF = 0), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see section 35.3.10. Error Detection. For the SPI's sequence control, see section 35.3.13.1. Master Mode Operation.

35.2.18 SPSR : SPI Status Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x52

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	SPDRF	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0.	R
7	SPDRF	SPI Receive Data Ready Flag 0: Receive data ready not detected 1: Receive data ready detected	R
8	OVRF	Overrun Error Flag 0: No overrun error is present. 1: An overrun error is present.	R

Bit	Symbol	Function	R/W
9	IDLNF	SPI Idle Flag 0: The SPI is in the idle state. 1: The SPI is in the transfer state.	R
10	MODF	Mode Fault Error Flag 0: Neither mode fault error nor underrun error is present. 1: A mode fault error or underrun error is present.	R
11	PERF	Parity Error Flag 0: No parity error is present. 1: A parity error is present.	R
12	UDRF	Underrun Error Flag This bit indicates error status in combination with the MODF flag. The UDRF bit is valid when MODF flag is 1. 0: Mode fault error occurred (MODF = 1) 1: Underrun error occurred (MODF = 1)	R
13	SPTEF	SPI Transmit Buffer Empty Flag 0: The number of empty stages in the transmit FIFO ≤ the value set in SPDCR2.TTRG 1: The number of empty stages in the transmit FIFO > the value set in SPDCR2.TTRG	R
14	CENDF	Communication End Flag 0: The SPI is not communicating or communicating. 1: The SPI communication completed.	R
15	SPRF	SPI Receive Buffer Full Flag 0: The number of data stored in the receive FIFO ≤ number of frames set by the SPDCR2.RTRG bit. 1: The number of data stored in the receive FIFO > number of frames set by the SPDCR2.RTRG bit.	R

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0 when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting (to 1) condition]

All the following two conditions are met:

- SPDRCR.SPDRC[7:0] ≠ 0x00
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.SPDRFC bit

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE bit = 1) in master mode (SPCR.MSTR bit = 1), no overrun error occurs and, therefore, this flag is not set to 1. For details, see section 35.3.10.1. Overrun Error.

[Setting (to 1) condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- The SPCR.TXMD[1:0] bits = 00b. (transmit-receive mode)
- The SPCR.TXMD[1:0] bits = 10b. (receive only)

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.OVRFC bit

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting (to 1) condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the [Transmit-Receive, Transmit-only Master mode] in [Clearing (to 0) conditions]

[Receive-only Master mode]

- When 1 is written to SPCRRM.RMSTTG bit

[Slave mode]

- SPCR.SPE = 1 (SPI function enabled)

[Clearing (to 0) conditions]

Communication status: 1-(1) to (6) * For details of communication status, see Table 35.4.

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met:

- SPCR.SPE = 0 (SPI initialization)
- All the following three conditions are met:
  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
  - SPSSR.SPCP[2:0] = 000b (at the beginning of sequence control)
  - The operation completed until the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met:

- SPCR.SPE = 0 (SPI initialization)
- Any of the following three conditions is met:
  - When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
  - When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
  - When RMFM[4:0] ≠ 0x00, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0 - (1) to (9)

- SPCR.SPE = 0 (SPI initialization)

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting (to 1) condition]

[Multi-master mode]

- The SSL0 pin input level becomes active level while the SPCR.MSTR bit = 1 (master mode) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.

[Slave, Motorola-SPI mode]

Any of the following two conditions is met:

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 0 (Motorola-SPI) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met:

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 1 (TI-SSP) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

The SSL signal active level depends on the SSLP.SSLiP bits (SSL signal polarity bits).

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.MODFC bit

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting (to 1) condition]

When the serial transfer ends and a parity error is detected with the SPCR.SPPE bit set to 1 under any of the following two conditions:

- The SPCR.TXMD[1:0] bits = 00b (transmit-receive)
- The SPCR.TXMD[1:0] bits = 10b (receive-only)

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.PERFC bit

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting (to 1) condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0 (slave mode) and the SPCR.TXMD[1:0] bits = 00b or 01b (transmit-receive or transmit-only) and the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.UDRFC bit

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting (to 1) condition]

Any of the following three conditions is met:

- The SPCR.SPE bit is set to 0 (SPI initialization)
- When the number of empty transmission FIFO stages > SPDCR2.TTRG[1:0]
- When 1 is written to SPFCR.SPFRST

[Clearing (to 0) condition]

Any of the following two conditions is met:

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 2) in one processing routine using DMAC
- When 1 is written to the SPSRC.SPTEFC bit

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1. If a value is written to the SPDR register while the SPTEF flag = 0, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting (to 1) condition]

Transmit-Receive / Transmit-only Master mode

Communication status: 1 - (1) to (6). For details of communication status, see Table 35.4.

The following three conditions are met:

- The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSSR.SPCP[2:0] are 000b (it means the head of the sequential control)
- Operation completed until the next access delay (the master main state machine has transitioned to the idle state)

Receive-only Master mode

Communication status: 1 - (7) to (9)

Any of the following three conditions is met:

- When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

Transmit-receive / transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (1), (4)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- SSL0 was negated

Transmit-receive / transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (2), (5)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- When the SSL negate delay is completed

Transmit-receive / transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)

Communication status: 0 - (3), (6)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- The last even edge of RSPCK of the frame was detected (when the SPCMD.CPHA bit is 1)

Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (7)

The following condition is met:

- SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer

Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (8)

The following condition is met:

- SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer

Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1).

Communication status: 0 - (9)

The following condition is met:

- The last even edge of RSPCK of the last frame received for SPFC set value was detected (when the SPCMD.CPHA bit is 1)

[Clearing (to 0) condition]

Transmit-Receive / Transmit-only Master mode

Communication status: 1 - (1) to (6)

Any of the following two conditions is met:

- The next transmit data was written to the transmit buffer (SPTX)
- When 1 is written to the SPSRC.CENDFC bit

Receive-only Master mode

Communication status: 1 - (7) to (9)

Any of the following two conditions is met:

- When 1 is written to the SPCRRM.RMSTTG bit with SPCR.SPE = 1
- When 1 is written to the SPSRC.CENDFC bit

Transmit-receive / transmit only slave mode

Communication status: 0 - (1) to (6)

Satisfy one of following conditions:

- The next transmit data is written to the transmit buffer (SPTX)
- When 1 is written to the SPSRC.CENDFC bit

Receive-only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (7) to (8)

Satisfy one of following conditions:

- SSL0 assertion of next data is detected
- When 1 is written to the SPSRC.CENDFC bit

Receive-only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1).

Communication status: 0 - (9)

Satisfy one of following conditions:

- The first edge of RSPCK of the next data is detected
- When 1 is written to the SPSRC.CENDFC bit

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPDR register.

[Setting (to 1) condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[1:0] bits in Transmit-Receive, Receive-only modes. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1. (See section 35.3.10. Error Detection.)

[Clearing (to 0) condition]

Any of the following three conditions is met:

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 2) in one processing routine using DMAC
- When 1 is written to the SPSRC.SPRFC bit
- When 1 is written to the SPFCR.SPFRST bit

35.2.19 SPTFSR : SPI Transfer FIFO Status Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x58

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TFDN[2:0]		
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
2:0	TFDN[2:0]	Transmit FIFO data empty stage number 0 0 0: Number of empty stages 0 0 0 1: Number of empty stages 1 0 1 0: Number of empty stages 2 0 1 1: Number of empty stages 3 1 0 0: Number of empty stages 4	R
7:3	—	These bits are read as 0.	R

Note: TFDN[2:0] is initialized by SPCR.SPE = 0.

35.2.20 SPRFSR : SPI Receive FIFO Status Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x5C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RFDN[2:0]	Receive FIFO data store stage number 0 0 0: Number of store stages 0 0 0 1: Number of store stages 1 0 1 0: Number of store stages 2 0 1 1: Number of store stages 3 1 0 0: Number of store stages 4	R
7:3	—	These bits are read as 0.	R

Note: RFDN[2:0] is initialized by SPCR.SPE = 0.

35.2.21 SPPSR : SPI Poling Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPEPS	SPI Polling Status 0: SPCR.SPE is 0 1: SPCR SPE is 1	R
31:1	—	These bits are read as 0.	R

Note: This bit shows a result of SPCR.SPE after synchronization by the operation clock (PCLKSPIn).

35.2.22 SPSRC : SPI Status Clear Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x6A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPRFC	CENDFC	SPTEFC	UDRFC	PERFC	MODFC	—	OVRFC	SPDRFC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0.	R
7	SPDRFC	SPI Receive Data Ready Flag Clear The SPI receive data ready flag can be cleared by writing 1. When read, 0 is read.	W
8	OVRFC	Overrun Error Flag Clear By writing 1, the Overrun Error Flag can be cleared. Reading value is always 0.	W
9	—	This bit is read as 0.	R
10	MODFC	Mode Fault Error Flag Clear By writing 1, the Mode Fault Error Flag can be cleared. Reading value is always 0. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1.	W
11	PERFC	Parity Error Flag Clear By writing 1, the Parity Error Flag can be cleared. Reading value is always 0.	W
12	UDRFC	Underrun Error Flag Clear By writing 1, the Underrun Error Flag can be cleared. Reading value is always 0. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).	W
13	SPTEFC	SPI Transmit Buffer Empty Flag Clear By writing 1, the SPI Transmit Buffer Empty Flag can be cleared. Reading value is always 0.	W
14	CENDFC	Communication End Flag Clear By writing 1, the Communication End Flag can be cleared. Reading value is always 0.	W
15	SPRFC	SPI Receive Buffer Full Flag Clear By writing 1, the SPI Receive Buffer Full Flag can be cleared. Reading value is always 0.	W

The SPSRC register clears the status flag (SPSR) that indicates the operating status of SPI.

35.2.23 SPFCR : SPI FIFO Clear Register

Base address: SPIn = 0x8000_3000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_2000

Offset address: 0x6C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SPFRST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPFRST	SPI FIFO clear By writing 1, the pointer in the FIFO and the stored data are initialized. Reading value is always 0.	W
7:1	—	The write value should be 0.	W

The SPFCR register is used to clear the FIFO.

If SPFCR is rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

35.3 Operation

In this section, a word "serial transfer period" is used as a word that means a period from the start of valid data drive to latching of the final valid data.

35.3.1 Overview of SPI Operations

The SPI can transfer data in the following five modes.

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

SPI modes can be set by the MSTR, MODFEN, SPMS and SPFRF bits in the SPCR register.

Table 35.7 lists the relationship between SPI modes and SPCR settings, and outline of each mode.

Table 35.7 Relationship between SPI modes and SPCR settings and description of each mode (1 of 2)

Mode	Slave (SPI operation)	Single-Master (SPI operation)	Multi-Master (SPI operation)	Slave (Clock synchronous operation)	Master (Clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
SPFRF bit setting	valid	valid	valid	In-valid	In-valid
RSPCK signal	Input	Output	Output/Hi-Z	Input	Output
MOSI signal	Input	Output	Output/Hi-Z	Input	Output
MISO signal	Output/Hi-Z	Input	Input	Output	Input
SSL0 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)

Table 35.7 Relationship between SPI modes and SPCR settings and description of each mode (2 of 2)

Mode	Slave (SPI operation)	Single-Master (SPI operation)	Multi-Master (SPI operation)	Slave (Clock synchronous operation)	Master (Clock synchronous operation)
SSL1 to SSL3 signals	Hi-Z (not used)	Output	Output/Hi-Z	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain
SSL polarity modification function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	2 types				
Clock phase	2 types*5	2 types*5	2 types*5	One (CPHA = 1)	2 types
First transfer bit	MSB/LSB				
Transfer data length	4 to 32 bits				
Burst transfer	Enabled (CPHA = 1)	Enabled (CPHA = 0, 1)	Enabled (CPHA = 0, 1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*6	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1	RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmission buffer empty detection	Supported*4	Supported	Supported	Supported*4	Supported
Reception buffer full detection	Supported*1				
Overrun error detection	Supported*1	Supported*1 *3	Supported*1 *3	Supported*1	Supported*1 *3
Parity error detection	Supported*1 *2				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*4	Not supported	Not supported	Supported*4	Not supported

Note 1. When SPI is transmit-master mode or transmit-slave mode (see Table 35.4), none of receive buffer full error, overrun error, and parity error is detected.
Note 2. When the SPCR.SPPE bit is 0, parity error is not detected.
Note 3. When the SPCR.SCKASE bit is 1, overrun error is not detected.
Note 4. When SPI is receive only slave mode (see Table 35.4), none of transmit buffer empty and underrun error is detected.
Note 5. CPHA = 0 is invalid in TI SSP mode. (Even if it is set, the operation is the same as when CPHA = 1.)
Note 6. Available only in TI SSP mode.

35.3.2 SPI Pin Control

The SPI automatically switches pin directions and output modes according to the settings of the SPCR.MSTR, SPCR.MODFEN and SPCR.SPMS bits and the SPPCR.SPOM bit.

When the SPPCR.SPOM bit is set to 0, each output becomes CMOS output, when the SPOM bit is set to 1, each output becomes open drain output.

Table 35.8 shows the relationship between pin state and set values of each bit.

For details of OE function, see section 35.3.5. Transfer Format (Frame Format).

Table 35.8 Relationship between pin states and set control bit values

Mode	Pin	Pin State*1	
		SPOM = 0	SPOM = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3	CMOS output	Open-drain output
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCK*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSL0	Input	Input
	SSL1 to SSL3*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSI*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISO	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCK	Input	Input
	SSL0	Input	Input
	SSL1 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Slave mode (Clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCK	Input	Input
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO	CMOS output	Open-drain output

Note 1. The set SPI value is not applied to multi-function pins for which the SPI function is not selected.
Note 2. When SSL0 is at the active level, the pin state is Hi-Z. Motorola-SPI: When SSL0 is active level, the pin state becomes Hi-Z. TI-SSP: The terminal status becomes Hi-Z until SSL0 is asserted after SPCR.SPE = 1 and communication completed.
Note 3. Motorola-SPI: When SSL0 is inactive level or when SPCR.SPE = 0, the pin state becomes Hi-Z. TI-SSP: When SSL0 is except the communication period or when SPCR.SPE = 0 (assertion after SPE = 1 and communication completed), the pin status changes to Hi-Z.
Note 4. These pins are available for use as I/O port pins.

The SPI in single master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal value in the SSL negation period (including the SSL hold period in burst transfer) according to the settings of the SPPCR.MOIFE and SPPCR.MOIFV bits, as listed in Table 35.9.

Table 35.9 Determining the MOSI signal value in the SSL negation period

MOIFE bit	MOIFV bit	MOSI signal value during SSL negation period
0	0, 1	Final data from previous transfer
1	0	Always low
1	1	Always high

35.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL signals is active level. When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TISSP.

35.3.3.1 Single Master/Single Slave (This LSI = Master)

Figure 35.7 shows an example of single master/single slave SPI system configuration where this LSI is used as a master. In the single master/single slave configuration, the SSL0 to SSL3 output signals of this LSI (master) are not used.

SSL input signals of the SPI slave are fixed to 0 level to always select the SPI slave. When SPCMD.CPHA = 0, some slave devices cannot fix SSL signals to active level in the relevant transfer format. If the SSL signal level cannot be fixed, connect the SSL output of this LSI to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

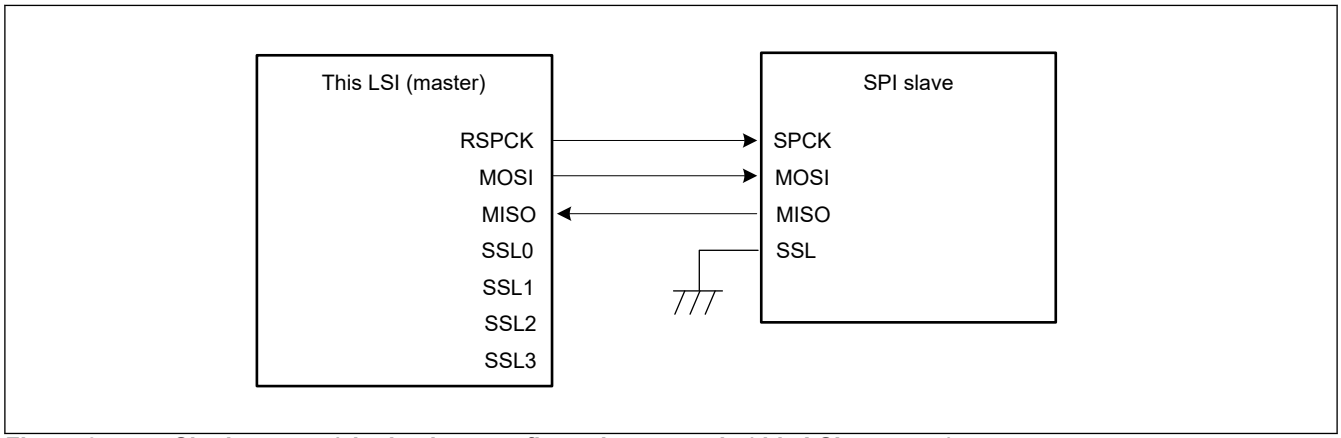

Figure 35.7 Single-master/single-slave configuration example (this LSI = master)

35.3.3.2 Single Master/Single Slave (This LSI = Slave)

Figure 35.8 shows an example of single master/single slave SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave, the SSL0 pin is used as SSL input. The SPI master always drives the RSPCK and MOSI pins. This LSI (slave) always drives the MISO pin. When the SSL0 level is inactive, the pin state becomes Hi-Z.

In the single slave configuration with the SPCMD.CPHA bit set to 1, set the SPCR.SPFRF bit to 0, and set the SPMS bit to 0. There is the SSL0 input level of this LSI (slave) is fixed to 0 so that this LSI (slave) can be always selected and serial transfer can also be performed (Figure 35.9). However, the communication end interrupt does not output when SSL0 input was fixed as Figure 35.9.

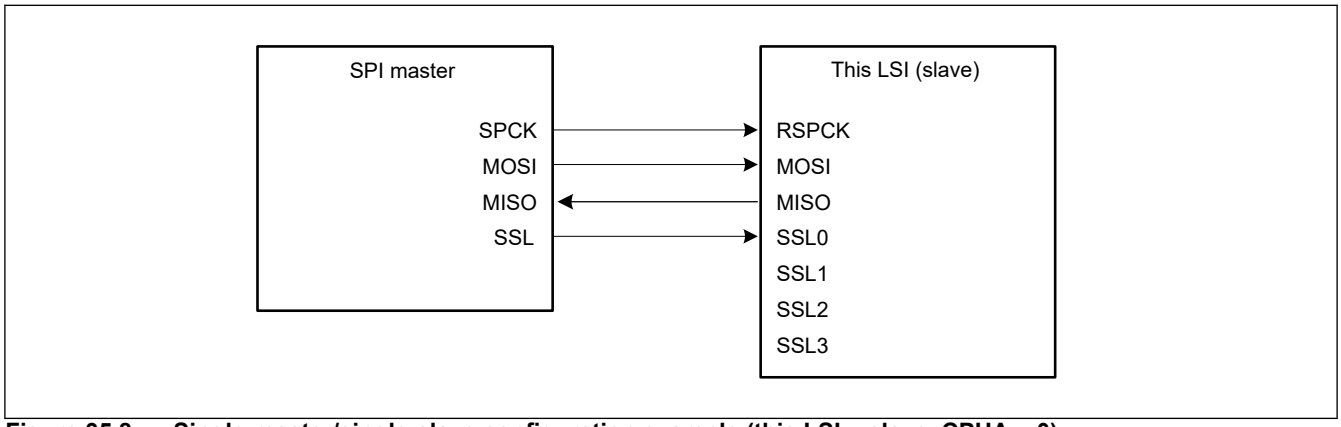

Figure 35.8 Single-master/single-slave configuration example (this LSI = slave, CPHA = 0)

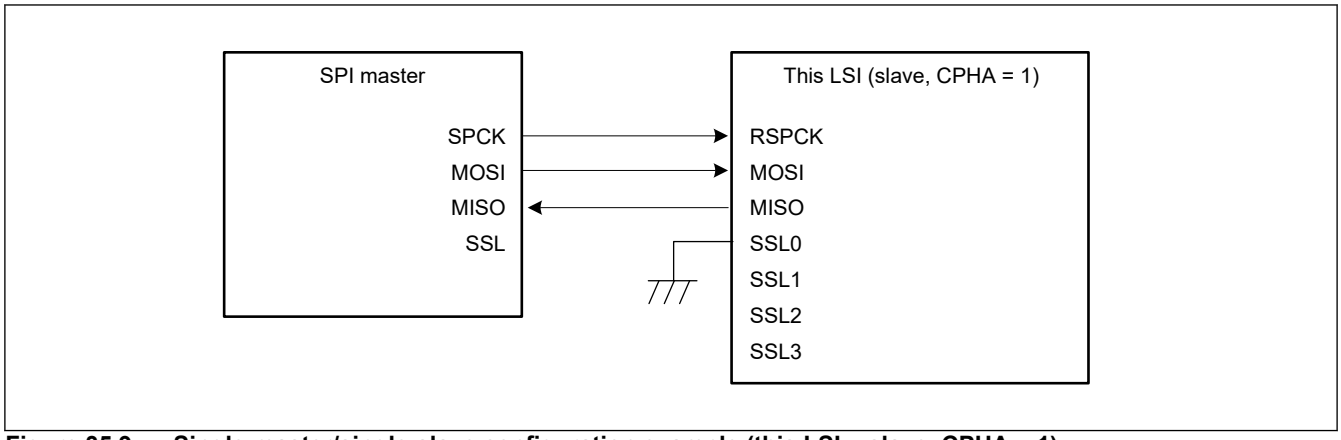

Figure 35.9 Single-master/single-slave configuration example (this LSI = slave, CPHA = 1)

35.3.3.3 Single Master/Multi-Slave (This LSI = Master)

Figure 35.10 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a master. In the example in Figure 35.10, the SPI system is comprised of this LSI (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK output and MOSI output pins of the master are connected to the RSPCK input and MOSI input pins of SPI slave 0 to SPI slave 3. All of the MISO output pins of SPI slave 0 to SPI slave 3 are connected to the MISO input pin of the master. The SSL0 to SSL3 output pins of this LSI (master) are connected to the SSL input pin of SPI slave 0 to SPI slave 3.

The master always drives RSPCK, MOSI, and SSL0 to SSL3 pins. The slave (out of SPI slave 0 to SPI slave 3) where 0 level is input to SSL input pin drives the MISO pin.

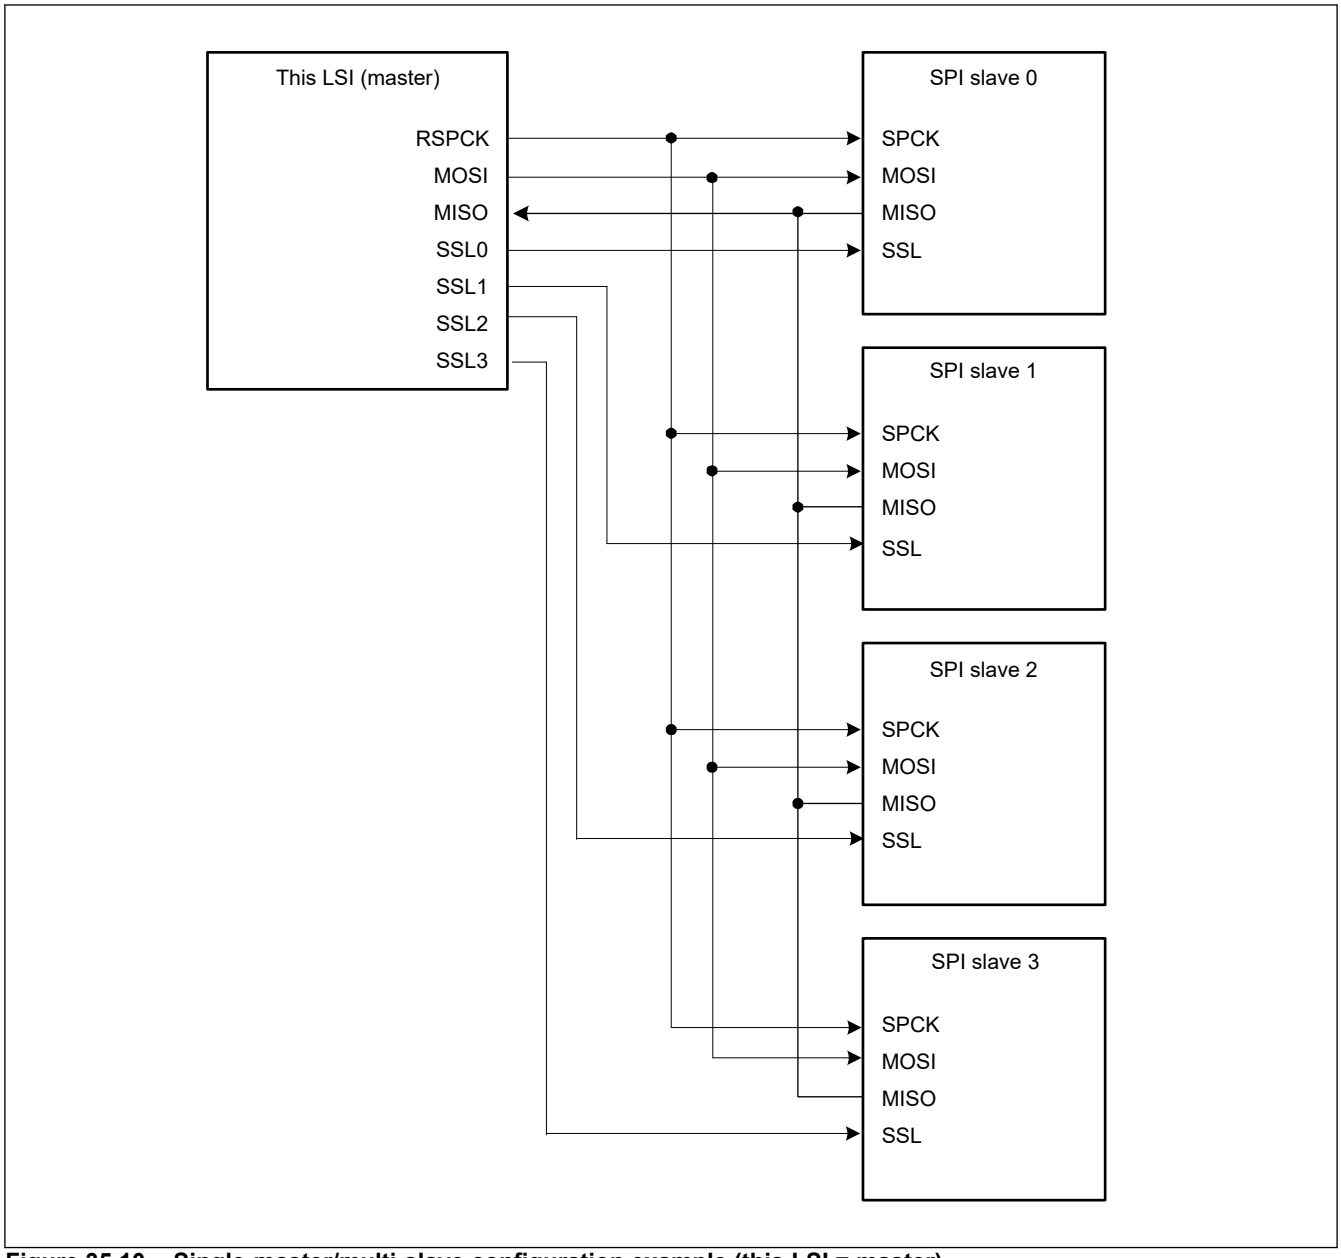

Figure 35.10 Single-master/multi-slave configuration example (this LSI = master)

35.3.3.4 Single Master/Multi-Slave (with This LSI Acting as Slave)

Figure 35.11 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a slave. In the example in Figure 35.11, the SPI system consists of the SPI master and two these LSIs (slave X, slave Y).

The RSPCK output and MOSI output pins of the SPI master are connected to the RSPCK input and MOSI input pins of the LSIs (slave X, slave Y). The MISO output pin of the LSIs (slave X, slave Y) is connected to the MISO input pin of the SPI master. The SSLX output and SSLY output pins of the SPI master are connected to the SSL0 input pin of the LSIs (slave X, slave Y).

The SPI master always drives the RSPCK, MOSI, SSLX, and SSLY pins. The slave X or slave Y (this LSI) where 0 level is input to the SSL0 input pin drives the MISO pin.

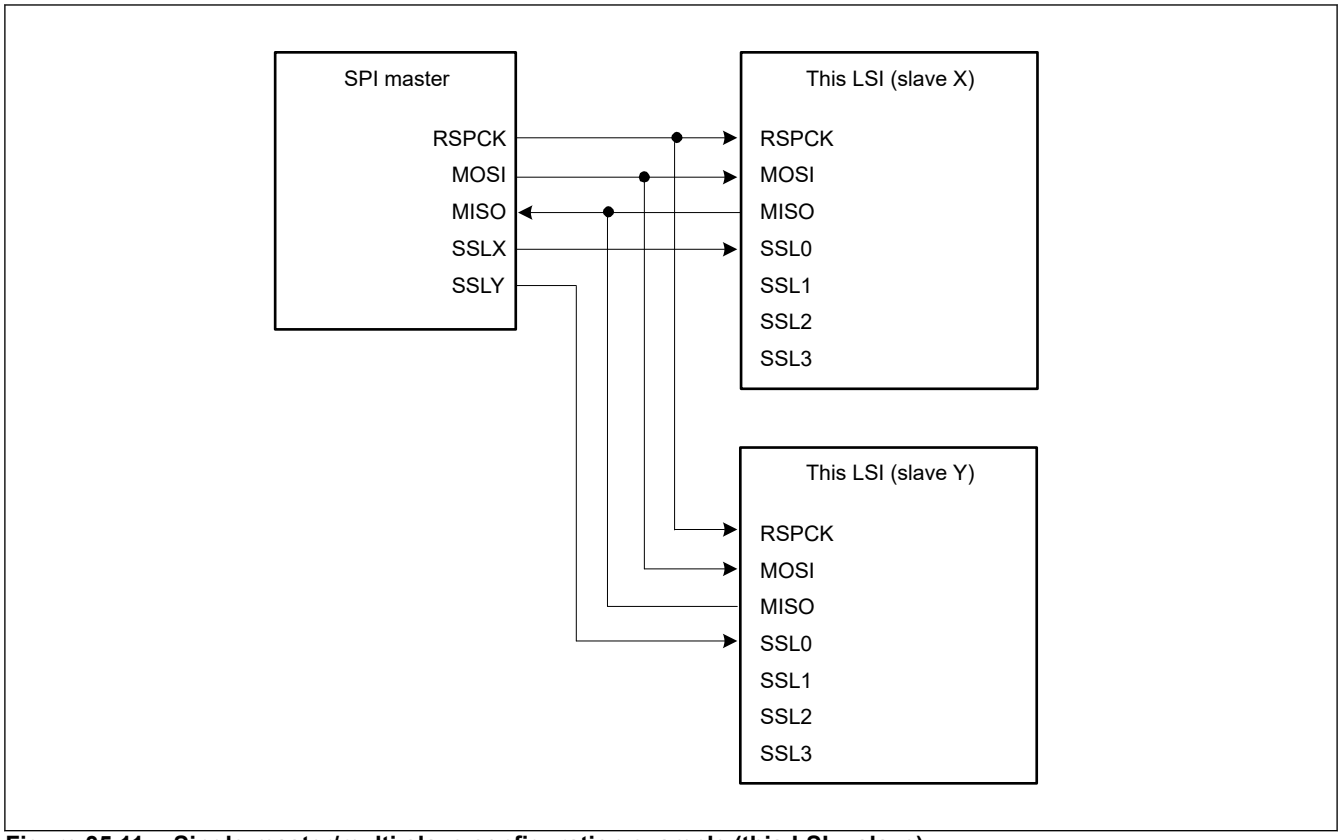

Figure 35.11 Single-master/multi-slave configuration example (this LSI = slave)

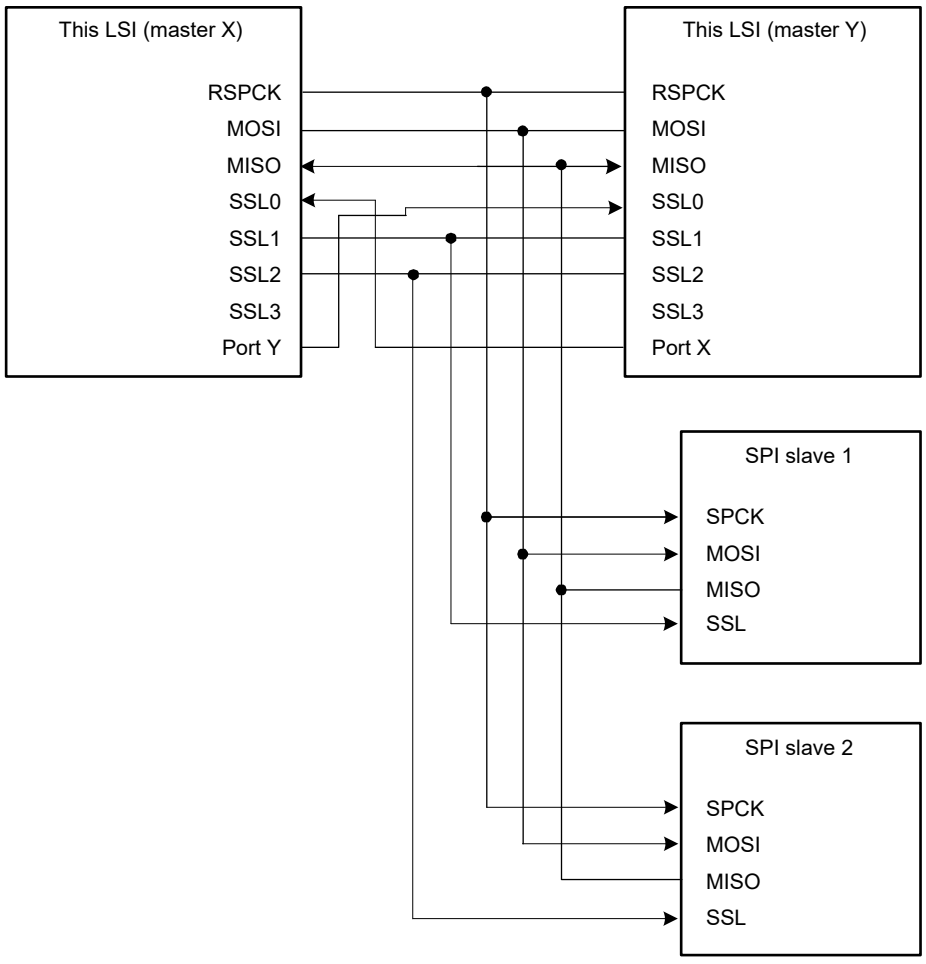
35.3.3.5 Multi-Master/Multi-Slave (with This LSI Acting as Master)

Figure 35.12 shows an example of multi-master/multi-slave SPI system configuration where this LSI is used as a master. In the example in Figure 35.12, the SPI system consists of two these LSIs (master X, master Y) and two SPI slaves (SPI slave 1, SPI slave 2).

The RSPCK output and MOSI output pins of these LSIs (master X, master Y) are connected to the RSPCK input and MOSI input pins of SPI slave 1 and SPI slave 2. The MISO output pin of SPI slave 1 and SPI slave 2 is connected to the MISO input pin of these LSIs (master X, master Y). The Port Y (general port) output pin of this LSI (master X) is connected to the SSL0 input pin of this LSI (master Y). The Port X (general port) output pin of this LSI (master Y) is connected to the SSL0 input pin of this LSI (master X). The SSL1 output and SSL2 output pins of these LSIs (master X, master Y) are connected to the SSL input pin of SPI slave 1 and SPI slave 2. In this configuration example, SSL3 output pins of this LSI are not used because the system can be configured only with SSL0 input pin and SSL1 output and SSL2 output pins for connecting slaves.

While the SSL0 input level is 1, this LSI drives the RSPCK, MOSI, SSL1, and SSL2 pins. While the SSL0 input level is 0, this LSI detects a mode fault error and changes the RSPCK, MOSI, SSL1, SSL2 pin levels to Hi-Z to release the SPI bus mastership for another master. SPI slave 1 or SPI slave 2 where 0 level is input to the SSL input pin drives the MISO pin.



Note: When setting TI SSP, enter the following levels for port X and port Y.
- Start of communication: the value of SSLP.SSL0P of the other master.
- End of communication: the inverted value of SSLP.SSL0P of the other master.

Figure 35.12 Multi-master/multi-slave configuration example (this LSI = master)

35.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (This LSI = Master)

Figure 35.13 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a master. In this configuration, the SSL0 to SSL3 output pins of this LSI (master) are not used.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

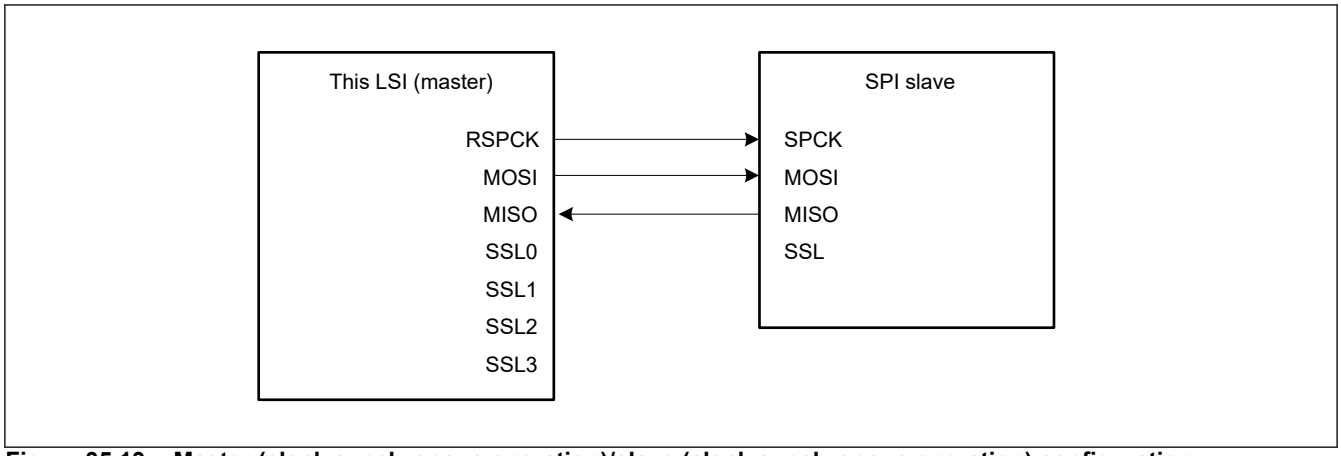


Figure 35.13 Master (clock synchronous operation)/slave (clock synchronous operation) configuration example (this LSI = master)

35.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (This LSI = Slave)

Figure 35.14 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave (clock synchronous operation), this LSI (slave) always drives the MISO pin and the SPI master always drives the RSPCK and MOSI pins.

Only in the single slave configuration with the SPCMD.CPHA bit set to 1, this LSI (slave) can perform serial transfer.

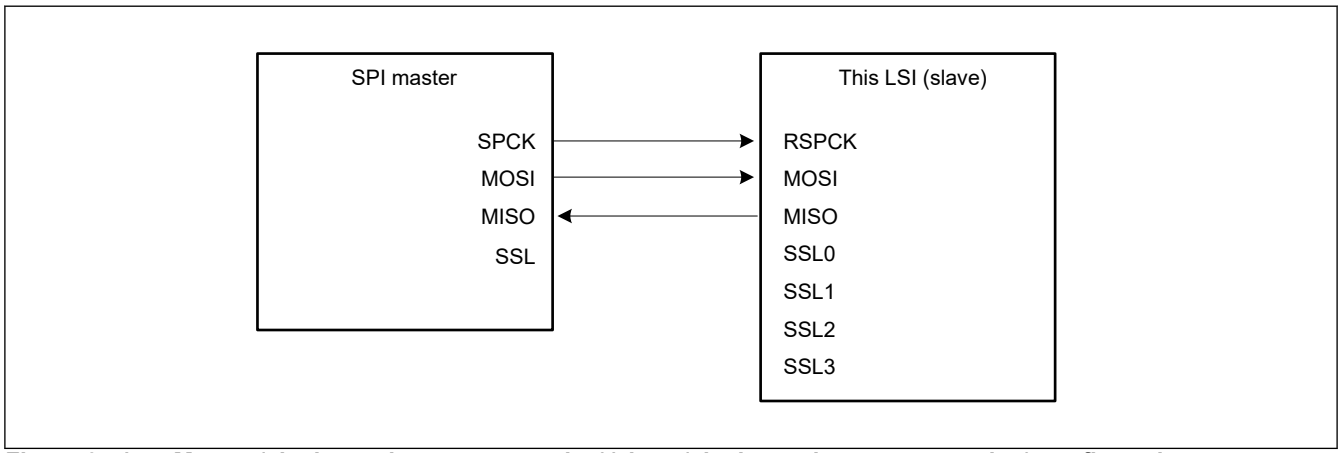

Figure 35.14 Master (clock synchronous operation)/slave (clock synchronous operation) configuration example (this LSI = slave, CPHA = 1)

35.3.4 Data Format

Data format of the SPI depends on the set values of the SPCMD register and the SPCR.SPPE bit. The SPI handles data of the set data length from the LSB in the SPDR register as transfer data regardless of MSB first or LSB first.

35.3.4.1 Data Format of One Frame

The data format of one frame for transmission and reception is shown below.

(1) With Parity Disabled (SPPE=0)

When the parity function is disabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received.

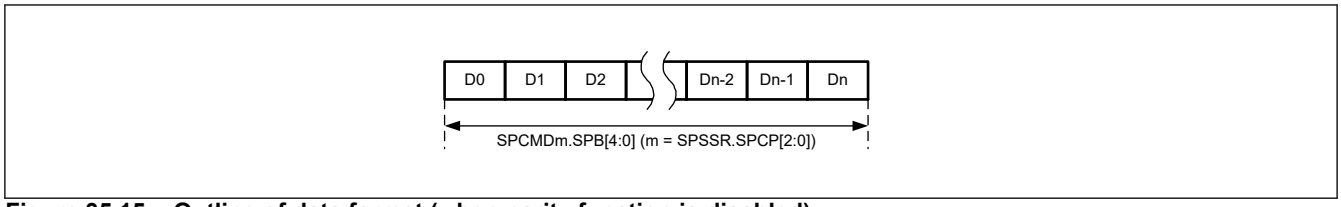

Figure 35.15 Outline of data format (when parity function is disabled)

(2) With Parity Enabled (SPPE = 1)

When the parity function is enabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received. However, the final bit is used as a parity bit.

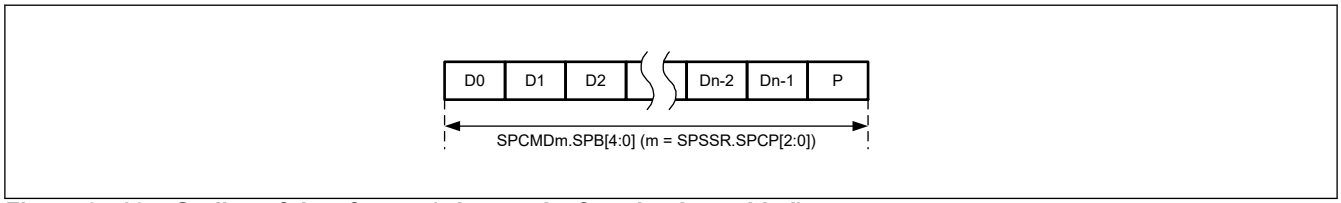

Figure 35.16 Outline of data format (when parity function is enabled)

35.3.4.2 When Parity is Disabled (SPPE = 0)

When the parity function is disabled, transmit buffer data is copied to the shift register without processing it. The following describes the relationship between SPDR, and shift register by using a combination of MSB first/LSB first and bit length.

(1) MSB First Transfer (32-Bit Data)

Figure 35.17 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function disabled.

In transmission, T31 to T00 in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R31 to R00, the shift register value is copied to the receive buffer.

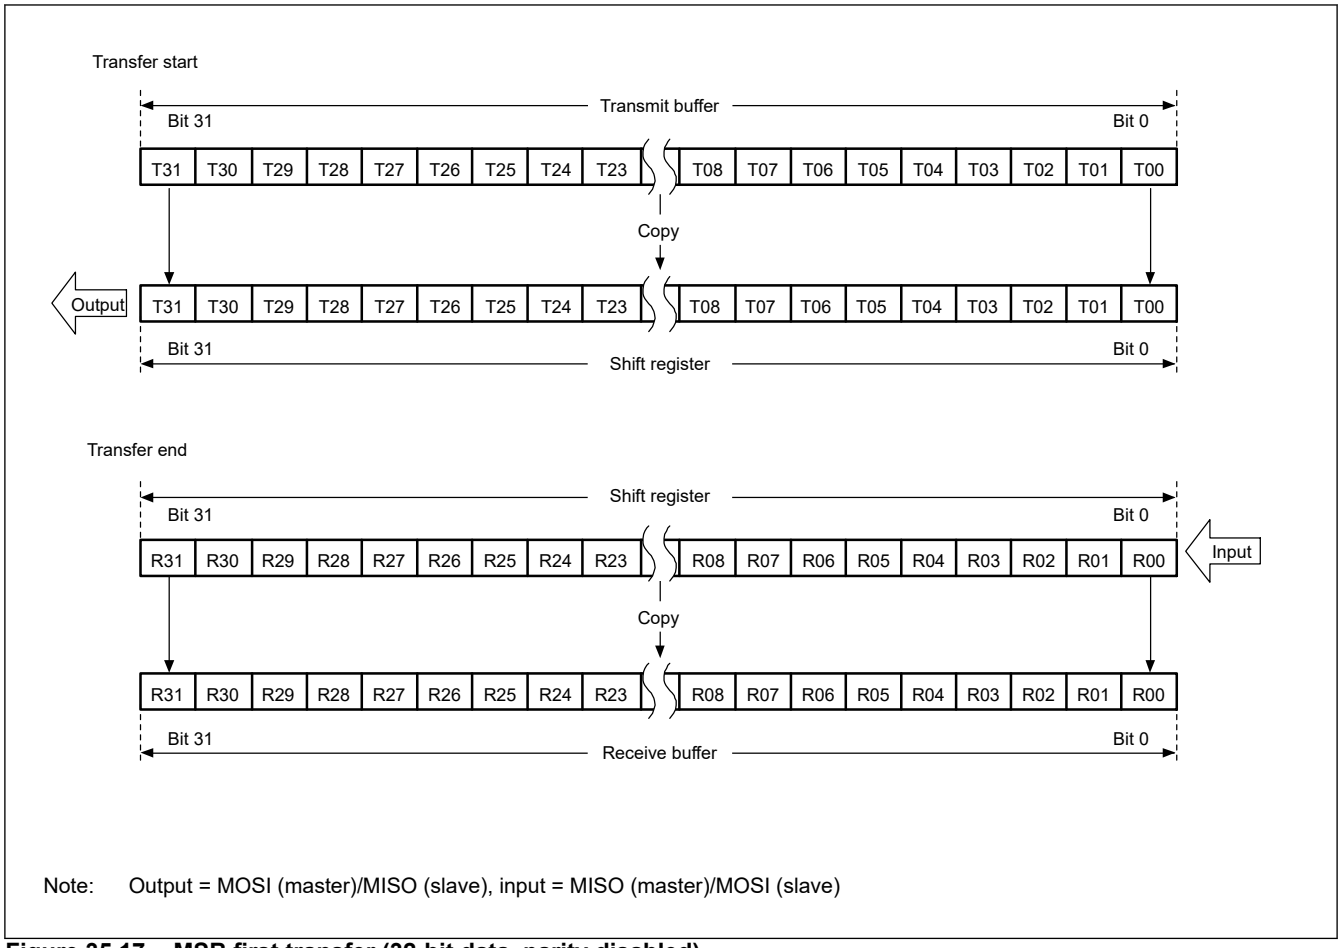

Figure 35.17 MSB first transfer (32-bit data, parity disabled)

(2) MSB First Transfer (24-Bit Data)

As an example of MSB-first transfer of data other than 32 bits with the parity function disabled, Figure 35.18 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24 bits (T23 to T00) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T23 → T22 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R23 to R00, the shift register value is copied to the receive buffer.

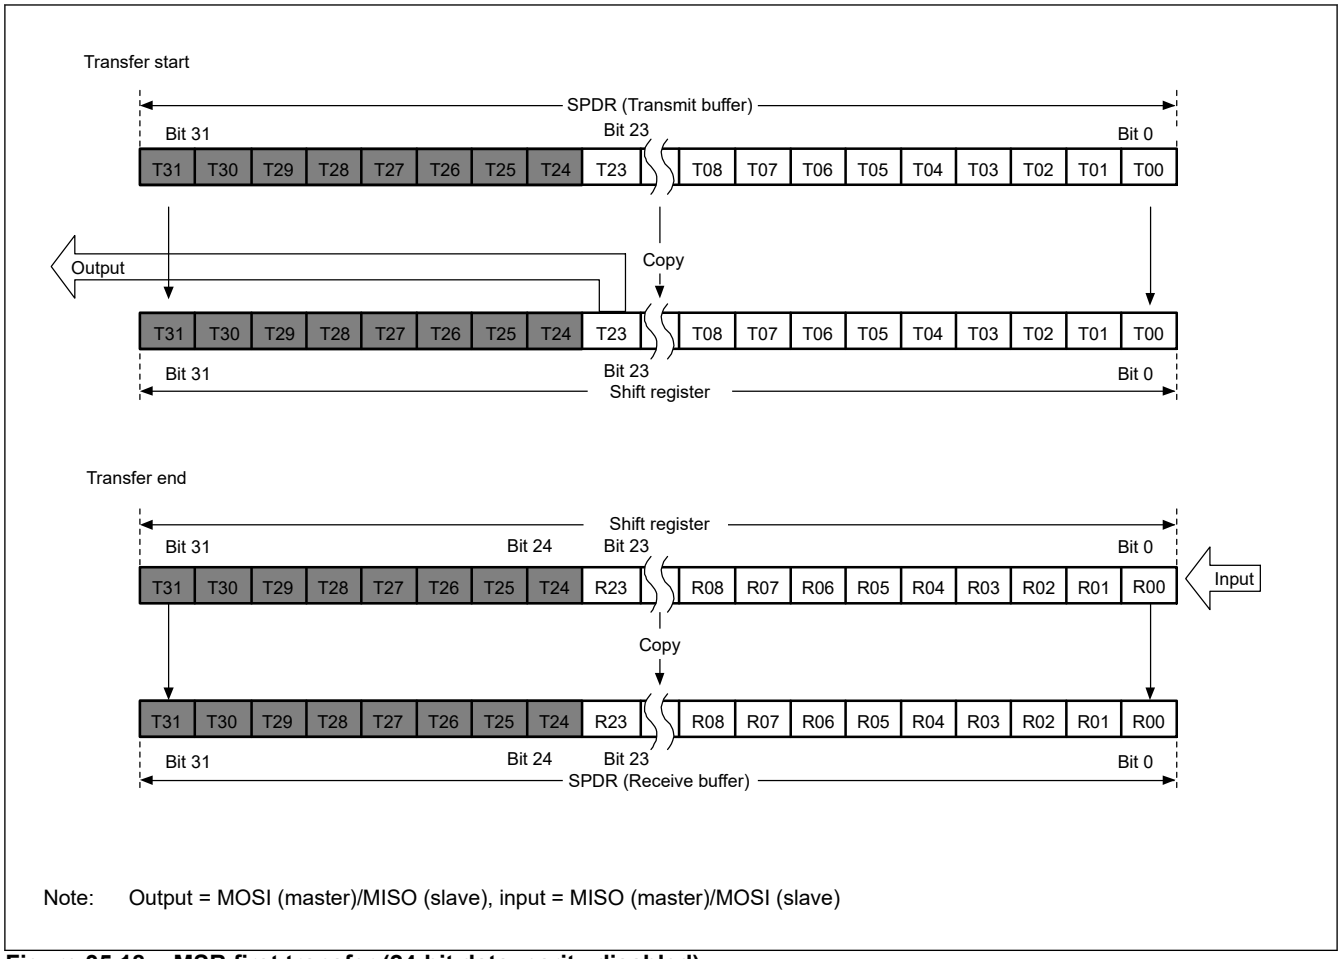

Figure 35.18 MSB first transfer (24-bit data, parity disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 35.19 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function disabled.

In transmission, bit values of the transmit buffer (T31 to T00) are reversed in bit units and are copied to the shift register in the order of T00 to T31. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

In reception, the first received data is stored in bit 0 of the shift register, and received data is shifted in units of data.

When necessary RSPCK cycles are input and data is stored from R00 to R31, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R31 to R00.

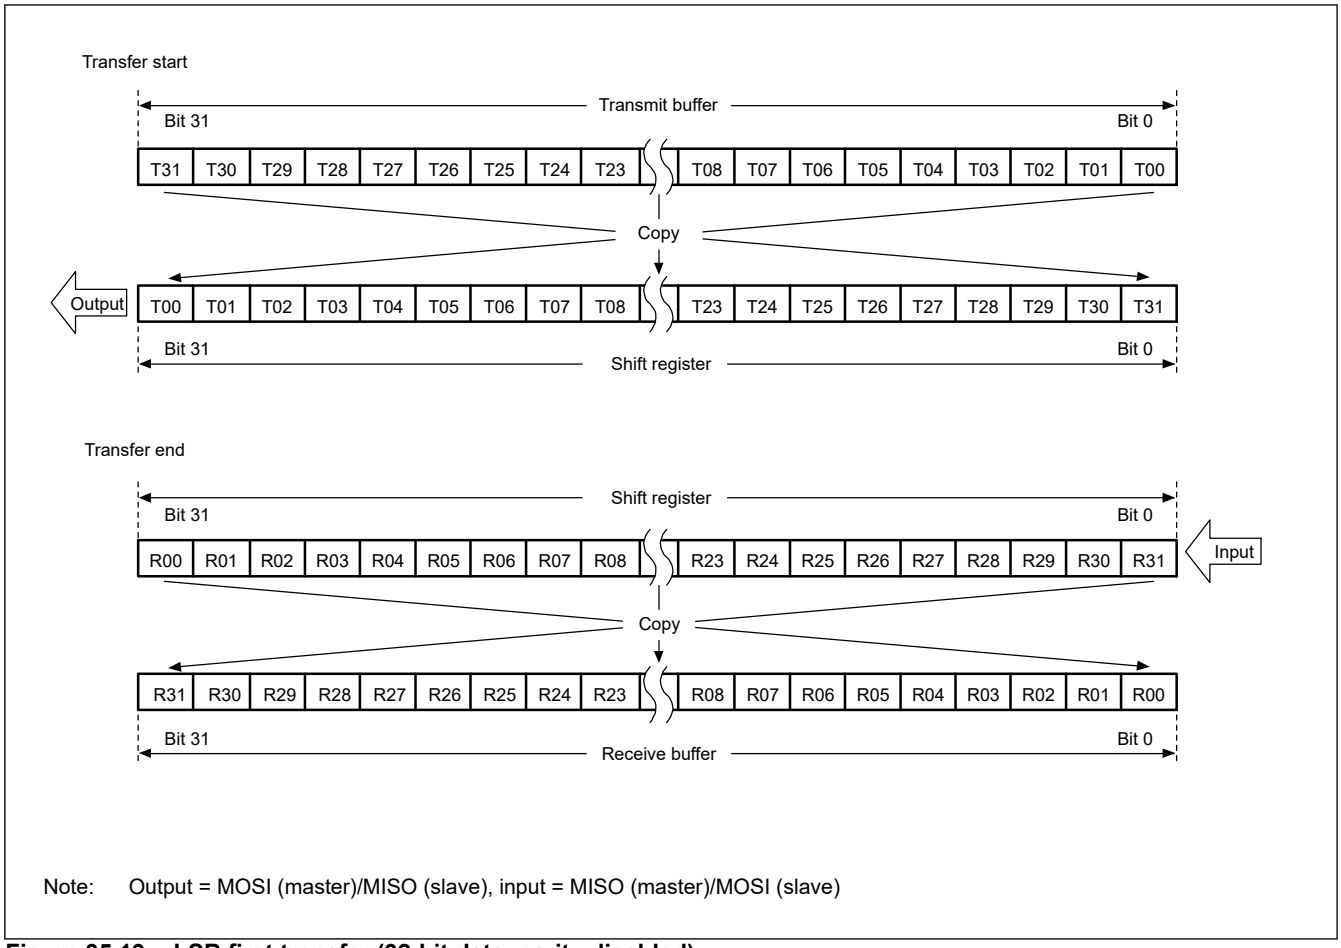

Figure 35.19 LSB first transfer (32-bit data, parity disabled)

(4) LSB First Transfer (24-Bit Data)

As an example of LSB-first transfer of data other than 32 bits with the parity function disabled, Figure 35.20 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24-bit values of the transmit buffer (T23 to T00) are reversed to the order from T00 to T23 in bit units and are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T00→ T01 → … → T23 as transmit data.

In reception, received data is stored in bit 8 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R00 to R23, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R23 (bit 23) to R00 (bit 0).

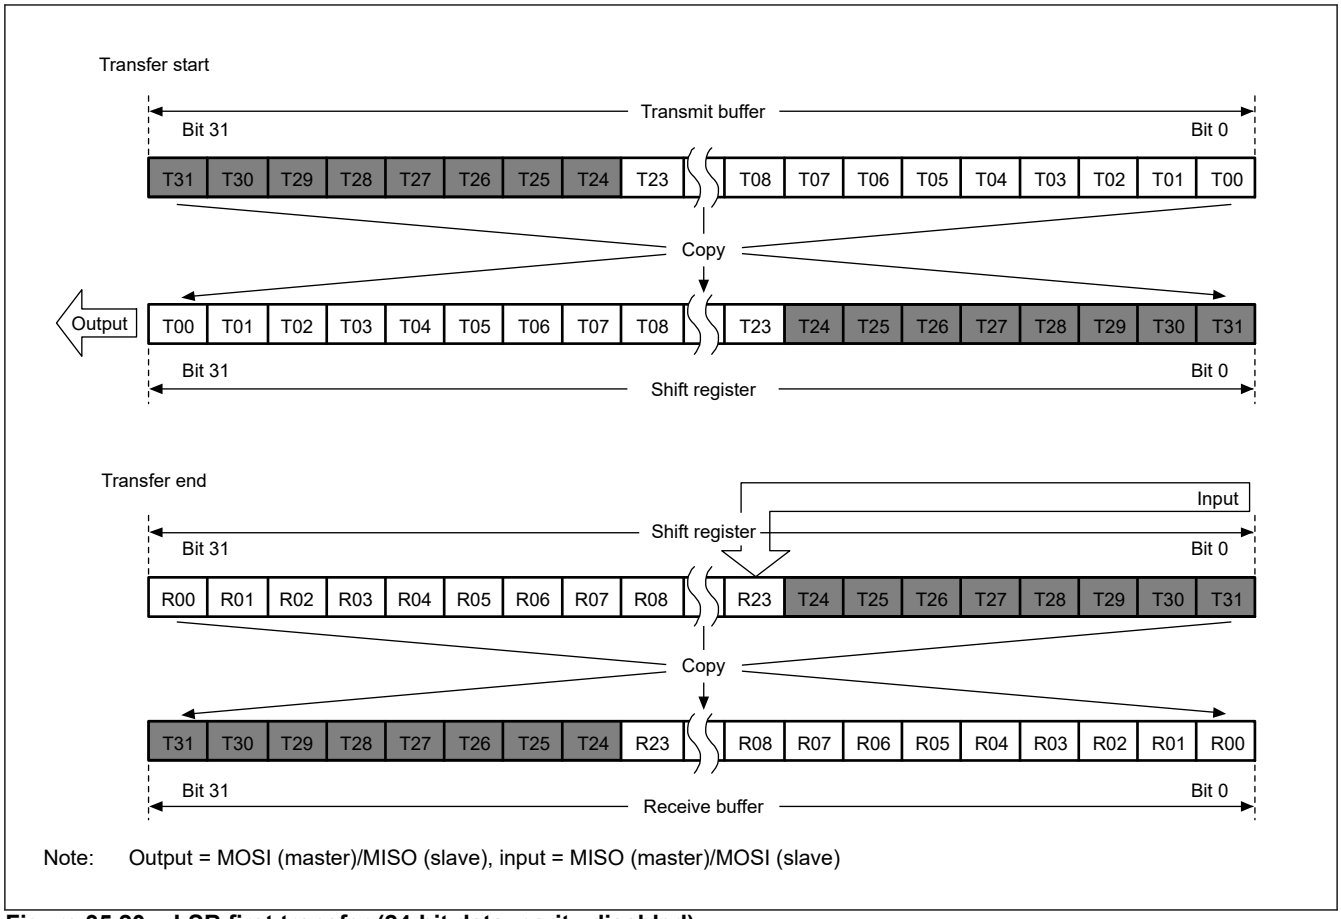

Figure 35.20 LSB first transfer (24-bit data, parity disabled)

35.3.4.3 When Parity is Enabled (SPPE = 1)

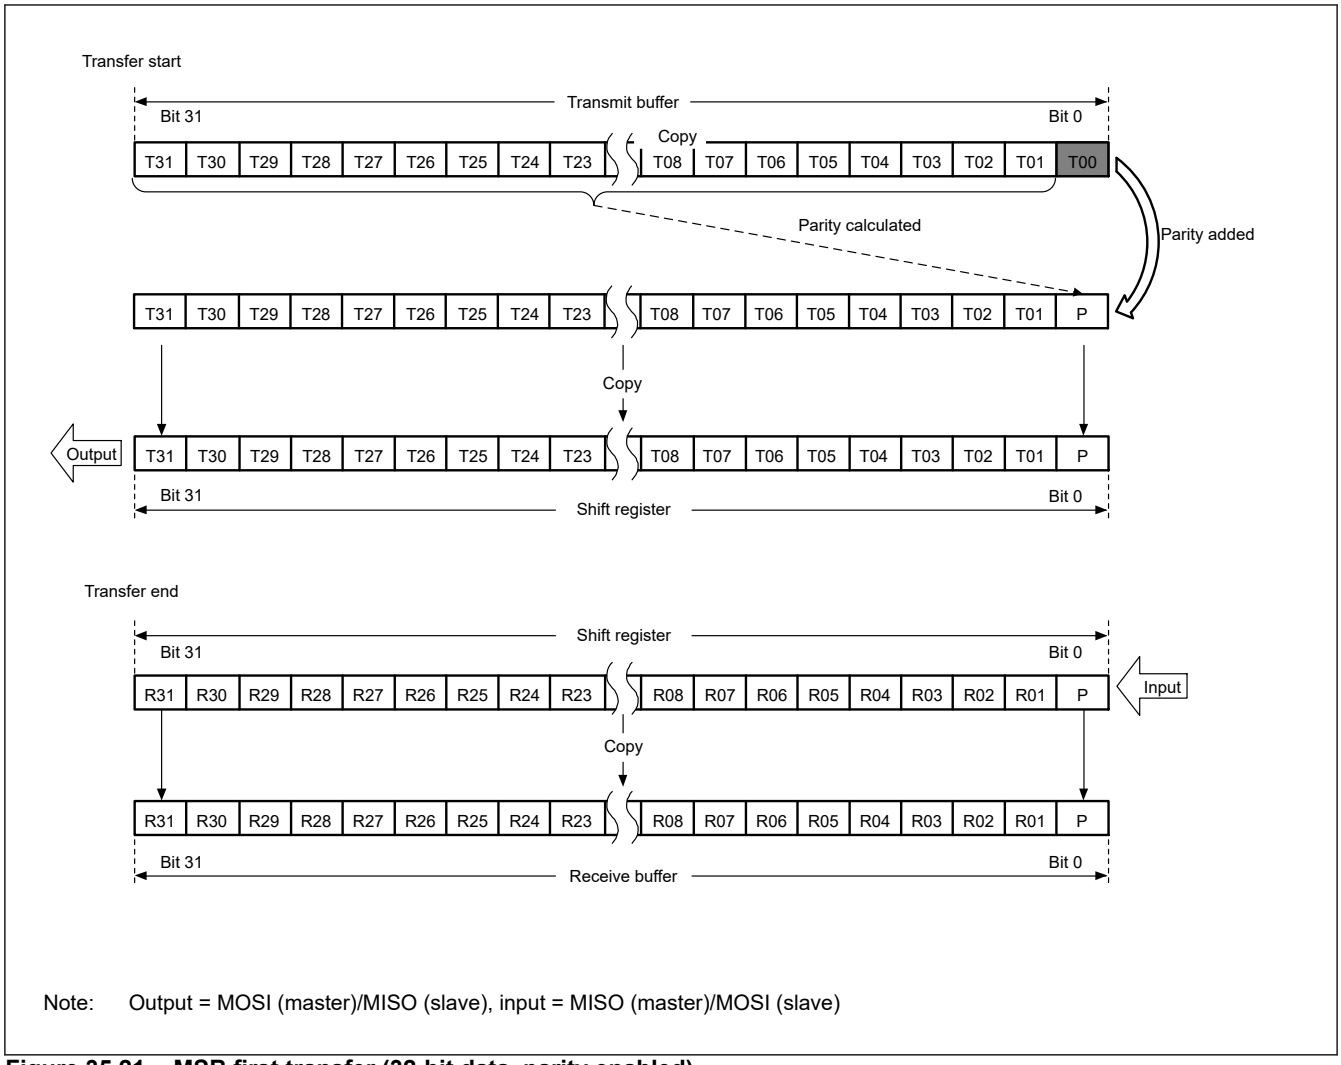
When the parity function is enabled, the LSB of transmit data or received data is converted to a parity bit. The parity bit value is calculated and converted by the hardware.

(1) MSB First Transfer (32-Bit Data)

Figure 35.21 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T31 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T31 → T30 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R31 to P, the shift register value is copied to the receive buffer, and at the same time, R31 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

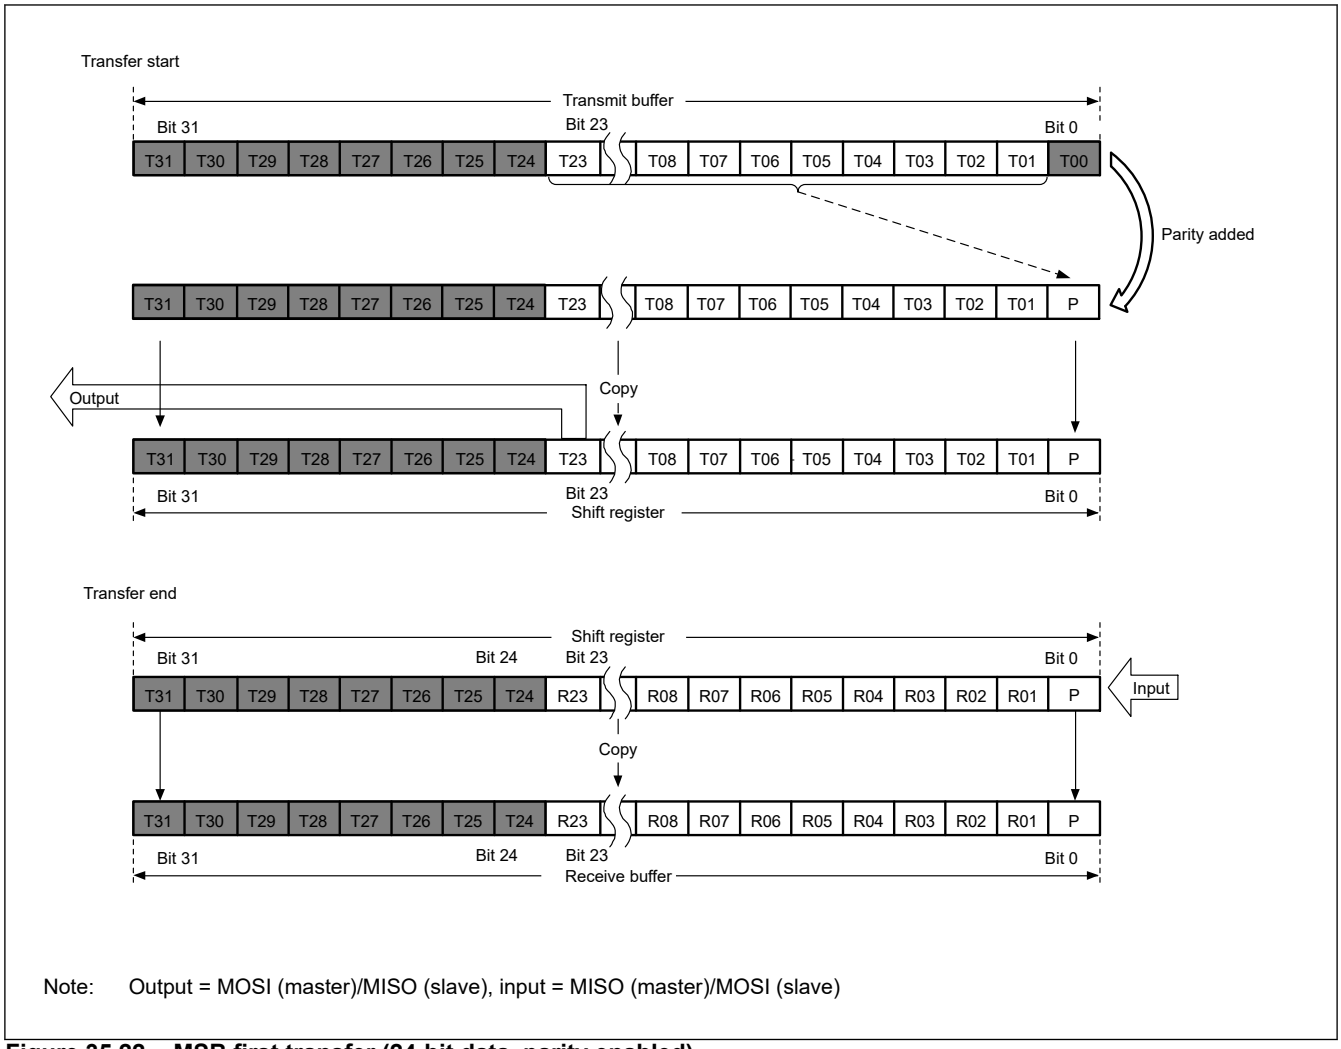
Figure 35.21 MSB first transfer (32-bit data, parity enabled)

(2) MSB First Transfer (24-Bit Data)

As an example of MSB-first transfer of data other than 32 bits with the parity function enabled, Figure 35.22 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T23 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T23 → T22 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R23 to P, the shift register value is copied to the receive buffer, and at the same time, R23 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

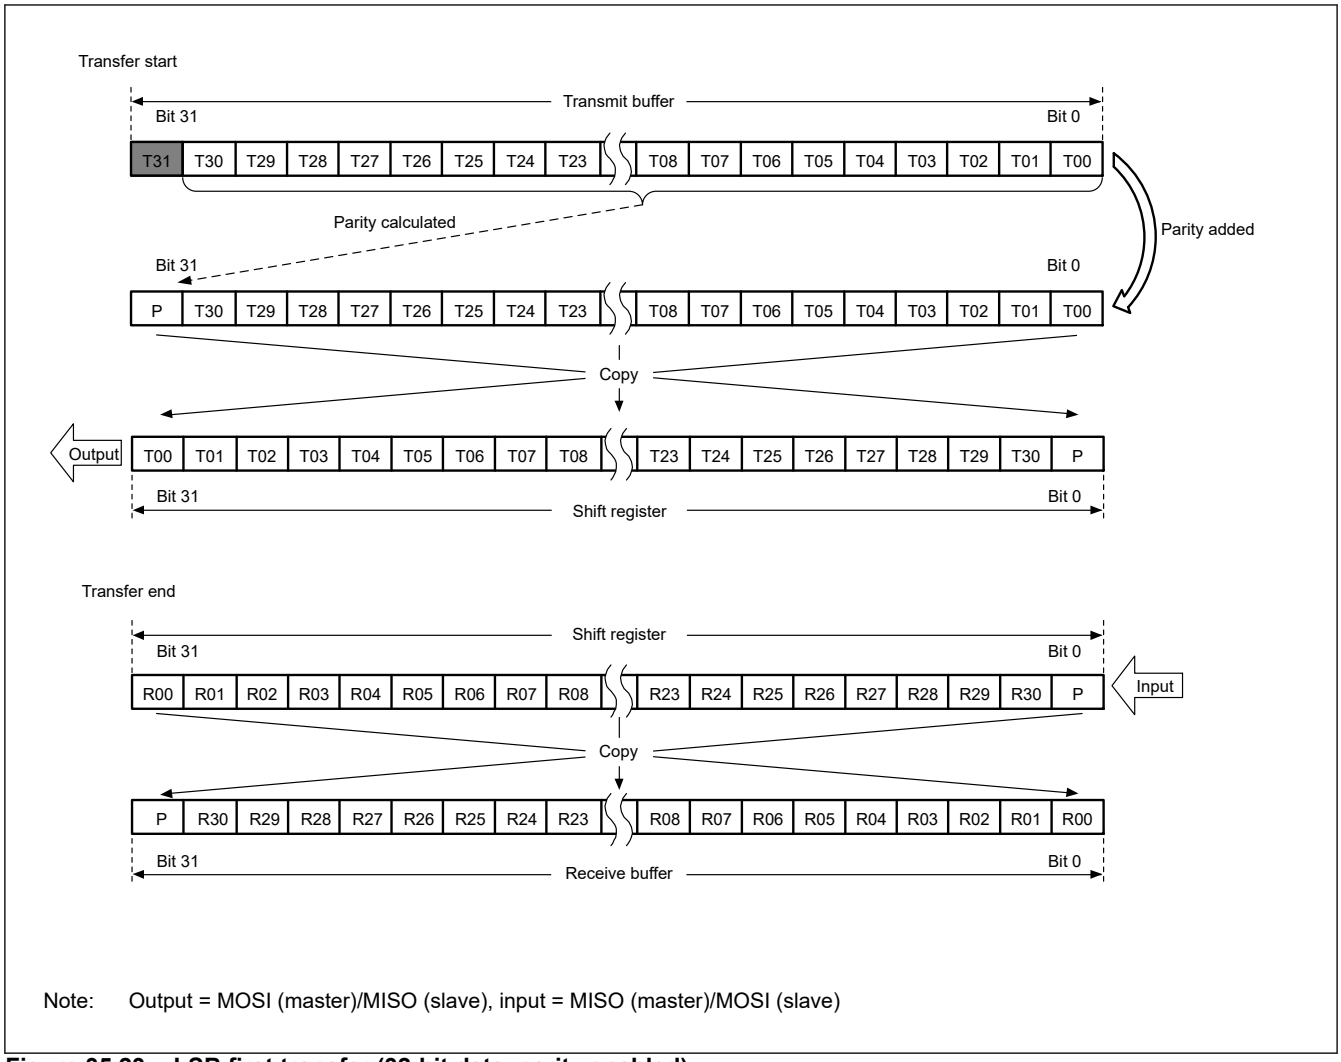
Figure 35.22 MSB first transfer (24-bit data, parity enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 35.23 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T30 to T00, then the final bit T31 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T30 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P to R00, and at the same time, R00 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 35.23 LSB first transfer (32-bit data, parity enabled)

(4) LSB First Transfer (24-Bit Data)

As an example of LSB-first transfer of data other than 32 bits with the parity function enabled, Figure 35.24 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T22 to T00, then the final bit T23 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00→ T01 → … → T22 → P.

In reception, received data is stored in bit 8 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P (bit 23) to R00 (bit 0), and at the same time, R00 to P data is checked to determine whether a parity error is present.

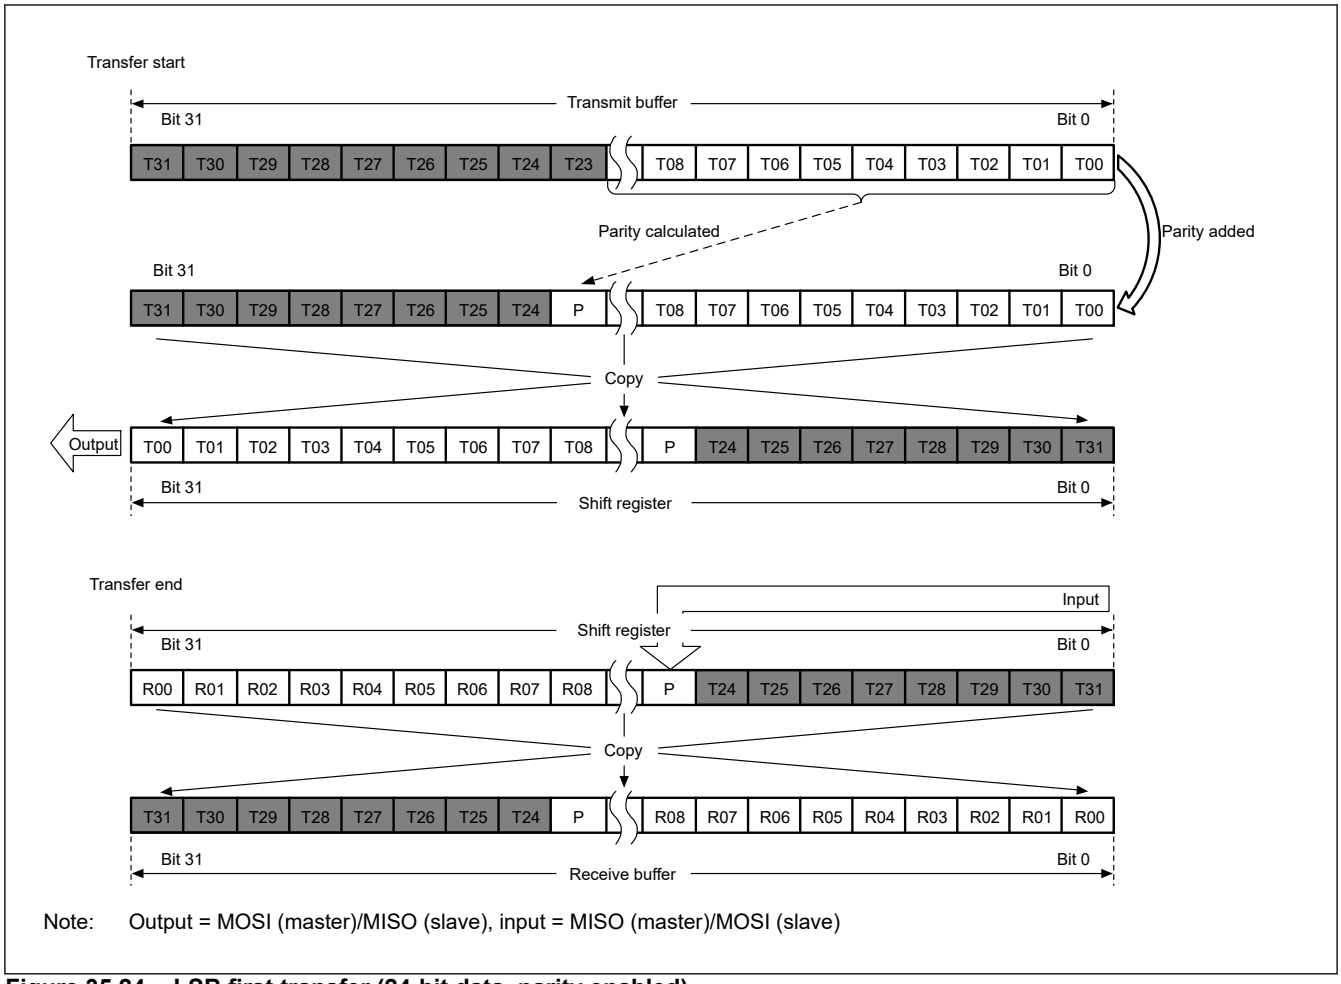


Figure 35.24 LSB first transfer (24-bit data, parity enabled)

35.3.4.4 Byte swap transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register.

(1) 32-bit data length

Figure 35.25 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.
2. **MSB First Transfer (When the byte swap is enabled.)**
   Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.
3. **LSB-first transfer (When the byte swap is disabled.)**
   Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].
   Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.
4. **LSB-first transfer (When the byte swap is enabled.)**
   Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

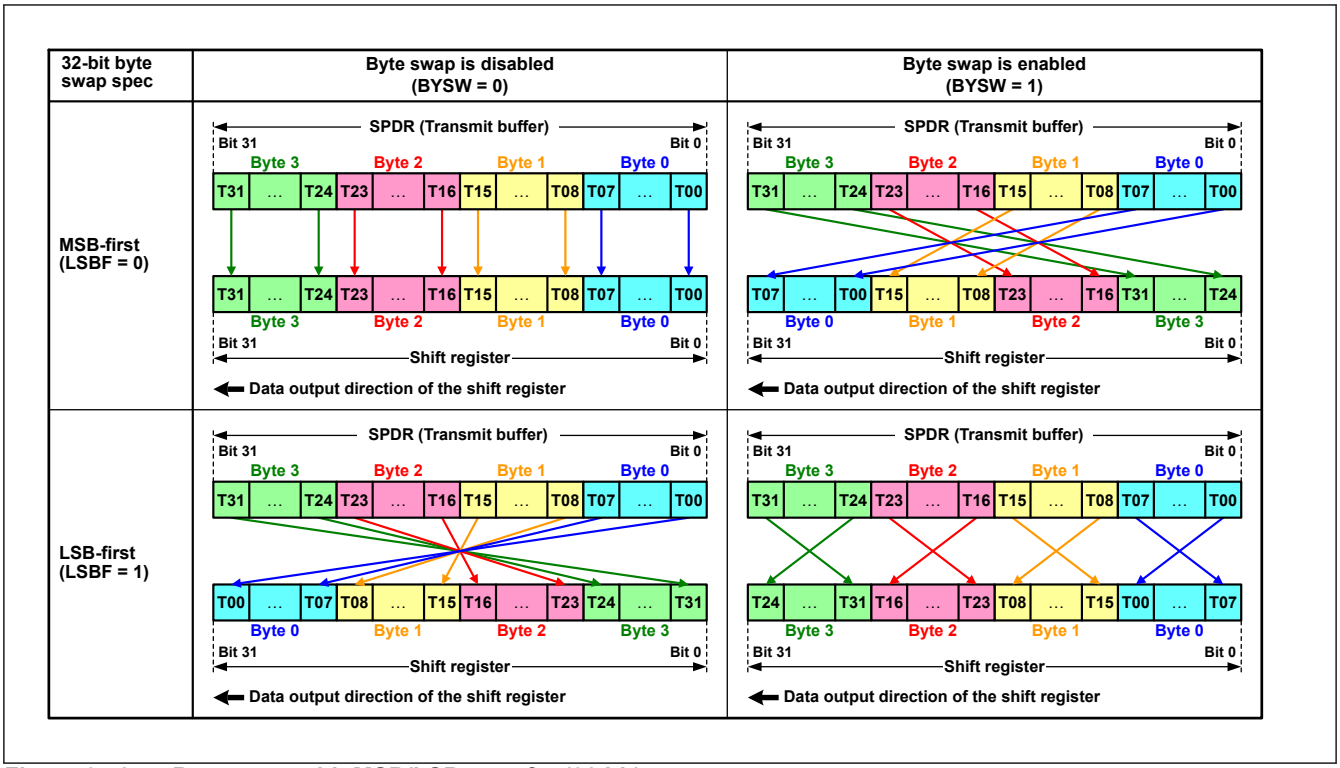

Figure 35.25 Byte swap with MSB/LSB transfer (32 bit)

(2) 16-bit data length

Figure 35.26 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … → T00 as transmit data.
2. **MSB First Transfer (When the byte swap is enabled.)**
   Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte1 [T07 to T00] to Byte0 [T15 to T08].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 as transmit data.
3. **LSB-first transfer (When the byte swap is disabled.)**
   Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15].
   Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T15 as transmit data.
4. **LSB-first transfer (When the byte swap is enabled.)**
   Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

Figure 35.26 Byte swap with MSB/LSB transfer (16 bit)

Note: When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting).
If setting the other length, the behavior is not guaranteed.

Note: When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0) .
If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.

Note: Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

35.3.4.5 Byte swap reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer.

(1) 32-bit data length

Figure 35.27 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. **MSB First Transfer (When the byte swap is enabled.)**
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. **LSB-first transfer (When the byte swap is disabled.)**
   The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

4. **LSB-first transfer (When the byte swap is enabled.)**
   The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

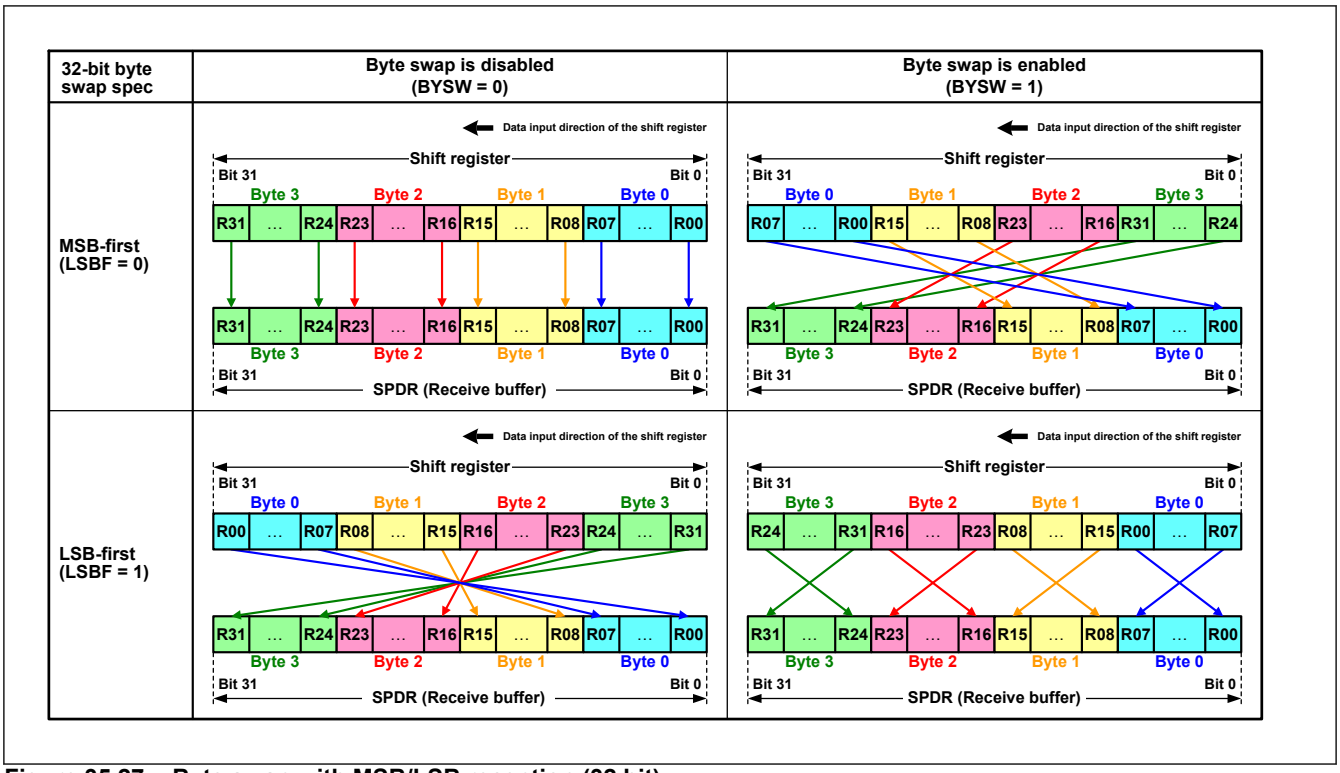

Figure 35.27 Byte swap with MSB/LSB reception (32 bit)

(2) 16-bit data length

Figure 35.28 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R15 to R08] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

2. **MSB First Transfer (When the byte swap is enabled.)**
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

3. **LSB-first transfer (When the byte swap is disabled.)**
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … → R15.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

4. **LSB-first transfer (When the byte swap is enabled.)**
   The first received data (R08) is stored in bit 0 of the shift register, and received data is shifted in the order of R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R08 to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

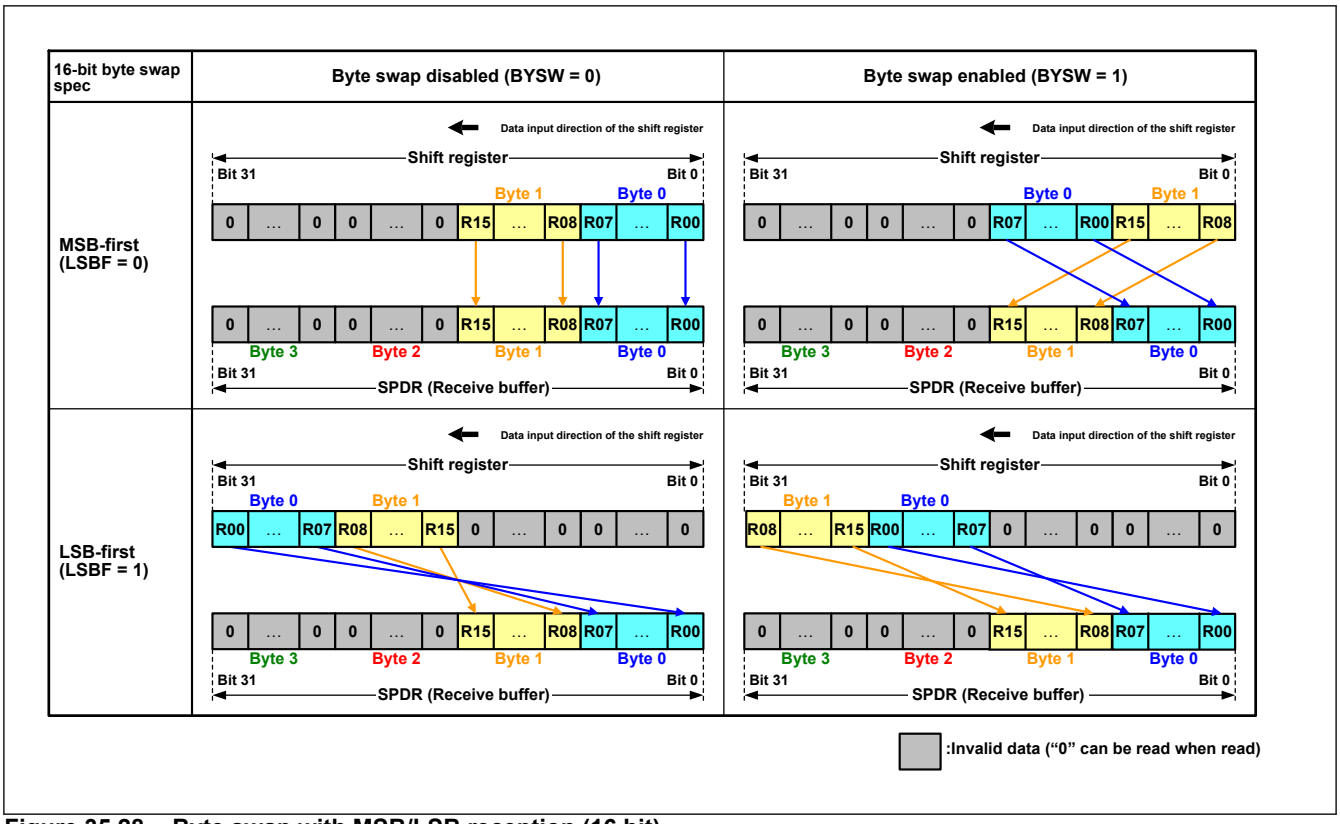

Figure 35.28 Byte swap with MSB/LSB reception (16 bit)

Note: When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting) .
If setting the other length, the behavior is not guaranteed.

Note: When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0).
If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.

Note: Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

35.3.5 Transfer Format (Frame Format)

35.3.5.1 CPHA = 0

Figure 35.29 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 0. However, when the SPI is in slave mode (SPCR.MSTR = 0) with the CPHA bit set to 0, clock synchronous operation (SPCR.SPMS = 1) is not guaranteed. In Figure 35.29, RSPCK (CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0, and RSPCK (SPCMD.CPOL = 1) is the RSPCK signal waveform when SPCMD.CPOL = 1. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI settings. (See section 35.3.2. SPI Pin Control.)

When SPCMD.CPHA = 0, output of valid data to the MOSI signal and valid data drive to the MISO signal start at the SSL signal assertion timing. The first RSPCK signal change timing after the SSL signal is asserted is the first transfer data latch timing. After this timing, data is sampled in each RSPCK cycle. The MOSI signal and the MISO signal change always after the half RSPCK cycles of the transfer data latch timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Period t1 is the period (RSPCK delay) from SSL signal assertion to RSPCK oscillation. Period t2 is the period (SSL negation delay) from RSPCK oscillation stop to SSL signal negation. Period t3 is the period (next-access delay) to inhibit SSL signal assertion for the next transfer after serial transfer is completed. Periods t1, t2, and t3 are controlled by the master device in the SPI system. For t1, t2, and t3 when this LSI (SPI) is in master mode, see section 35.3.13.1. Master Mode Operation.

[In the Motorola-SPI case]

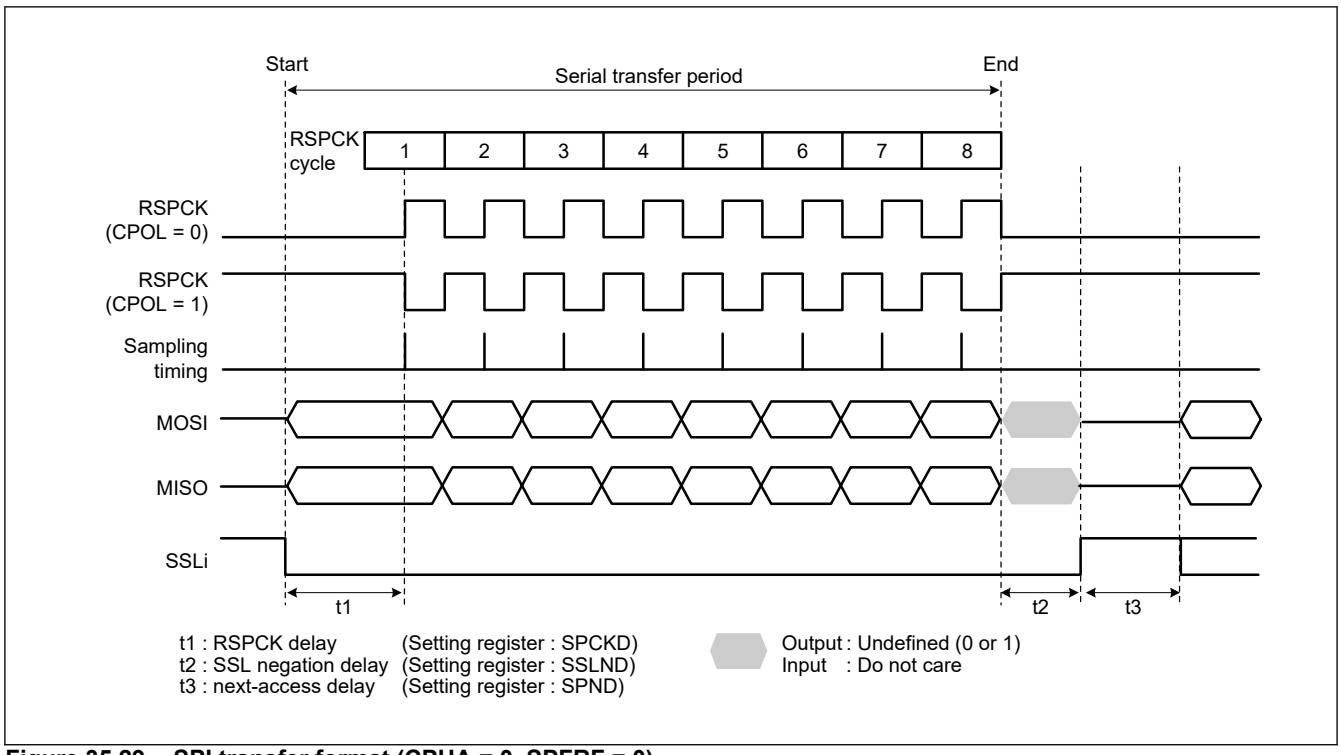

Figure 35.29 SPI transfer format (CPHA = 0, SPFRF = 0)

35.3.5.2 CPHA = 1

Figure 35.30 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 1. However, when SPCR.SPMS = 1, communication is performed by using only RSPCK, MOSI, and MISO signals without using the SSL signal. In Figure 35.30, RSPCK (CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0, and RSPCK (SPCMD.CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI mode (master or slave mode). (See section 35.3.2. SPI Pin Control.)

When SPCMD.CPHA = 1, invalid data drive to the MISO signal starts at the SSL signal assertion timing. Output of valid data to the MOSI and MISO signals starts at the first RSPCK signal change timing after the SSL signal is asserted.

After this timing, data is updated in each RSPCK cycle. Transfer data is always latched after 1/2 RSPCK cycle of this timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Periods t1, t2, and t3 are the same as when CPHA = 0. For t1, t2, and t3 when this LSI (SPI) is in master mode, see section 35.3.13.1. Master Mode Operation.

[In the Motorola-SPI case]

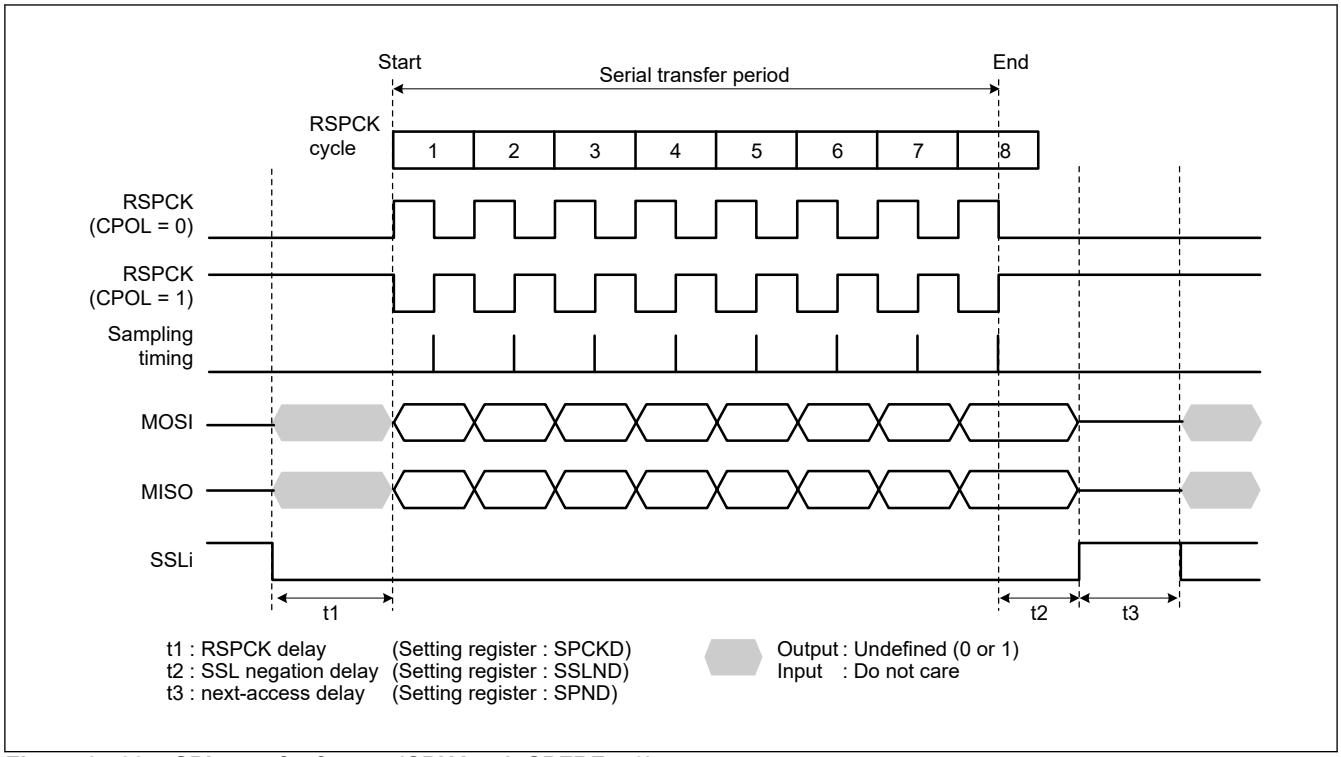

Figure 35.30 SPI transfer format (CPHA = 1, SPFRF = 0)

35.3.6 Communications Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD[1:0]) of the SPCR register.

SPDR access described in Figure 35.31, Figure 35.32, and Figure 35.33 shows an access to the SPDR register. W shows a write cycle.

35.3.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 35.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example in Figure 35.31, the SPI performs 8-bit data serial transfer with the settings of RTRG = FIFO stage - 1, SPDCR2.TTRG = 0, SPCMD.CPHA = 1, and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

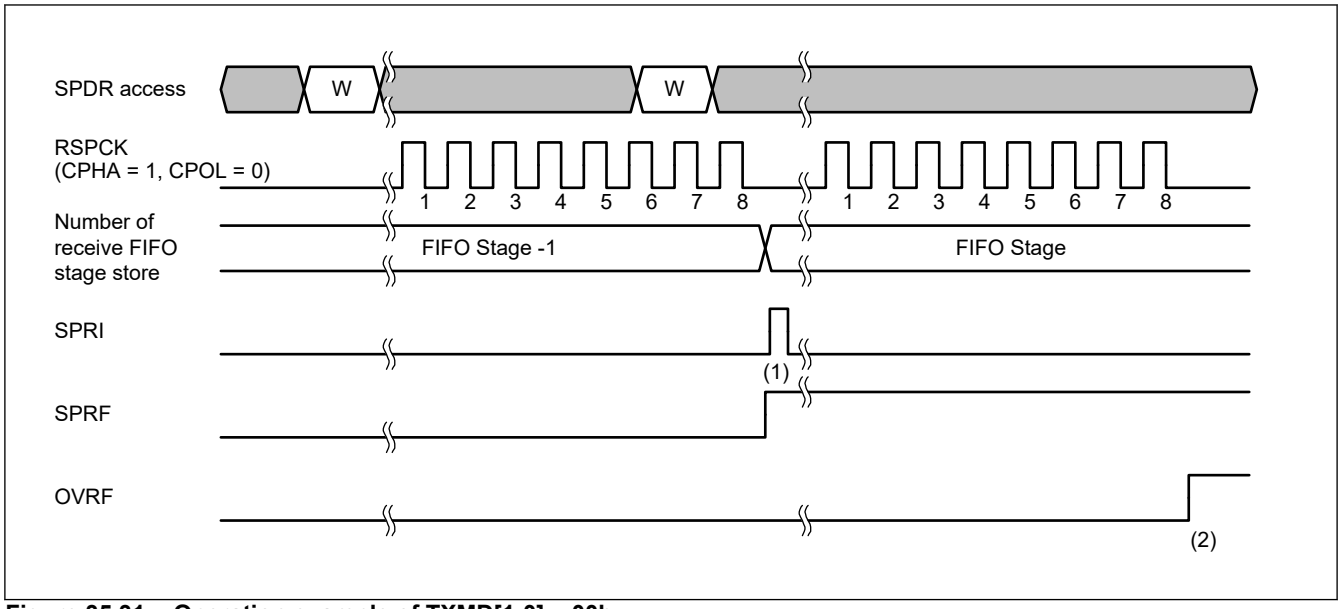

Figure 35.31 Operation example of TXMD[1:0] = 00b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR register to 1 and discards the received data in the shift register.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

35.3.6.2 Transmit-Only Serial Communication (TXMD[1:0] = 01b)

Figure 35.32 shows an example of operation when the communication mode select bits (TXMD[1:0]) in the SPCR register are set to 01b. In the example in Figure 35.32, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 00b, SPDCR2.RTRG[1:0] = 00b, SPCMD.CPHA = 1, and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

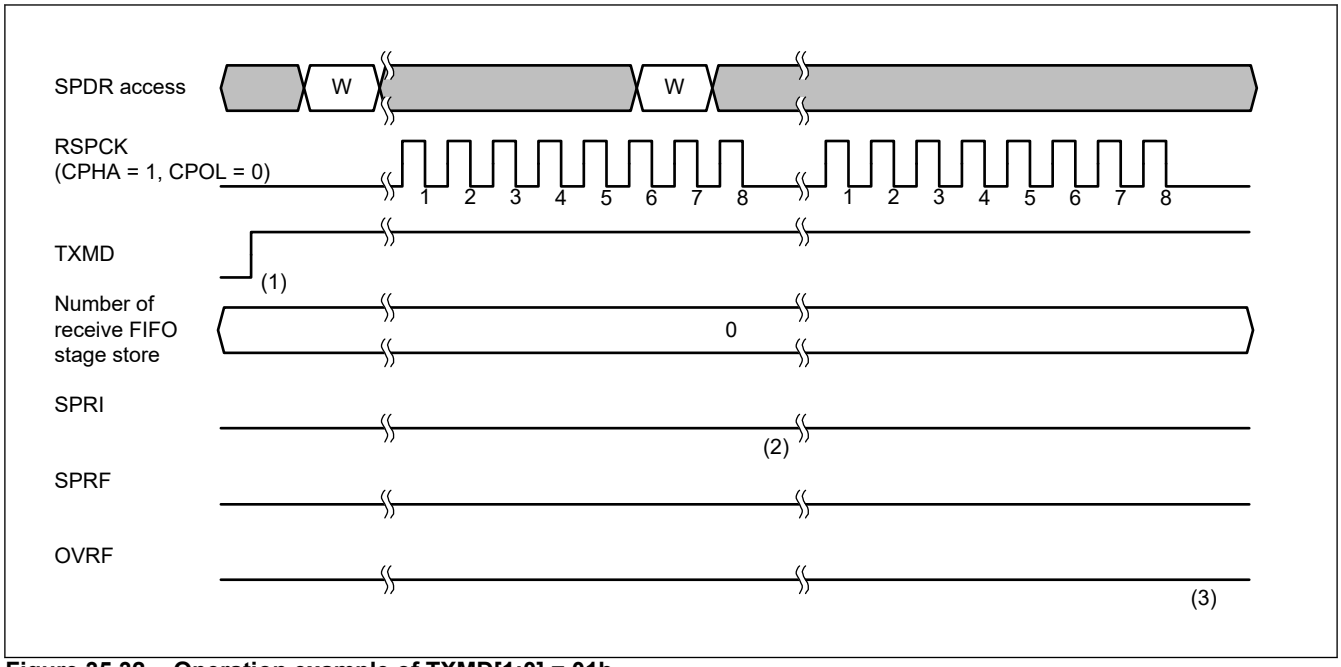

Figure 35.32 Operation example of TXMD[1:0] = 01b

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) Before setting TXMD[1:0] to 01b (transmit-only serial communication), confirm that the receive buffer is empty and that the SPRF and OVRF flags in the SPSR register are 0.

(2) In transmit-only serial communication (TXMD[1:0] = 01b), when serial transfer ends without receiving data in the receiving FIFO of SPDR, the SPRF flag remains 0 and the shift register data is not copied to the receive buffer.

(3) The OVRF flag remains 0 even after serial transfer ends because previously received data is not remaining in the SPDR's receive buffer, and the shift register data is not copied to the receive buffer.

In transmit-only serial communication (TXMD[1:0] = 01b), transmit data is transmitted but receive data is not received.

Therefore, the SPRF flag and the OVRF flag remain 0 at each timing of (1) to (3).

35.3.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 35.33 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1. In the example in Figure 35.33, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 0, SPDCR2.RTRG[1:0] = FIFO stage - 1, SPCMD.CPHA = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

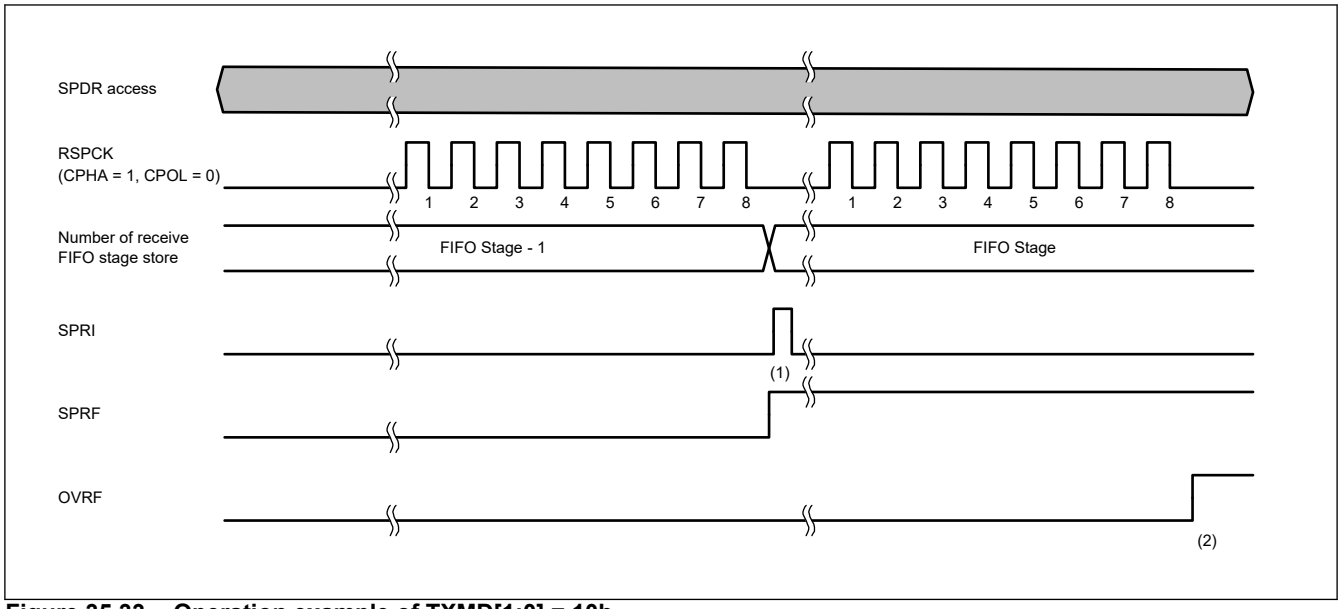

Figure 35.33 Operation example of TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR.SPI register to 1 and discards the received data in the shift register.

35.3.7 Transmission Buffer Empty/Receive Buffer Full Interrupt

Figure 35.34 show an example of operation of SPI transmit buffer empty interrupt (SPTI) and SPI receive buffer full interrupt (SPRI) respectively. "SPDR access" described in Figure 35.34 and shows an access to the SPDR register. W shows a write cycle and R shows a read cycle. In each example of operation, the SPI performs 8-bit data serial transfer with the settings of SPCR.TXMD[1:0] = 00b, SPDCR2.TTRG = 0, SPDCR2.RTRG = 0, SPCMD.CPHA = 0 (Figure 35.34), and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

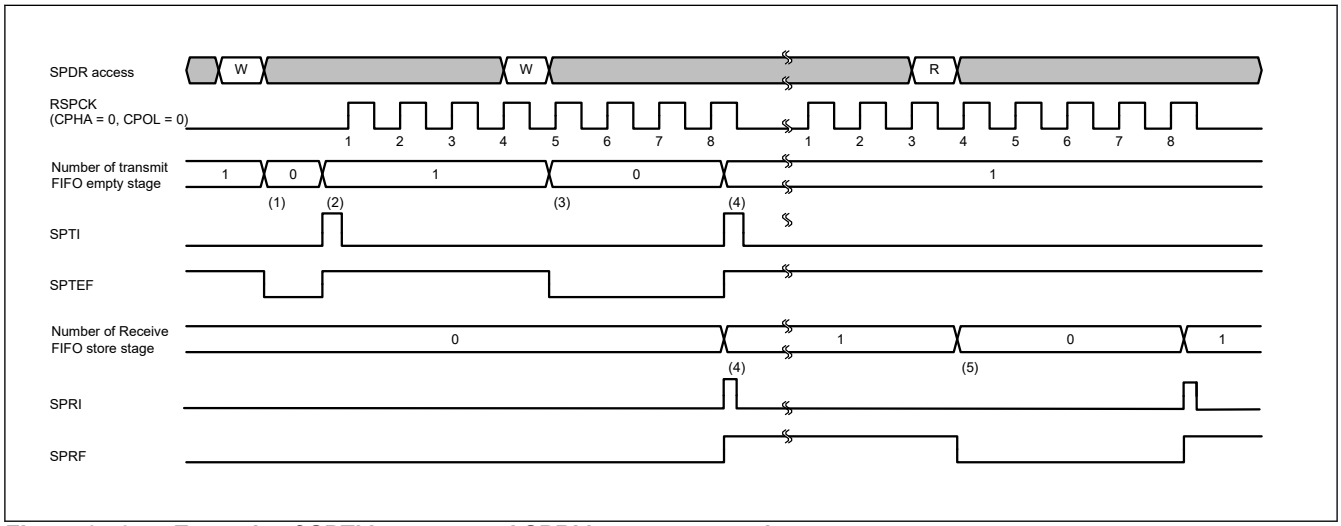

Figure 35.34 Example of SPTI interrupt and SPRI interrupt operations

The following describes operation at timings (1) to (5) in the figure above.

(1) When transmit data is written to SPDR before the data for the next transfer is not set to the FIFO of the SPDR, the SPI writes data to the transmission buffer. When transmit data is written to SPDR in one processing routine using DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.

(2) When the shift register is empty, the SPI copies transmit buffer data to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPTI) and sets the SPTEF flag to 1. How to start serial transfer depends on SPI mode. (See section 35.3.13. SPI Operation and section 35.3.14. Clock Synchronous Operation.)

(3) When transmit data is written to SPDR upon a transmit buffer empty interrupt request (SPTI) or in the transmit buffer empty determination processing due to the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DMAC, the SPTEF flag is cleared to 0 at the last access. The SPI does not copy transmit buffer data to the shift register because the shift register contains serial transfer data.

(4) When serial transfer ends (data sampling clock edge in the final bit is detected) while the receive buffer of SPDR > FIFO stage number, the SPI copies the received data in the shift register to the receive buffer. At this time, a receive buffer full interrupt request is generated and the SPRF flag is set to 1. When serial transfer ends, the shift register becomes empty. If the next transfer data is set in the transmit FIFO before serial transfer ends, the SPI set the SPTEF flag to 1 and copies transmit buffer data to the shift register. Even if received data is not copied from the shift register to the receive buffer while an overrun error is present, the SPI determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(5) When SPDR is read upon a receive buffer full interrupt request (SPRI) or in the receive buffer full determination processing due to the SPRF flag, received data can be read. If the received data is read from SPDR in one processing routine using DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update transmit buffer data. Write transmit data to the SPDR register upon a transmit buffer empty interrupt request or check the empty or not the transmission buffer by the SPTEF flag.

While SPCR.SPTIE = 1, when the SPI is disabled (SPCR.SPE = 0), an SPI transmit buffer empty interrupt is generated. However, SPI transmit buffer empty interrupt is inhibited by disabling SPI transmit buffer empty interrupt (SPCR.SPTIE = 0) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI detects an overrun error without copying data from the shift register to the receive buffer (as described in section 35.3.10. Error Detection). To prevent overrun of received data, read received data before the next serial transfer ends.

Transmit buffer state and receive buffer state can be monitored by an SPI transmit buffer empty interrupt and an SPI receive buffer full interrupt or a corresponding interrupt flag or by the SPTEF and SPRF flags.

35.3.8 Idle Interrupt

The idle interrupt during master mode operation is when the SPCP[2:0] of the SPSSR register becomes 000b (start of sequence control), the IDLNF flag in the SPSR register is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

(1) In the Motorola-SPI case

Figure 35.35 shows an example of idle interrupt operation during normal operation.

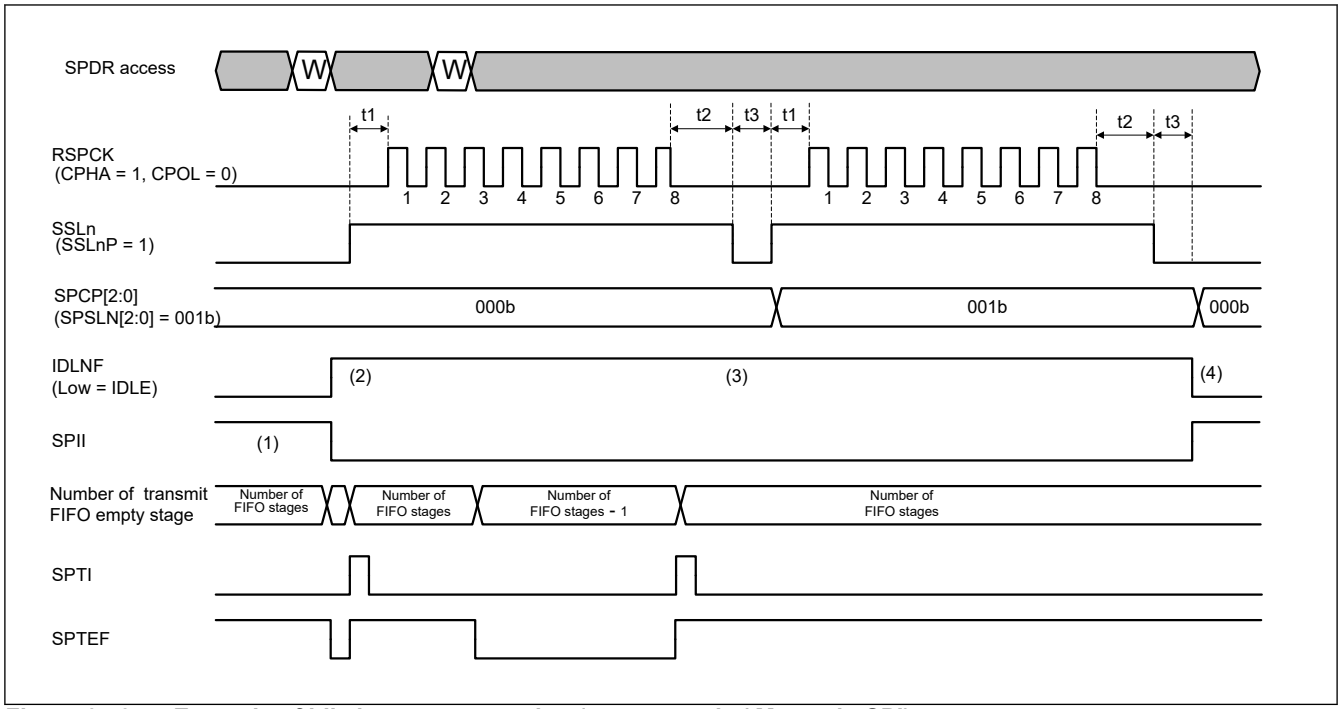

Figure 35.35 Example of idle interrupt operation (master mode / Motorola-SPI)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPII interrupt is output.

(2) In the TI-SSP case

Figure 35.36 shows an example of idle interrupt operation during normal operation.

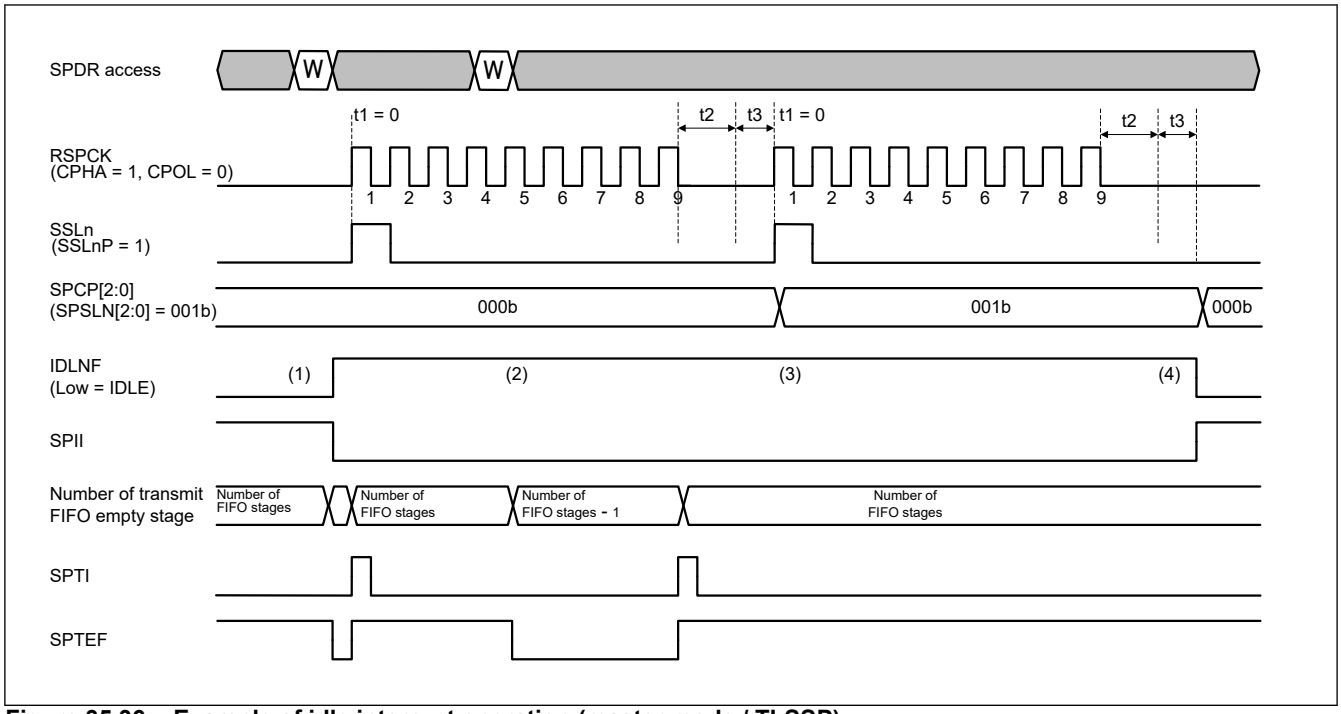

Figure 35.36 Example of idle interrupt operation (master mode / TI-SSP)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When SPCR.SPIIE = 1 currently, an SPII interrupt is output.

35.3.9 Communication End Interrupt

35.3.9.1 Transmit-Receive/Transmit-only in Master Mode

Refer to the description of the CENDF bit in section 35.2.19. SPTFSR : SPI Transfer FIFO Status Register and section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

(1) In the Motorola-SPI case

Figure 35.37 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

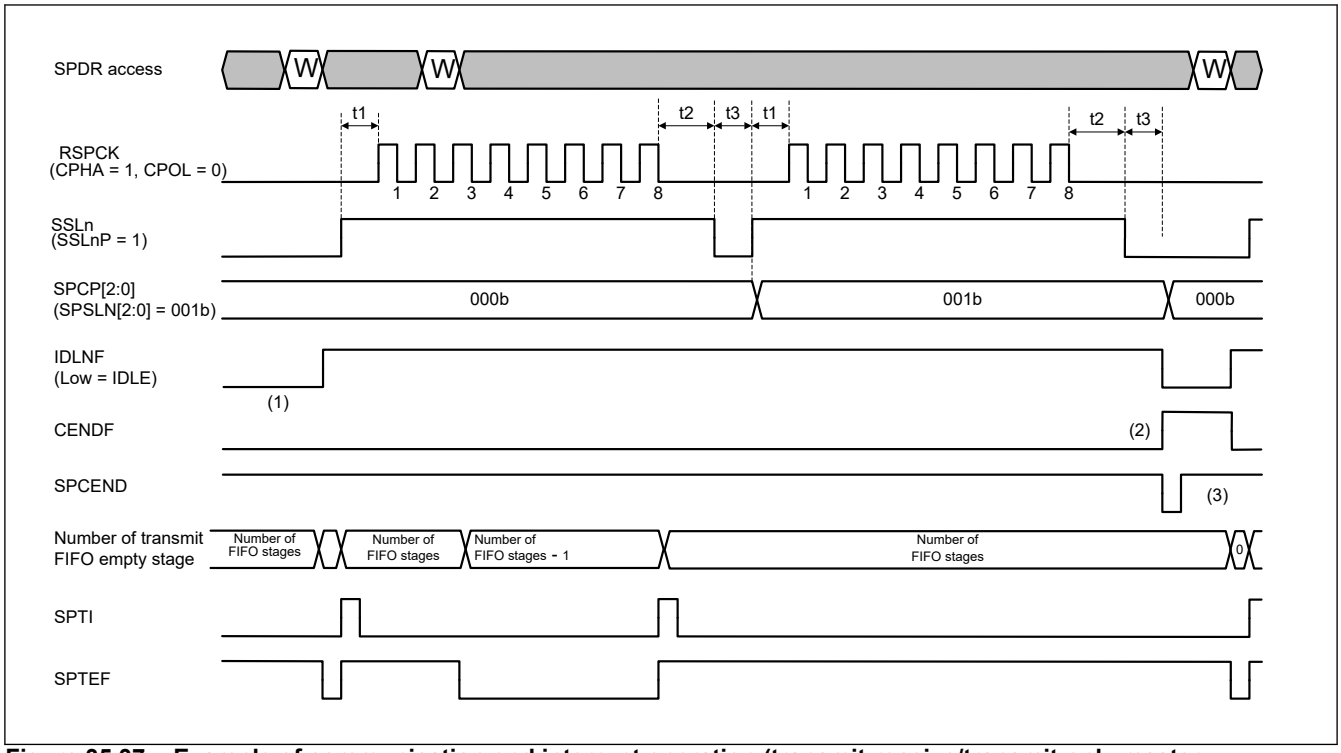

Figure 35.37 Example of communication end interrupt operation (transmit-receive/transmit-only master mode / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 35.38 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

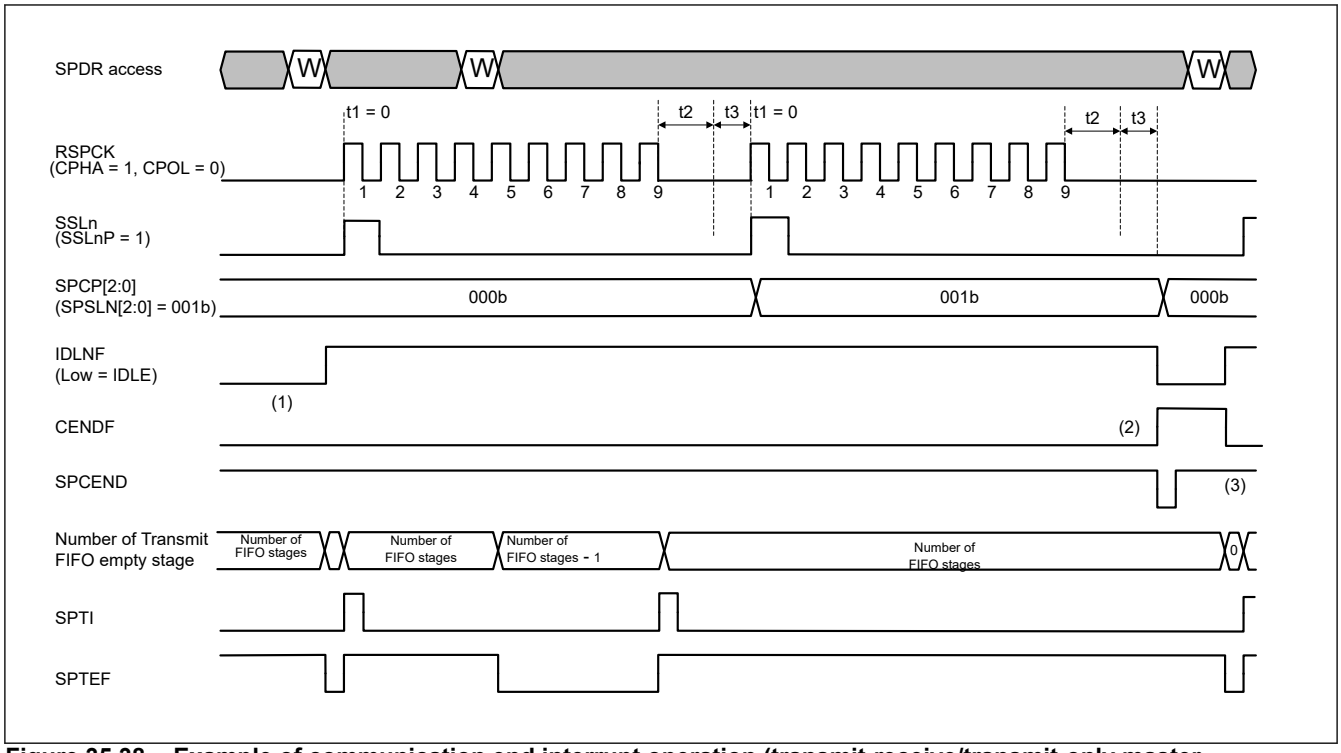

Figure 35.38 Example of communication end interrupt operation (transmit-receive/transmit-only master mode / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

35.3.9.2 Receive-only in Master Mode

Refer to the description of the CENDF bit in section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 35.39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 0x00.

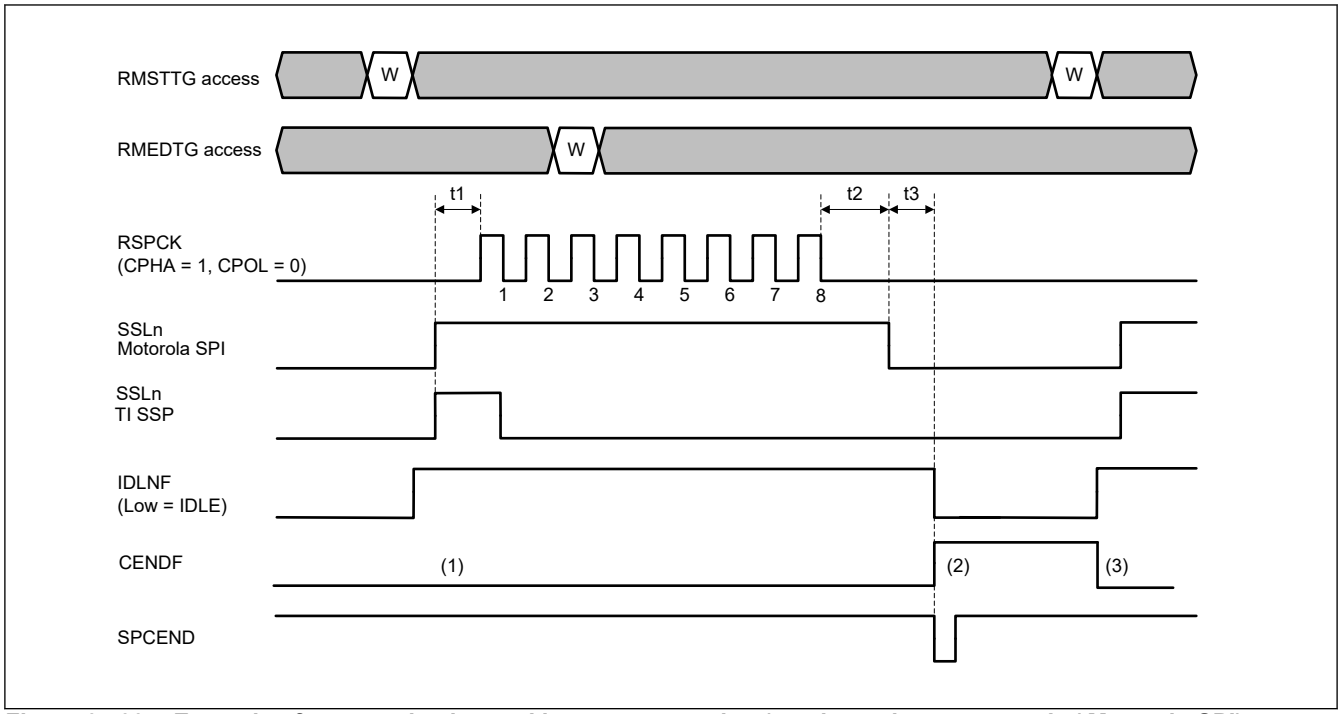

Figure 35.39 Example of communication end interrupt operation (receive-only master mode / Motorola-SPI) at RMFM[4:0] = 0x00

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, by writing 1 to RMEDTG during the communication frame. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1 to RMSTTG, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 35.40 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 0x00.

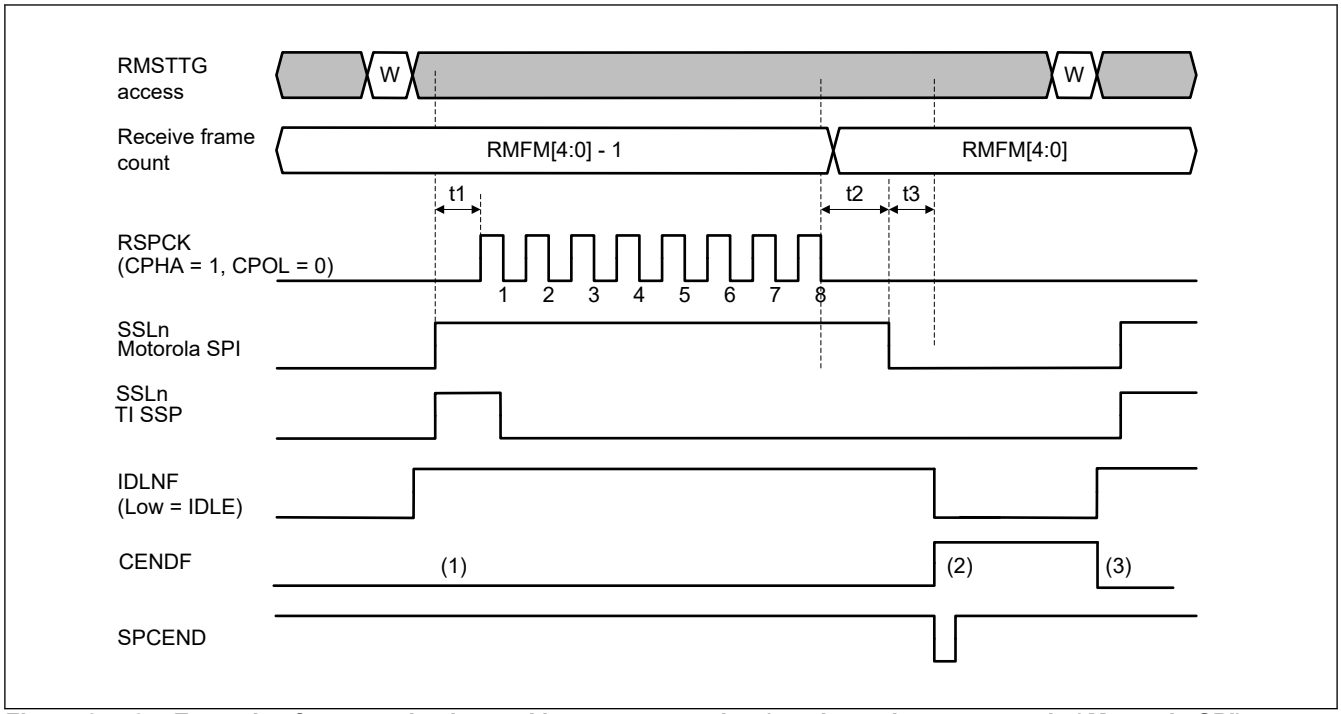

Figure 35.40 Example of communication end interrupt operation (receive-only master mode / Motorola-SPI) at RMFM[4:0] ≠ 0x00

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, after receiving the number of frames set by RMFM[4:0]. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1 to RMSTTG, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is dependent on the value of the SPCR.SPMS bit (SPI mode select bit). The clear timing of the communication end interrupt is dependent on the communication mode (transmit-receive or transmit-only or receive-only).

35.3.9.3 Transmit-Receive/Transmit-only in Slave Mode on SPI Operation (4-wire)

See the description for the CENDF bit in section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 35.41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

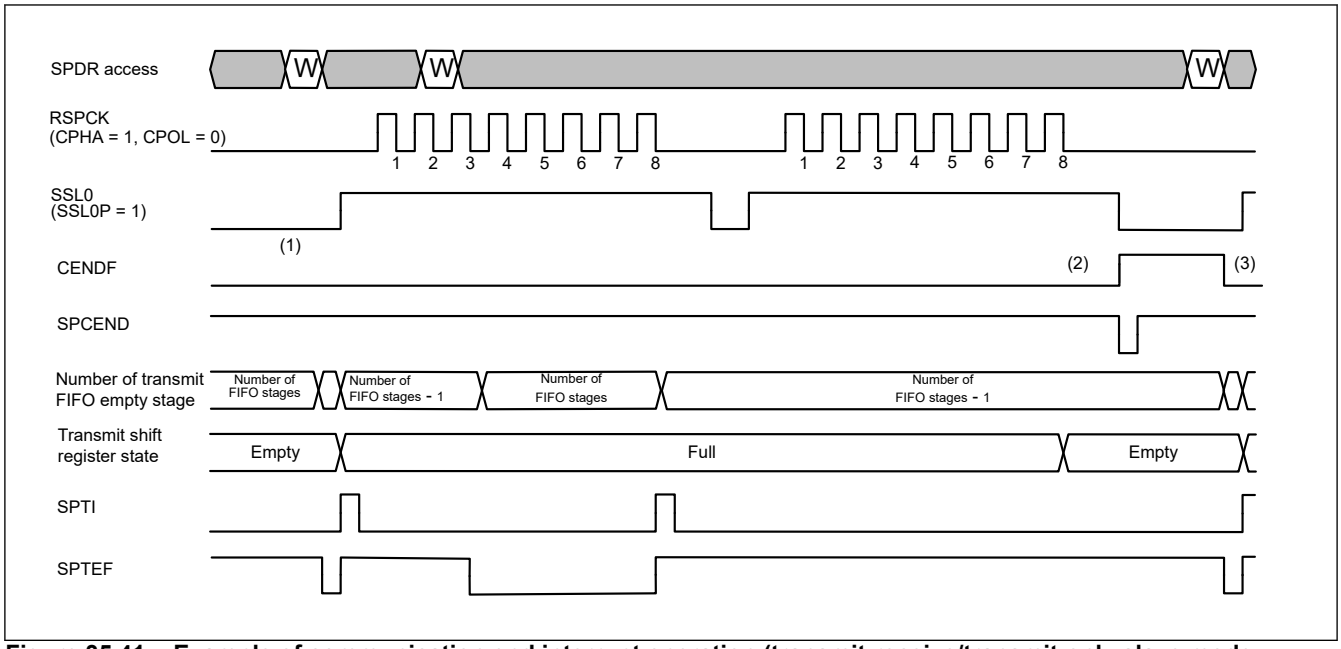

Figure 35.41 Example of communication end interrupt operation (transmit-receive/transmit-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the timing of SSL0 negate, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when the next transmition data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 35.42 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

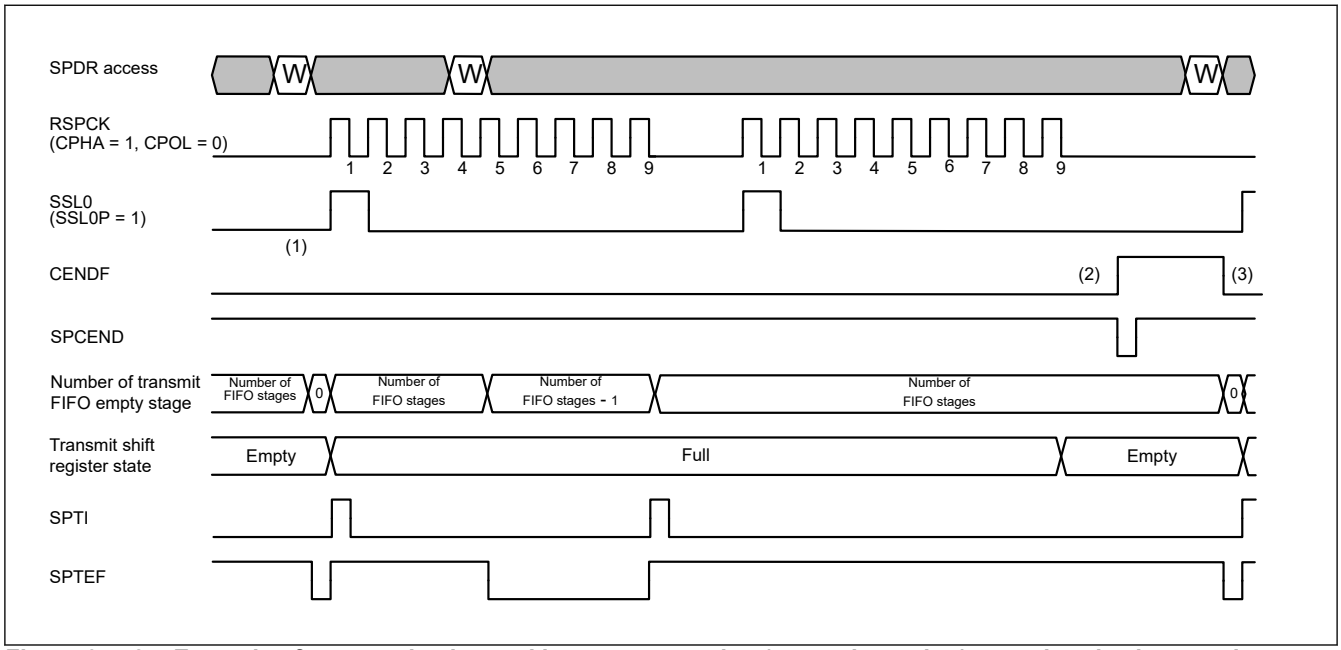

Figure 35.42 Example of communication end interrupt operation (transmit-receive/transmit-only slave mode on SPI operation / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

35.3.9.4 Receive Only in Slave Mode on SPI Operation (4-wire)

Refer to the description of the CENDF bit in section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 35.43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

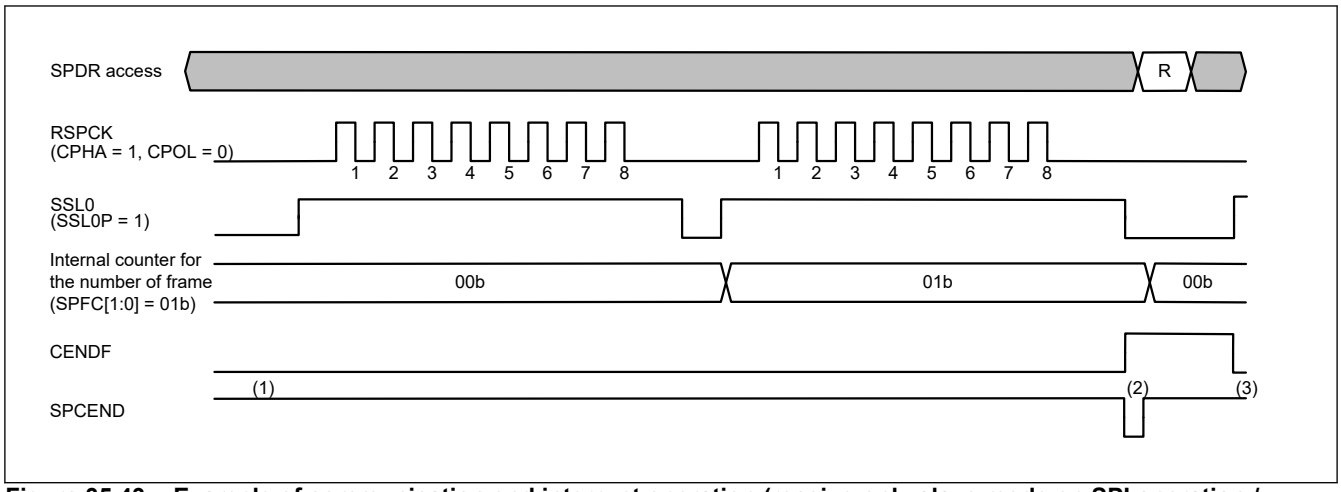

Figure 35.43 Example of communication end interrupt operation (receive-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) After store the frames for the SPDCR.SPFC register set value in the receive buffer, the CENDF flag becomes 1 (communication completed) at the timing of SSL0 negation. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 35.44 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

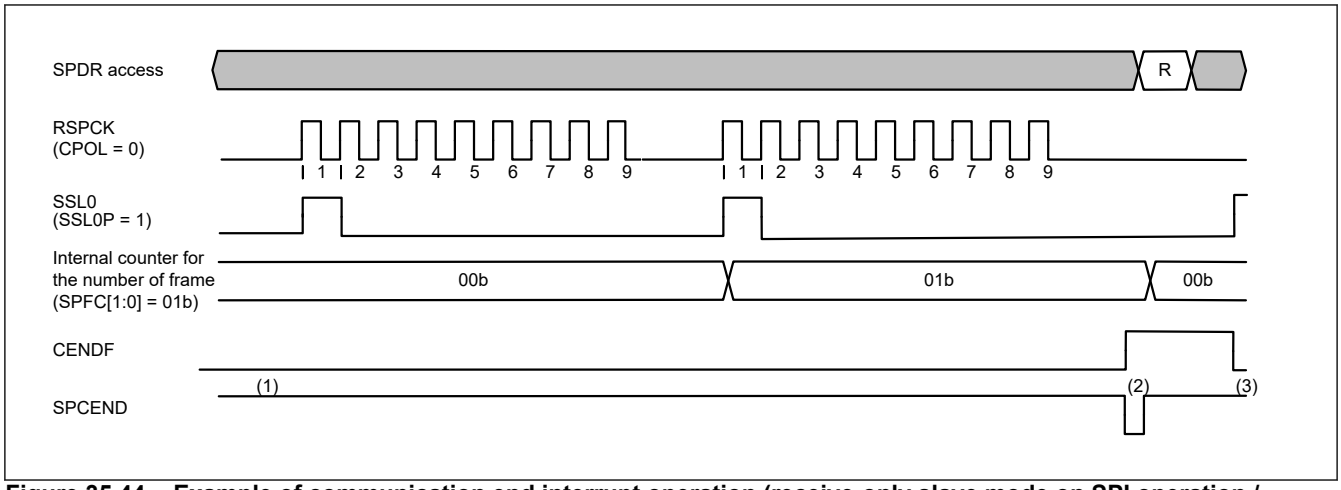

Figure 35.44 Example of communication end interrupt operation (receive-only slave mode on SPI operation / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the last frame transmission ends. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

35.3.9.5 Transmit-Receive/Transmit-only in Slave Mode on Clock Synchronous Operation (3-wire)

Refer to the description of the CENDF bit in section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

Figure 35.45 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

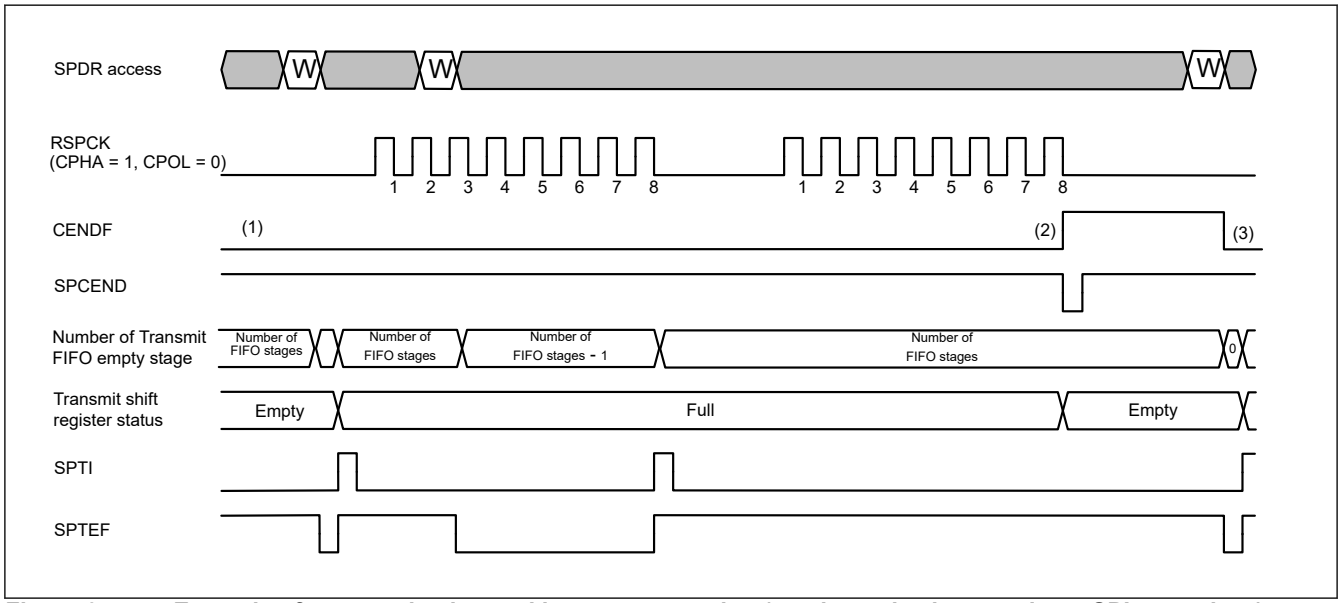

Figure 35.45 Example of communication end interrupt operation (receive-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, the SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

35.3.9.6 Receive only in Slave Mode on Clock Synchronous Operation (3-wire)

Refer to the description of the CENDF bit in section 35.2.19. SPTFSR : SPI Transfer FIFO Status Register and section 35.2.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive -only in Slave Mode on Clock Synchronous (3-wire).

Figure 35.46 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

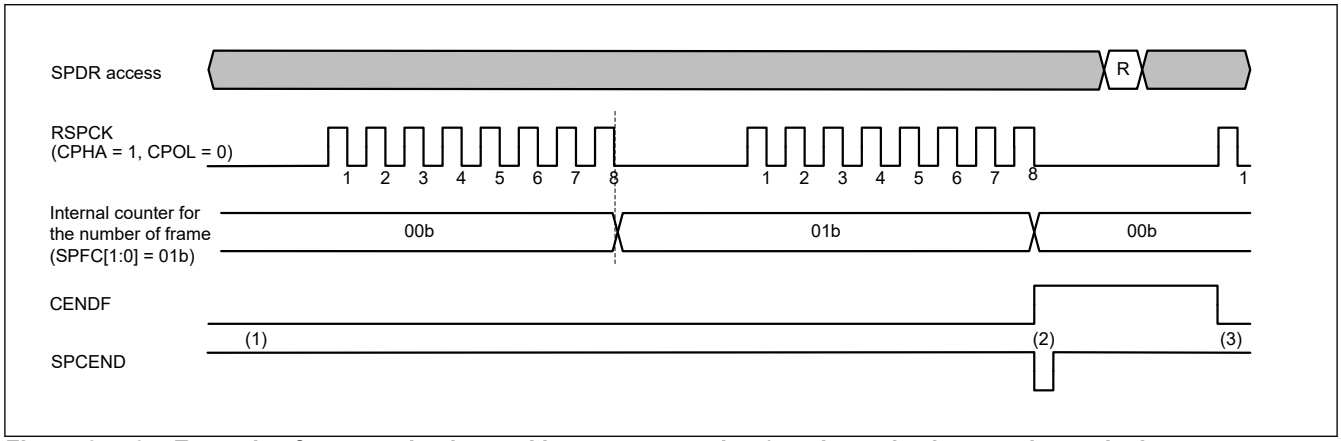

Figure 35.46 Example of communication end interrupt operation (receive-only slave mode on clock synchronous operation)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCK in the last frame communication when the last frame of the SPDCR.SPFC bit set value is received. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the first edge of RSPCK for the next transmission, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

35.3.9.7 Common Operation

In this Section, the operation common to each mode communication in section 35.3.9.1. Transmit-Receive/Transmit-only in Master Mode to section 35.3.9.6. Receive only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

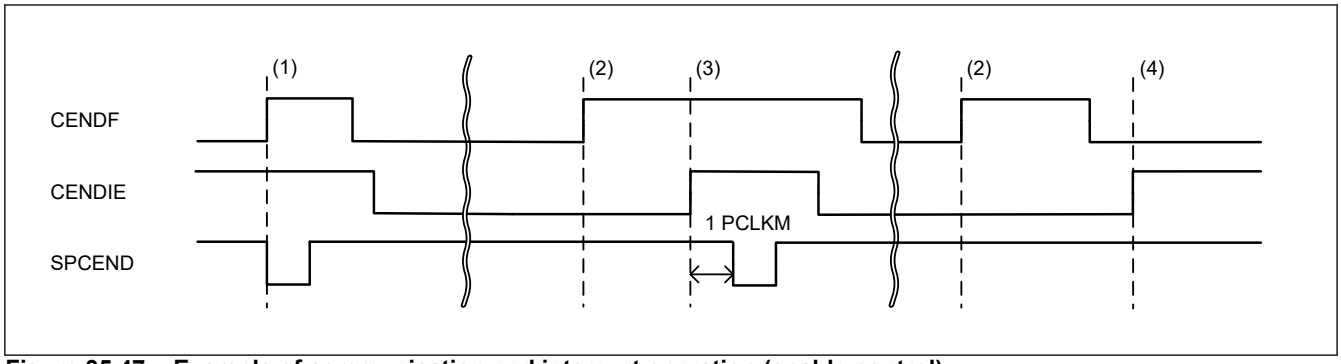

Figure 35.47 Example of communication end interrupt operation (enable control)

(1) When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following two are the same timing

a flag of communication end (CENDF)

the communication end interrupt

(2) When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following occurs, but no interrupt.

a flag of communication end (CENDF)

(3) After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKM.

(4) After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

35.3.10 Error Detection

In normal serial transfer of SPI, data written to the transmit buffer in the SPDR register is transmitted in serial and received serial data can be read from the SPDR's receive buffer. Depending on the transmit buffer or receive buffer status when SPDR is accessed and the SPI status at the start or end of serial transfer, abnormal transfer is performed.

When some abnormal transfer operation takes place, the SPI detects it as an underrun error, overrun error, parity error, or mode fault error. Table 35.10 shows the relationship between abnormal transfer operation and the SPI's error detection function.

Table 35.10 Abnormal transfer occurrence conditions and error detection function of SPI (1 of 2)

	Transfer occurrence condition	SPI operation	Error detection
1	SPDR is written when while no empty stages in the transmit FIFO.	• Transmit buffer data is retained. • No write data is present.	None
2	SPDR is read while no data stored in receive FIFO.	Received data and previously received serial data are read.	None
3	Serial transfer starts in transmit slave mode or transmit-only slave mode, before transmit data output is ready.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Receive FIFO data is retained. • No serial receive data is present.	Overrun error
5	Incorrect parity bit has been received with the parity function enabled in following mode. • Transmit / receive-only master mode • Transmit / receive slave mode • Receive-only slave mode	The parity error flag is asserted.	Parity error
6	The SSL0 input signal is asserted when the serial transfer is idle state in multi-master mode.	• Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error

Table 35.10 Abnormal transfer occurrence conditions and error detection function of SPI (2 of 2)

	Transfer occurrence condition	SPI operation	Error detection
7	The SSL0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error
8	[In the Motorola-SPI case] The SSL0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error
9	[In the TI-SSP case] The SSL0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error

The SPI does not detect any error for the operation shown in No.1 in Table 35.10. To prevent missing of data during SPDR writing, write data to SPDR upon a transmit buffer empty interrupt request or while the SPSR.SPTEF flag is 1.

The SPI does not detect any error also for the operation shown in No.2 in Table 35.10. To prevent reading of unnecessary data, read data from SPDR upon a receive buffer full interrupt request or while the SPSR.SPRF flag is 1.

The underrun error shown in No.3 in Table 35.10 is described in section 35.3.10.4. Underrun Error.

The overrun error shown in No.4 in Table 35.10 is described in section 35.3.10.1. Overrun Error.

The parity error shown in No.5 in Table 35.10 is described in section 35.3.10.2. Parity Error.

The mode fault error shown in No.6 to No.9 in Table 35.10 is described in section 35.3.10.3. Mode Fault Error.

For transmission and reception interrupts, see section 35.3.7. Transmission Buffer Empty/Receive Buffer Full Interrupt.

35.3.10.1 Overrun Error

When serial transfer ends while the receive buffer in the SPDR register is full, the SPI detects an overrun error and sets the OVRF flag in SPSR to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, data before an error occurs is retained in the receive buffer. To clear the OVRF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

Figure 35.48 shows operation of the SPRF flag and the OVRF flag in SPSR. "SPSR access" and "SPDR access" described in Figure 35.48 show an access to SPSR and SPDR respectively. "W" shows a write cycle and "R" shows a read cycle. In the example in Figure 35.48, the SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1 and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

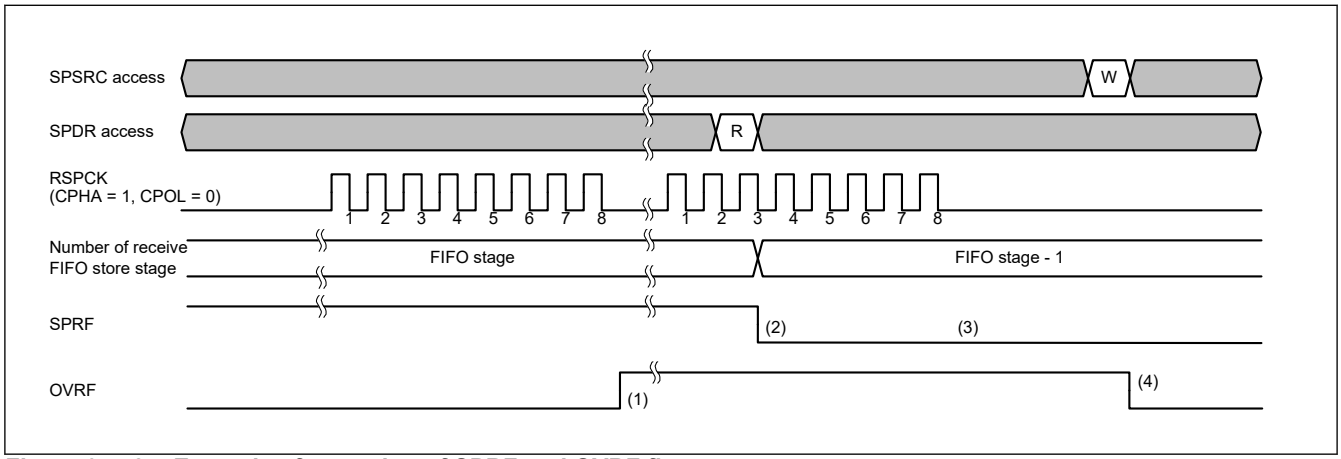

Figure 35.48 Example of operation of SPRF and OVRF flags

The following describes operation of flags at timings (1) to (4) in the figure above.

(1) When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity

error even when SPPE = 1. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits.

(2) The SPI can read receive buffer data by reading SPDR. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DMAC.

(3) When serial transfer ends while the OVRF flag is 1 (overrun error), the SPI does not copy shift register data to the receive buffer (SPRF flag remains 0) and no SPI receive buffer full interrupt is generated. The SPI does not detect a parity error even when SPPE = 1. In master mode, the SPI does not update the SPSSR.SPECM[2:0] bits. When the SPI does not copy received data from the shift register to receive buffer while an overrun error is present, the SPI also determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(4) When 1 is written to the SPSRC.OVRFC bit.

Whether an overrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To perform serial transfer without using an SPI error interrupt, read SPDR and then immediately read SPSR to quickly detect an overrun error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM bits. When an overrun error occurs and the OVRF flag is set to 1, successful reception is disabled until the OVRF flag is cleared to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 35.49 and Figure 35.50 show the clock stop waveform when a serial transfer continues while the reception buffer is full in master mode.

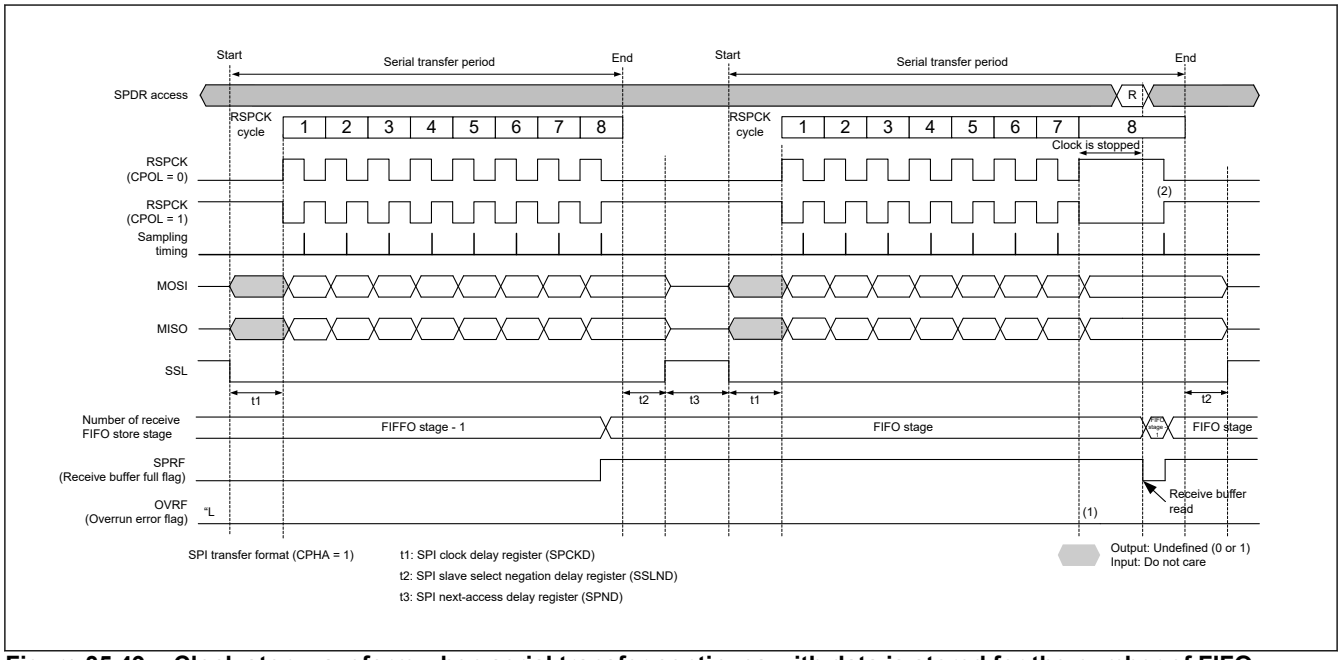

Figure 35.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 1)

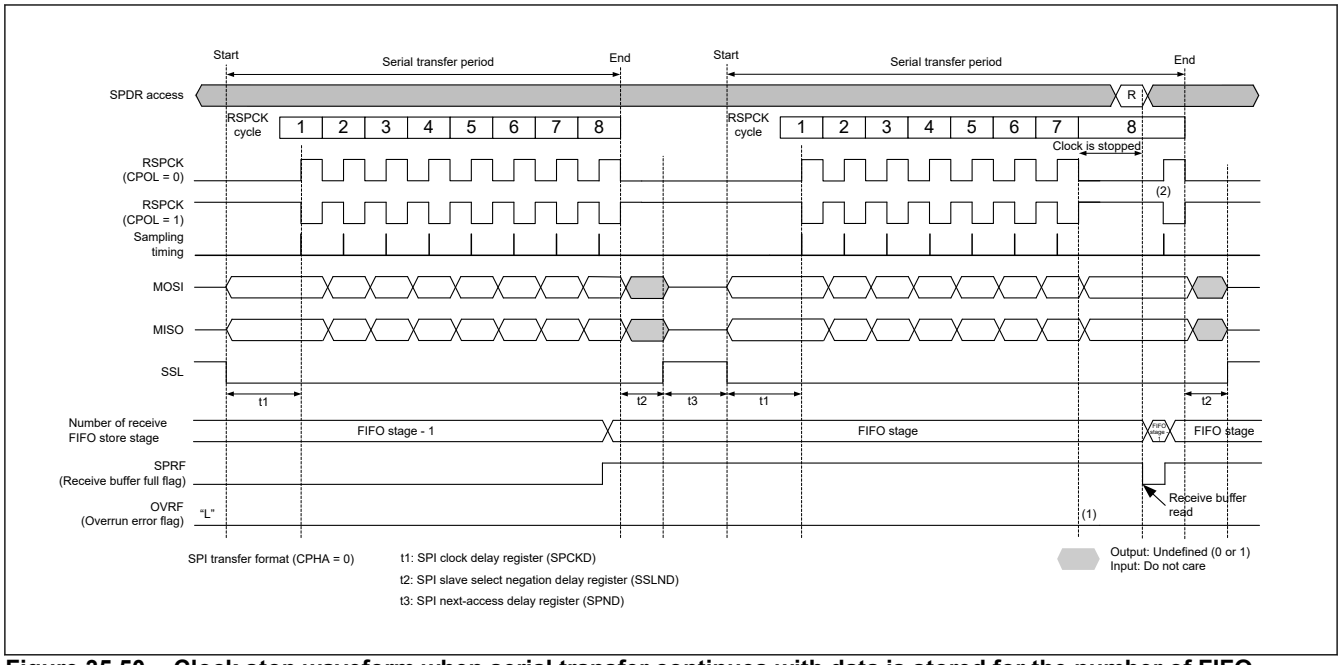

Figure 35.50 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. The Figure 35.51 and the Figure 35.52 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

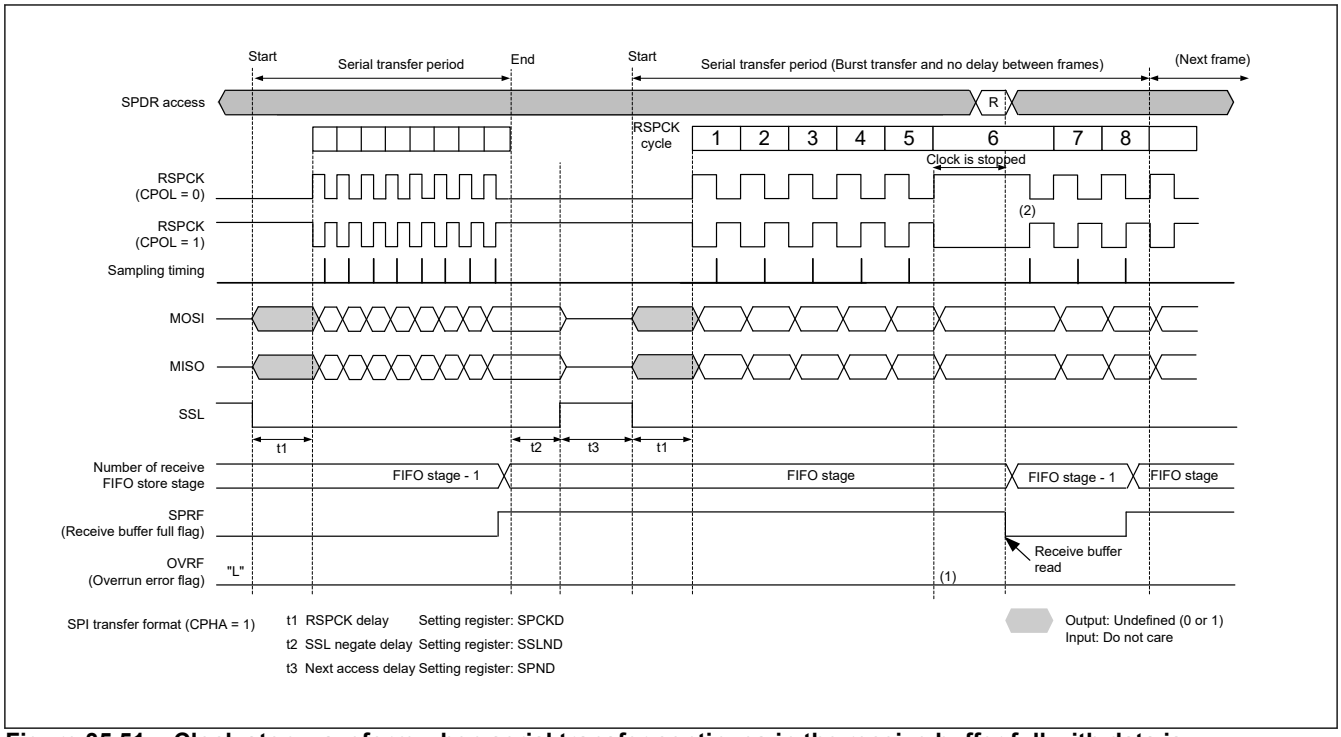

Figure 35.51 Clock stop waveform when serial transfer continues in the receive buffer full with data is stored for the number of FIFO stages in master mode (at burst transfer and no delay between frames CPHA = 1)

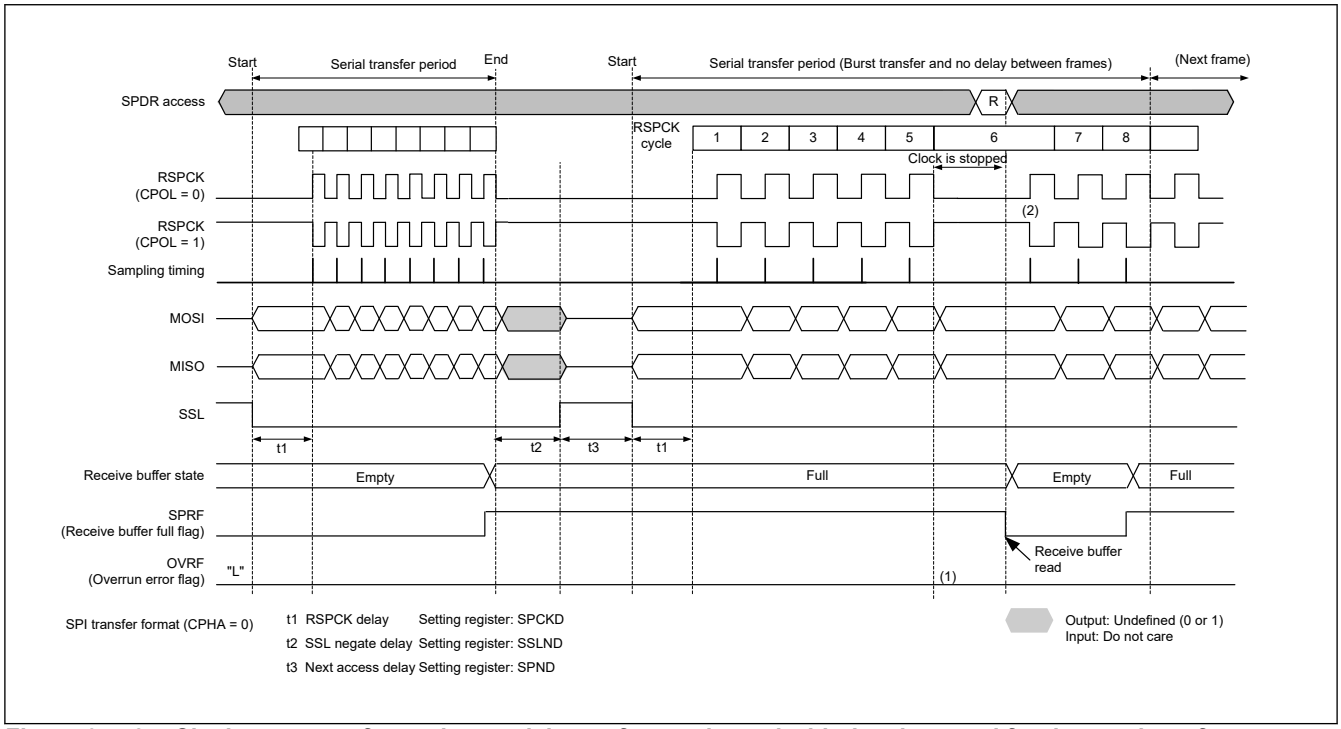

Figure 35.52 Clock stop waveform when serial transfer continues i with data is stored for the number of FIFO stages in master mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

35.3.10.2 Parity Error

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPCR.SPPE = 1, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPSR register is set to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or write 1 to the SPSRC.PERFC bit.

Figure 35.53 shows operation of the OVRF and PERF flags in SPSR. "SPSR access" described in Figure 35.53 shows an access to SPSR. "W" shows a write cycle and "R" shows a read cycle. In the example in Figure 35.53, the SPI performs transmit-receive serial communication while SPCR.SPPE = 1. The SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1 and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

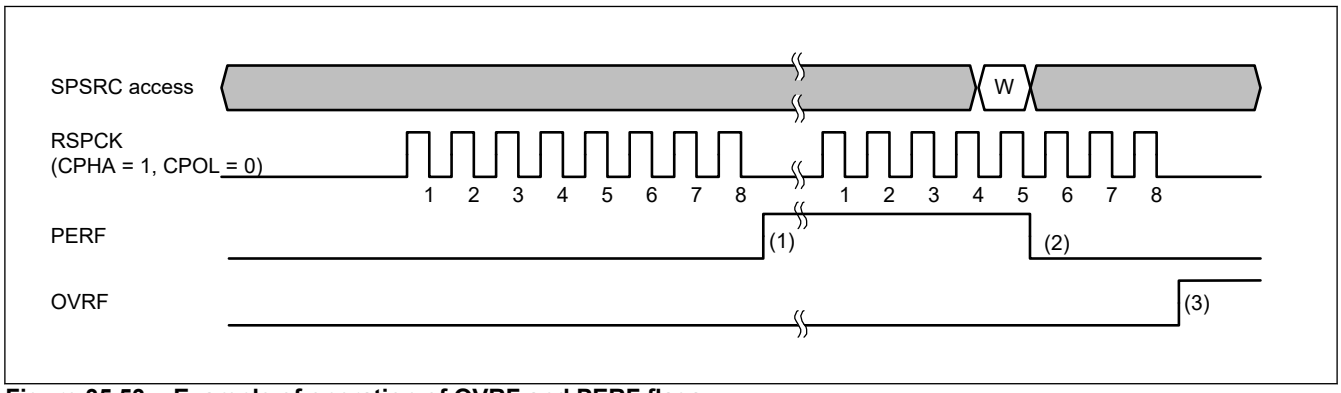

Figure 35.53 Example of operation of OVRF and PERF flags

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPCM [2:0] bits.

(2) When 1 is written to the SPSRC.PERFC bit.

(3) When the SPI detects an overrun error and terminates the serial transfer, the SPI does not copy shift register data to the receive buffer and does not detect a parity error.

Whether a parity error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To use an SPI error interrupt, set the SPCR.SPEIE bit to 1. To perform serial transfer without using an SPI error interrupt, read SPDR to quickly detect a parity error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

35.3.10.3 Mode Fault Error

When the SPCR.MSTR = 1, SPCR.SPMS = 0, and SPCR.MODFEN = 1, the SPI operates in multi-master mode. When an active level is input to the SSL0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of serial transfer status and sets the MODF flag in the SPSR register to 1. When a mode fault error is detected, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits. The SSL0 signal active level depends on the SSL0P bit in the SSLP register.

While SPCR.MSTR = 0, the SPI operates in slave mode. When SPCR.SPMS = 0 and SPCR.MODFEN = 1 in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error while any of the following 2 conditions is met.

(1) In the Motorola-SPI case

When the SSL0 input signal is negated while serial data transfer.

(2) In the TI-SSP case

When the SSL0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSL0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPCR.SPE bit.

When the SPE bit is cleared, the SPI function is disabled (as described in section 35.3.12. SPI Initialization). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

35.3.10.4 Underrun Error

While the SPI is operating in slave mode (SPCR.MSTR = 0) and the communication mode select SPCR.TXMD[1:0] bits are set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the MODF and UDRF flags in the SPSR register to 1.

When the SPI detects an underrun error, it stops driving output signals and clears the SPE bit to 0. When the SPE bit is cleared, the SPI function is disabled (as described in section 35.3.12. SPI Initialization)

Whether an underrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR.

To detect an underrun error without using an SPI error interrupt, poll SPSR.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after an underrun error is detected, clear the MODF flag to 0 without fail.

35.3.11 Received Data Ready Detection

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPDRCR.SPDRC[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPDR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs ≤ the threshold value and the value set in SPDRCR.SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt can be selected as SPRI or SPEI with the SPCR.SPDRES bit.

Figure 35.54 shows an example of reception data ready detection operation.

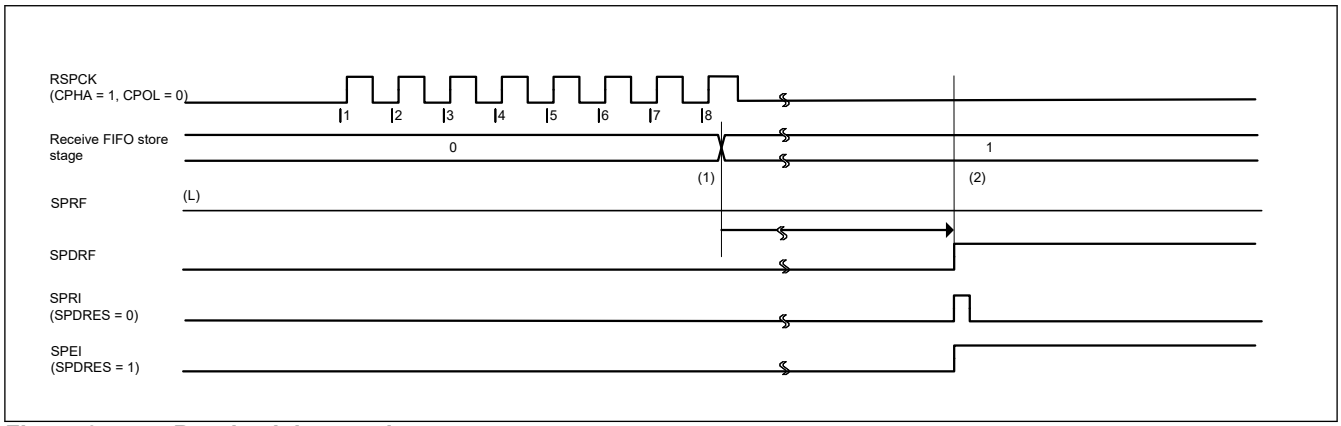

Figure 35.54 Received data ready

The following describes operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage ≤ RTRG.

(2) Set SPDRF and assert SPRI or SPEI because there is no writing to the receive FIFO for the amount of SPDRC[7:0] set from (1).

35.3.12 SPI Initialization

When 0 is written to the SPCR.SPE bit or when the SPI clears the SPE bit to 0 after it detects a mode fault error or an underrun error, the SPI disables the SPI function and initializes a part of module functions. Furthermore, the SPI initializes

all module functions when a system reset occurs. The following describes initialization by clearing the SPCR.SPE bit and by using a system reset.

35.3.12.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is cleared to 0, the SPI performs the following initialization:

- Suspends the ongoing serial transfer.
- Stops driving output signals (Hi-Z) in slave mode.
- Resets the internal SPI state.
- SPSR.SPTEF flag = 1.

In initialization by clearing the SPE bit, control bits in SPI are not initialized. For this reason, re-setting the SPE bit to 1 activates the SPI with the pre-initialization transfer mode.

Values of the CENDF flag, the SPRF flag, OVRF flag, MODF flag, PERF flag, and UDRF flag in SPSR are not initialized. The SPSSR register value is not initialized either. For this reason, it is possible to read receive buffer data and check the communication completion status and the error status during SPI transfer also after the SPI is initialized.

SPSR.SPTEF flag is initialized to 1. Therefore, if the SPCR.SPTIE bit is set to 1 after the SPI is initialized, an SPI transmit buffer empty interrupt is generated. When the CPU initializes the SPI, write 0 to the SPE bit and the SPTIE bit to disable an SPI transmit buffer empty interrupt.

35.3.12.2 System Reset

In initialization by using a system reset, all SPI control bits, status bits, and data register are initialized in addition to the initialization described in section 35.3.12.1. Initialization by Clearing the SPE Bit to completely initialize the SPI.

35.3.13 SPI Operation

35.3.13.1 Master Mode Operation

Single master mode operation and multi-master mode operation are different from each other only in mode fault error detection (see section 35.3.10. Error Detection). The SPI in single master mode (SPI) detects no mode fault error.

The SPI in multi-master mode detects a mode fault error. The following describes operations common to single master mode and multi-master mode.

(1) Starting a Serial Transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR.

While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format). The SSL output signal polarity depends on the set SSLP register value.

(2) Terminating a Serial Transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format).

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer.
- When writing SPCRRM.RMEDTG = 1 during the serial transfer period, the SPI terminates the serial transfer.

When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format).

(3) Sequence Control

The transfer format in master mode is determined as follows.

The transfer format in master mode is determined by the SPSCR register, SPCMDm (m = 0 to 7) register, SPBR register, SPCKD register, SSLND register, and SPND register.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. The SSL output signal value, MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7.

A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPE bit in the SPCR register is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

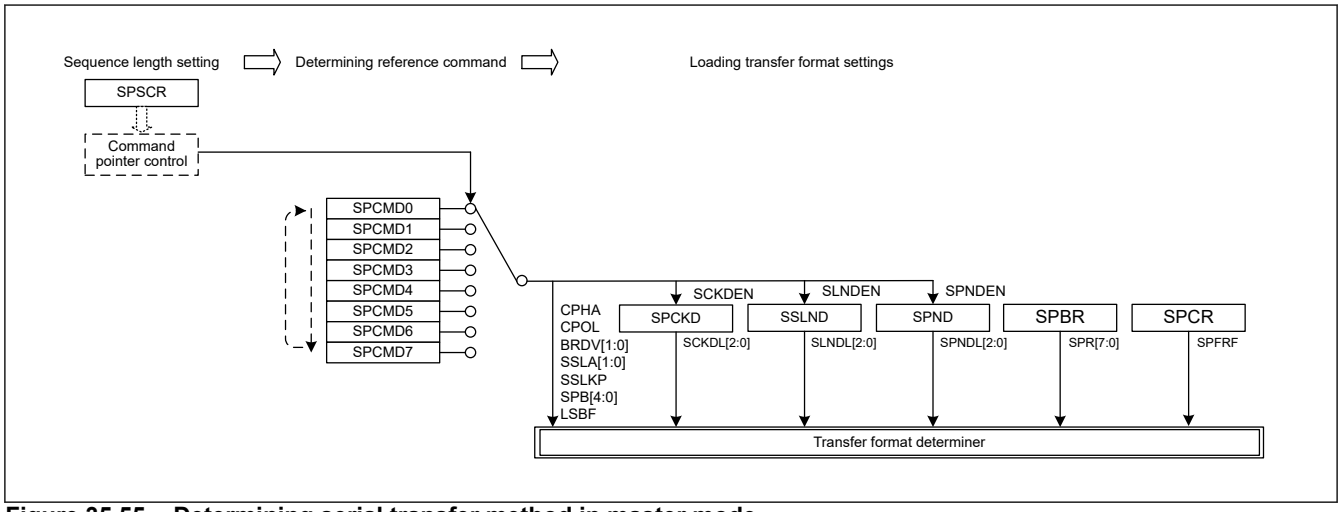

Figure 35.55 Determining serial transfer method in master mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm).

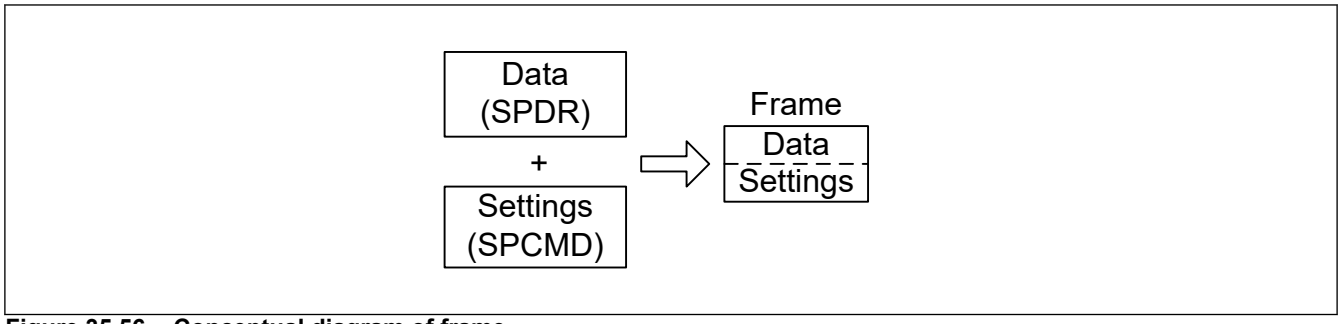

Figure 35.56 Conceptual diagram of frame

Figure 35.57 shows the correspondence between the SPI command register and transmit buffer (SPTXn, n = 0 to 3)/receive buffer (SPRXn, n = 0 to 3) in the sequence operation.

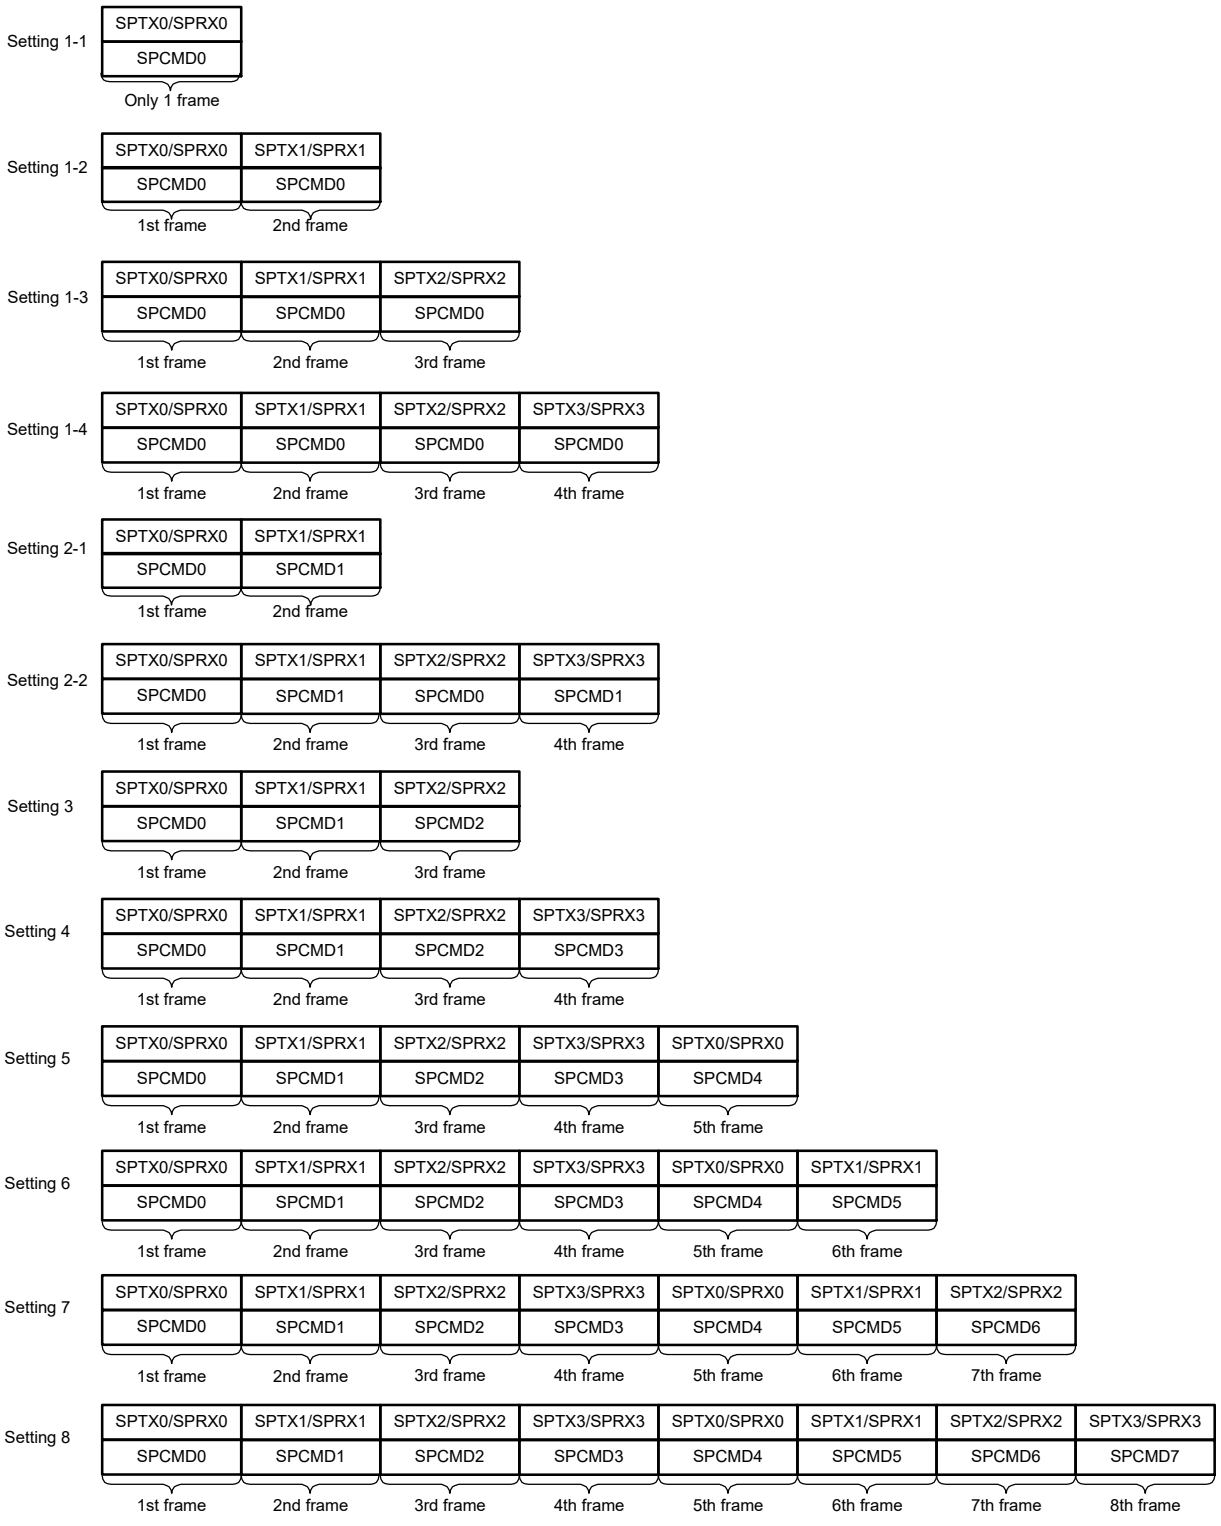

Figure 35.57 Correspondence between SPI command register and transmit/receive buffers in sequence operation

(4) Burst Transfer

This section describes burst transfer during transmit-receive / transmit-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0

Figure 35.58 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 35.58. The SSL output signal polarity depends on the set the SSLP register.

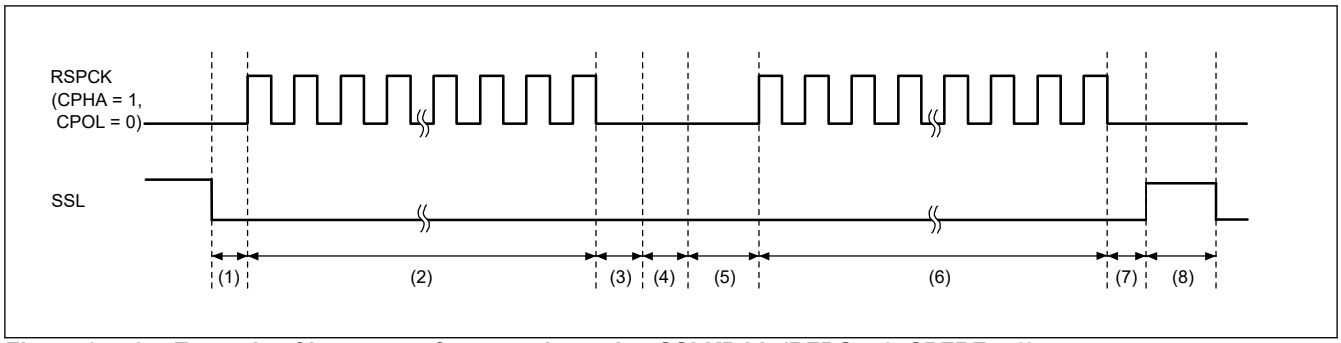

Figure 35.58 Example of burst transfer operation using SSLKP bit (BFDS = 0, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1. This period additionally continues for 5 PCLKSPIn cycles (at minimum) that is the same as the next-access delay time of SPCMD0. When the shift register is empty after the minimum period has passed, this period continues until transmit data for the next transfer is stored in the shift register.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 35.3.13. SPI Operation.)

(b) SPCR.BFDS = 1

Figure 35.59 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 35.59. The SSL output signal polarity depends on the set SSSLP register value.

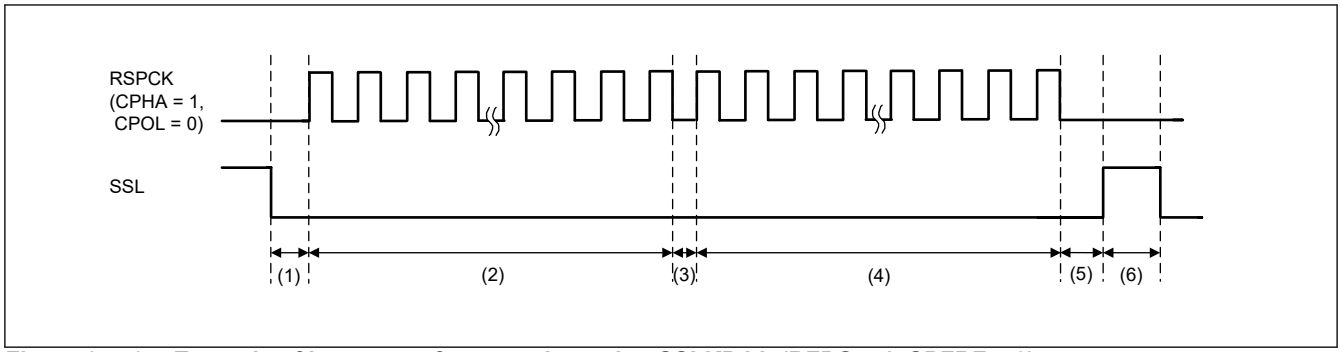

Figure 35.59 Example of burst transfer operation using SSLKP bit (BFDS = 1, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmisshon.

(2) Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.

(3) The value of SSL signal according to SPCMD0 was hold, because SPCMD0.SSLKP = 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(a) SPCMD.SSLKP = 1 and SPCR.BFDS = 1

SPCMD0 to SPCMD1 are shown in Figure 35.60. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

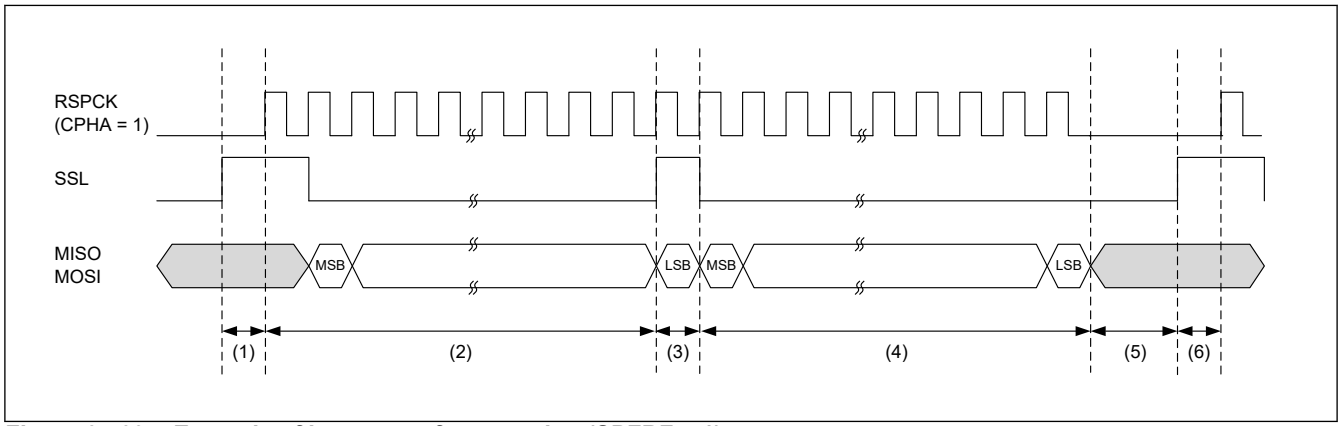

Figure 35.60 Example of burst transfer operation (SPFRF = 1)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because the SPCMD1.SSLKP = 0.

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0

Figure 35.61 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 35.61. The SSL output signal polarity depends on the set SSLP register value.

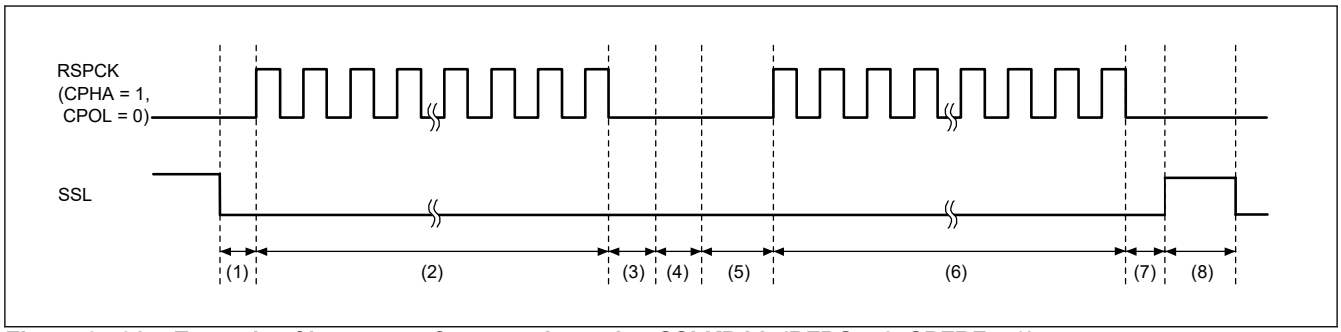

Figure 35.61 Example of burst transfer operation using SSLKP bit (BFDS = 0, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1. This period additionally continues for 5 PCLKSPIn cycles (at minimum) that is the same as the next-access delay time of SPCMD0.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1

If the SSL signal output setting and the SSL signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 35.3.13. SPI Operation.)

(b) SPCR.BFDS = 1

Figure 35.62 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 35.62. The SSL output signal polarity depends on the set SSLP register value.

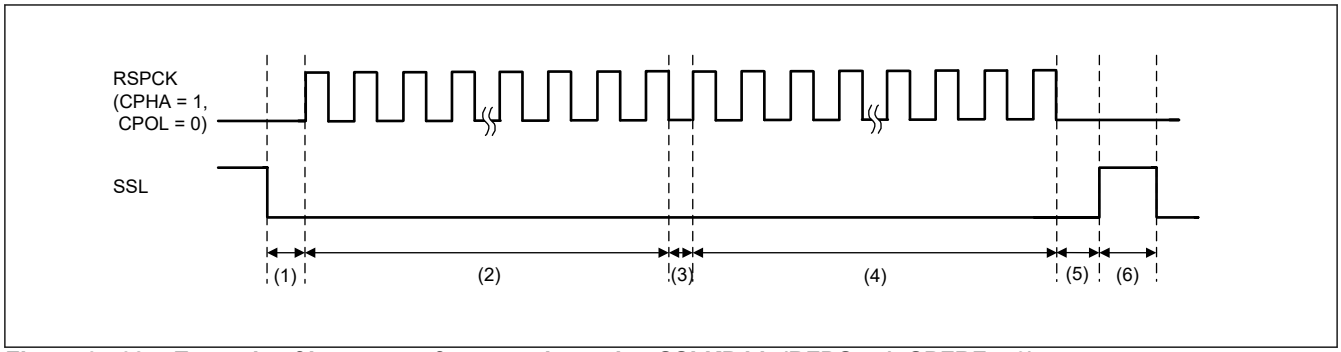

Figure 35.62 Example of burst transfer operation using SSLKP bit (BFDS = 1, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Since it is not the last frame, the SSL signal value at SPCMD0 is retained. RSPCK negation between frames is 0.5 RSPCK for the next frame.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last time.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCRRM.RMEDTG = 1 has been accepted.

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(a) SPCMD.SSLKP = 1 and SPCR.BFDS = 1

SPCMD0 to SPCMD1 are shown in Figure 35.63. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SSLP register value.

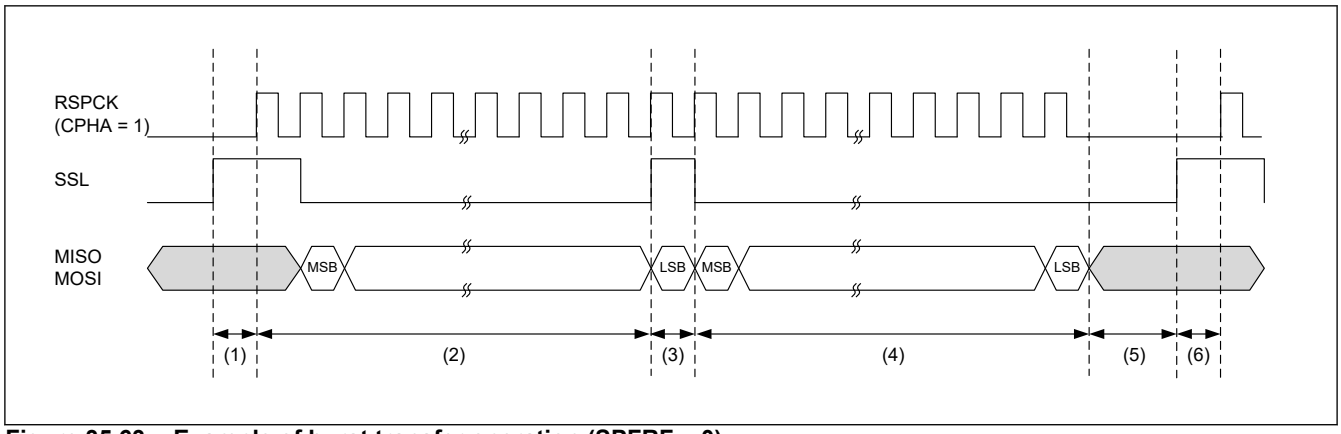

Figure 35.63 Example of burst transfer operation (SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously.

(4) Perform serial transfer according to SPCMD1.

(5) Insert Output disable delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCRRM.RMEDTG = 1 has been accepted.

If the SSL signal output setting between the SPCMDs used for burst transfer differs from the SSL signal output setting, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK Delay (t1)

The RSPCK delay value of the SPI in master mode depends on the settings of the SPCMD.SCKDEN and SPCKD.SCKDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SCKDEN bit and SPCKD.SCKDL[2:0] bits as shown in Table 35.11. For the definition of RSPCK delay, see section 35.3.5. Transfer Format (Frame Format).

RSPCK delay insert to only the first frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 35.11 Relationship between SCKDEN/SPCKD and RSPCK delay value

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay value	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the SPI in master mode depends on the settings of the SPCMD.SLNDEN bit and SSLND.SLNDL[2:0]. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the SSL negation delay value for serial transfer by using the selected SPCMD.SLNDEN and SSLND.SLNDL[2:0] as shown in Table 35.12. For the definition of SSL negation delay, see section 35.3.5. Transfer Format (Frame Format).

SSL negate delay insert to only the last frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 35.12 Relationship between SSLND and SSL negation delay value (1 of 2)

SLNDEN	SSLND.SLNDL[2:0] bits	SSL negation delay value
0	000b to 111b	1 RSPCK cycle

Table 35.12 Relationship between SSLND and SSL negation delay value (2 of 2)

SLNDEN	SSLND.SLNDL[2:0] bits	SSL negation delay value
1	000b	1 RSPCK cycle
	001b	2 RSPCK cycle
	010b	3 RSPCK cycle
	011b	4 RSPCK cycle
	100b	5 RSPCK cycle
	101b	6 RSPCK cycle
	110b	7 RSPCK cycle
	111b	8 RSPCK cycle

(7) Next-Access Delay (t3)

The next-access delay value of the SPI in master mode depends on the settings of the SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits as shown in Table 35.13. For the definition of next-access delay, see section 35.3.5. Transfer Format (Frame Format).

Next-Access delay insert to only the last frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 35.13 Relationship between SPNDEN bit, SPND bits, and next-access delay value

SPNDEN bit	SPND.SPNDL[2:0] bits	Next-access delay value
0	000b to 111b	1 RSPCK + 5 PCLKSPIn cycle
1	000b	1 RSPCK + 5 PCLKSPIn cycle
	001b	2 RSPCK + 5 PCLKSPIn cycle
	010b	3 RSPCK + 5 PCLKSPIn cycle
	011b	4 RSPCK + 5 PCLKSPIn cycle
	100b	5 RSPCK + 5 PCLKSPIn cycle
	101b	6 RSPCK + 5 PCLKSPIn cycle
	110b	7 RSPCK + 5 PCLKSPIn cycle
	111b	8 RSPCK + 5 PCLKSPIn cycle

(8) Initialization Flowchart

Figure 35.64 shows an example of initialization flow when using the SPI in master-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

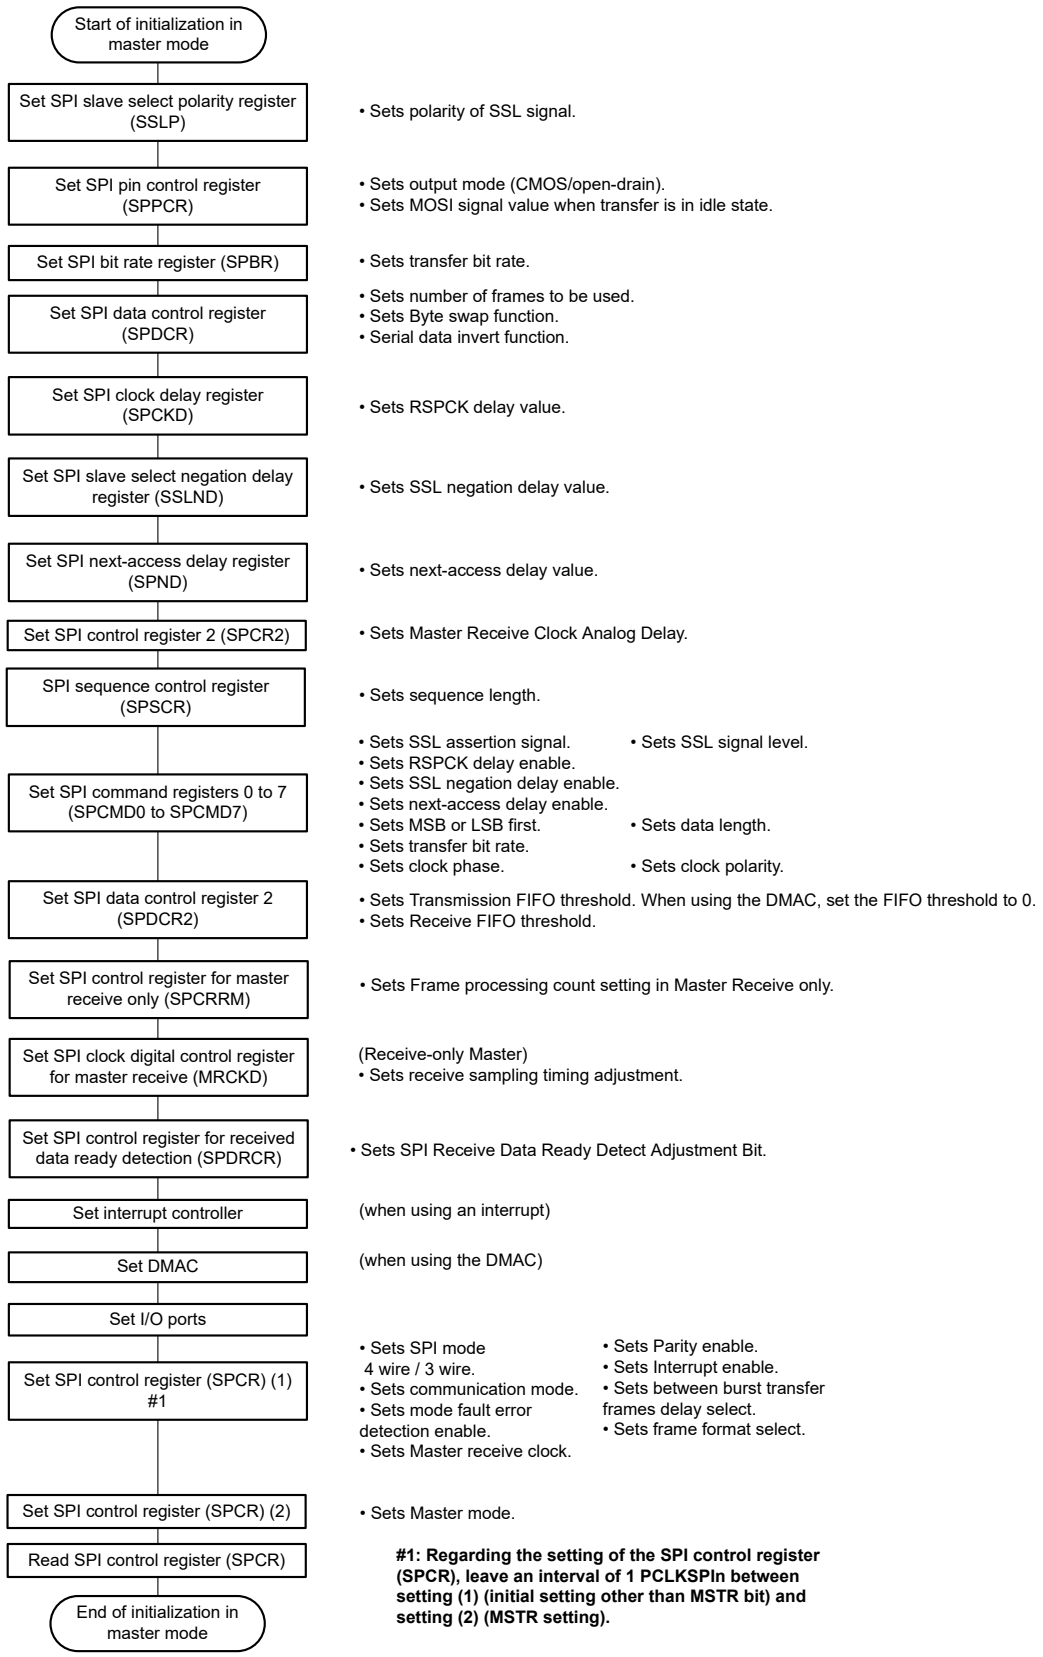

Figure 35.64 Example of initialization flowchart in master mode (SPI operation)

(9) Software Processing Flow

Figure 35.65 to Figure 35.68 show examples of the flow of software processing.

(a) Transmit Processing Flow

Enabling an SPII or SPCEND interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.

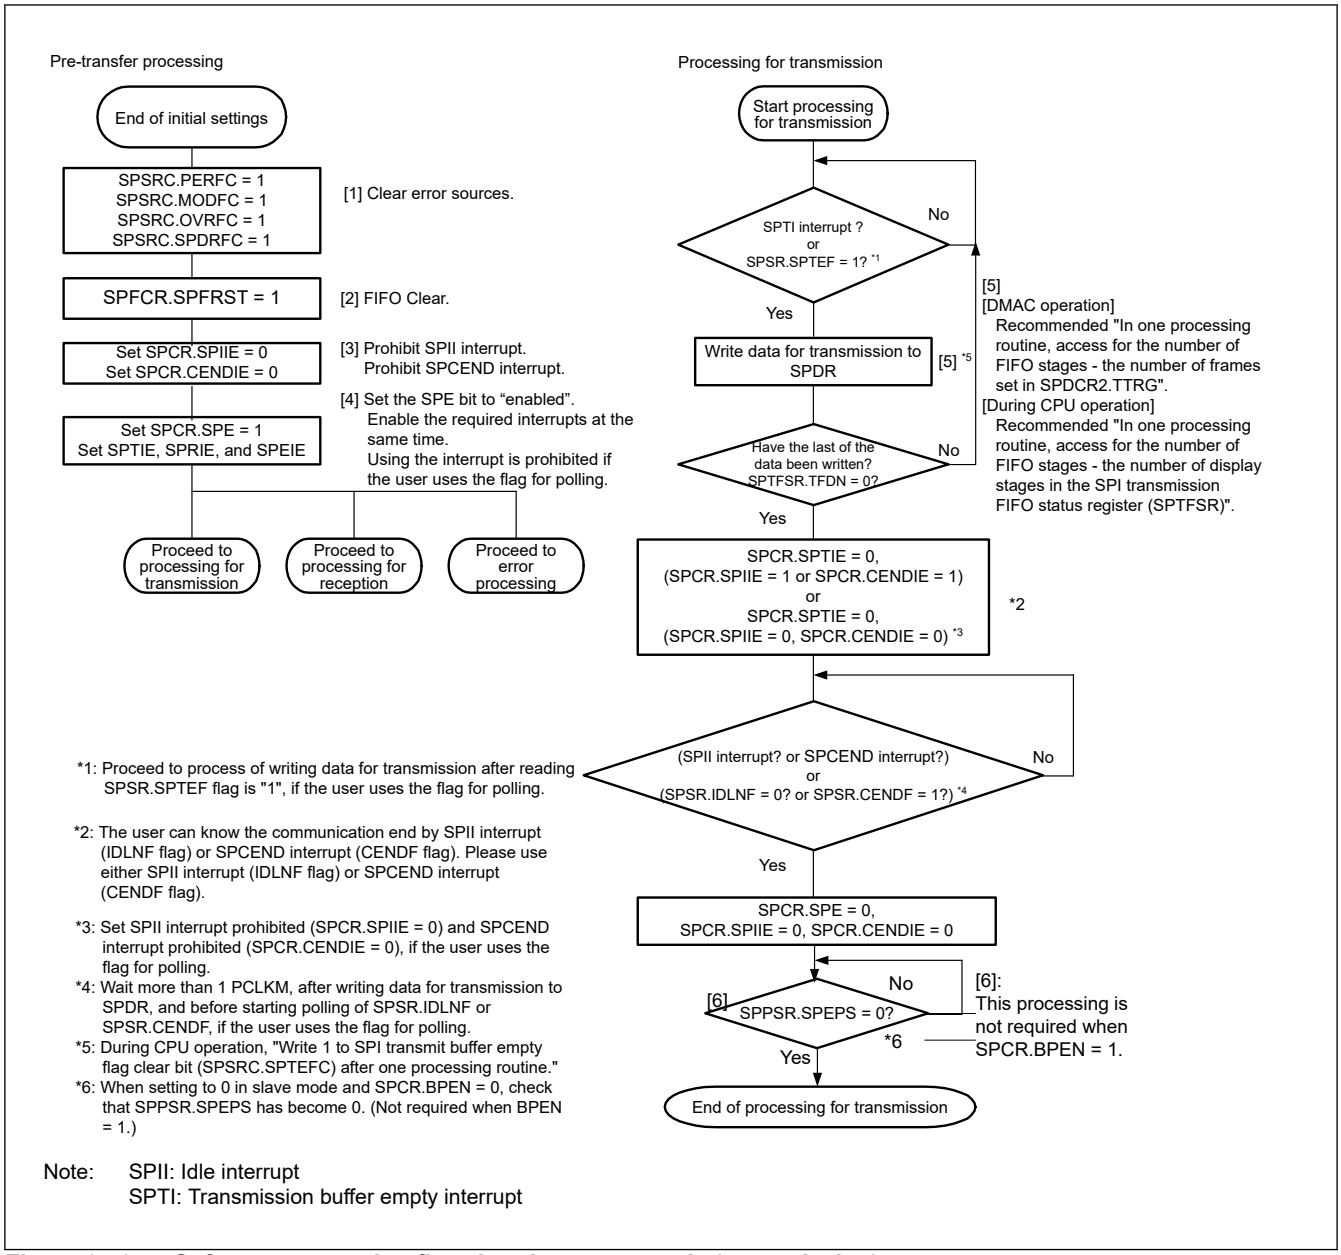

Figure 35.65 Software processing flowchart in master mode (transmission)

(b) Reception Processing Flow

The SPI always requires transmission because it does not have reception-only operation.

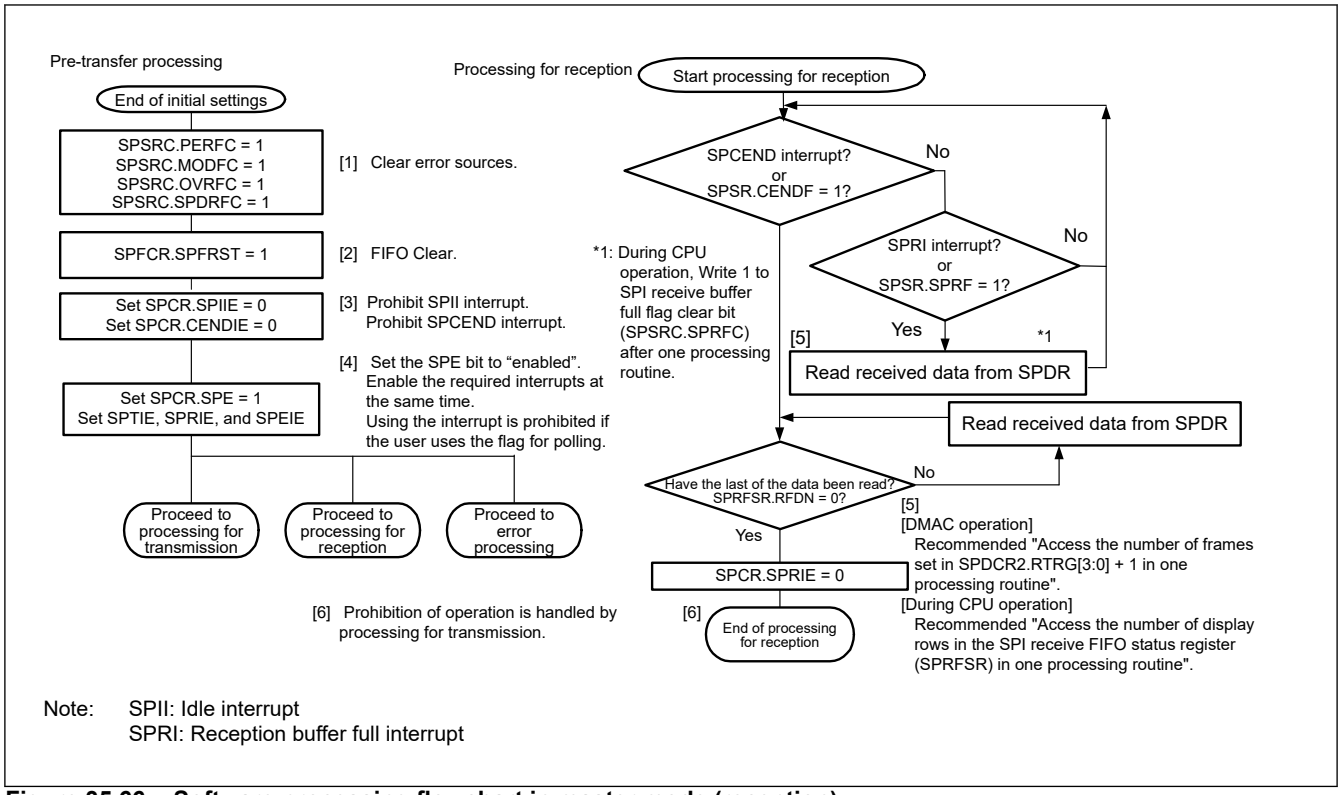

Figure 35.66 Software processing flowchart in master mode (reception)

(c) Master Reception-only processing flow

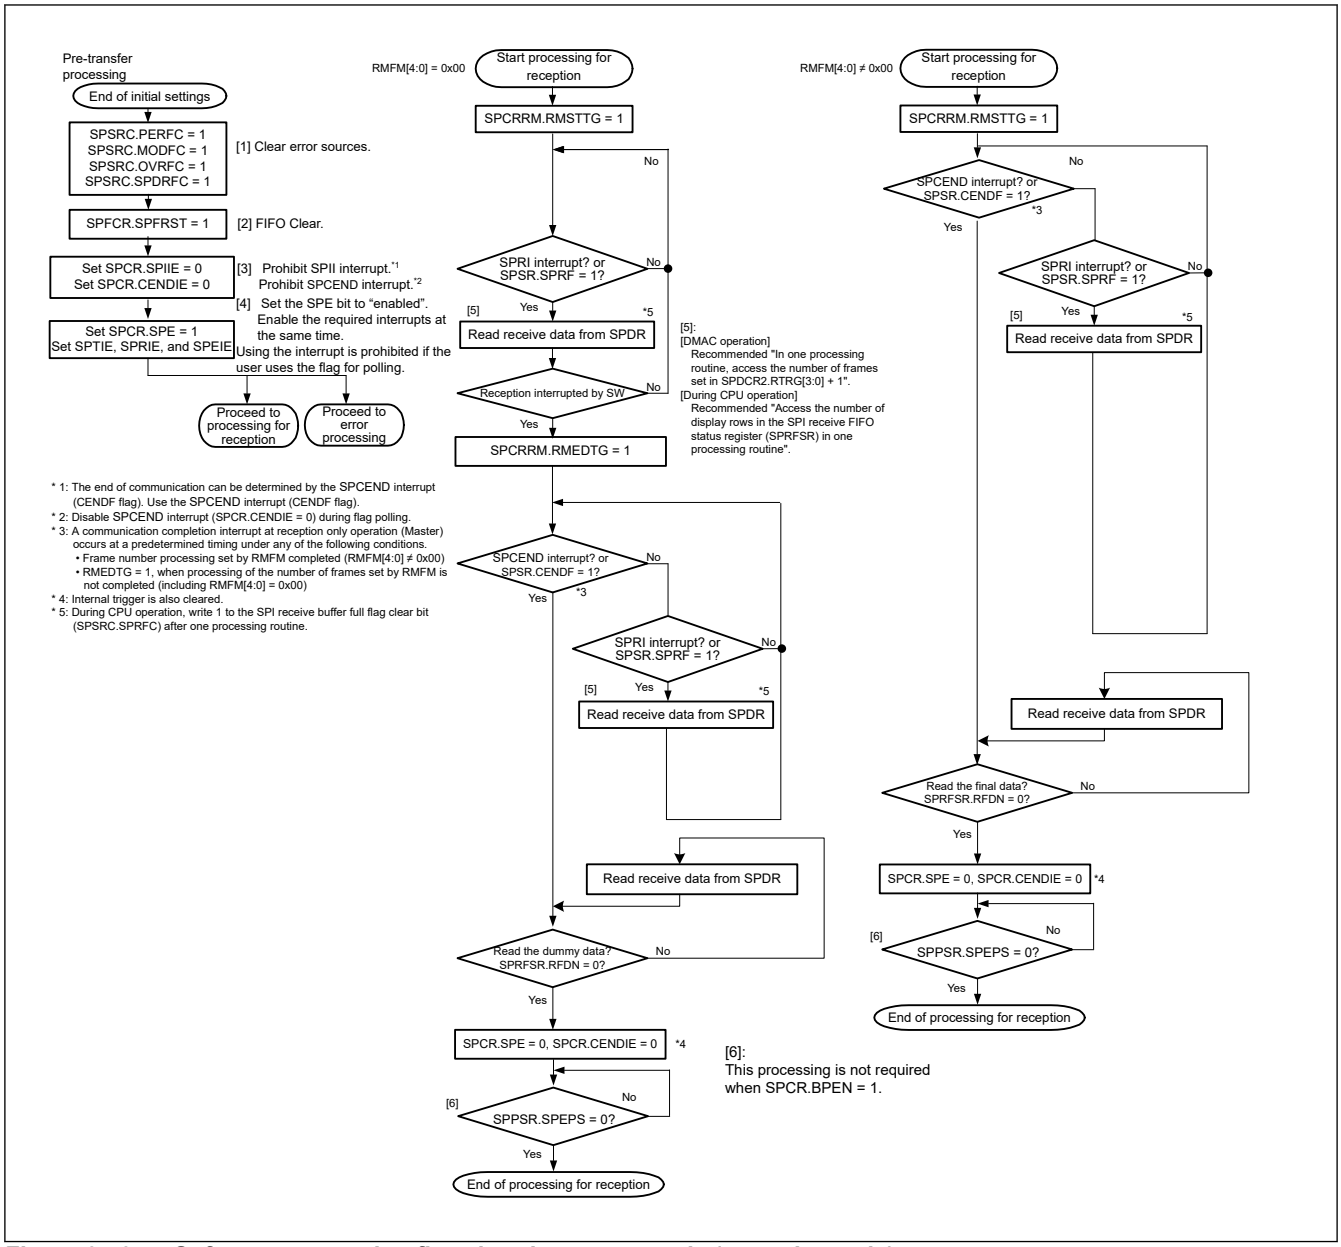

Figure 35.67 Software processing flowchart in master mode (reception-only)

(d) Error processing flow

When a mode fault error occurs, the SPE bit is automatically cleared to stop transmission and reception operations.

However, other error sources do not clear the SPE bit or stop transmission and reception operations. For this reason, if an error occurs due to another source different from the source of the error occurred first, the SPECM[2:0] value is updated. Therefore, we recommend that you clear the SPE bit to stop the ongoing operation.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.

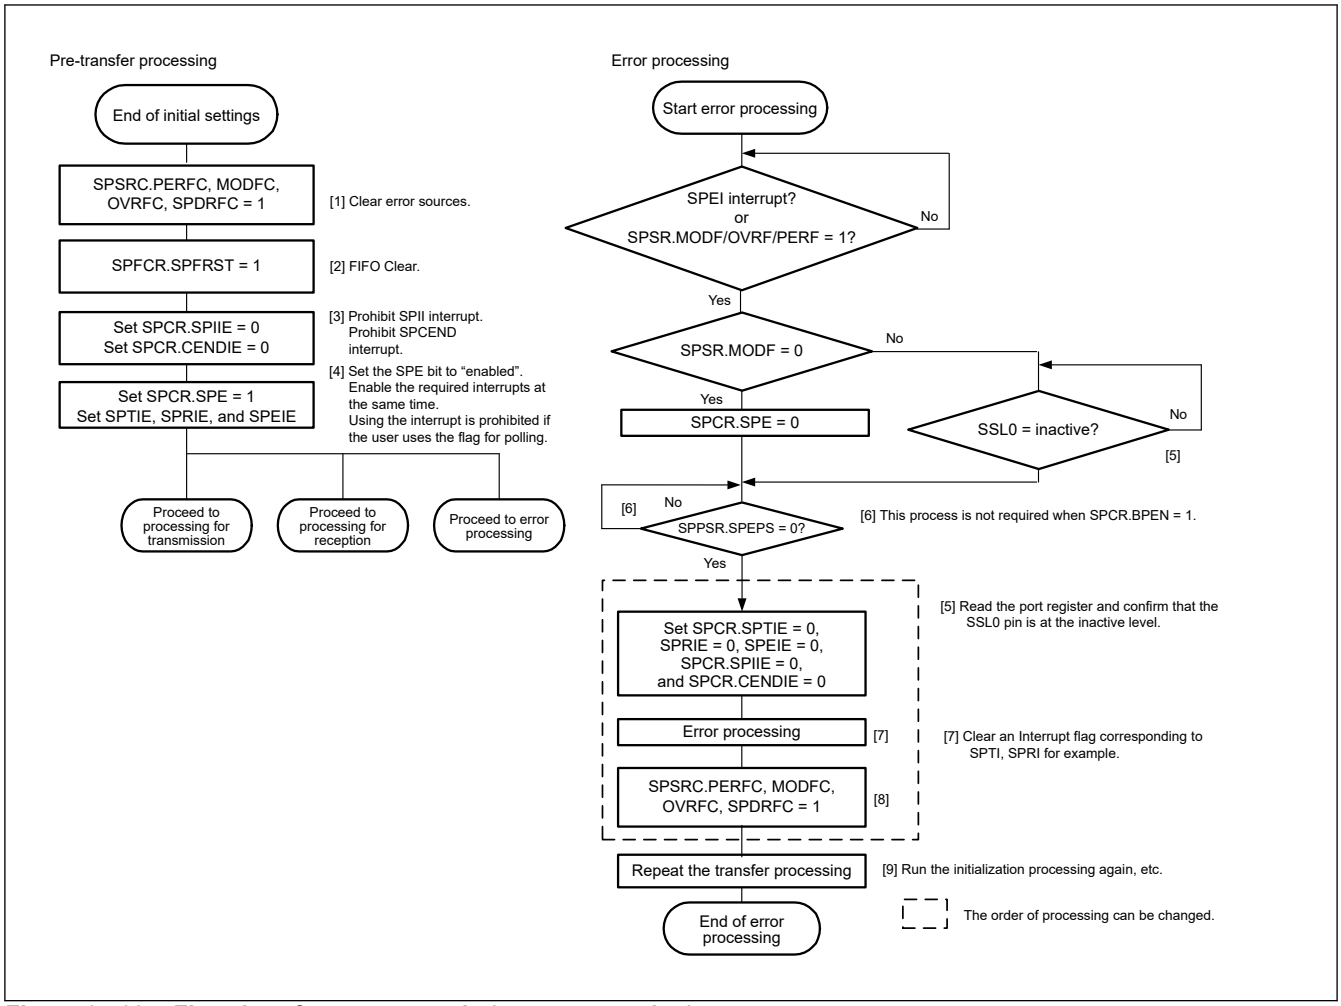

Figure 35.68 Flowchart for master mode (error processing)

35.3.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPI detects SSL0 input signal assertion while SPCMD0.CPHA = 0, valid data drive to the MISO output signal must be started. For this reason, the SSL0 input signal assertion becomes a trigger to start serial transfer.

While SPCMD0.CPHA = 1, when the SPI detects the first RSPCK edge with the SSL0 input signal asserted, valid data drive to the MISO output signal must be started. For this reason, the first RSPCK edge in the SSL0 signal assertion state becomes a trigger to start serial transfer when SPCMD0.CPHA = 1.

The SPI starts driving the MISO output signal at the SSL0 signal assertion timing independently of the CPHA bit setting. Data that the SPI outputs is enabled or disabled depending on the set CPHA bit value.

For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format). The SSL0 input signal polarity depends on the set SSL0P bit value in the SSLP register.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing regardless of the value of SPCMD0.CPHA bit, the SPI terminates serial transfer. When the number of data stored in the receive FIFO is smaller than the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. When the SPI detects SSL0 input signal negation during a period from serial transfer start to the end of serial transfer, a mode fault error occurs. (See section 35.3.10. Error Detection.)

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. The SSL0 input signal polarity depends on the set value of SSLP.SSL0P bit. For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format).

(3) Notes on Single-Slave Operations

[In the Motorola-SPI case]

Upon detecting the SSL0 input signal assertion edge while SPCMD0.CPHA = 0, the SPI starts serial transfer. When using the SPI in single slave mode in a configuration as shown in the example in Figure 35.9, the SPI cannot start serial transfer correctly while CPHA is set to 0 because the SSL0 input signal is always active. To correctly perform transmission and reception of the SPI in slave mode in a configuration where the SSL0 input signal is fixed to active state, set the CPHA bit to 1. If the CPHA bit needs to be set to 0, do not fix the SSL0 input signal.

[In the TI-SSP case]

When TI SSP is set, when SPI is used as a single slave in the configuration shown in the example of Figure 35.9, the SSL0 input signal is always fixed to the inactive state, SPI cannot start serial transfer correctly.

When using a single slave, use the configuration shown in the example in Figure 35.8.

(4) Burst Transfer

[In the Motorola-SPI case]

When SPCMD0.CPHA = 1, continuous serial transfer (burst transfer) is possible while maintaining the SSL0 input signal assertion state. When SPCMD0.CPHA = 1, the period (from the first RSPCK edge in the SSL0 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL0 input signal is always at the active level, start of an access can be detected, which allows burst transfer.

When SPCMD0.CPHA = 0, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSL input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL input signal, SSL must be asserted between frames.

(5) Initialization Flowchart

Figure 35.69 shows an example of initialization flow when using the SPI in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

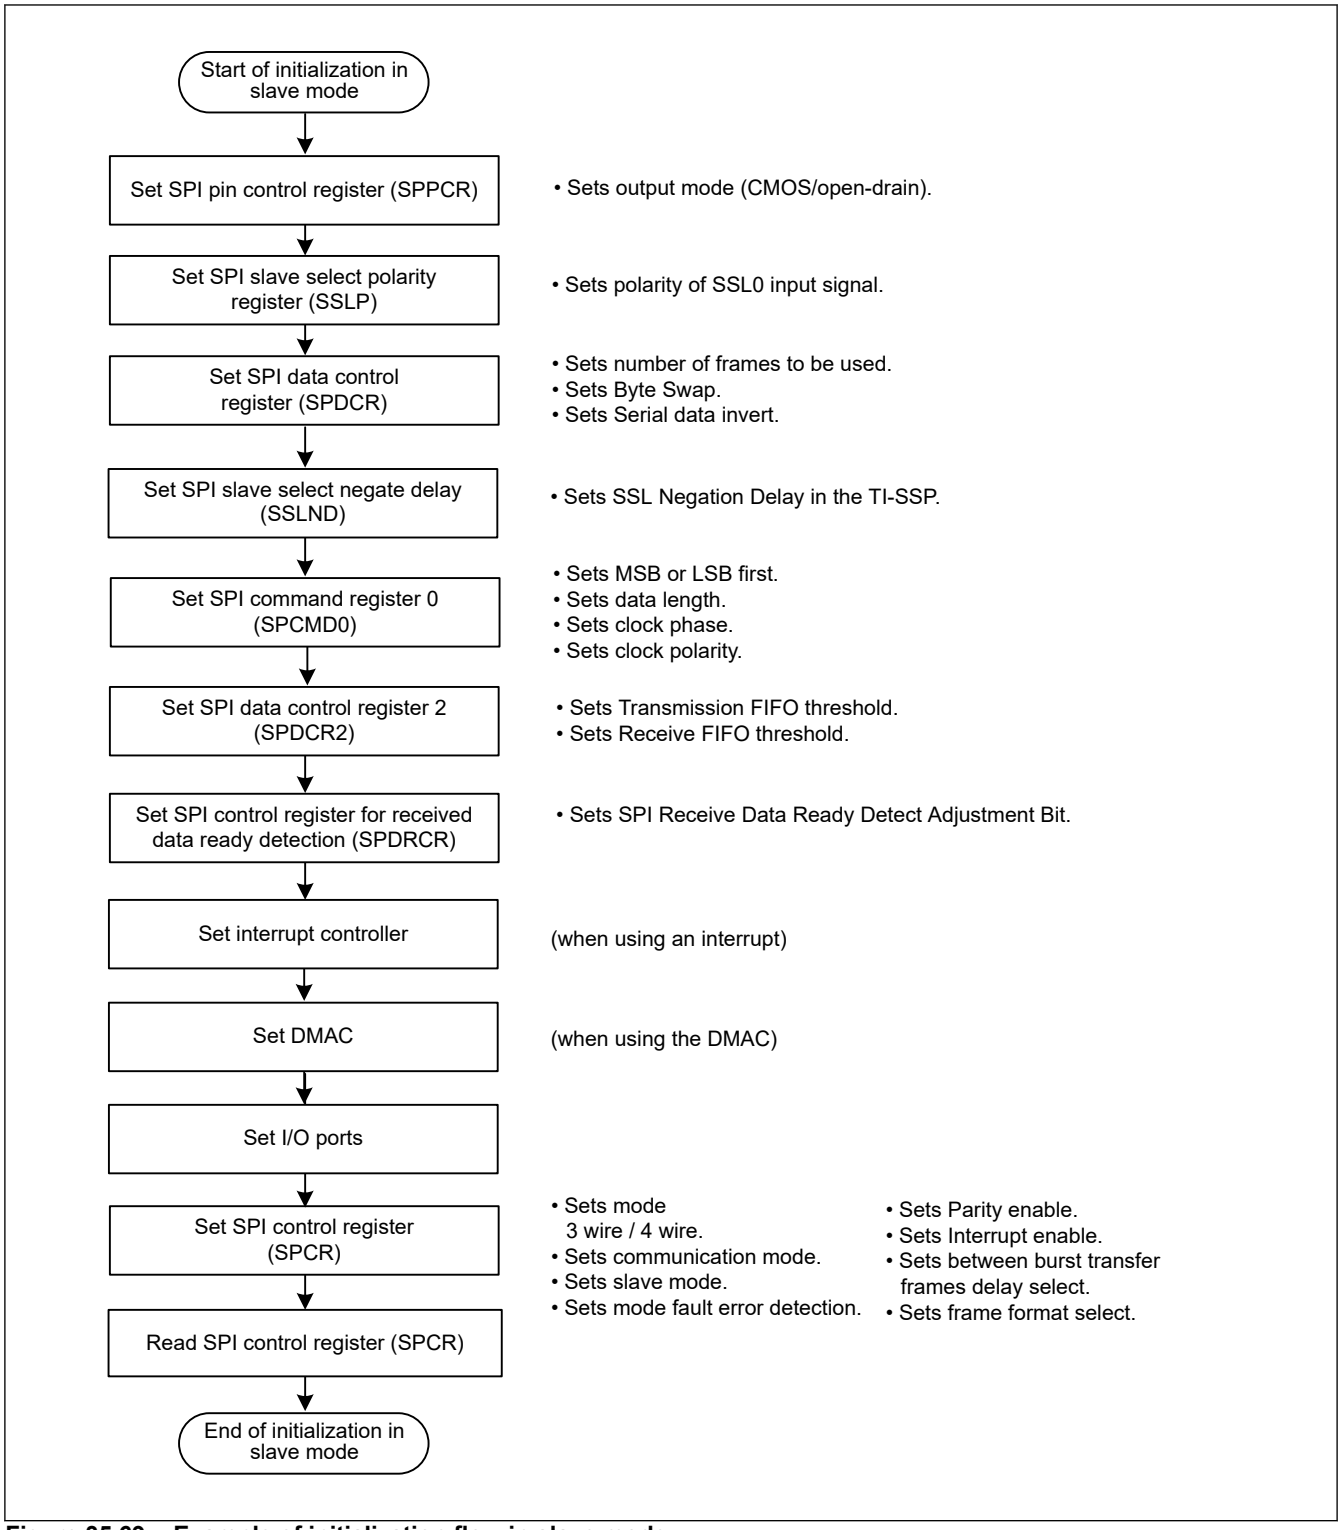

Figure 35.69 Example of initialization flow in slave mode

(6) Software Processing Flow

Figure 35.70 to Figure 35.73 show examples of the flow of software processing.

(a) Transmit Processing Flow

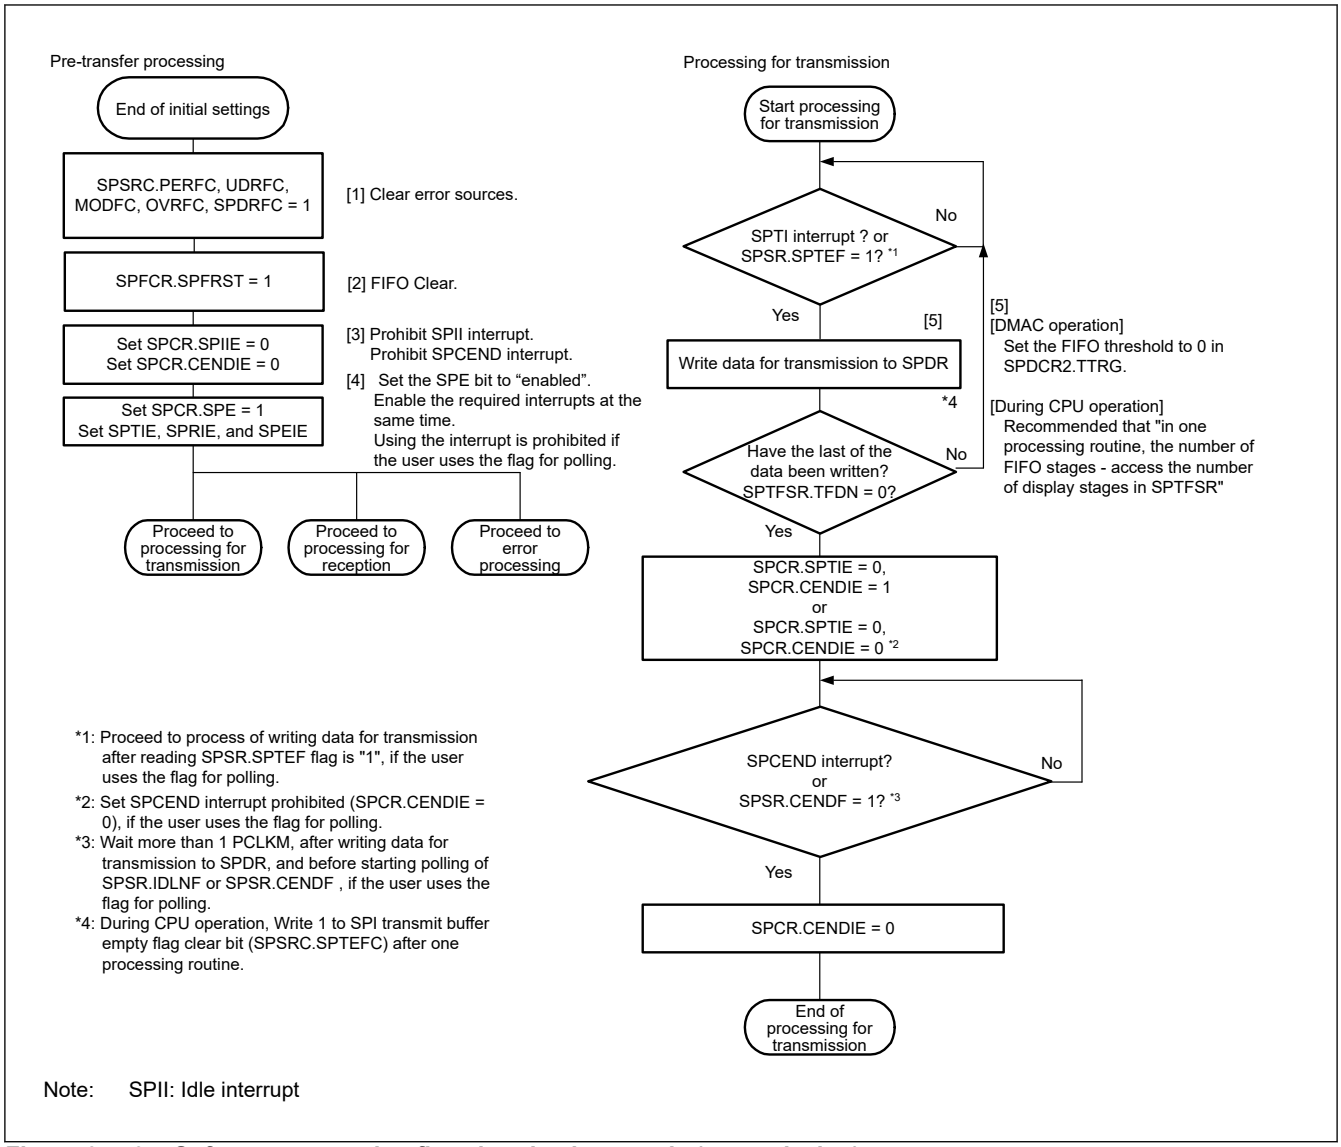

Figure 35.70 Software processing flowchart in slave mode (transmission)

(b) Reception Processing Flow

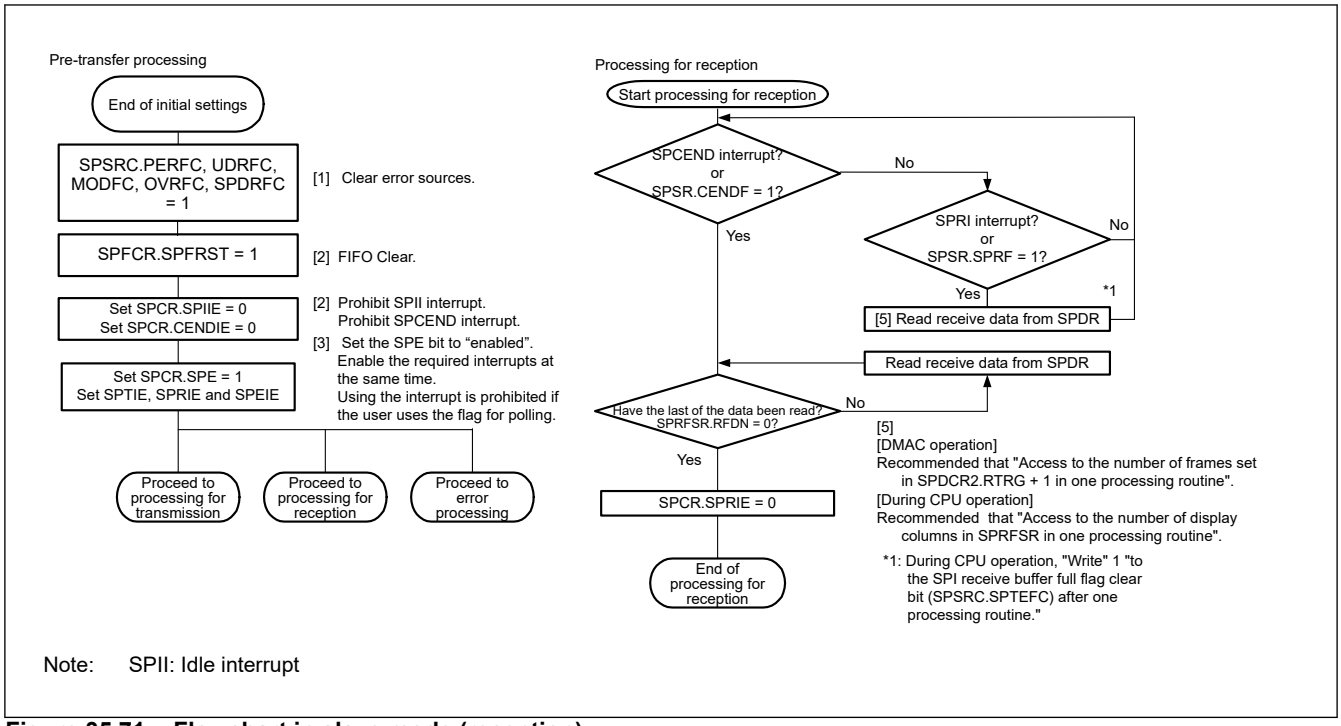

Figure 35.71 Flowchart in slave mode (reception)

(c) Master Reception-only processing Flow

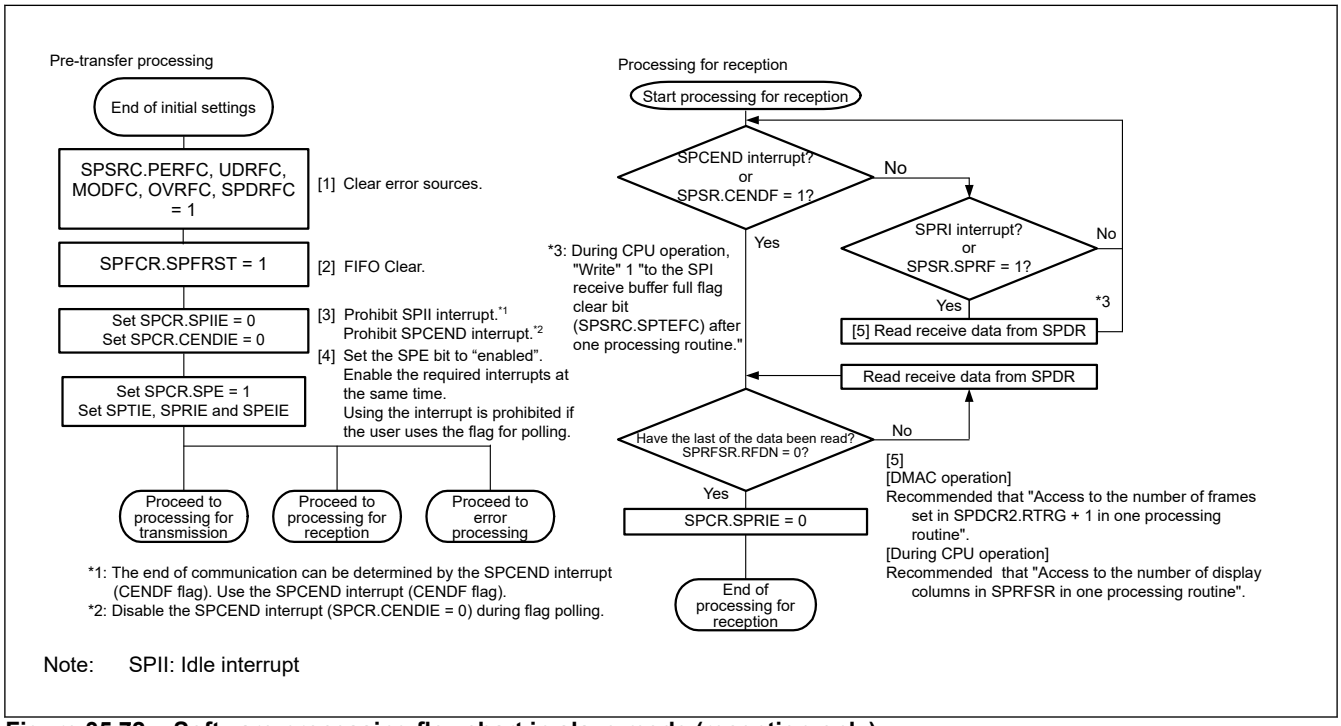

Figure 35.72 Software processing flowchart in slave mode (reception-only)

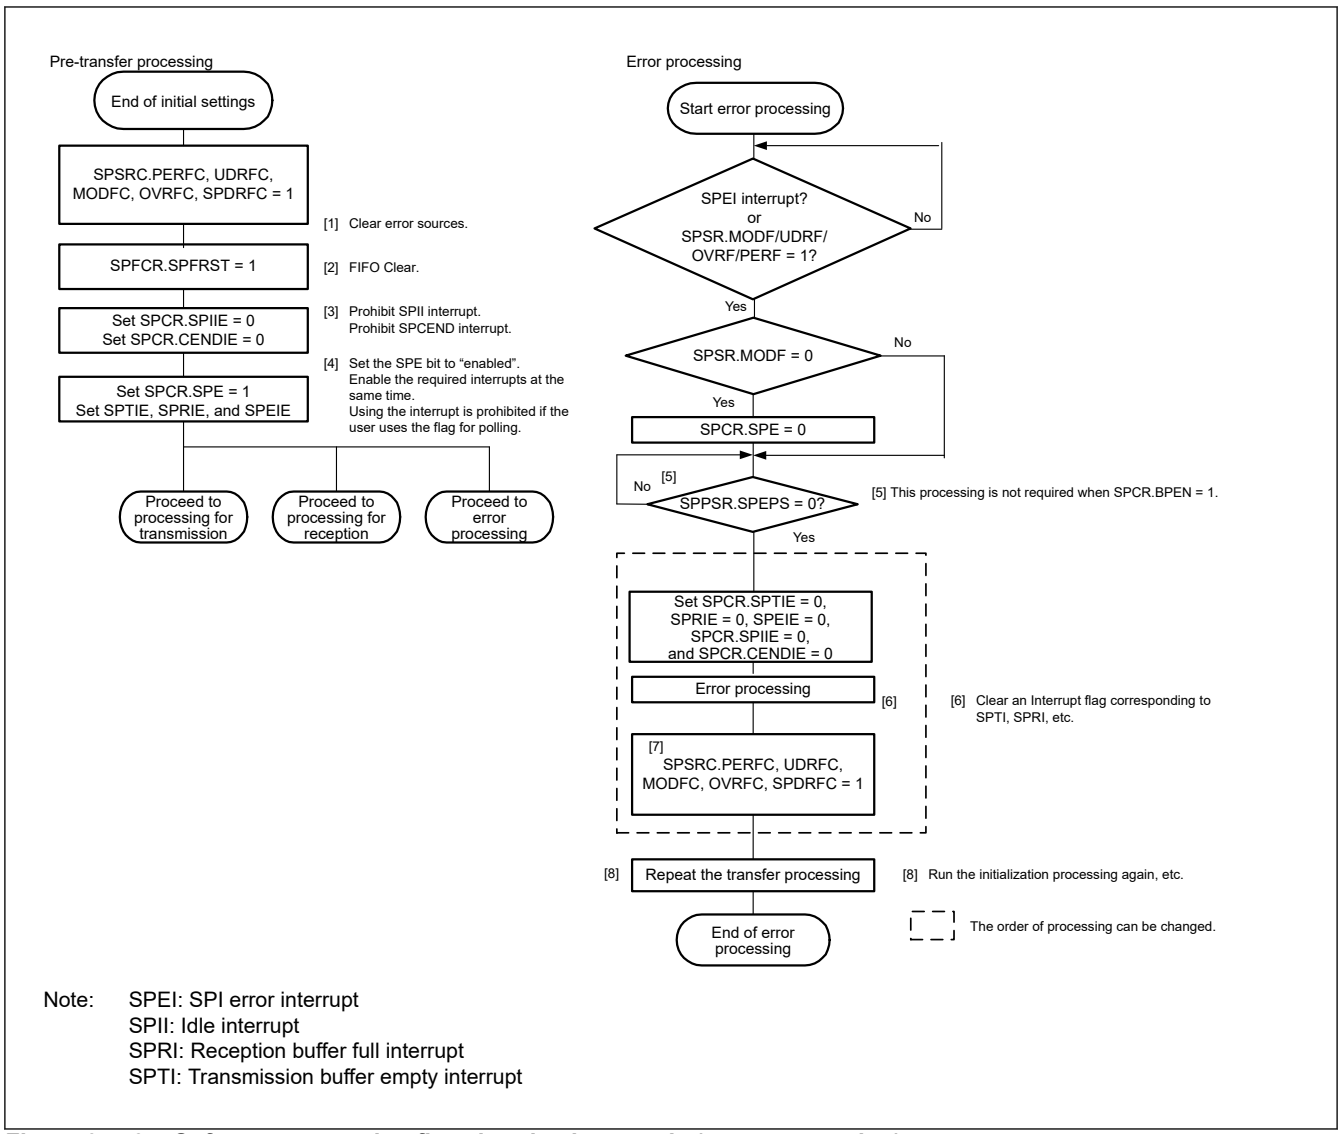
(d) Error processing flow

In slave mode operation, the MODF flag can be cleared regardless of the SSL0 pin status even when a mode fault error is present.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.



Note: SPEI: SPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 35.73 Software processing flowchart in slave mode (error processing)

35.3.14 Clock Synchronous Operation

When SPCR.SPMS bit = 1, the SPI operates in synchronization with clock. Clock synchronous operation enables communication by using three pins RSPCK, MOSI, and MISO without using SSL pins. SSL pins can be used as I/O ports.

Clock synchronous operation does not use SSL pins for communication, but the module operates internally in the similar manner to SPI operation. In master mode operation and slave mode operation, communication is possible according to the flow similar to SPI operation, but no mode fault error is detected because SSL pins are not used.

In clock synchronous operation, if the SPCMD.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

35.3.14.1 Master Mode Operation

(1) Starting a Serial Transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(3) Sequence Control

The transfer format in master mode is determined by the SPSCR, SPCMDm (m = 0 to 7), SPBR, SPCKD, SSLND, and SPND registers. These settings are valid though SSL signals are not output in clock synchronous operation.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7. A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer when the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

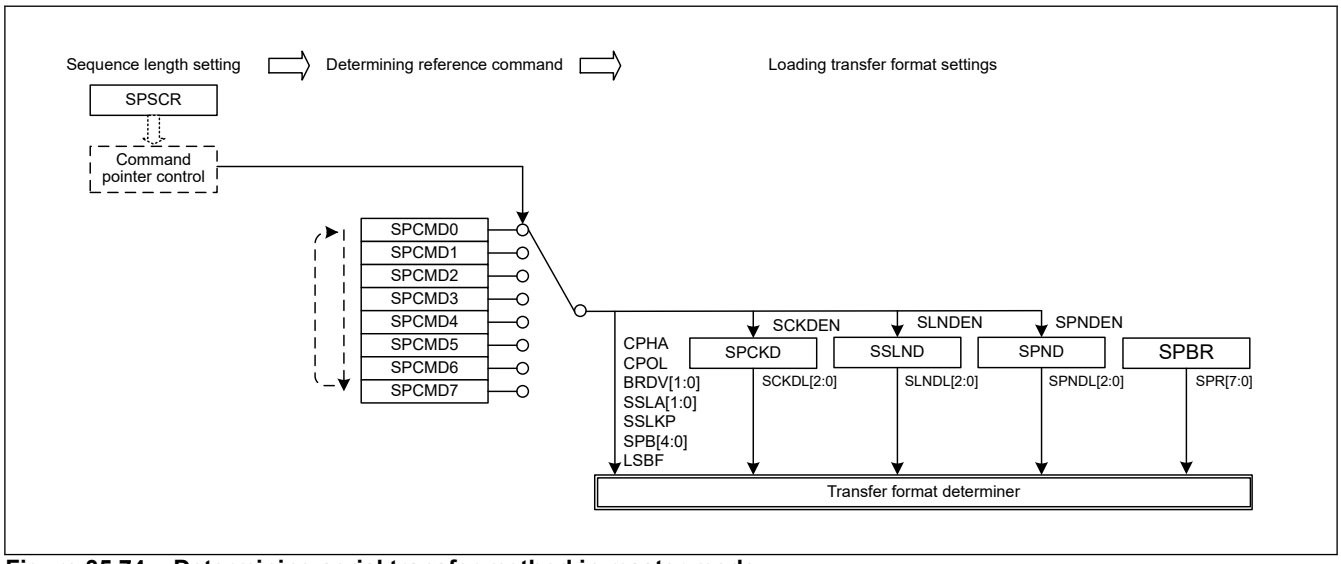


Figure 35.74 Determining serial transfer method in master mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm (m = 0 to 7)).

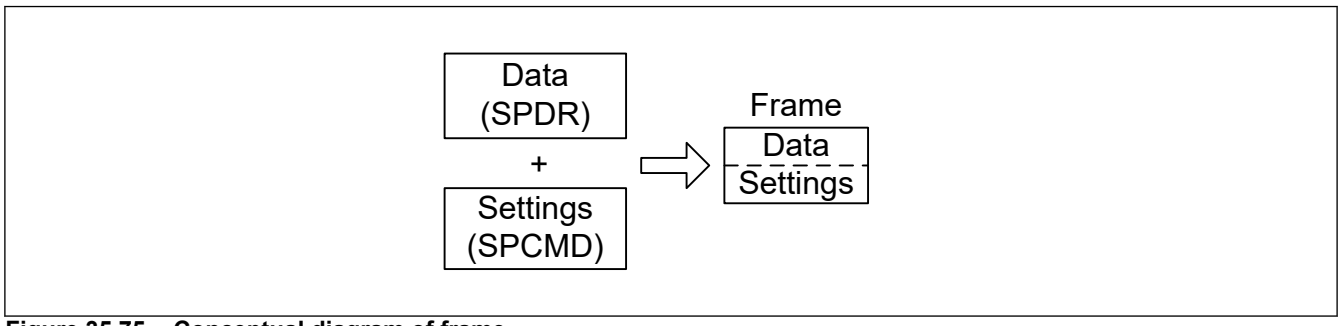

Figure 35.75 Conceptual diagram of frame

Figure 35.76 shows the correspondence between the command in the sequence operation performed and the transmit buffer/ receive buffer.

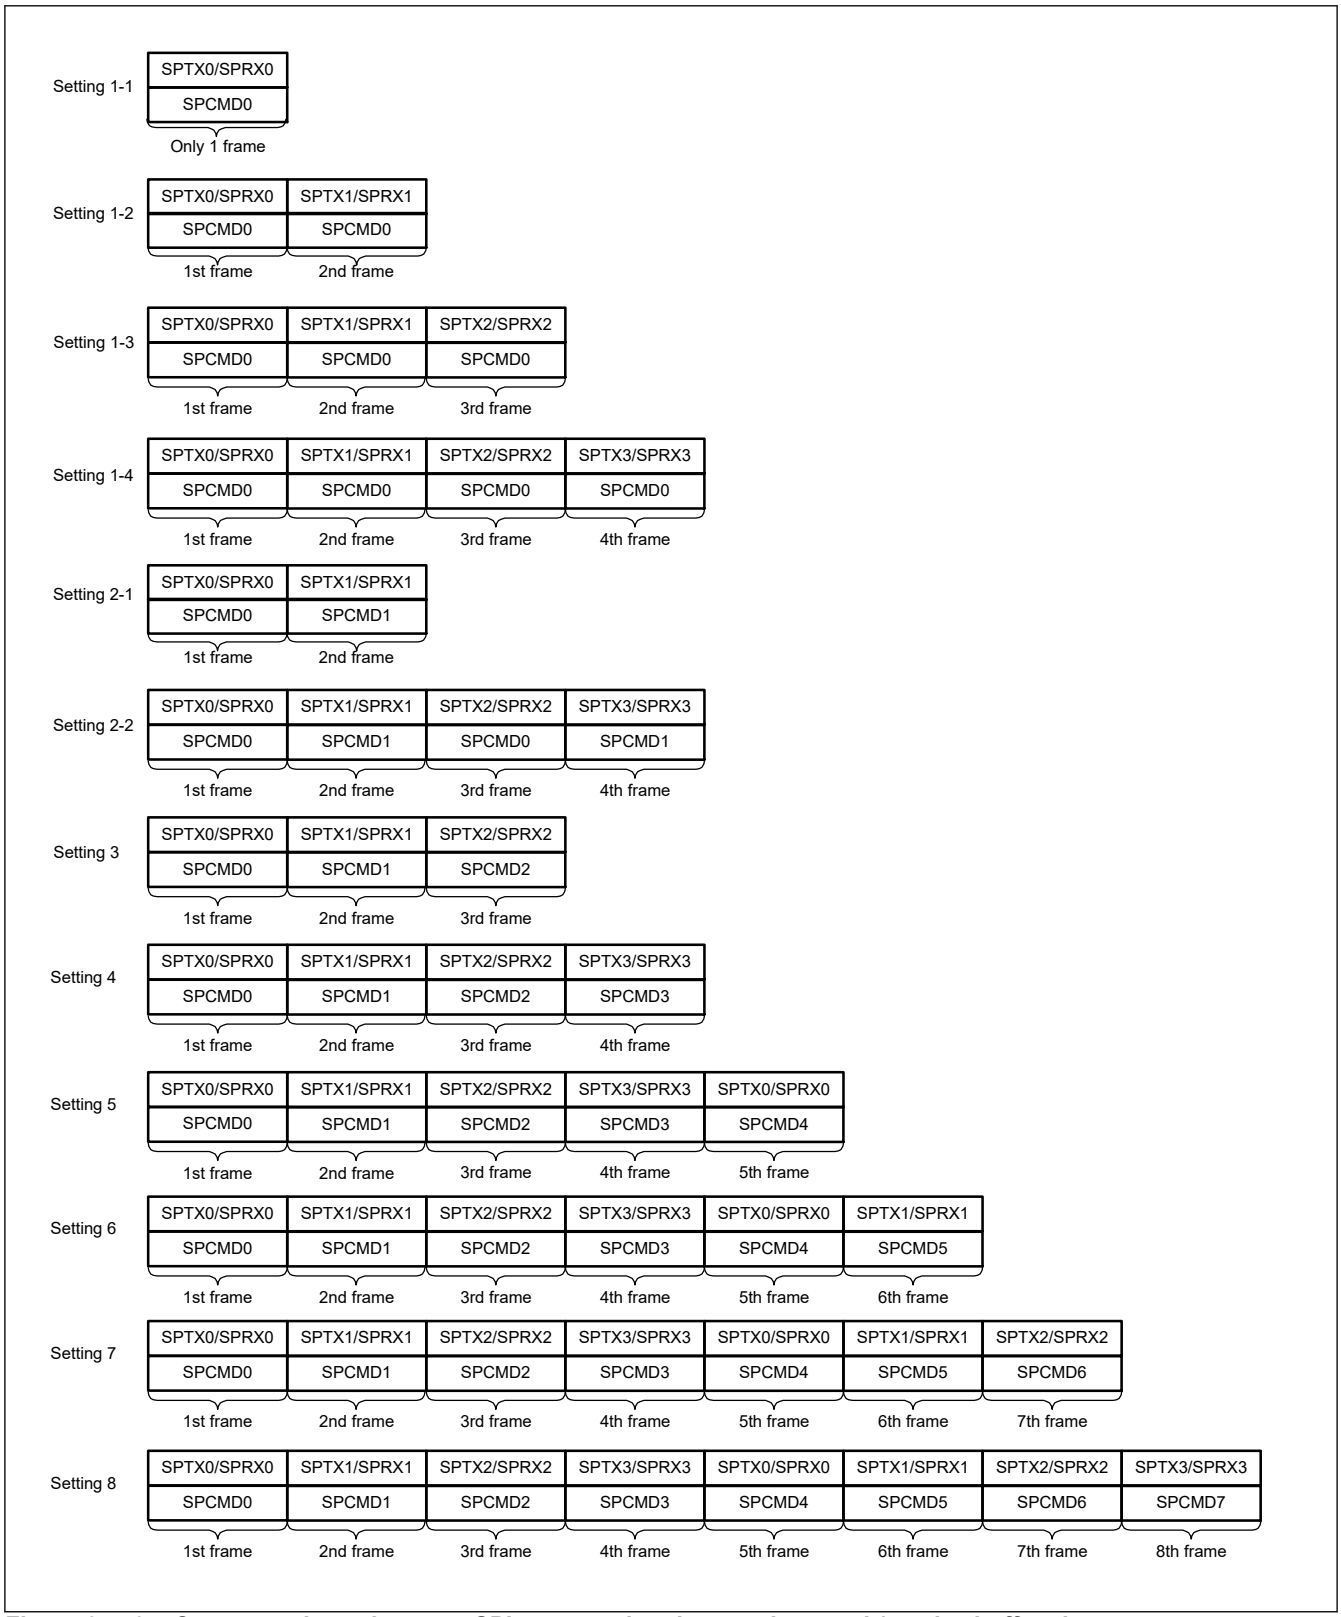

Figure 35.76 Correspondence between SPI command register and transmit/receive buffers in sequence operation

(4) Initialization Flow

Figure 35.77 shows an example of initialization flow when using the SPI in master-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

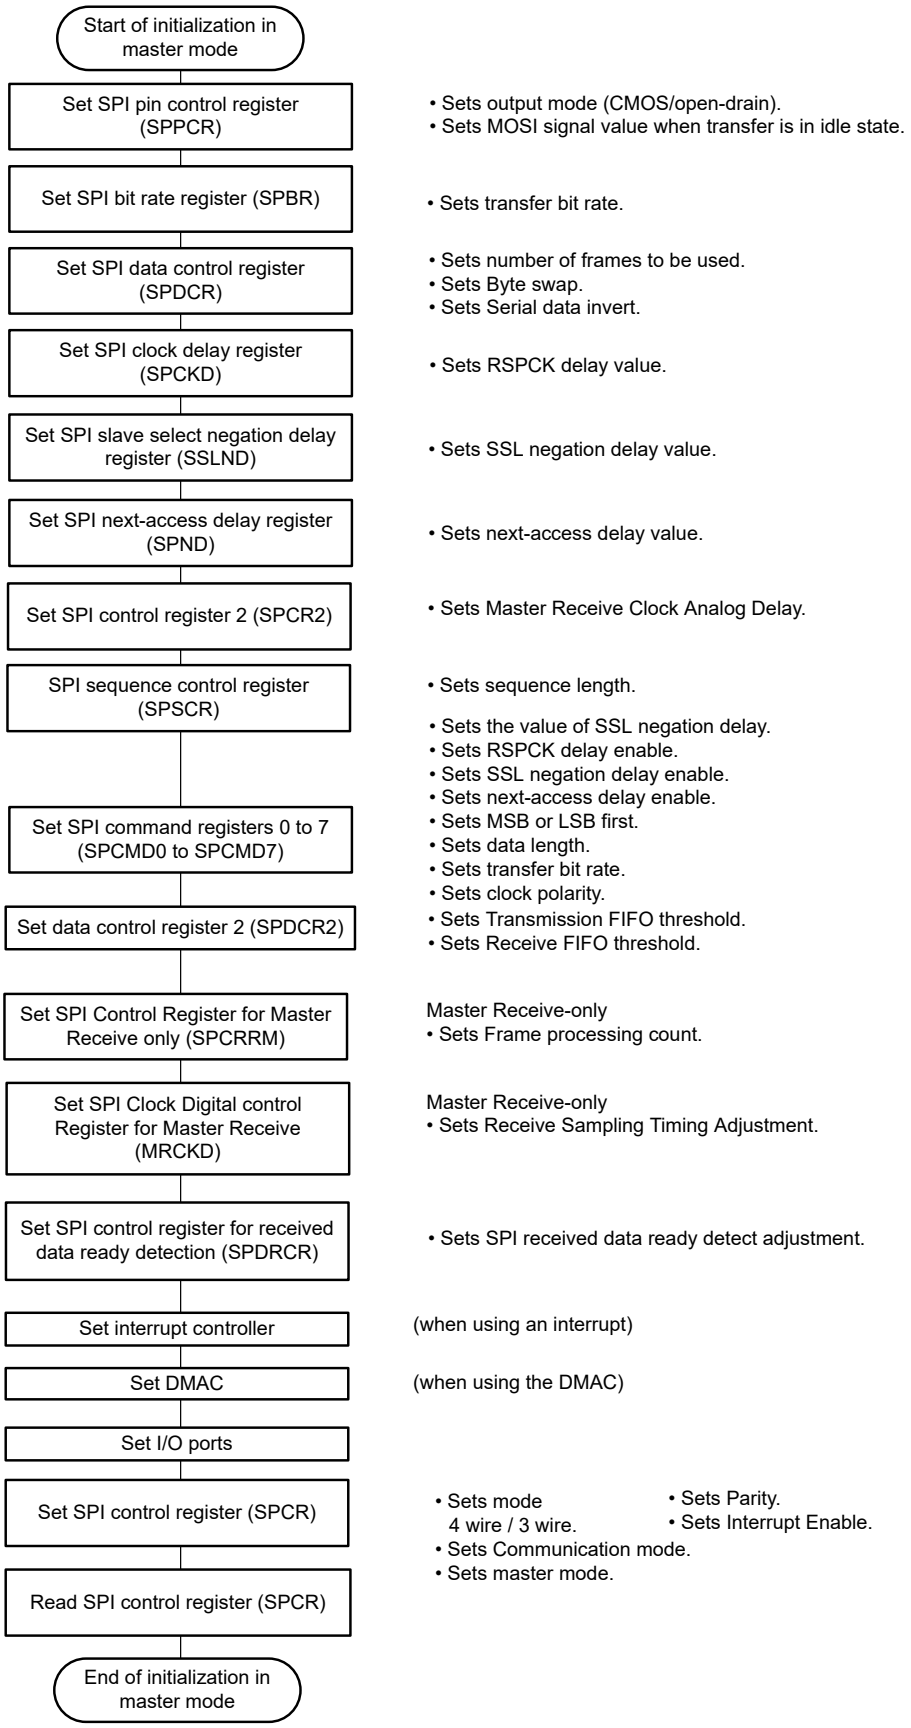

Figure 35.77 Example of initialization flowchart in master mode (clock synchronous operation)

(5) Flow of Software Processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

35.3.14.2 Slave Mode Operation

(1) Starting a Serial Transfer

When SPCR.SPMS = 1, the first RSPCK edge becomes a trigger to start serial transfer of the SPI.

While SPCR.SPMS = 1, the SPI always drives the MISO output signal.

For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 input signal is not used.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. For details about the SPI transfer format, see section 35.3.5. Transfer Format (Frame Format).

(3) Initialization Flowchart

Figure 35.78 shows an example of initialization flow when using the SPI in slave-mode clock synchronous operation.

For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

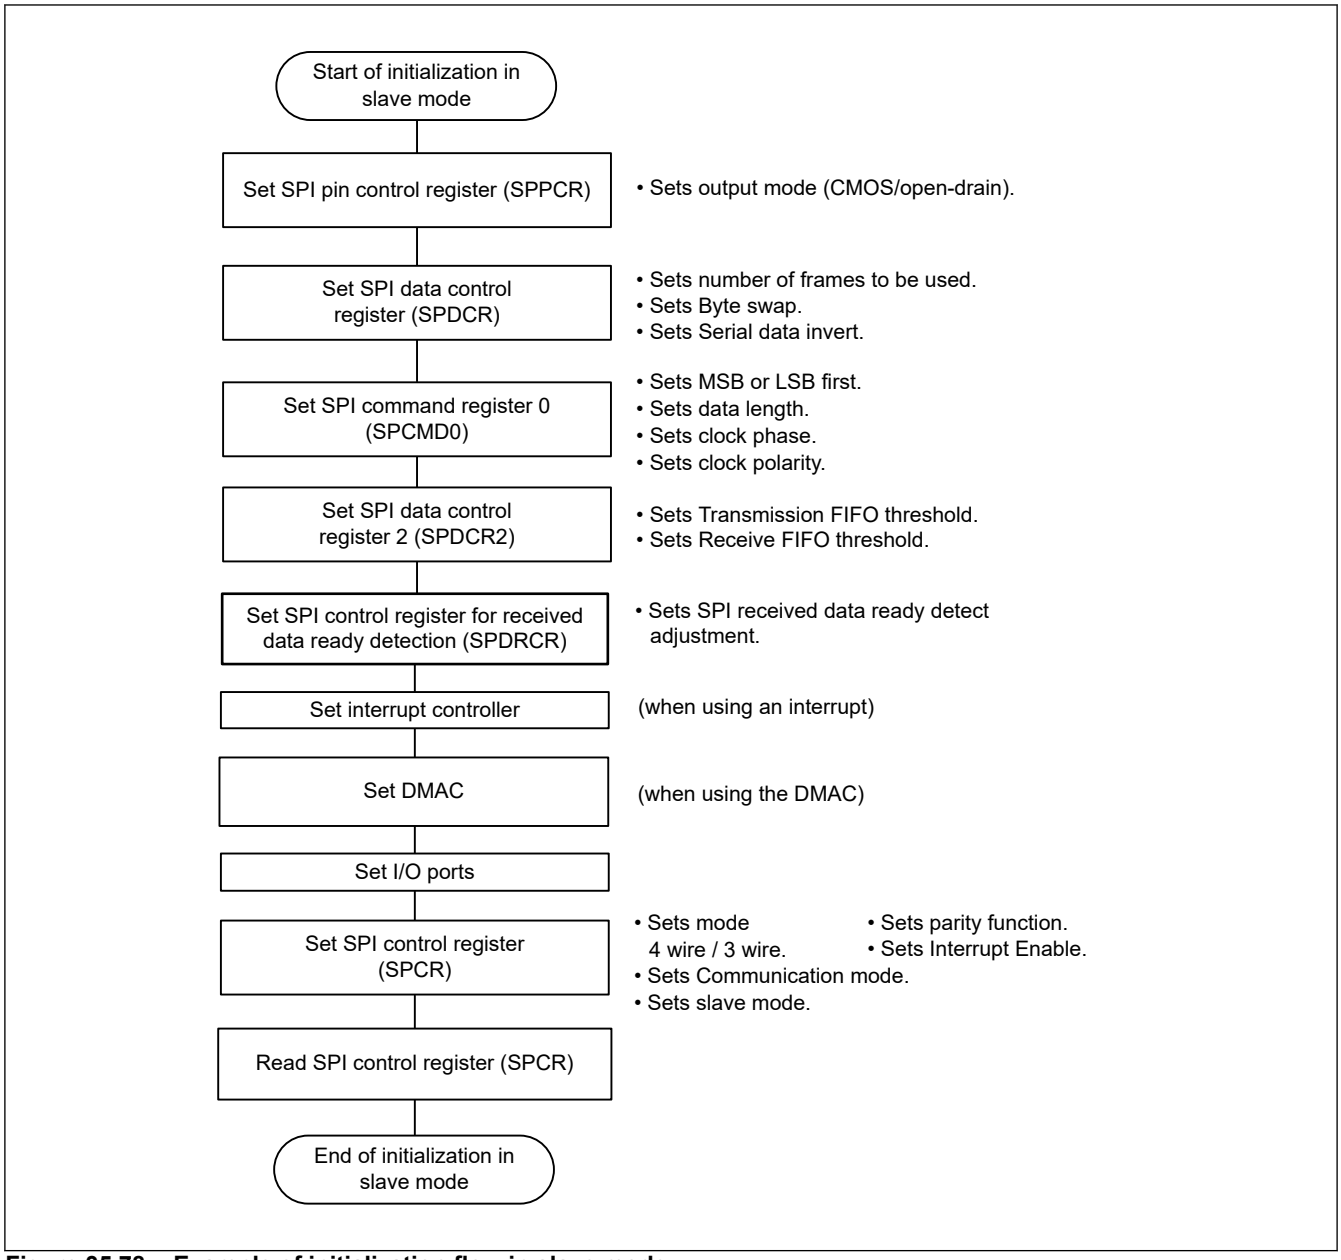

Figure 35.78 Example of initialization flow in slave mode

(4) Flow of Software Processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

35.3.15 Loopback Mode

When 1 is written to the SPPCR.SPLP bit or SPPCR.SPLP2 bit, the SPI disconnects the path between MISO pin and shift register (when SPCR.MSTR = 1) or between MOSI pin and shift register (when SPCR.MSTR = 0), and then connects the shift register input path to the output path. When SPCR.MSTR = 1, the SPI does not disconnect the path between MOSI pin and shift register. When SPCR.MSTR = 0, the SPI does not disconnect the path between MISO pin and shift register.

When serial transfer is performed in loopback mode, transmit data or inverted transmit data of the SPI becomes received data of the SPI.

Figure 35.79 shows the relationship between settings of the SPLP2 and SPLP bits and received data.

Table 35.14 SPLP2 and SPLP bit settings and received data

SPPCR.SPLP2 bit	SPPCR.SPLP bit	Received data
0	0	Input data from the MOSI pin or MISO pin
0	1	Inversed transmit data
1	0	Transmit data
1	1	Transmit data

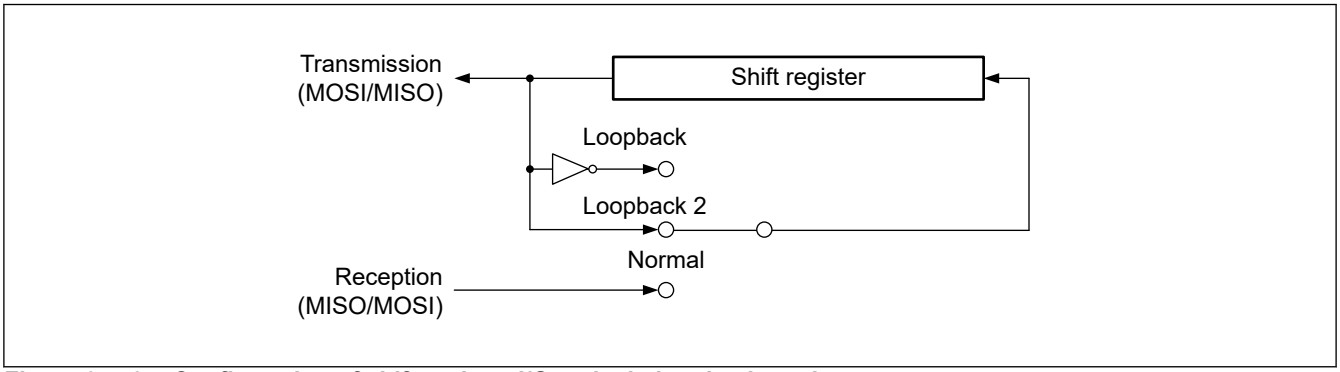

Figure 35.79 Configuration of shift register I/O paths in loopback mode

35.3.16 Self-Diagnosis of Parity Function

The parity circuit consists of a section to add a parity bit to transmit data and a section to detect an error in receive data.

To detect a failure of these sections of the parity circuit, self-diagnosis of the parity circuit is performed according to the flow in Figure 35.80.

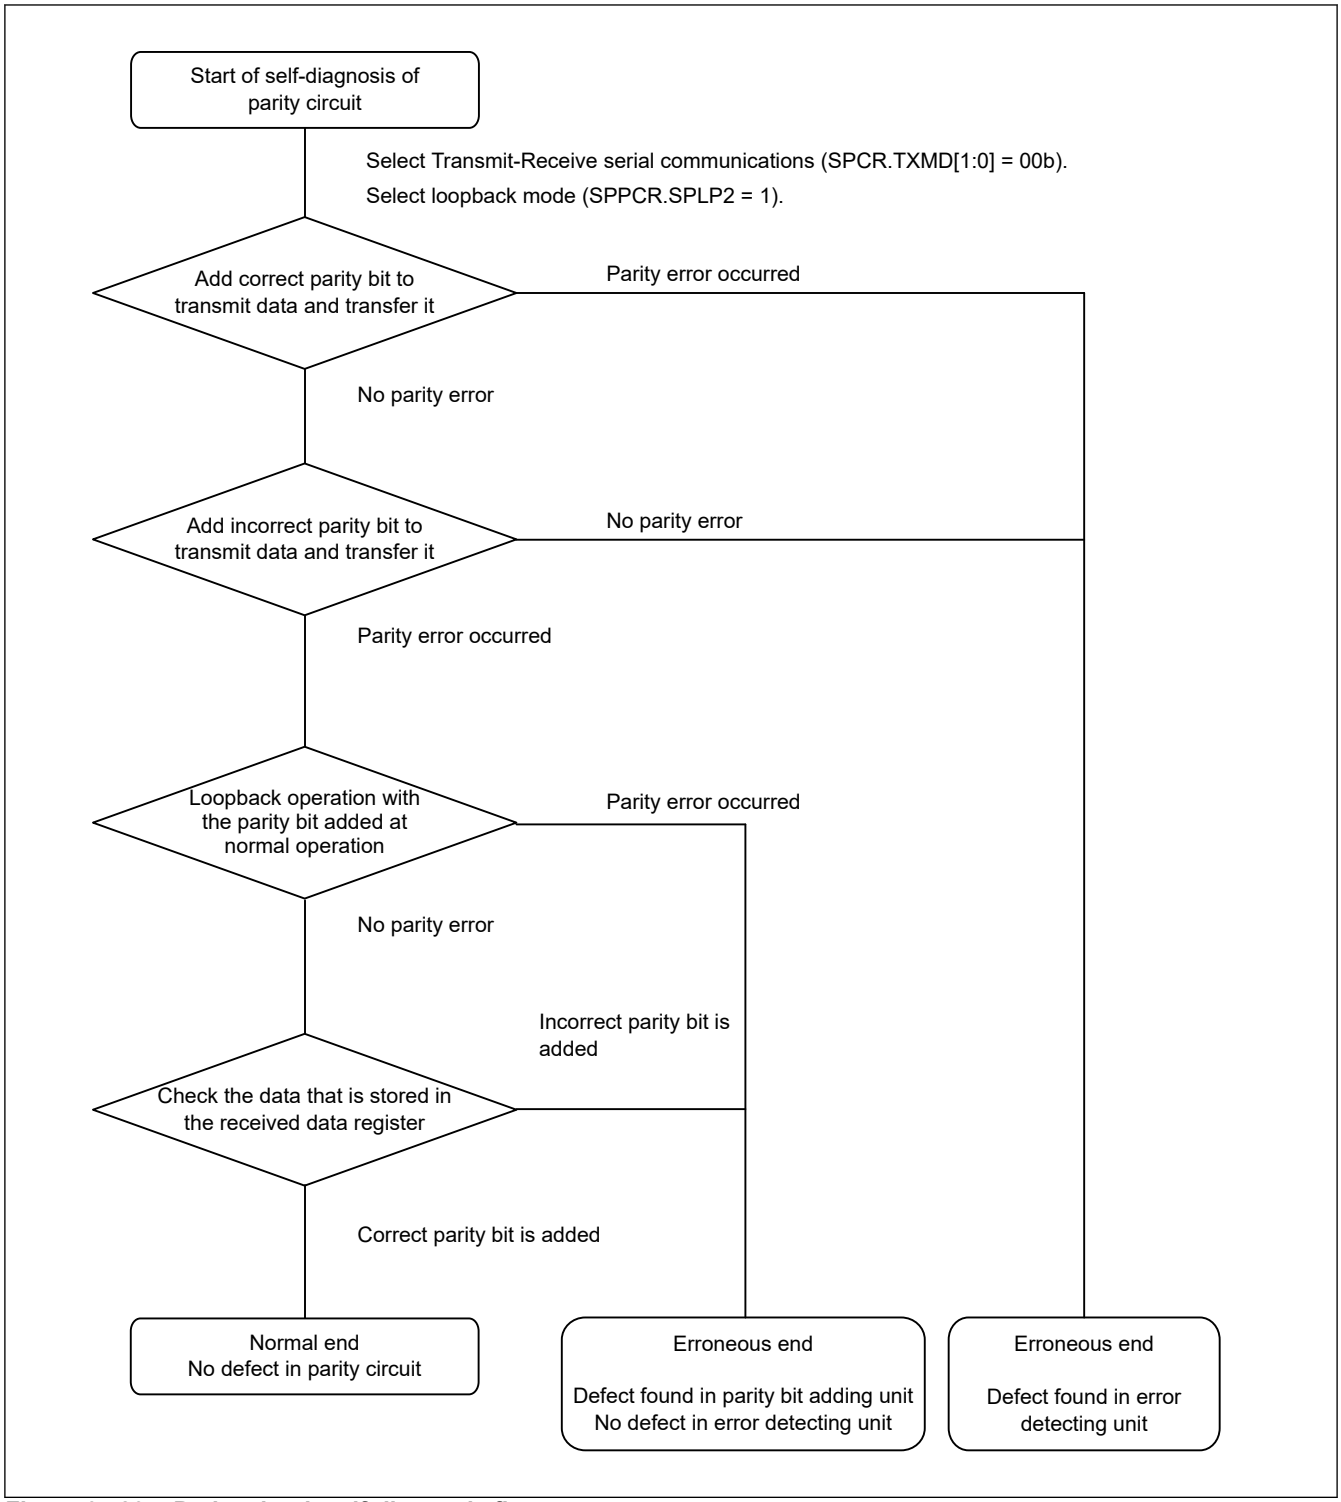

Figure 35.80 Parity circuit self-diagnosis flow

35.3.17 Interrupt Requests

The SPI has the following interrupt sources: receive buffer full, transmit buffer empty, mode fault, underrun, overrun, parity error, SPI idle, communication end, and received data ready. Furthermore, the DMAC can be activated by a receive buffer full interrupt request and a transmit buffer empty interrupt request to start data transfer.

Mode fault, underrun, overrun, parity error, and received data ready (SPCR.SPDRES = 1) interrupt requests are allocated to vector addresses in SPEI. Therefore, identify these interrupt sources by reading respective flags. Table 35.15 lists SPI's interrupt sources. When each interrupt condition in Table 35.15 is met, an interrupt is generated. Clear the receive buffer full and transmit buffer empty interrupt sources by performing data transfer.

When starting transmission or reception by using the DMAC, configure the DMAC to enable it, and then configure the SPI.

Even when the transmit buffer empty interrupt or receive buffer full interrupt condition is met while an Interrupt flag is 1, an interrupt request is not output to ICU but is internally retained. (Only one request per source can be internally retained.) When an Interrupt flag is cleared to 0, the retained interrupt request is output to ICU and then automatically cleared. An internally retained interrupt request can also be cleared by setting the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.

Table 35.15 Interrupt sources of SPI

Interrupt source	Symbol	Interrupt condition	DMAC activation
Reception buffer full	SPRI	SPRIE = 1 and (receive buffer full (SPRF = 1) | (SPDRES = 0 and Receive data ready (SPDRF = 1)))	Activated
Transmission buffer empty	SPTI	SPTIE = 1 and transmit buffer empty (SPTEF = 1)	Activated
SPI errors (mode fault, underrun, overrun, and parity error, received data ready)	SPEI	SPEIE = 1 and (MODF = 1 | UDRF = 1 | OVRF = 1 | PERF = 1 | (SPDRES = 1 and SPDRF = 1))	—
SPI idle	SPII	SPIIE = 1 and IDLNF = 0	—
Communication end*1	SPCEND	CENDIE = 1 and CENDF = 1	—

Note 1. See section 35.3.9.7. Common Operation for details on the communication completion interrupt output conditions.

35.4 Usage Notes

35.4.1 Notes on Communication Start

When an Interrupt flag is 1 at the beginning of communication, perform the following procedure to clear an interrupt request before enabling operation (setting the SPCR.SPE bit to 1).

1. Confirm that communication is not going (SPCR.SPE = 0).
2. Set the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that it is 0.
4. Set the Interrupt flag to 0.

35.4.2 Notes on the Module-Stop Function

To stop this module using the power consumption reducing function, be sure to set the SPE bit in SPCR to 0 to terminate communication and then use the power consumption reducing function.

35.4.3 Notes on SPRF and SPTEF Flags

When using the SPRF and SPTEF flags in SPSR by polling them, set the SPRIE and SPTIE bits in SPCR to 0.

35.4.4 Notes on Receive Sampling Function

When using the receive sampling function (sampling receive data with MRIOCLK or MRCLK), set the SSLND register considering the delay of the receive data sampling clock (MRIOCLK or MRCLK) from RSPCK. Please see section 35.2.3. SSLND : SPI Slave Select Negation Delay Register.

35.4.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between SPCMD with the SSLKP bit set to 1 and SPCMD used in the next transfer is prohibited.

1. SSL Signal Assertion setting (SSLA[1:0] bits)
2. RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

35.4.6 Notes on TI-SSP in Slave Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals.

Secure the following intervals on the master side.

[Master side: interval from RSPCK edge of last bit to RSPCK edge of next SSL] > [Slave side: Output enable delay time = PCLKSPIn × (1 to 2) + SLNDL[2:0] setting value]

35.4.7 Notes at SPE = 1

(1) When SPCR.SPE = 1, if the following register bits are rewritten, subsequent operations are not guaranteed.

Table 35.16 Communication end event generating conditions (receive only slave mode) (1 of 2)

Register name	Bit name
SPCKD	SCKDL[2:0]
SSLND	SLNDL[2:0]
SPND	SPNDL[2:0]
MRCKD	ARST[2:0]

	RTRG[1:0]
SPFCR	SPFRST

Note 1. Rewriting prohibited in slave mode. In master mode, this is possible only when there is no next transfer data in the transmit FIFO.

(2) After rewriting from SPE = 1 to 0 when SPCR.BPEN = 0, or when SPSR.MODF is set to 1, check that the SPPSR.SPEPS bit is set to 0, then do the next operation.

36. Expanded Serial Peripheral Interface (xSPI)

36.1 Overview

This LSI has two units of Expanded Serial Peripheral Interface (xSPI). The xSPI protocol specifies the interface for Memory Devices, which provides high data throughput, low signal count, and limited backward compatibility with legacy SPI devices. The electrical interface can deliver up to 200 MB per second raw data throughput.

Table 36.1 lists the xSPI specifications, Figure 36.1 shows a block diagram, and Table 36.2 lists the I/O pins.

Table 36.1 xSPI Specifications

Item	Description
Number of channels	2 units
Protocol	Compliant for the xSPI protocol
Data transmission and reception	Issue the transaction for up to 2 slaves for unit 0 and 1 slave for unit 1 as Master
Transfer speed	Support the transfer at xSPI200
Mode	• Support Protocol modes below – 1/4/8pin with SDR/DDR (1S-1S-1S, 4S-4D-4D, 8D-8D-8D) – 2/4pin with SDR (1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S) • Configurable address length • Configurable initial access latency cycle • Support XiP mode
xSPI function	• Support Write Data Mask • Support In-band Reset • Memory-mapping – Support up to 64 MB address space each CS – Prefetch function for burst-read with low latency – Outstanding buffer for burst-write with high throughput • Manual command – Configurable up to 4 commands – Status Register Polling function • Input Strobe port timing shift
Interrupt source	2 interrupts
Module-stop function	Module-stop state can be set to reduce power consumption

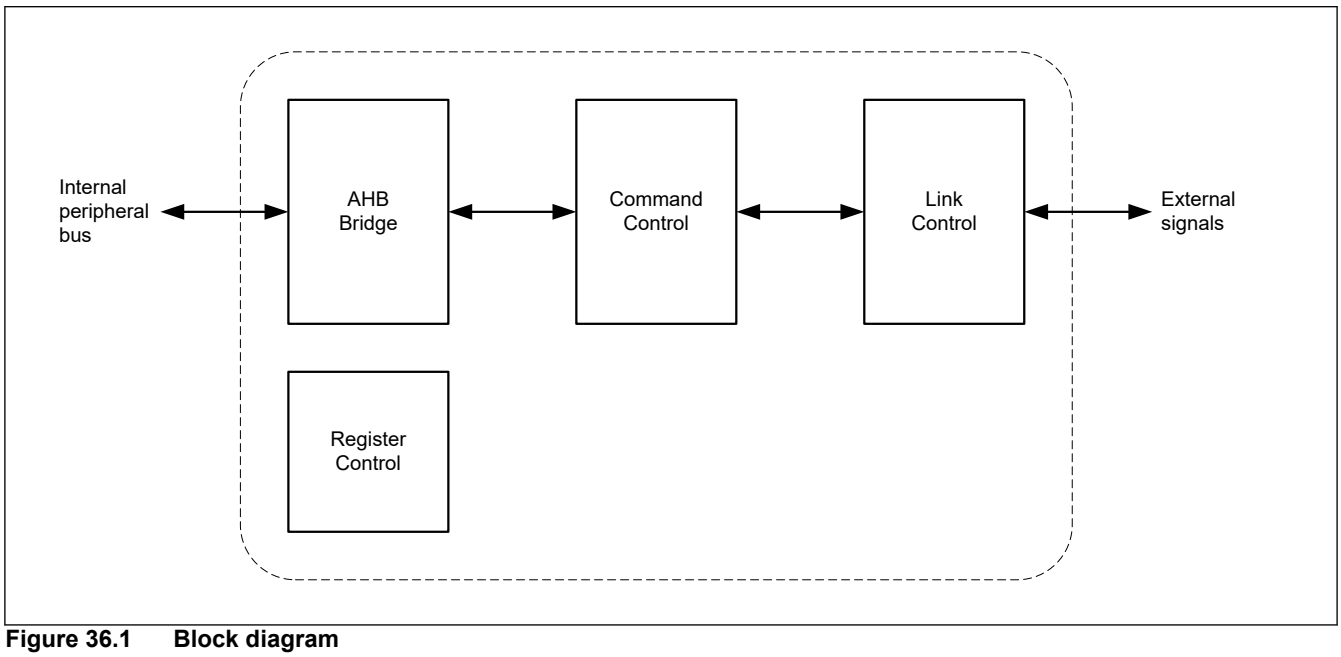

Figure 36.1 Block diagram

Table 36.2 xSPI I/O pins

Channel	Pin name	I/O	Function
xSPIm (m = 0, 1)	XSPIm_CKP	Output	Clock Positive
	XSPI0_CKN*1	Output	Clock Negative
	XSPIm_CS0#	Output	Chip Select for slave0
	XSPI0_CS1#*1	Output	Chip Select for slave1
	XSPIm_DS	I/O	Read Data Strobe / Write Data Mask
	XSPIm_IO0	I/O	Data 0 input/output
	XSPIm_IO1	I/O	Data 1 input/output
	XSPIm_IO2	I/O	Data 2 input/output
	XSPIm_IO3	I/O	Data 3 input/output
	XSPIm_IO4	I/O	Data 4 input/output
	XSPIm_IO5	I/O	Data 5 input/output
	XSPIm_IO6	I/O	Data 6 input/output
	XSPIm_IO7	I/O	Data 7 input/output
	XSPI0_RESET0#*1	Output	Master reset status for slave0
	XSPI0_RESET1#*1	Output	Master reset status for slave1
	XSPI0_RSTO0#*1	Input	Slave reset status for slave0
	XSPI0_RSTO1#*1	Input	Slave reset status for slave1
	XSPI0_INT0#*1	Input	Interrupt for slave0
	XSPI0_INT1#*1	Input	Interrupt for slave1
	XSPI0_ECS0#*1	Input	Error Correction Status for slave0
	XSPI0_ECS1#*1	Input	Error Correction Status for slave1
	XSPI0_WP0#*1	Output	Write Protect for slave0
	XSPI0_WP1#*1	Output	Write Protect for slave1

Note 1. These pins are available in unit 0 only.

Table 36.3 Address map

Channel	Internal address	Space
xSPI0	0x4000_0000 to 0x43FF_FFFF	CS0 mirror
	0x4400_0000 to 0x47FF_FFFF	CS1 mirror
	0x6000_0000 to 0x63FF_FFFF	CS0
	0x6400_0000 to 0x67FF_FFFF	CS1
xSPI1	0x4800_0000 to 0x4BFF_FFFF	CS0 mirror
	0x6800_0000 to 0x6BFF_FFFF	CS0

36.2 Register Descriptions

36.2.1 xSPI Configuration Registers

These registers configure xSPI Master function. These registers should be configured in the initialization phase before issuing xSPI transaction.

36.2.1.1 WRAPCFG : xSPI Wrapper Configuration Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DSSFTCS1[4:0]				—	—	—	—	—	—	—	—	—	—	—	DSSFTCS0[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DSSFTCS0[4:0]	DS shift for slave0 These bits configure the number of delay cell for XSPIm_DS pin. It is used to adjust the DS sampling timing. 1 cell delay is around 125 ps. When enabled automatic calibration, it can be updated automatically. 0x00: No shift 0x01: Add a delay of 1 cell ⋮ 0x1E: Add a delay of 30 cells 0x1F: Add a delay of 31 cells	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DSSFTCS1[4:0]	DS shift for slave1 The function is same as one of slave0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

36.2.1.2 COMCFG : xSPI Common Configuration Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OENEGEX	OEASTEX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	OEASTEX	Output Enable Asserting extension This bit extends 1 cycle output enable of Data and DS during output enable asserting. When set to 1, CS asserting should be extended (LIOCFGCSn.CSASTEX = 1 (n = 0, 1)). This bit shall not be used in case of no latency cycle. Because xSPI output data could be conflicted with xSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
17	OENEGEX	Output Enable Negating extension This bit extends 1 cycle output enable of Data and DS during output enable negating. This bit should not be used in case of no latency cycle. Because SPI output data could be conflicted with SPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W

Bit	Symbol	Function	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

36.2.1.3 BMCFG : xSPI Bridge Map Configuration Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MWRSIZE[7:0]								MWRCOMB	—	—	—	—	—	—	WRMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WRMD	AHB Write Response mode This bit selects the timing of AHB write response in memory-mapping mode. When set to 1, it returns the response after transmitting a frame on xSPI bus. When enabled this mode, Memory Write Combination mode must be disabled. 0: Return response after storing to Internal Write Buffer 1: Return response after issuing write transaction to xSPI bus	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	MWRCOMB	Memory Write Combination mode This bit selects to combine the xSPI data in write access of memory-mapping mode. When set to 0, xSPI data size depends on AHB Burst type. When set to 1, it depends on Memory Write Size bit. When set to 1, any write transaction could be held in this xSPI master temporarily. 0: Disable combination mode 1: Enable combination mode	R/W
15:8	MWRSIZE[7:0]	Memory Write Size These bits select the size to combine incremental address in memory-mapping mode. It transmits an xSPI frame with the data combined up to the configured size while the address is incremental. When detected non-incremental address or a read transaction before reaching to the target size, it transmits the pending data into xSPI bus. 0x00: Combine incremental address up to 4 bytes 0x01: Combine incremental address up to 8 bytes ⋮ 0x0E: Combine incremental address up to 60 bytes 0x0F: Combine incremental address up to 64 bytes Others: Setting prohibited	R/W
16	PREEN	Prefetch enable This bit enables prefetch function for read transaction in memory-mapping mode. It could reduce the latency for AHB read transaction with incremental address. 0: Disable prefetch function 1: Enable prefetch function	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

36.2.1.4 CMCFG0CSn : xSPI Command Map Configuration Register 0 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x010 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDRPCD[7:0]								ADDRPEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	ADDSIZE[1:0]		FFMT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FFMT[1:0]	Frame format These bits configure xSPI frame format in memory-mapping mode. Please see Table 36.9 for detail. 0 0: Normal format: Command 1 byte, Address ADDSIZE, Data to AHB transaction. 0 1: 8D-8D-8D profile 1.0 format: Command 2 bytes, Address ADDSIZE, Data to AHB transaction 1 0: 8D-8D-8D profile 2.0 Command Modifier format: Command & Modifier 6 bytes, Data to AHB transaction 1 1: 8D-8D-8D profile 2.0 Commands with Extended Command Modifier format: Command & Modifier 6 bytes, Data to AHB transaction	R/W
3:2	ADDSIZE[1:0]	Address size These bits configure the number of address byte in memory-mapping mode. In case of 8D-8D-8D profile 2.0, it should be configured to 4 bytes. 0 0: 1 byte (256-byte address space) 0 1: 2 bytes (64 KB address space) 1 0: 3 bytes (16 MB address space) 1 1: 4 bytes (4 GB address space)	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ADDRPEN[7:0]	Address Replace Enable These bits select the bits to replace for MSByte of AHB address in memory-mapping mode. 0: No replacement (xSPI frame address field is same as AHB address) 1: Replacement	R/W
31:24	ADDRPCD[7:0]	Address Replace Code These bits configure the code to replace the MSByte of AHB address in memory-mapping mode. It replaces the corresponding bits when Address Replace Enable bit is set to 1.	R/W

This register has functions to configure xSPI Master function.

36.2.1.5 CMCFG1CSn : xSPI Command Map Configuration Register 1 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x014 + 0x010 × n

Bit position:	31											20		16	15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RDLATE[4:0]			RDCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RDCMD[15:0]	Read command These bits configure the command field of read transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	RDLATE[4:0]	Read latency cycle These bits configure the latency cycle of read transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

36.2.1.6 CMCFG2CSn : xSPI Command Map Configuration Register 2 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x018 + 0x010 × n

Bit position:	31											20				16	15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	WRLATE[4:0]					WRCMD[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WRCMD[15:0]	Write command These bits configure the command field of write transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	WRLATE[4:0]	Write latency cycle These bits configure the latency cycle of write transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

36.2.1.7 LIOCFGCSn : xSPI Link I/O Configuration Register CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x050 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DDRSMPEX[3:0]				SDRSMPSFT[3:0]				SDRS MPMD	SDRD RV	CSNE GEX	CSAS TEX	CSMIN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WRMS KMD	LATE MD	PRTMD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>9:0</td><td>PRTMD[9:0]</td><td>Protocol mode
These bits configure the protocol mode and the pin to sample data inputs.
In case of using not SPI clock but Data strobe for sampling in SDR mode, it is required to set PRTMD[9] to 1.
0x000: 1S-1S-1S
0x3B2: 4S-4D-4D
0x3FF: 8D-8D-8D
0x048: 1S-2S-2S

0x090: 1S-4S-4S
0x092: 4S-4S-4S
Others: Setting prohibited</td><td>R/W</td></tr>
<tr><td>10</td><td>LATEMD</td><td>Latency mode
This bit selects the behavior of initial access latency phase for both direct-manual mode and memory-mapping mode. When set to 0, the latency cycle is equal to each configured cycle from transmitting address field. When set to 1, the latency cycle is incremented from the last byte-pair of Address field and is extended 2 times of each configured cycle depending on data strobe port.
It is used only for profile 2.0 frame format of 8D-8D-8D protocol mode with 6 bytes command/address field. Please refer to xSPI protocol for detail.
<table>
<tr><th>Value: Function</th><th>Frame format</th><th>Usage</th></tr>
<tr><td rowspan="2">0: Configurable latency</td><td>profile 2.0</td><td>The configurable latency cycle should be set as minus 1.</td></tr>
<tr><td>Others</td><td>Latency cycle increments after address field.</td></tr>
<tr><td rowspan="2">1: Variable latency</td><td>profile 2.0</td><td>Latency cycle increments from address [23:16]. And it should not be set to 1.</td></tr>
<tr><td>Others</td><td>Not support</td></tr>
</table></td><td>R/W</td></tr>
<tr><td>11</td><td>WRMSKMD</td><td>Write mask mode
This bit selects to use Data strobe port as write data mask. It could be useful for write access of odd byte.
It is used only for 8D-8D-8D protocol mode.
0: Write mask disable
1: Write mask enable</td><td>R/W</td></tr>
<tr><td>15:12</td><td>—</td><td>These bits are read as 0. The write value should be 0.</td><td>R/W</td></tr>
<tr><td>19:16</td><td>CSMIN[3:0]</td><td>CS minimum idle term
This bit configures the minimum cycle between xSPI frames.
0x0: 1 cycle
0x1: 2 cycles
⋮
0xE: 15 cycles
0xF: 16 cycles</td><td>R/W</td></tr>
<tr><td>20</td><td>CSASTEX</td><td>CS asserting extension
This bit extends 1 cycle chip select pins when asserting.
0: No extension

This bit extends 1 cycle chip select pins when negating.
0: No extension
1: Extend 1 cycle</td><td>R/W</td></tr>
<tr><td>22</td><td>SDRDRV</td><td>SDR driving timing
This bit configures the timing of data output in SDR.
This bit should not be used in case of no latency cycle. Because SPI output data could be conflicted with SPI input data.
0: Drive at 1/2 cycle before CK rising-edge
1: Drive at CK rising-edge</td><td>R/W</td></tr>
</table>

Bit	Symbol	Function	R/W
23	SDRSMPMD	SDR Sampling mode This bit selects the edge of sampling in SDR. In DDR, regardless of this setting, it samples data input ports with both edges of DS. When set to 1, it samples at rising-edge before falling-edge. 0: Samples data input at falling-edge 1: Samples data input at rising-edge	R/W
27:24	SDRSMPSFT[3:0]	SDR Sampling window shift These bits shift the timing of CK sampling in SDR. In case of using DS in SDR, there is no influence on the behavior. In case of DDR or using DS in SDR, it should be set to 0. 0x0: Sample without delay 0x1: Sample at 1 cycle delay ⋮ 0x6: Sample at 6 cycle delay 0x7: Sample at 7 cycle delay Others: Setting prohibited	R/W
31:28	DDRSMPEX[3:0]	DDR sampling window extend These bits configure the cycle of extending the sampling window in DDR. In DDR, the input data is sampled during the expected cycle soon after latency cycle. The input data out of range is ignored. It can be configured depending on DS propagation delay. 0x0: Expand no cycle 0x1: Expand 1 cycle ⋮ 0x6: Expand 6 cycles 0x7: Expand 7 cycles Others: Setting prohibited	R/W

This register has functions to configure xSPI Master function.

36.2.2 xSPI Control Registers

These registers control xSPI Master function.

36.2.2.1 BMCTL0 : xSPI Bridge Map Control Register 0

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CS1ACC[1:0]		CS0ACC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	CS0ACC[1:0]	AHB channel to slave0 memory area access enable These bits enable the access from AHB channel to CS0 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W

Bit	Symbol	Function	R/W
3:2	CS1ACC[1:0]	AHB channel to slave1 memory area access enable These bits enable the access from AHB channel to CS1 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.2 BMCTL1 : xSPI Bridge Map Control Register 1

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PBUFCLR	—	MWRPUSH	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The write value should be 0.	W
8	MWRPUSH	Memory Write Data Push This bit requests to push the pending data in combination mode. 0: No command 1: Push request	W
9	—	The write value should be 0.	W
10	PBUFCLR	Prefetch Buffer clear This bit requests to clear the prefetch buffer when enabled the prefetch function. It should not be set during memory access (COMSTT.MEMACC = 1). 0: No command 1: Clear request	W
31:11	—	The write value should be 0.	W

This register has functions to control xSPI Master function.

36.2.2.3 CMCTL : xSPI Command Map Control Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x068

Bit position:	31	16	15	8	7	0
Bit field:	—	XIPEN	XIPEXCODE[7:0]		XIPENCODE[7:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0	0 0 0 0 0 0 0 0		0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
7:0	XIPENCODE[7:0]	XiP mode enter code These bits configure the code to enter XiP mode in memory-mapping mode.	R/W

Bit	Symbol	Function	R/W
15:8	XIPEXCODE[7:0]	XiP mode exit code These bits configure the code to exit XiP mode in memory-mapping mode.	R/W
16	XIPEN	XiP mode enable This bit enables XiP mode in memory-mapping mode. When set to 1, XiP enter code is inserted in the latency field, and the command field in next transaction is omitted. When set to 0, XiP exit code is inserted in the latency field. And it is set to 0 automatically when transmitting XiP disable pattern. It should not be used for 8D-8D-8D protocol mode profile 2.0 frame format. 0: Disable XiP mode 1: Enable XiP mode	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.4 CSSCTL : xSPI CS Size Control Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x06C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CS1SIZE[5:0]						—	—	CS0SIZE[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CS0SIZE[5:0]	CS0 (slave0) size This bit selects the size of CS0 (slave0). 0x00: 1 MB 0x01: 2 MB 0x03: 4 MB 0x07: 8 MB 0x0F: 16 MB 0x1F: 32 MB 0x3F: 64 MB Others: Setting prohibited	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	CS1SIZE[5:0]	CS1 (slave1) size This bit selects the size of CS1 (slave1). 0x00: 1 MB 0x01: 2 MB 0x03: 4 MB 0x07: 8 MB 0x0F: 16 MB 0x1F: 32 MB 0x3F: 64 MB Others: Setting prohibited	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.5 CDCTL0 : xSPI Command Manual Control Register 0

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PEREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]		CSSEL	—	PERMD	TRREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRREQ	Transaction request This bit requests to issue the transaction of manual-command. When set to 1, it starts the transaction. It is cleared to 0 when the transaction completed. The transaction is canceled by clearing to 0 while the transaction is ongoing. 0: No transaction 1: Request transaction	R/W
1	PERMD	Periodic mode This bit enables the periodic transaction mode. When set to 1, it repeats a transaction periodically and compares the read value with the expected value. It alternates the status polling operation for external memory. 0: Direct manual-command mode 1: Periodic manual-command mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue manual-command. 0: CS0 1: CS1	R/W
5:4	TRNUM[1:0]	Transaction number These bits configure the number of transactions in normal manual-command mode. In periodic manual-command, regardless of this setting, it issues the transaction using only command buffer 0. 0 0: Issue 1 command (using command buffer 0) 0 1: Issue 2 commands (using command buffer 0-1) 1 0: Issue 3 commands (using command buffer 0-2) 1 1: Issue 4 commands (using command buffer 0-3)	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	PERITV[4:0]	Periodic transaction interval These bits configure the interval of transaction in periodic manual-command mode. Too short interval compared with CPU bus cycle could result in no store into command buffer0. The interval should be longer than 4 times of CPU bus cycle. 0x00: 2 (= 2^1) cycles 0x01: 4 (= 2^2) cycles ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycles 0x1F: 4,294,967,296 (= 2^{32}) cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W

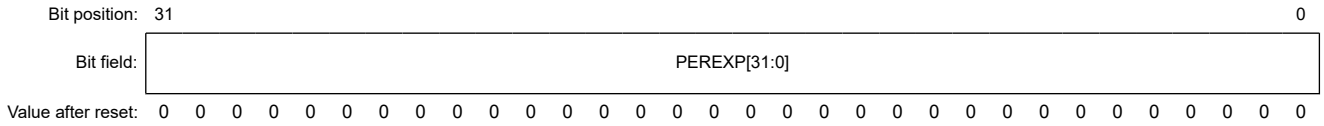
Bit	Symbol	Function	R/W
27:24	PERREP[3:0]	Periodic transaction repeat These bits configure the number of transaction repetitions in periodic manual-command mode. 0x0: 1 (= 2^0) time 0x1: 2 (= 2^1) times ⋮ 0xE: 16384 (= 2^{14}) times 0xF: 32768 (= 2^{15}) times	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.6 CDCTL1 : xSPI Command Manual Control Register 1

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x074



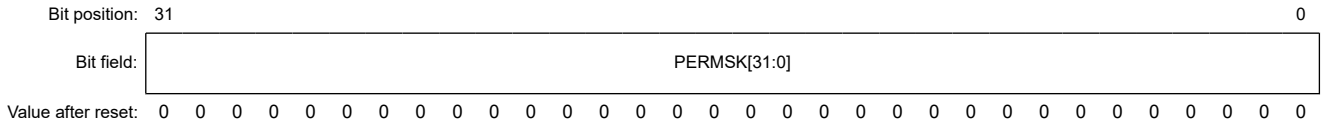
Bit	Symbol	Function	R/W
31:0	PEREXP[31:0]	Periodic transaction expected value These bits configure the expected value to compare with the read value in periodic manual-command mode. For example, in case of comparing 1 byte, the lower byte should be configured.	R/W

This register has functions to control xSPI Master function.

36.2.2.7 CDCTL2 : xSPI Command Manual Control Register 2

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x078



Bit	Symbol	Function	R/W
31:0	PERMSK[31:0]	Periodic transaction masked value These bits configure the masked value for the expected value in periodic manual-command mode. When set 1 to any bit, the corresponding bit configured as expected value (CDCTL1.PEREXP[31:0]) is ignored. In 8D-8D-8D, the data bytes are transferred only in byte pairs on SPI bus. It means the dummy read data could be stored. It should be masked for unused bits. For example, in case of read lower 1 byte, it should be configured to 0xFFFFFF00.	R/W

This register has functions to control xSPI Master function.

36.2.2.8 CDTBUFn : xSPI Command Manual Type Buf n (n = 0 to 3)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x080 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRTYPE	—	LATE[4:0]					DATASIZE[3:0]				ADDSIZE[2:0]			CMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes Others: Setting prohibited	R/W
4:2	ADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	DATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, the data bytes are transferred only in byte pairs on SPI bus. For example, even if configuring 1 byte for read, 2 bytes data is received. The last byte should be ignored. The 0 bytes must not configured for read transaction. 0x0: 0 bytes (No data phase) 0x1: 1 byte ⋮ 0x7: 7 bytes 0x8: 8 bytes Others: Setting prohibited	R/W
13:9	LATE[4:0]	Latency cycle These bits configure the latency cycle in manual-command mode. 0x0: No latency 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	TRTYPE	Transaction Type This bit selects the type of transaction. 0: Read transaction (Readout data from slave device) 1: Not read transaction	R/W

Bit	Symbol	Function	R/W
31:16	CMD[15:0]	Command (1-2 bytes) These bits configure the command field in manual-command mode. The number of bytes configured in Command Size bit is transferred. 1S-1S-1S, 4S-4D-4D: CMD[15:8] is command field, CMD[7:0] is not used. 8D-8D-8D profile 1.0: CMD[15:8] is command field, CMD[7:0] is extension field. 8D-8D-8D profile 2.0: CMD[15:0] is upper 2 bytes of command & modifier field. (bit 47-32 in xSPI protocol)	R/W

This register has functions to control xSPI Master function.

36.2.2.9 CDABUFn : xSPI Command Manual Address Buf n (n = 0 to 3)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x084 + 0x10 × n

Bit position:	31																												0
Bit field:	ADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ADD[31:0]	Address These bits configure the address field in manual-command mode. 1S-1S-1S, 4S-4D-4D, 8D-8D-8D profile 1.0: It is address field. 8D-8D-8D profile 2.0: It is lower 4 bytes of command & modifier field. (bit 31-0 in xSPI protocol)	R/W

This register has functions to control xSPI Master function.

36.2.2.10 CDD0BUFn : xSPI Command Manual Data 0 Buf n (n = 0 to 3)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x088 + 0x10 × n

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

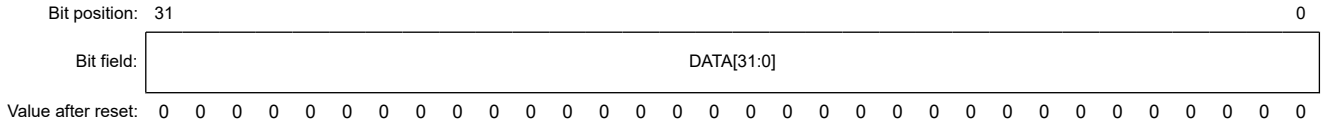
Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

This register has functions to control xSPI Master function.

36.2.2.11 CDD1BUFn : xSPI Command Manual Data 1 Buf n (n = 0 to 3)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x08C + 0x10 × n



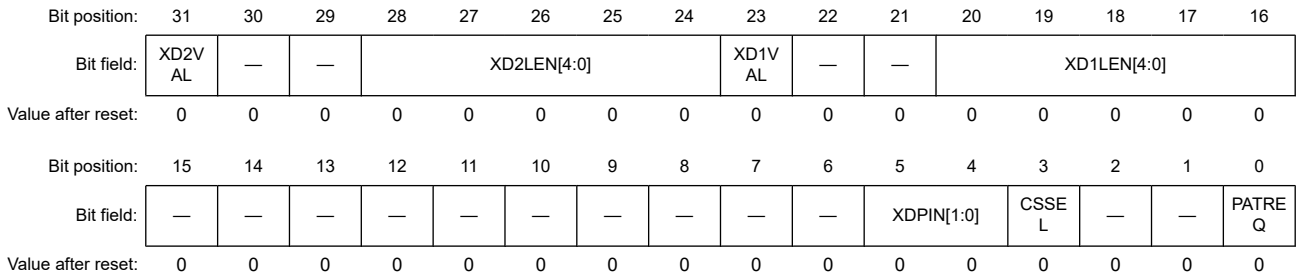
Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

This register has functions to control xSPI Master function.

36.2.2.12 LPCTL0 : xSPI Link Pattern Control Register 0

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x100



Bit	Symbol	Function	R/W
0	PATREQ	Pattern request This bit requests to issue the pattern. When set to 1, it starts the pattern. It is cleared to 0 when the pattern completed. 0: No request XiP Disable pattern 1: Request XiP Disable pattern	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	XDPIN[1:0]	XiP Disable pattern pin These bits select the data output pins to transmit XiP Disable pattern. 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	XD1LEN[4:0]	XiP Disable pattern 1st phase length These bits select the length of 1st phase in XiP disable pattern. The pattern with zero-length both 1st phase and 2nd phase should not be configured. 0x0: 0 cycles 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	XD1VAL	XiP Disable pattern 1st phase value This bit selects the value of 1st phase in XiP disable pattern. 0: Low drive 1: High drive	R/W
28:24	XD2LEN[4:0]	XiP Disable pattern 2nd phase length These bits select the length of 2nd phase in XiP disable pattern. 0x00: 0 cycles 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	XD2VAL	XiP Disable pattern 2nd phase value This bit selects the value of 2nd phase in XiP disable pattern. 0: Low drive 1: High drive	R/W

This register has functions to control xSPI Master function.

36.2.2.13 LPCTL1 : xSPI Link Pattern Control Register 1

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RSTSU[2:0]			—	RSTWID[2:0]			—	—	RSTREP[1:0]		CSSEL	—	PATREQ[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PATREQ[1:0]	Pattern request These bits request to issue the pattern. When set to 01b or 10b, it starts the pattern. It is cleared to 00b when the pattern completed. 0 0: No request 0 1: Request Reset pattern 1 0: Request CS only pattern 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W

Bit	Symbol	Function	R/W
5:4	RSTREP[1:0]	Reset pattern repeat These bits select the repeating time to toggle CS from LOW to HIGH. 0 0: 4 times (Specified on Reset Signaling Protocol) 0 1: 5 times 1 0: 6 times 1 1: 7 times	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RSTWID[2:0]	Reset pattern width These bits configure the width of cycle in reset pattern and CS only pattern. It toggles CS with the configured cycle. 0 0 0: 2 (= 2^1) cycles 0 0 1: 4 (= 2^2) cycles ⋮ 1 1 0: 128 (= 2^7) cycles 1 1 1: 256 (= 2^8) cycles	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
14:12	RSTSU[2:0]	Reset pattern data output setup time These bits configure the number of setup cycle for data output based on the edge of CS in reset pattern. It needs enough setup time because xSPI slave samples any data at the rising edge of CS. This cycle of setup time should be less than the cycle of reset pattern width (RSTWID[2:0]). 0 0 0: 1 cycle 0 0 1: 2 cycles ⋮ 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.14 LIOCTL : xSPI Link I/O Control Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTCS1	RSTCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WPCS1	WPCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	WPCS0*1	WP drive for slave0 This bit controls the value of Write Protect port. It can be useful only for xSPI slave with write protect port. 0: Drive Low level 1: Drive High level	R/W
1	WPCS1*1	WP drive for slave1 This function is same as WPCS0. 0: Drive Low level 1: Drive High level	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	RSTCS0*1	Reset drive for slave0 This bit controls the value of xSPI reset port. It can be useful only for xSPI slave with reset port. 0: Drive Low level 1: Drive High level	R/W
17	RSTCS1*1	Reset drive for slave1 This function is same as RSTCS0. 0: Drive Low level 1: Drive High level	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. For xSPI1, these bits are not available.

This register has functions to control xSPI Master function.

36.2.2.15 CCCTL0CSn : xSPI Command Calibration Control Register 0 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x130 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CASFTEND[4:0]					—	—	—	CASFTSTA[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAITV[4:0]					—	—	—	—	—	—	CANOWR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAEN	Automatic Calibration Enable This bit enables the automatic calibration. When set to 1, it transmits the calibration sequence periodically and adjusts the value of phase shift. When set to 0 during the calibration sequence, it stops after completed ongoing calibration sequence, and then this bit is cleared. 0: Disable automatic calibration 1: Enable automatic calibration	R/W
1	CANOWR	Calibration no write mode This bit selects to omit write command in calibration sequence. It can be used for any slave device with fixed calibration pattern data. 0: Calibration sequence with write command 1: Calibration sequence without write command	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
12:8	CAITV[4:0]	Calibration interval These bits configure the interval between calibration patterns. 0x00: 2 (= 2^1) cycle wait 0x01: 4 (= 2^2) cycle wait ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycle wait 0x1F: 4,294,967,296 (= 2^{32}) cycle wait	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CASFTSTA[4:0]	Calibration DS shift start value These bits configure the start value of DS shift.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CASFTEND[4:0]	Calibration DS shift end value These bits configure the end value of DS shift. It should be equal or more than the start value (CASFTSTA).	R/W

Bit	Symbol	Function	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

36.2.2.16 CCCTL1CSn : xSPI Command Calibration Control Register 1 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x134 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CARDLATE[4:0]					—	—	—	CAWRLATE[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CADATASIZE[3:0]				CAADDSIZE[2:0]			CACMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CACMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
4:2	CAADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	CADATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, it should be configured with even byte. 0x0: 1 byte 0x1: 2 bytes ⋮ 0xE: 15 bytes 0xF: 16 bytes	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CAWRLATE[4:0]	Write Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
28:24	CARDLATE[4:0]	Read Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.17 CCCTL2CSn : xSPI Command Calibration Control Register 2 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x138 + 0x020 × n

Bit position:	31															16	15														0
Bit field:	CARDCMD[15:0]																CAWRCMD[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CAWRCMD[15:0]	Calibration pattern write command These bits configure the calibration pattern write command.	R/W
31:16	CARDCMD[15:0]	Calibration pattern read command These bits configure the calibration pattern read command.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.18 CCCTL3CSn : xSPI Command Calibration Control Register 3 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x13C + 0x020 × n

Bit position:	31																														0
Bit field:	CAADD[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

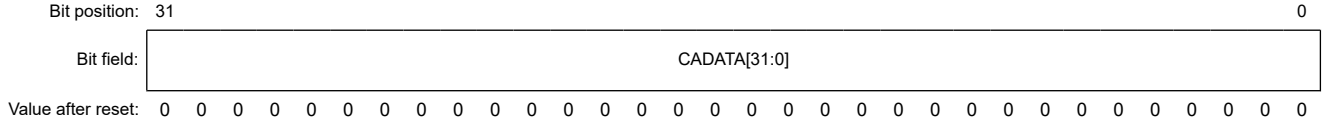
Bit	Symbol	Function	R/W
31:0	CAADD[31:0]	Calibration pattern address These bits configure the calibration pattern address.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.19 CCCTL4CSn : xSPI Command Calibration Control Register 4 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x140 + 0x020 × n



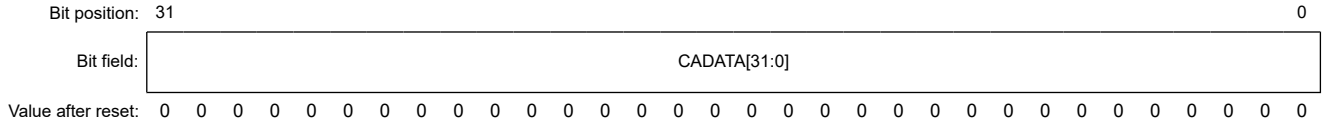
Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.20 CCCTL5CSn : xSPI Command Calibration Control Register 5 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x144 + 0x020 × n



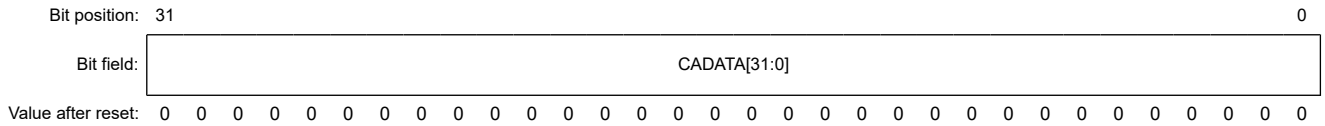
Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.21 CCCTL6CSn : xSPI Command Calibration Control Register 6 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x148 + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.2.22 CCCTL7CSn : xSPI Command Calibration Control Register 7 CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x14C + 0x020 × n

Bit position:	31																												0
Bit field:	CADATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

36.2.3 xSPI Status Registers

These registers monitor the status of xSPI Master.

36.2.3.1 VERSTT : xSPI Version Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x180

Bit position:	31																												0
Bit field:	VER[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	VER[31:0]	Version These bits indicate this IP version.	R

This register indicates the status of xSPI Master.

36.2.3.2 COMSTT : xSPI Common Status Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	RSTOCS1	INTCS1	ECSCS1	—	RSTOCS0	INTCS0	ECSCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	WRBUFNE	—	PBUFNE	—	—	—	MEMACC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMACC	Memory access ongoing 0: AHB channel is not accessing to memory. 1: AHB channel is accessing to memory.	R
3:1	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
4	PBUFNE	Prefetch Buffer Not Empty 0: Empty 1: Not empty	R
5	—	This bit is read as 0.	R
6	WRBUFNE	Write Buffer Not Empty 0: Empty 1: Not empty	R
15:7	—	These bits are read as 0.	R
16	ECSCS0*1	ECS monitor for slave0 This bit indicates the value of ECS port. 0: Low level 1: High level	R
17	INTCS0*1	INT monitor for slave0 This bit indicates the value of INT port. 0: Low level 1: High level	R
18	RSTOCS0*1	RSTO monitor for slave0 This bit indicates the value of RSTO port. 0: Low level 1: High level	R
19	—	This bit is read as 0.	R
20	ECSCS1*1	ECS monitor for slave1 This function is same as ECSCS0. 0: Low level 1: High level	R
21	INTCS1*1	INT monitor for slave1 This function is same as INTCS0. 0: Low level 1: High level	R
22	RSTOCS1*1	RSTO monitor for slave1 This function is same as RSTOCS0. 0: Low level 1: High level	R
31:23	—	These bits are read as 0.	R

Note 1. For xSPI1, these bits are not available.

This register indicates the status of xSPI Master.

36.2.3.3 CASTTCSn : xSPI Calibration Status Register CSn (n = 0, 1)

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x188 + 0x004 × n

Bit position:	31																													0
Bit field:	CASUC[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CASUC[31:0]	Calibration Success These bits indicate the calibration success for each DS shift value. It is updated when completed each calibration sequence. CASUC[x] indicates calibration success in DS shift value = x.	R

This register indicates the status of xSPI Master.

36.2.4 xSPI Interrupt Registers

These registers control the interrupt function of xSPI Master.

36.2.4.1 INTS : xSPI Interrupt Status Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x190

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1	CASUCCS0	CAFAILCS1	CAFAILCS0	—	—	—	—	—	—	—	BUSERR	—	BRGUF	—	BRGOF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1	INTCS0	—	—	ECSCS1	ECSCS0	—	—	DSTOCS1	DSTOCS0	PERTO	INICMP	PATCMP	CMDCMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMP	Command Completed This bit is set to 1 when completed the requested manual-command. In direct manual-command, it means all transactions completed. In periodic manual-command, it means the read data matches with the expected data. 0: No detection 1: Detection	R
1	PATCMP	Pattern Completed This bit is set to 1 when completed the requested pattern. 0: No detection 1: Detection	R
2	INICMP	Initial Sequence Completed This bit is set to 1 when completed the initial sequence. 0: No detection 1: Detection	R
3	PERTO	Periodic transaction timeout This bit is set to 1 when the read value does not match with the expected value in periodic manual-command mode. 0: No detection 1: Detection	R
4	DSTOCS0	DS timeout for slave0 This bit is set to 1 when lost DS in read transaction with using DS. It means not receiving the data during expected read phase. In this case, xSPI master stops the read transaction and the following transaction. 0: No detection 1: Detection	R
5	DSTOCS1	DS timeout for slave1 This function is same as DSTOCS0. 0: No detection 1: Detection	R
7:6	—	These bits are read as 0.	R
8	ECSCS0	ECC error detection for slave0 This bit is set to 1 when detected the falling edge on ECS port. It can be useful only for xSPI slave with ECC detection function. 0: No detection 1: Detection	R
9	ECSCS1	ECC error detection for slave1 This function is same as ECSCS0. 0: No detection 1: Detection	R

Bit	Symbol	Function	R/W
11:10	—	These bits are read as 0.	R
12	INTCS0	Interrupt detection for slave0 This bit is set to 1 when detected the falling edge on INT port. It can be useful only for xSPI slave with interrupt function. 0: No detection 1: Detection	R
13	INTCS1	Interrupt detection for slave1 This function is same as INTCS0. 0: No detection 1: Detection	R
15:14	—	These bits are read as 0.	R
16	BRGOF	Bridge Buffer overflow This bit is read as 0.	R
17	—	This bit is read as 0.	R
18	BRGUF	Bridge Buffer underflow This bit is read as 0.	R
19	—	This bit is read as 0.	R
20	BUSERR	AHB bus error This bit is set to 1 when an error response occurs on AHB channel.	R
27:21	—	These bits are read as 0.	R
28	CAFAILCS0	Calibration failed for slave0 This bit is set to 1 when failed calibration. 0: No detection 1: Detection	R
29	CAFAILCS1	Calibration failed for slave1 This function is same as CAFAILCS0. 0: No detection 1: Detection	R
30	CASUCCS0	Calibration success for slave0 This bit is set to 1 when success calibration. 0: No detection 1: Detection	R
31	CASUCCS1	Calibration success for slave1 This function is same as CASUCCS0. 0: No detection 1: Detection	R

This register indicates the status of interrupt. The bits in this register are cleared to 0 when writing 1 on the corresponding bit of INTC register.

36.2.4.2 INTC : xSPI Interrupt Clear Register

Base address: XSPIm = 0x8022_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1C	CASUCCS0C	CAFAILCS1C	CAFAILCS0C	—	—	—	—	—	—	—	BUSERRC	—	BRGUFC	—	BRGOFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1C	INTCS0C	—	—	ECSCS1C	ECSCS0C	—	—	DSTOCS1C	DSTOCS0C	PERTOC	INICMPC	PATCMPC	CMDCMPC

17	—	This bit is read as 0. The write value should be 0.	R/W
18	BRGUFE	Bridge Buffer underflow interrupt enable 0: Disabled 1: Enabled	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	BUSERRE	AHB bus error interrupt enable 0: Disabled 1: Enabled	R/W
27:21	—	These bits are read as 0. The write value should be 0.	R/W
28	CAFAILCS0E	Calibration failed for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
29	CAFAILCS1E	Calibration failed for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
30	CASUCCS0E	Calibration success for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
31	CASUCCS1E	Calibration success for slave1 interrupt enable 0: Disabled 1: Enabled	R/W

This register enables the interrupt.

36.3 Operation

xSPI Master interface has the functions to issue the transaction for external memory with xSPI Slave interface. It allows to write to registers in external memory or read from it.

This xSPI Master mainly has two modes to issue the transaction. One is a manual-command mode; Software configures all fields of xSPI frame and starts the transaction by software request. The other is a memory-mapping mode; it automatically converts AHB access for pre-configured memory area into xSPI transaction. It enables to access from AHB to external memory area outside of chip via xSPI bus.

This section describes the xSPI bus operation, the direct control of xSPI frame (manual-command), the control of memory access (memory-mapping), the error operation, and the flow to operation.

36.3.1 xSPI Bus

This section describes the xSPI bus operation.

36.3.1.1 Supported Protocol Mode

This xSPI Master supports various protocol modes. It is configured by Protocol mode bits (LIOCFGCSn.PRTMD[9:0]). The table below shows the summary of protocol modes.

Table 36.4 Supported protocol mode (1 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
1S-1S-1S	Command, Address, and Data fields are transferred at SDR with using 1 pin. Read data is sampled with CK.	0x000	Specified by xSPI protocol
4S-4D-4D	Command field is transferred at SDR with using 4 pins. Address and Data fields are transferred at DDR with using 4 pins. Read data is sampled with DS.	0x3B2	Specified by xSPI protocol

Table 36.4 Supported protocol mode (2 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
8D-8D-8D	Command, Address, and Data fields are transferred at DDR with using 8 pins. Read data is sampled with DS.	0x3FF	Specified by xSPI protocol
1S-2S-2S	Command field is transferred at SDR with using 1 pin. Address and Data fields are transferred at SDR with using 2 pins. Read data is sampled with CK.	0x048	—
2S-2S-2S	Command, Address, and Data fields are transferred at SDR with using 2 pins. Read data is sampled with CK.	0x049	—
1S-4S-4S	Command field is transferred at SDR with using 1 pin. Address and Data fields are transferred at SDR with using 4 pins. Read data is sampled with CK.	0x090	—
4S-4S-4S	Command, Address, and Data fields are transferred at SDR with using 4 pins. Read data is sampled with CK.	0x092	—

Note: In case of XiP mode enable, XiP code is inserted in Latency field. It is valid only for memory-mapping mode.

The table below shows a description of the main internal signals.

Table 36.5 Internal signals

Signal name	I/O	Function
clk_spi	I	xSPI control clock
spi_ck	O	xSPI Clock (Same as XSPIm_CKP pin)
spi_cs0	O	xSPI Chip Select for slave0 (Same as XSPIm_CS0# pin)
spi_cs1	O	xSPI Chip Select for slave1 (Same as XSPIm_CS1# pin)
spi_doe[7:0]	O	xSPI Data Output Enable
spi_do[7:0]	O	xSPI Data Output
spi_di[7:0]	I	xSPI Data Input
spi_dsoe	O	xSPI Data Strobe Output Enable
spi_dso	O	xSPI Data Strobe Output
spi_dsi	I	xSPI Data Strobe Input

The bytes of Command and Address fields are transferred in highest order to lowest order sequence. The sequential bytes of Data field are transferred in lowest address to highest address order. In case of using multiple pins, the least significant bit of each byte is placed on spi_do/di[0] with each higher order bit on the successively higher numbered spi_do/di signals.

The figure below shows timing-chart for 1S-1S-1S protocol mode. The spi_do[0] signal is used for output data and the spi_di[1] signal is used for input data.

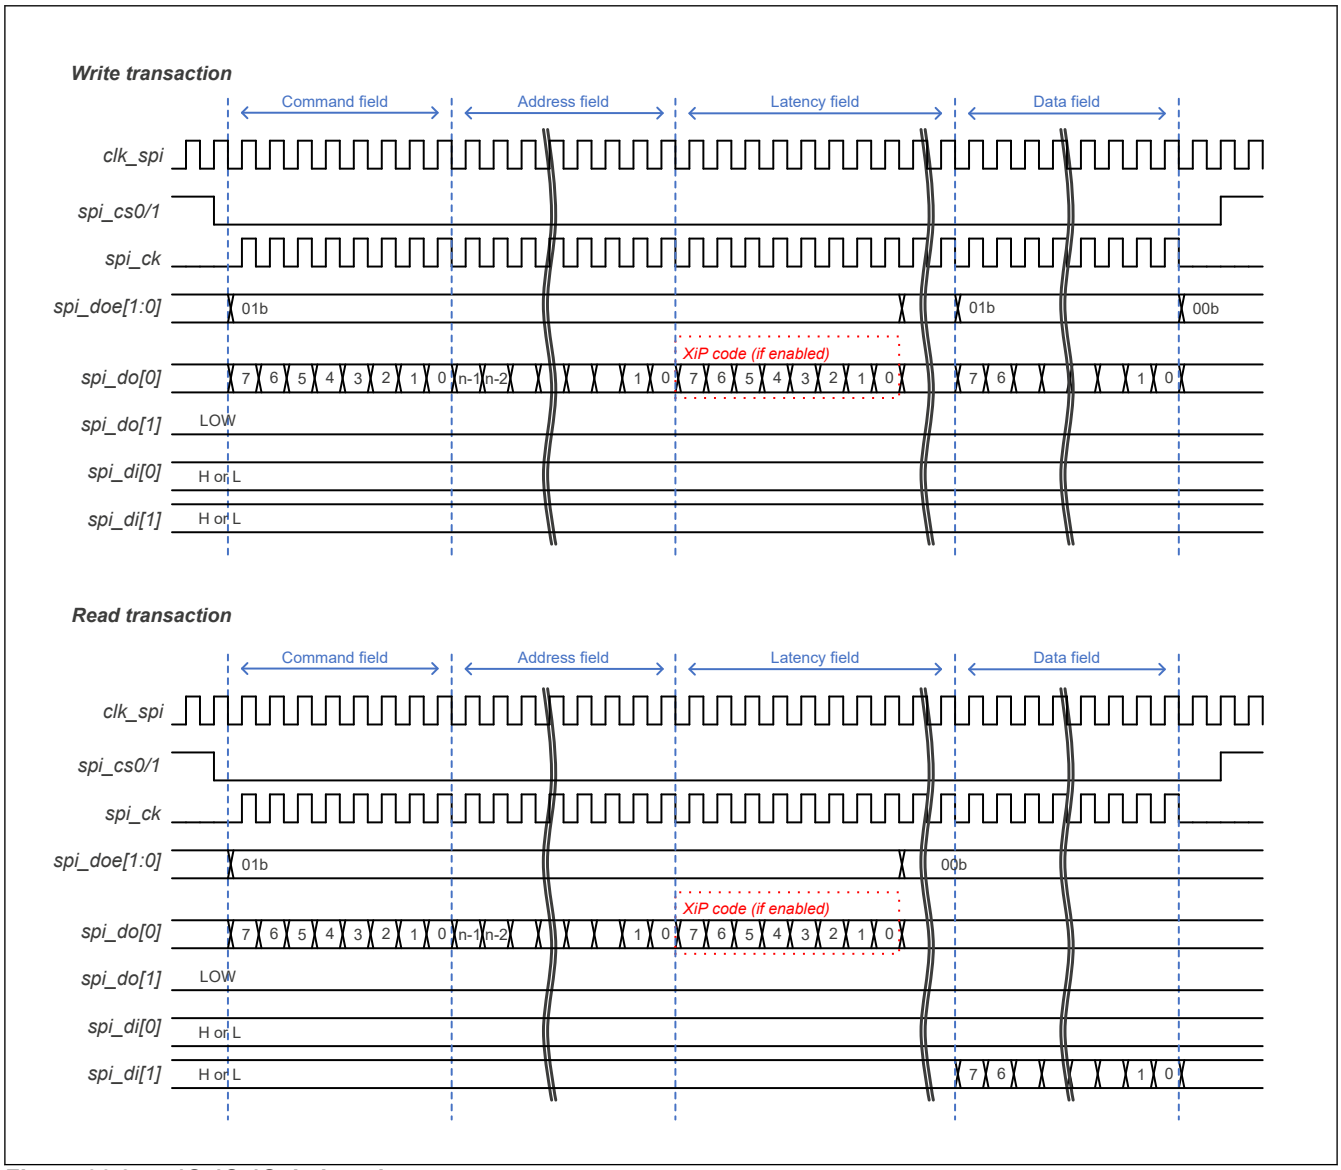

Figure 36.2 1S-1S-1S timing-chart

The figure below shows timing-chart for 1S-2S-2S protocol mode.

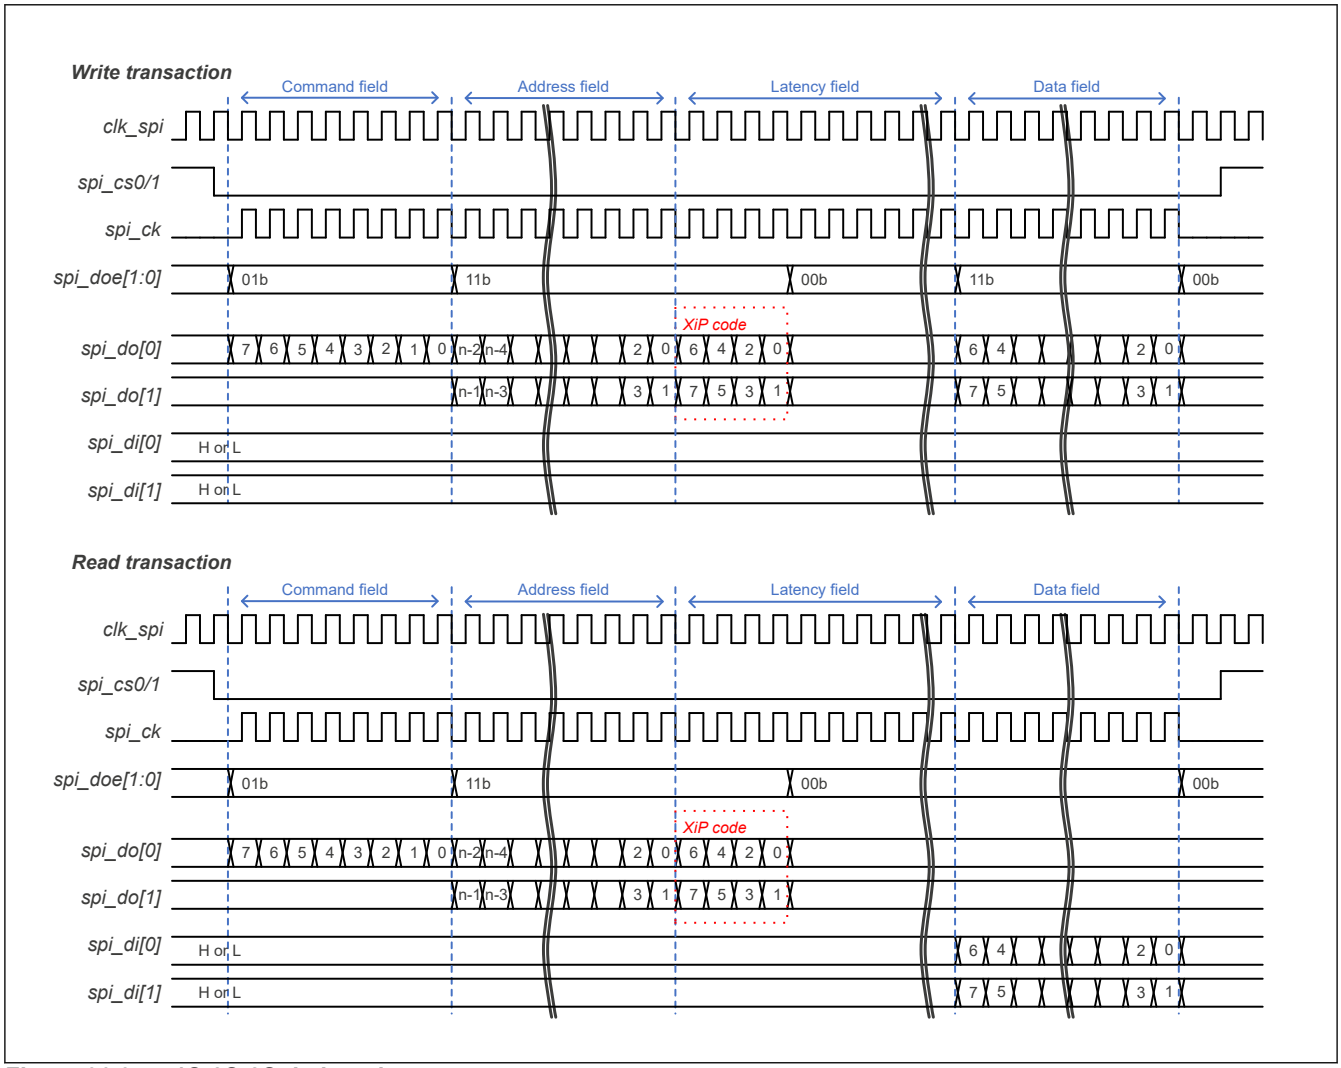

Figure 36.3 1S-2S-2S timing-chart

The figure below shows timing-chart for 4S-4D-4D protocol mode.

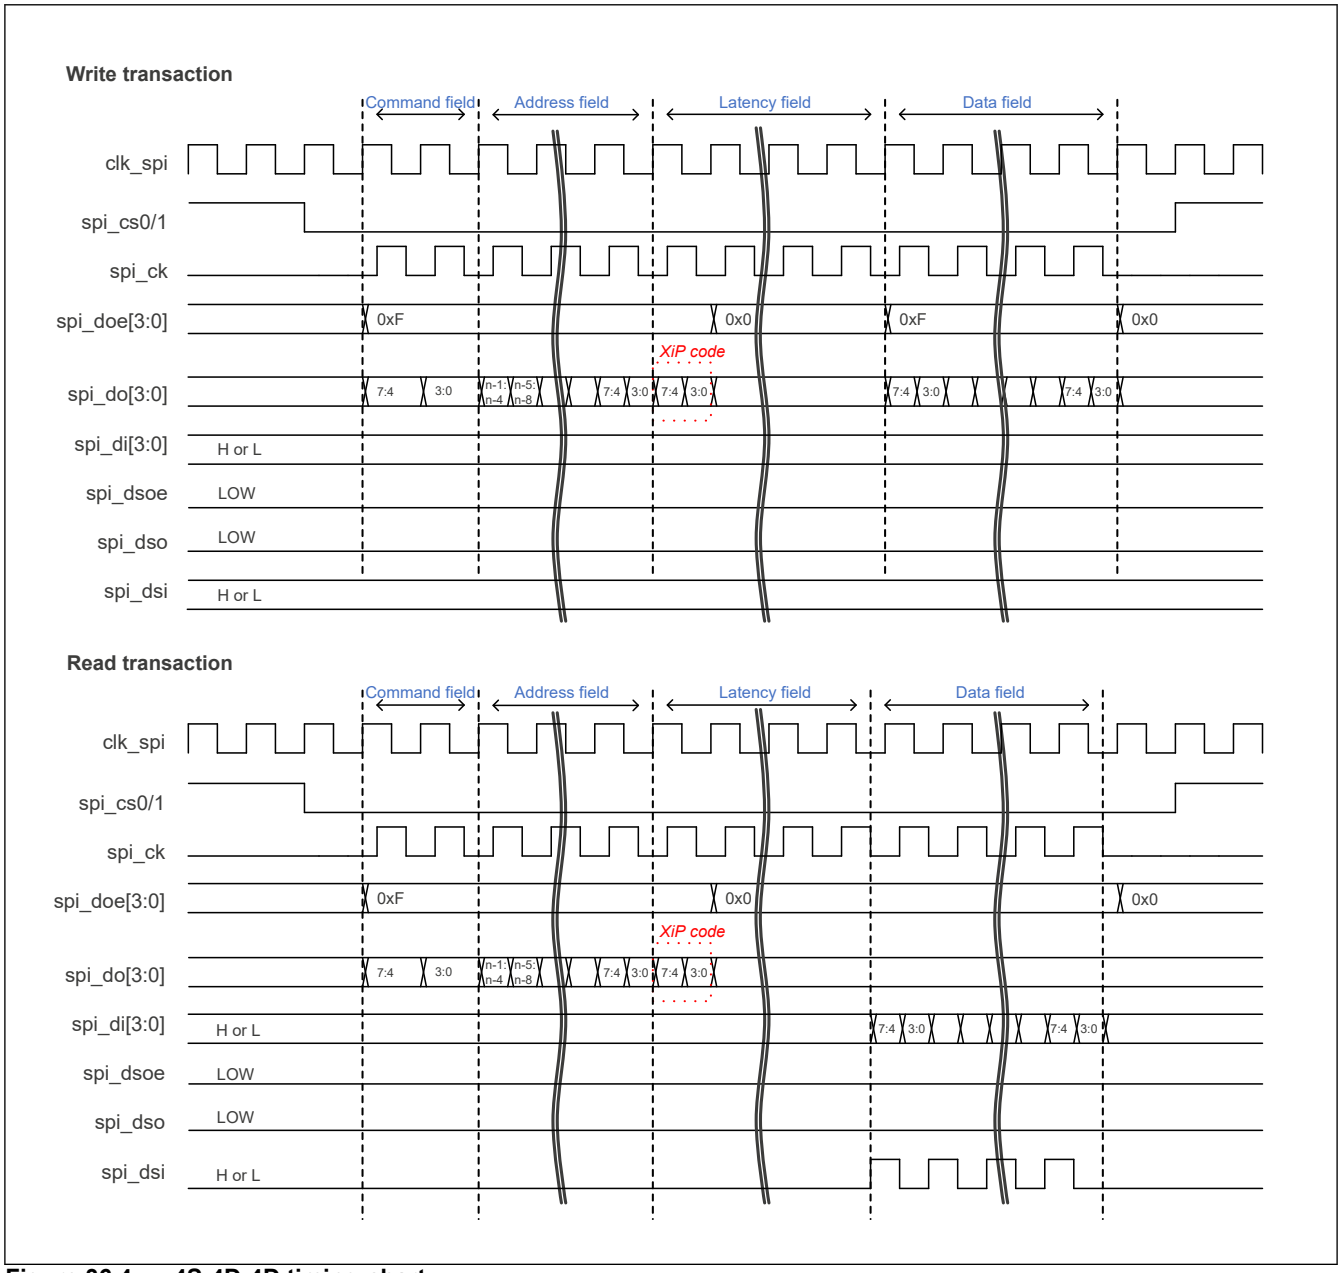

Figure 36.4 4S-4D-4D timing-chart

The figure below shows timing-chart for 8D-8D-8D profile 1.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

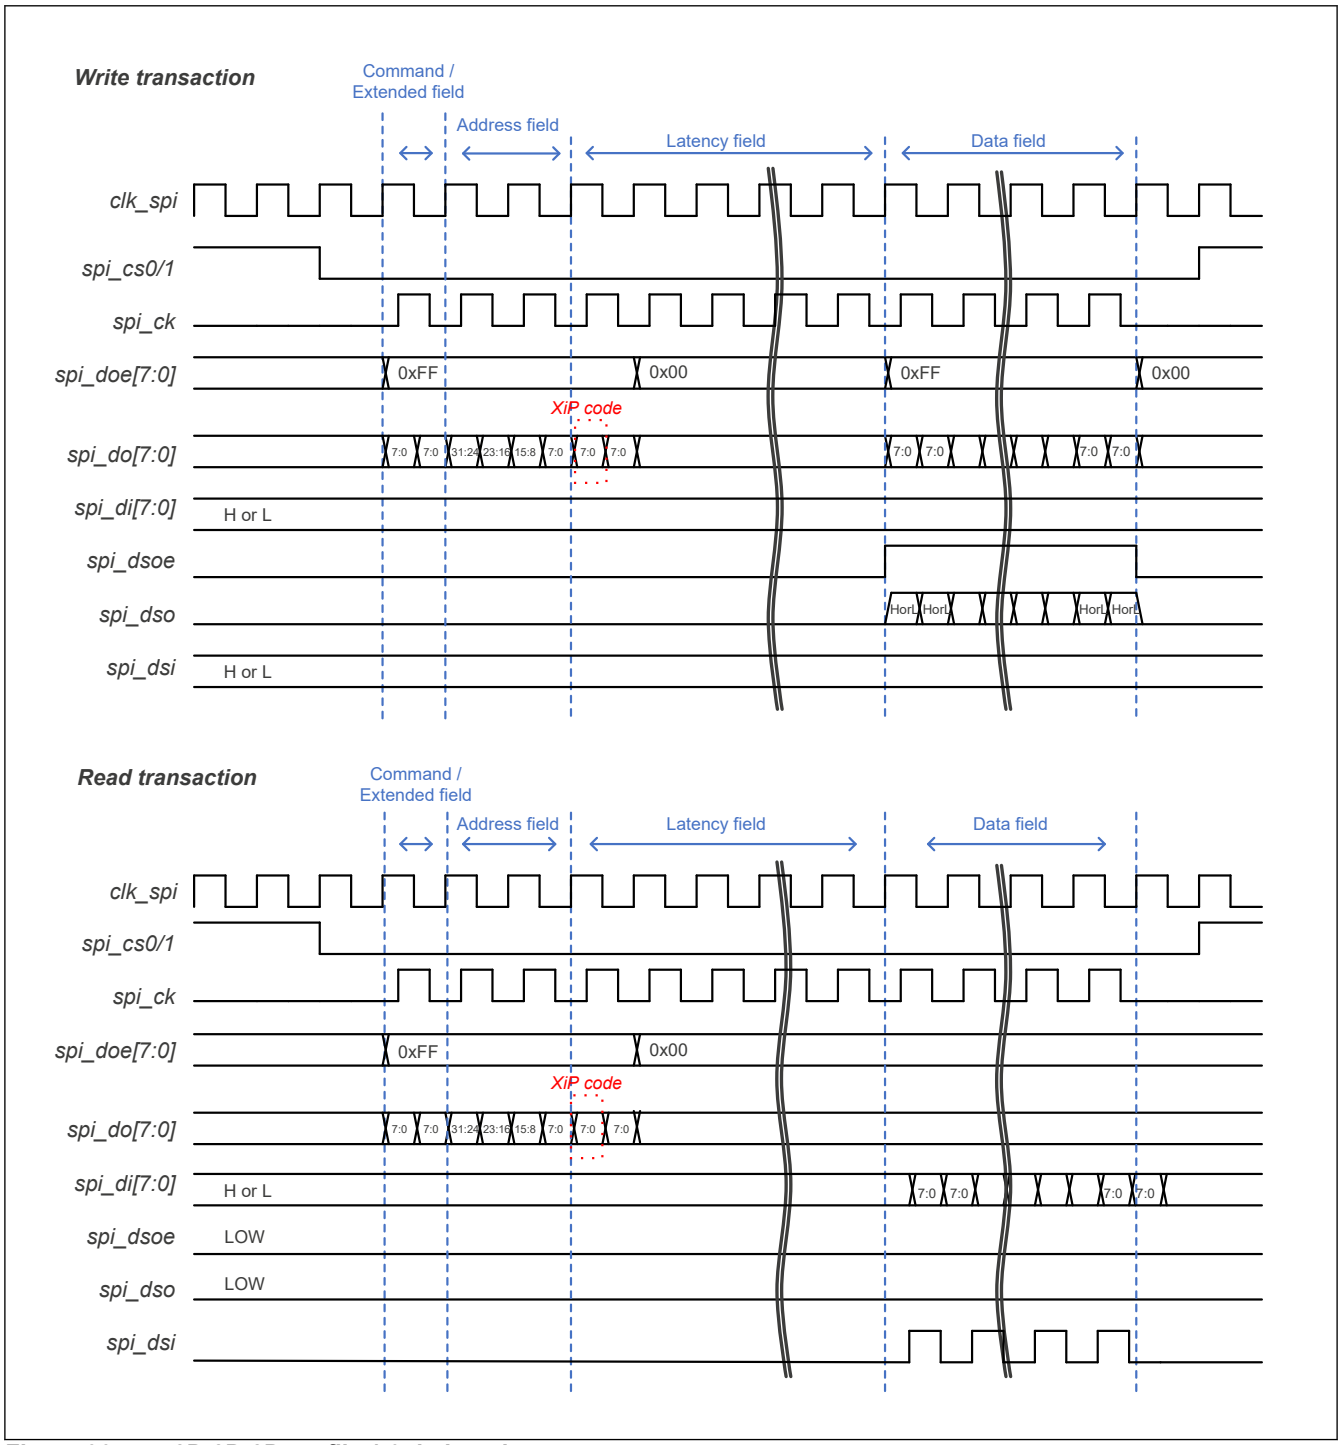

Figure 36.5 8D-8D-8D profile 1.0 timing-chart

The figure below shows timing-chart for 8D-8D-8D profile 2.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

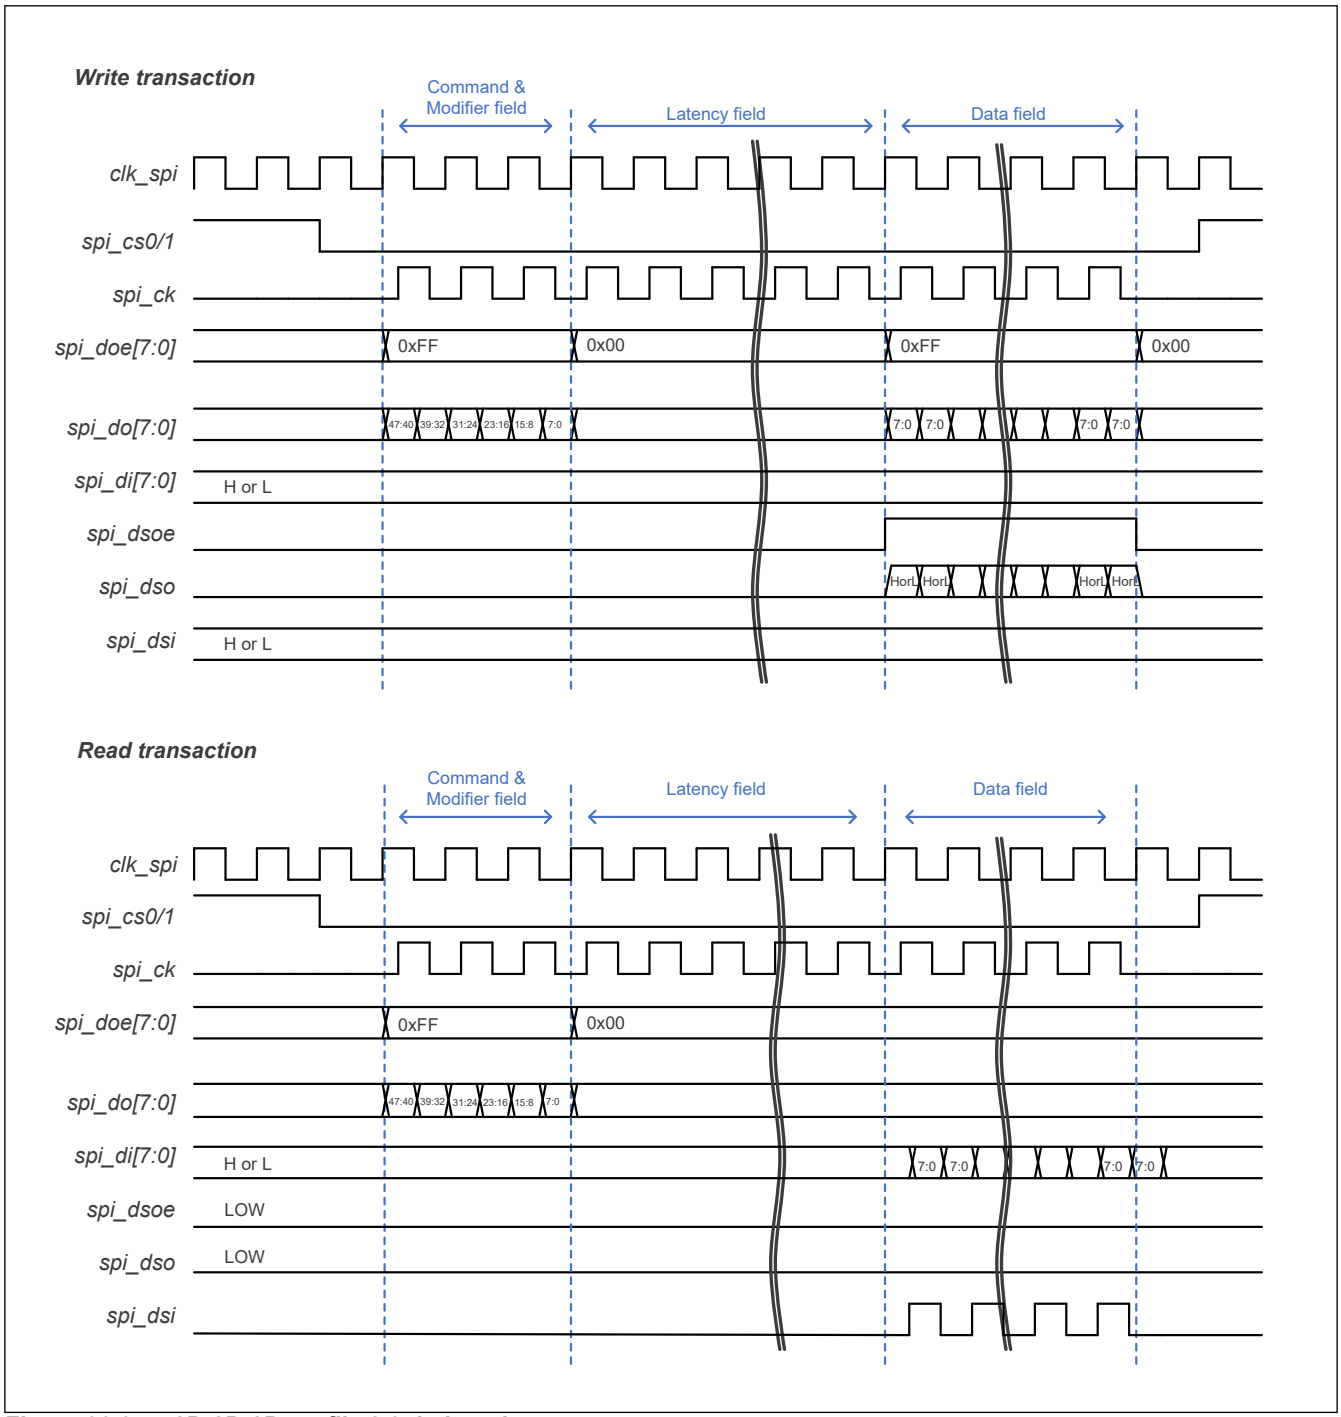

Figure 36.6 8D-8D-8D profile 2.0 timing-chart

36.3.1.2 xSPI Frame Interval

The interval between xSPI frames is configured with CS minimum idle term bits (LIOCFGCSn.CSMIN[3:0]). It depends on the specification of xSPI slave device.

36.3.1.3 xSPI Signals Timing Control

This xSPI Master supports both SDR and DDR. And it is possible to sample input data with Data-Strobe (DS) signal at SDR. For various modes and easy implementation, this xSPI Master could adjust the timing to drive/sample xSPI interface signals statically. The table below shows the summary of xSPI Interface signal timing control.

Table 36.6 Summary of xSPI signals timing control

Signal	Mode	Default operation	Timing Control (n = 0, 1)
CS (spi_cs) drive	—	Asserting 1 cycle before the rising-edge of first spi_ck	1 cycle extension for asserting with LIOCFGCSn.CSASTEX bit
		Negating 1.5 cycle after the falling-edge of last spi_ck	1 cycle extension for negating with LIOCFGCSn.CSNEGEX bit
CK (spi_ck) drive	SDR without DS SDR with DS	Reference point	—
	DDR with DS	Reference point	—
DO/DOE (spi_do/doe) drive	SDR without DS SDR with DS	Falling edge of clk_spi	0 or 0.5 cycle shift with LIOCFGCSn.SDRDRV bit
	DDR with DS	Both edges of clk_spi	—
DI (spi_di) sample	SDR without DS	Falling edge of spi_ck on expected data size	0 to 7 cycle shift (1 cycle unit) with LIOCFGCSn.SDRSMPSFT[3:0] bits 0 or 0.5 cycle shift with LIOCFGCSn.SDRSMPMD bit
	SDR with DS	Falling edge of spi_dsi signal on expected data size	Sample at rising edge with LIOCFGCSn.SDRSMPMD bit 0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits
	DDR with DS	Both edges of spi_dsi signal on expected data size	0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits

Note: In DDR on xSPI protocol, CK or DS should be aligned for center of data. It means to shift the phase by 0.25 cycle (90 degrees). This xSPI master supports to adjust this phase depending on the usage conditions.

The figure below shows the default operation and timing control for SDR without DS.

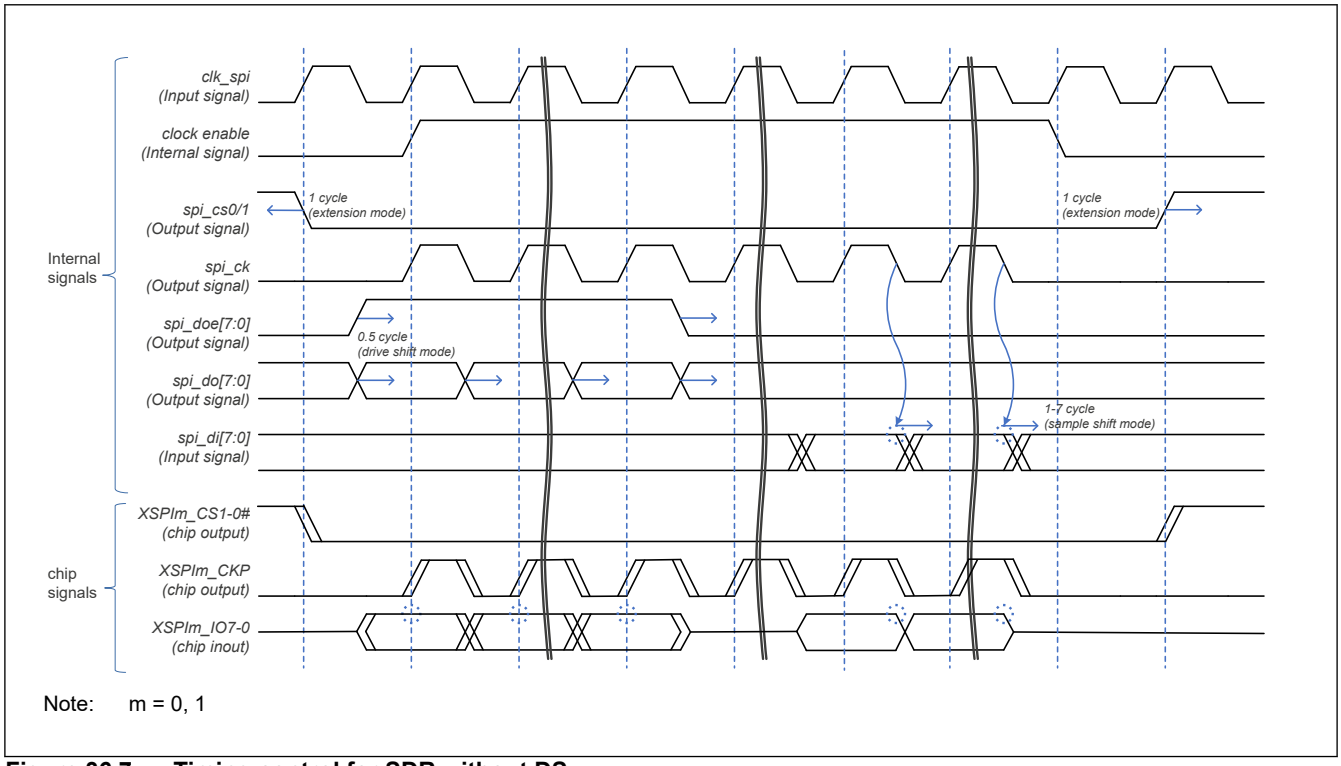

Figure 36.7 Timing control for SDR without DS

The figure below shows the default operation and timing control for SDR with DS.

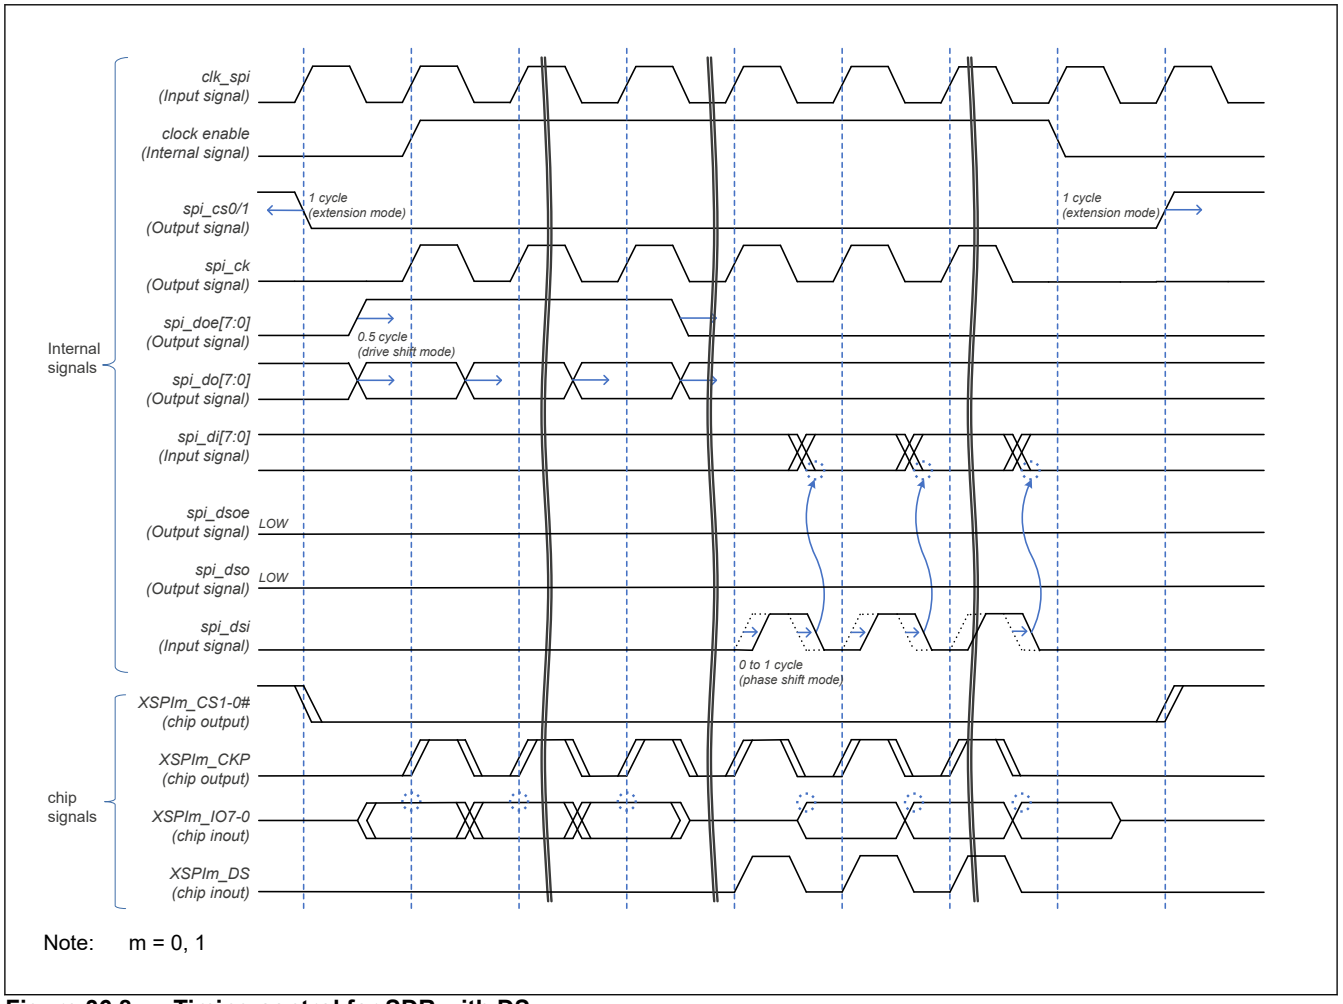

Figure 36.8 Timing control for SDR with DS

The figure below shows the default operation and timing control for DDR with DS.

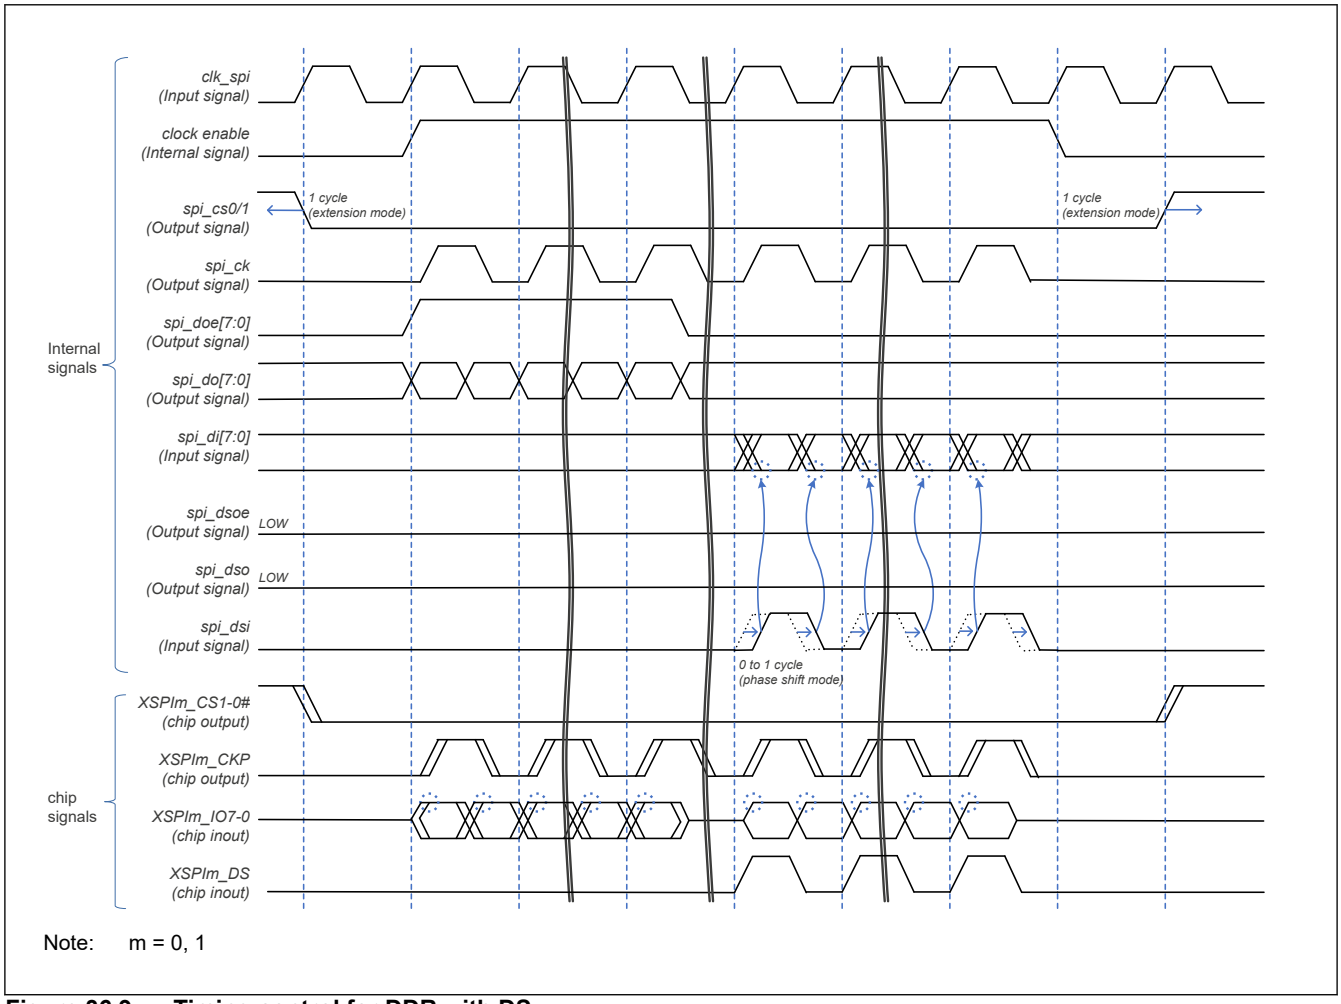

Figure 36.9 Timing control for DDR with DS

36.3.2 Manual-command

This section describes the manual-command mode. The manual-command has two functional modes: direct mode and periodic mode.

36.3.2.1 Direct Mode

This mode sequentially can issue up to four xSPI transactions configured and requested by Software. A series of transaction can be issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 0). The number of transactions (CDCTL0.TRNUM[1:0]) can be configured up to 4. It can be used to change the mode or read the status of xSPI slave device.

The table below shows the configured register bits for direct manual-command. The operating flow is illustrated in Figure 36.22.

Table 36.7 Manual-command configuration for direct mode (1 of 2)

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
1st Transaction	CDTBUF0.TRTYPE	CDTBUF0.CMD[15:0]	CDTBUF0.CMDSIZE[1:0]	CDABUF0.ADD[31:0]	CDTBUF0.ADDSIZE[2:0]	CDDxBUF0.DATA[31:0]	CDTBUF0.DATASIZE[3:0]	CDTBUF0.LATE[4:0]

Table 36.7 Manual-command configuration for direct mode (2 of 2)

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
2nd Transaction	CDTBUF1.TRTYPE	CDTBUF1.CMD[15:0]	CDTBUF1.CMDSIZE[1:0]	CDABUF1.ADD[31:0]	CDTBUF1.ADDSIZE[2:0]	CDDxBUF1.DATA[31:0]	CDTBUF1.DATASIZE[3:0]	CDTBUF1.LATE[4:0]
3rd Transaction	CDTBUF2.TRTYPE	CDTBUF2.CMD[15:0]	CDTBUF2.CMDSIZE[1:0]	CDABUF2.ADD[31:0]	CDTBUF2.ADDSIZE[2:0]	CDDxBUF2.DATA[31:0]	CDTBUF2.DATASIZE[3:0]	CDTBUF2.LATE[4:0]
4th Transaction	CDTBUF3.TRTYPE	CDTBUF3.CMD[15:0]	CDTBUF3.CMDSIZE[1:0]	CDABUF3.ADD[31:0]	CDTBUF3.ADDSIZE[2:0]	CDDxBUF3.DATA[31:0]	CDTBUF3.DATASIZE[3:0]	CDTBUF3.LATE[4:0]

36.3.2.2 Periodic Mode

This mode periodically issues an xSPI read transaction configured and requested by Software. And it can compare the read value up to 4 bytes with expected value. The transaction is issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 1). It can be used to alternate the status polling operation of xSPI slave device.

The periodic term is configured in Periodic transaction interval bits (CDCTL0.PERITV[4:0]). The expected value is configured in Periodic transaction expected and masked value bits (CDCTL1.PEREXP[31:0] and CDCTL2.PERMSK[31:0]). The table below shows the configured register bits for periodic manual-command. The operating flow is illustrated in Figure 36.23.

Table 36.8 Manual-command configuration for periodic mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
Read Transaction	CDTBUF0.TRTYPE	CDTBUF0.CMD[15:0]	CDTBUF0.CMDSIZE[1:0]	CDABUF0.ADD[31:0]	CDTBUF0.ADDSIZE[2:0]	CDDxBUF0.DATA[31:0]	CDTBUF0.DATASIZE[3:0]	CDTBUF0.LATE[4:0]

36.3.3 Memory-mapping

This section describes the memory-mapping mode. This mode automatically converts AHB access for pre-configured memory area into xSPI transaction.

36.3.3.1 Configuration

In this operation, the payload of address and data field are delivered from AHB signals. The information of command field and size are delivered from the configured register bits. The table below shows the register bits configured for memory-mapping.

Table 36.9 Memory-mapping configuration for memory area access (n = 0, 1) (1 of 2)

AHB Transaction	Format Change mode	Command	Command size	Address size	Latency cycle
Write for slave n memory area	Normal	CMCFG2CSn.WRCMD[15:8]	1 byte	CMCFG0CSn.ADDSIZE[1:0]	CMCFG2CSn.WRLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG2CSn.WRCMD[15:0]	2 bytes		
	8D-8D-8D profile 2.0 Command Modifier	CMCFG2CSn.WRCMD[15:8]	1 byte	5 bytes	
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG2CSn.WRCMD[15:13]	3 bits	45 bits	

Table 36.9 Memory-mapping configuration for memory area access (n = 0, 1) (2 of 2)

AHB Transaction	Format Change mode	Command	Command size	Address size	Latency cycle
Read for slave n memory area	Normal	CMCFG1CSn. RDCMD[15:8]	1 byte	CMCFG0CSn. ADDSIZE[1:0]	CMCFG1CSn. RDLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG1CSn. RDCMD[15:0]	2 bytes		
	8D-8D-8D profile 2.0 Command Modifier	CMCFG1CSn. RDCMD[15:8]	1 byte	5 bytes	
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG1CSn. RDCMD[15:13]	3 bits	45 bits	

Note: The MSByte of Address can be replaced with Address Replace Enable and Code bits (CMCFG0CSn.ADDRPEN[7:0] / ADDRPCD[7:0]).

36.3.3.2 Write Access Operation

In AHB write access for memory area, this xSPI Master stores all payload data in internal bridge buffer and then issues a write transaction into xSPI slave. The figure below shows the operation summary.

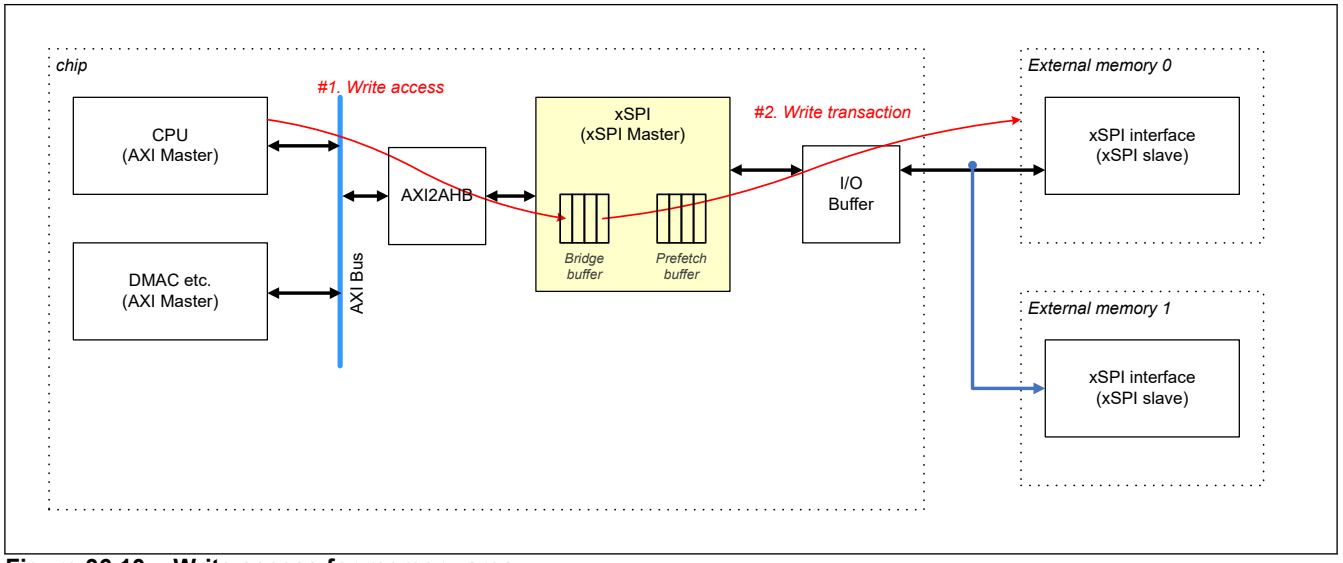

Figure 36.10 Write access for memory area

The operation of xSPI bus changes depending on AHB burst type. When HBURST is SINGLE or INCR, one AHB transaction occurs for one xSPI frame. When HBURST is INCR4, INCR8, or INCR16, AHB transactions equal to burst size occur for one xSPI frame. When HBURST is WRAP4, WRAP8, or WRAP16, AHB transactions occur for two xSPI frames. The figure below shows the relationship between AHB and xSPI frames.

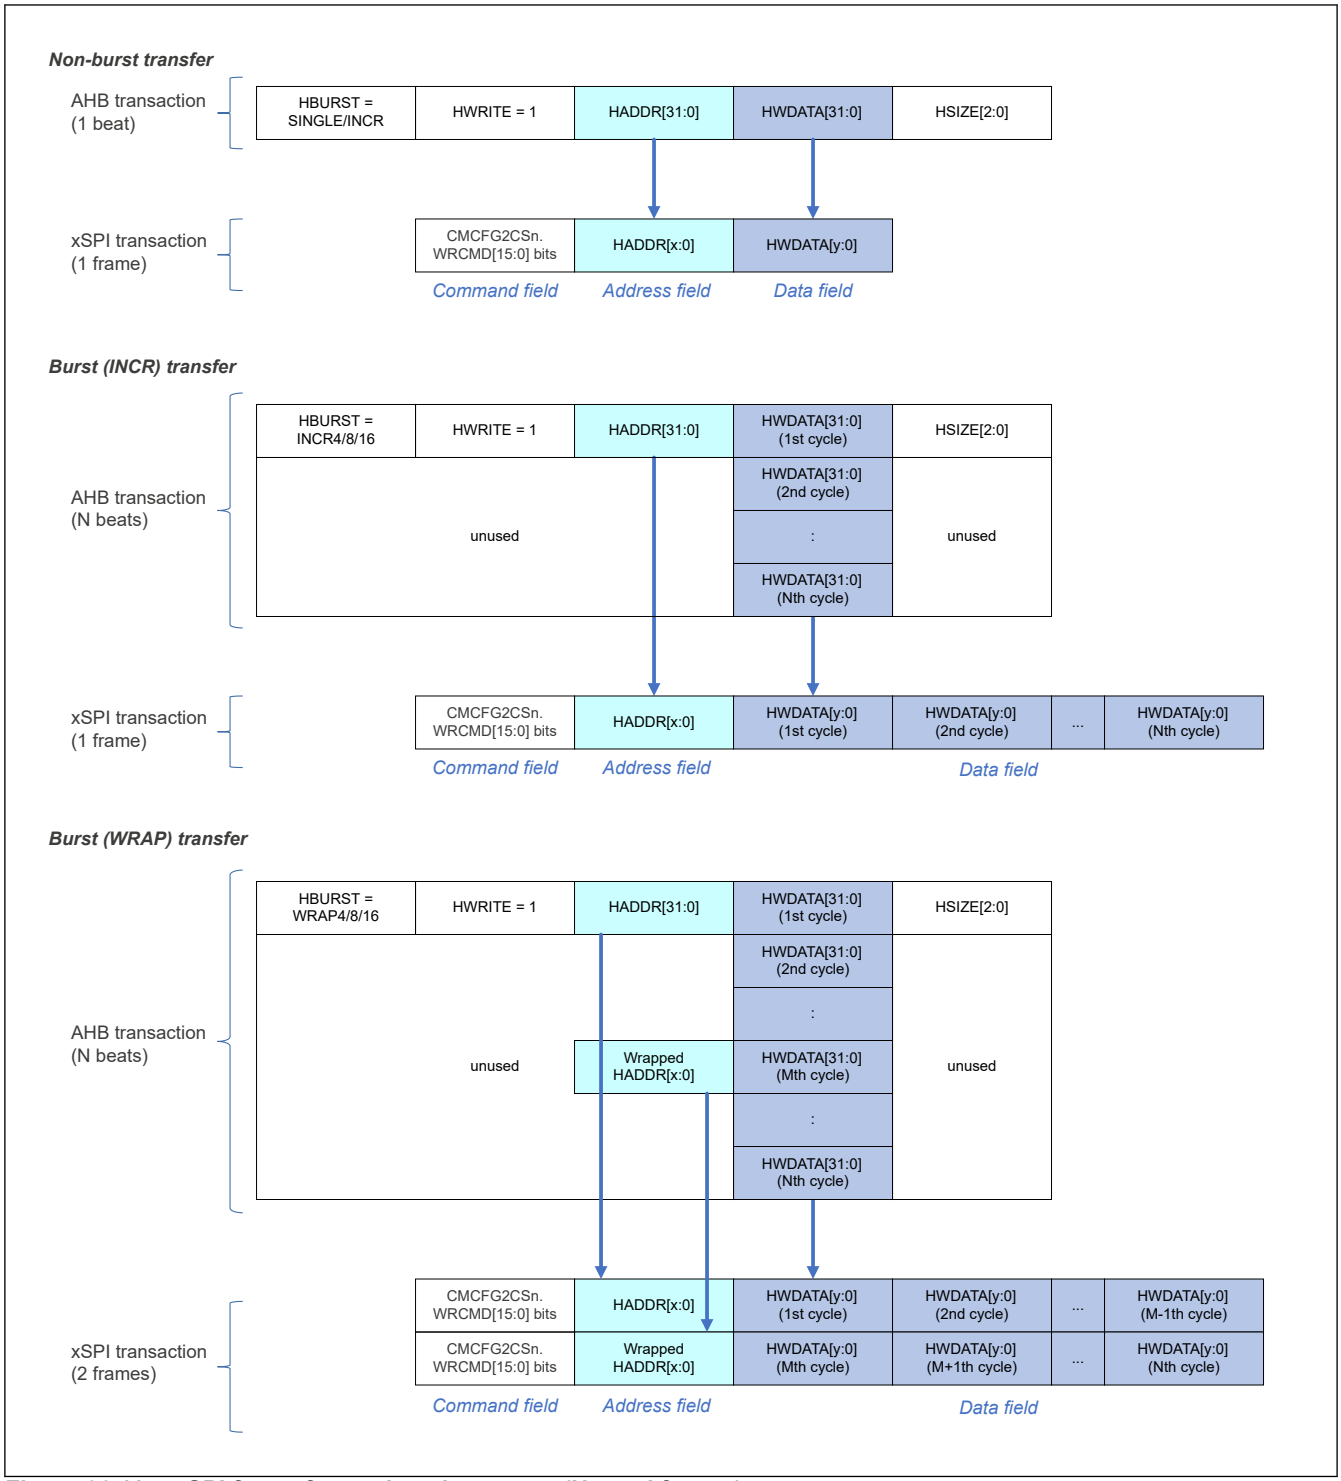

Figure 36.11 xSPI frame format in write access (Normal format)

36.3.3.3 Combination Function

In AHB write access for memory area, this xSPI master has the function to combinate the write data for high throughput on xSPI bus. When enabled this function (BMCFG.MWRCOMB = 1), this xSPI master transmits an xSPI frame with the selected size while the sequential address is incremental. When detected any transaction with non-incremental address, any transaction for different slave, or a read transaction before reaching to the target size (BMCFG.MWRSIZE[7:0]), it transmits the pending data into xSPI bus. And also, when set Memory Write Data Push bit (BMCTL1.MWRPUSH), it transmits the pending data into xSPI bus.

This function could be useful for any slave device to request a chunk of data at a time. In the case, AHB Master should continue to provide the fixed data size with incremental address. Ex. there is any device to request to write in page unit.

The figure below shows the operation when enable the combination function.

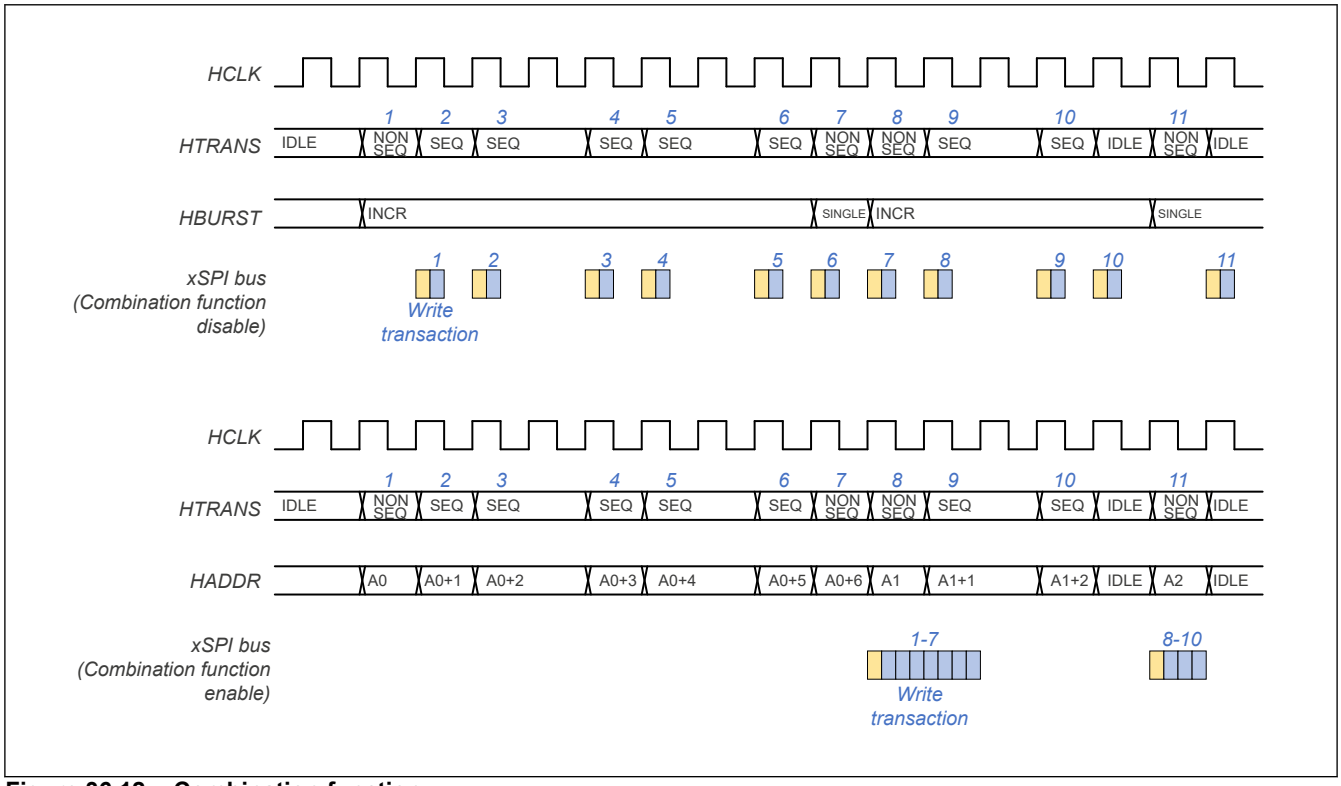

Figure 36.12 Combination function

36.3.3.4 Read Access Operation

In AHB read access for memory area, soon after detected the read access, this xSPI Master issues a read transaction into xSPI slave. The figure below shows the operation summary.

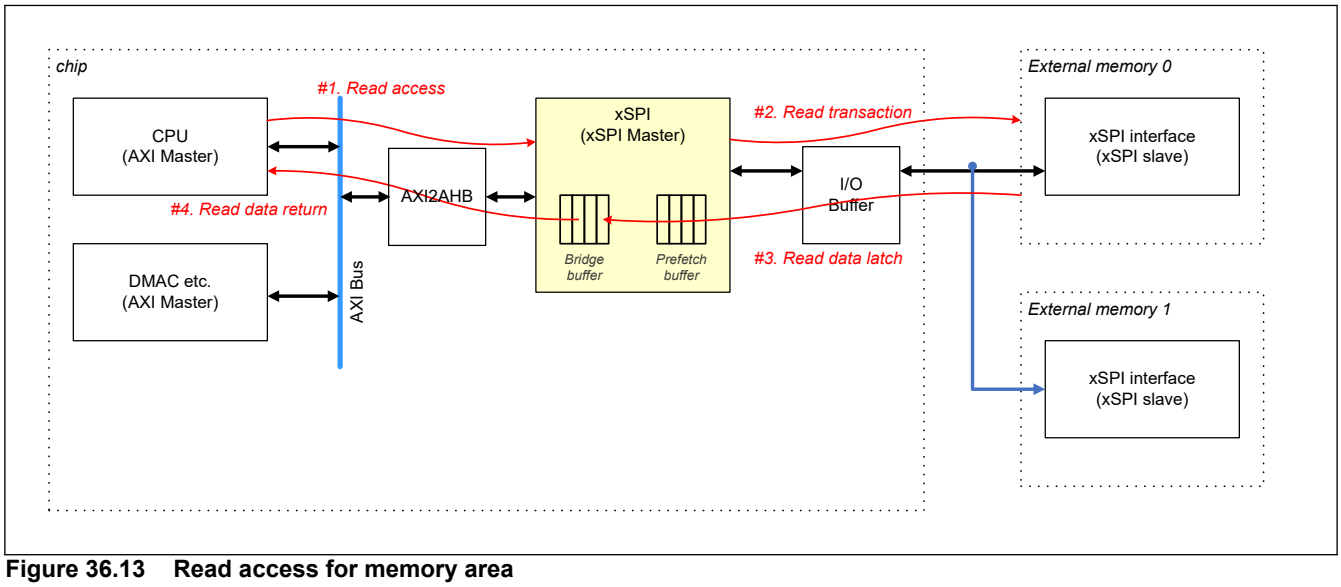

Figure 36.13 Read access for memory area

The operation of xSPI bus changes depending on AHB burst type. When HBURST is SINGLE or INCR, one AHB transaction triggers for one xSPI frame. When HBURST is INCR4, INCR8, or INCR16, AHB transactions equal to burst size triggers for one xSPI frame. When HBURST is WRAP4, WRAP8, or WRAP16, AHB transactions trigger for two xSPI frames. The figure below shows the relationship between AHB and xSPI frames.

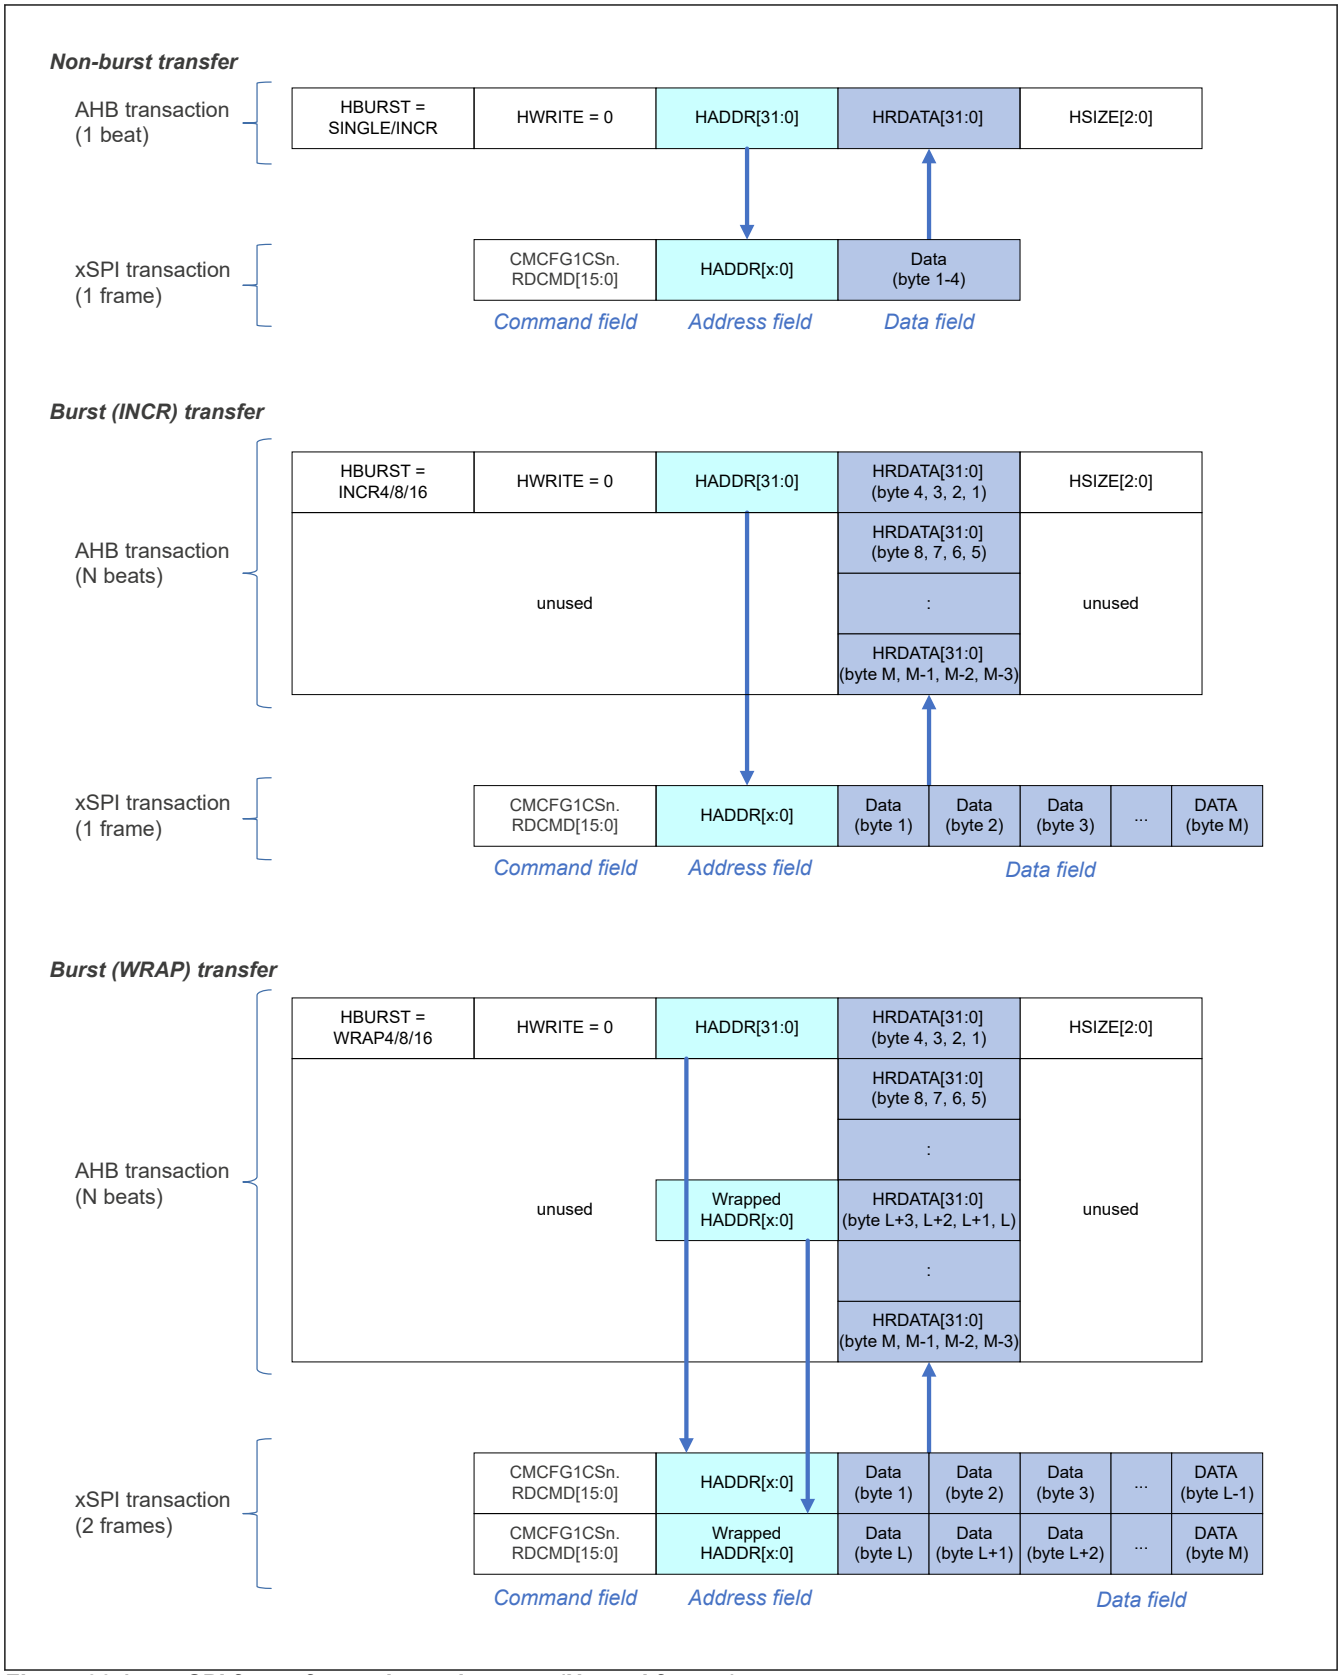

Figure 36.14 xSPI frame format in read access (Normal format)

36.3.3.5 Prefetch Function

In AHB read access for memory area, this xSPI Master has the function to prefetch the read data for lower latency. When enabled this function (BMCFG.PREEN = 1), this xSPI Master continues to read the incremental address and store the read

data from xSPI slave in internal prefetch buffer. And the following AHB read access searches for prefetch buffer. If found the target read data in prefetch buffer, this xSPI Master returns the data from prefetch buffer. If not found, this xSPI Master clears prefetch buffer and newly issues a read transaction into xSPI slave. This function is effective in application such as the consecutive read addresses are close. But it is not effective in application such as the consecutive read addresses are not incremental because xSPI read frame for prefetch uses xSPI bus. The figure below shows the operation summary.

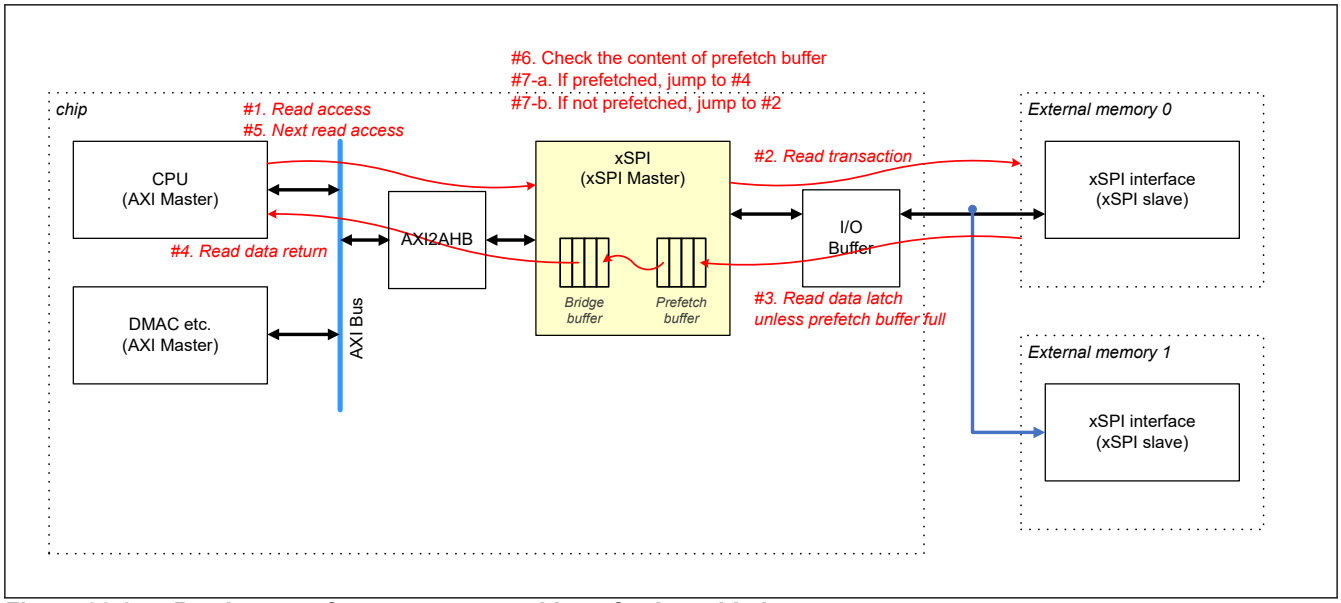

Figure 36.15 Read access for memory area with prefetch enabled

Note: When enabled this prefetch function, AHB Master could read from not a slave device but the internal prefetch buffer. When accessed to the same address from multiple AHB Masters, this xSPI Master does not guarantee to read the latest data. If AHB Master wish to read the latest data from a slave device, it should read after cleared the prefetch buffer (BMCTL1.PBUFCLR).

Note: Prefetch buffer is implemented as FIFO-based, and when read access is issued, the data before the access address is discarded from the buffer. And when next access is issued to the region which is discarded at previous access, this module issues the xSPI read access again to fill the prefetch buffer.

36.3.3.6 XiP Mode

Some slave devices have a mode (XiP mode) in which the command phase is not required for lower latency. While in this mode, the xSPI master skips sending the command and the slave device implicitly performs the command that was executed in the previous transaction. When enabled XiP mode bit (CMCTL.XIPEN = 1), this xSPI master inserts XiP enter code (CMCTL.XIPENCODE[7:0]) in latency field. When disabled XiP mode bit (CMCTL.XIPEN = 0), this xSPI master inserts XiP exit code (CMCTL.XIPEXCODE[7:0]) in latency field. This function is available only for memory-mapping mode.

And when transmitting XiP disable pattern, this xSPI master clears XiP mode bit and disables XiP mode.

Note: In case of no cycle inserting XiP code in latency field, this xSPI Master could not insert XiP code.

Note: XiP mode could be used only for unidirectional access to a slave. The write transaction and read transaction should be separated.

36.3.4 Pattern Control

This xSPI Master has the function to transmit any pattern which is not xSPI frame format. It starts to transmit by the pattern issue trigger bits (LPCTL0-1.PATREQ). It is possible to transmit 3 types of patterns.

36.3.4.1 XiP Disable Pattern

XiP Disable pattern transmits any pattern with the configured length and value (LPCTL0.XD1LEN[4:0] / XD1VAL / XD2LEN[4:0] / XD2VAL). It uses spi_ck, spi_doe/do signals. The number of output pin can be configured by XiP Disable pattern pin bits (LPCTL0.XDPIN[1:0]). It may be used to disable XiP mode for legacy SPI. The figure below shows the timing-chart.

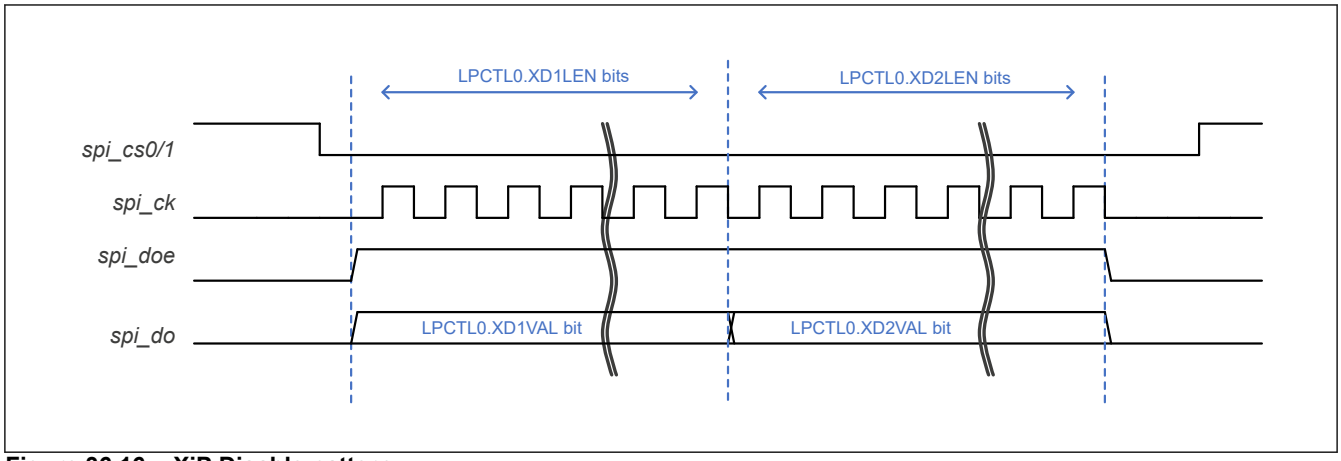

Figure 36.16 XiP Disable pattern

36.3.4.2 Reset Pattern

Reset pattern transmits the pattern specified in Serial Flash Reset Signaling Protocol. The figure below shows the timing-chart. CS Low/High width is configured with Reset Pattern Length bits (LPCTL1.RSTWID[2:0]). xSPI slave will sample the data input at the rising edge of CS. Setup time for data output is configured with Reset pattern data output setup time bits (LPCTL1.RSTSU[2:0]). The setup time should be less than Reset pattern width always. The figure below shows the timing-chart.

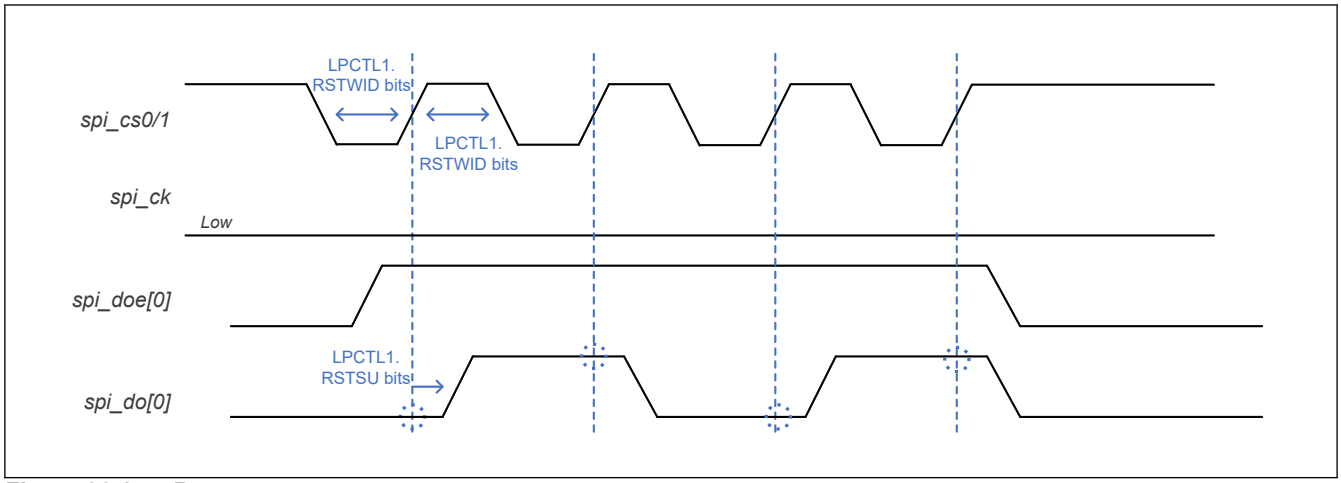

Figure 36.17 Reset pattern

Note: In the protocol, CS Low/High width is defined as minimum 500 ns and Setup time is defined as minimum 6 ns.

36.3.4.3 CS Only Pattern

CS Only pattern activates CS port with the configured length bits (LPCTL1.RSTWID[2:0]). It may be used to resume from Deep Power Down state. The figure below shows the timing-chart.

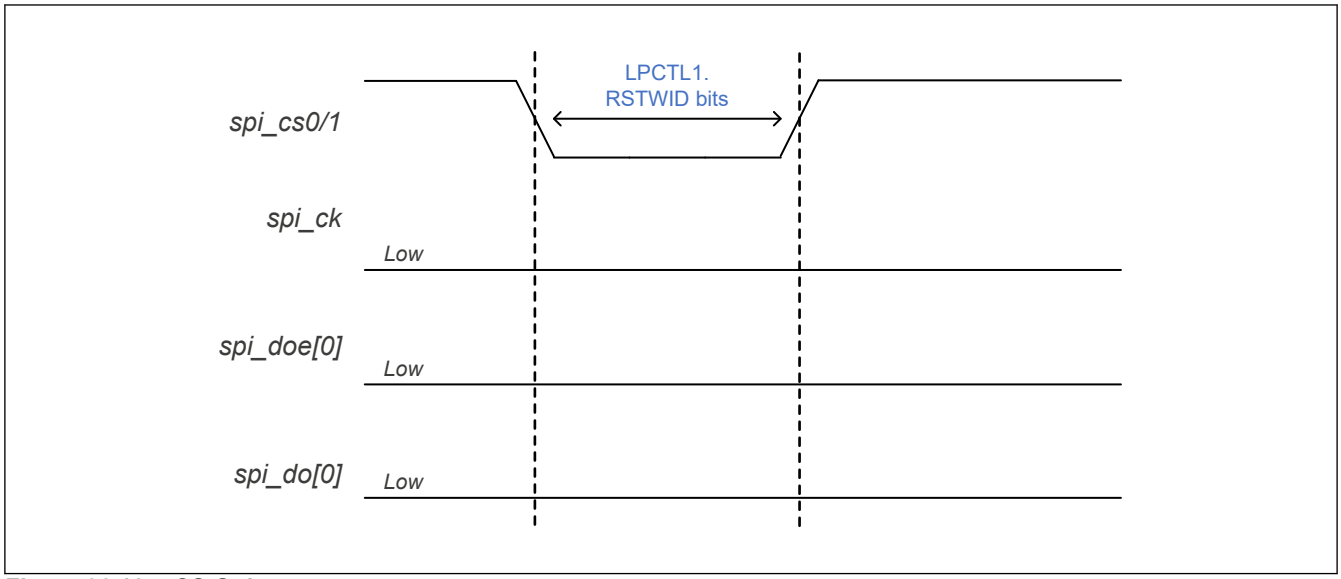

Figure 36.18 CS Only pattern

36.3.5 Integrity Checking

This xSPI Master can detect some errors. The table below shows the error list and the detail behavior.

When reset of xSPI master is needed due to fatal error, set module reset register (MRCTLA) to reset xSPI master. After confirming it is reset surely, release module reset.

Table 36.10 Error list

Error type	Event	Flag bit	Note (action)
Calibration failed	When the read data did not match the expected value during automatic calibration	INTS. CAFAILCS0-1	It results in writing unexpected data to xSPI slave.
AHB bus error	When an error response occurred on AHB slave interface for memory-mapping	INTS. BUSERR	This is a fatal error. This xSPI master shall be initialized. When detected this error in AHB write transaction, the internal bridge buffer is cleared. It means the pending write data is lost.
ECC error detection	When detected the falling edge on ECS port It can be useful only for xSPI slave with ECC detection function.	INTS. ECSCS0-1	Only notify the error event of xSPI slave.
DS timeout	When DS does not toggle in read transaction with using DS	INTS. DSTOCS0-1	Both xSPI master and xSPI slave should be reset for fatal error.
Periodic transaction timeout	When the read value does not match with the expected value in periodic manual-command mode	INTS. PERTO	Depending on the status of function

36.3.6 Interrupts

This xSPI Master has an interrupt port.

It can monitor with Interrupt Status Register (INTS). In case of initialization phase, it can be programmable with Interrupt Enable register (INTE). The table below shows the related register bit.

Table 36.11 xSPI interrupt sources

Name	Interrupt Sources	CPU0 GIC Request	DMAC Activation
XSPIm_INT	Interrupt	Possible	Not possible
XSPIm_INTERR	Error interrupt	Possible	Not possible

Note: m = 0, 1

Table 36.12 Interrupt register bit

Flag bit	Enable bit	Clear bit	Interrupt Sources (m = 0, 1)
CASUCCS1	CASUCCS1E	CASUCCS1C	XSPIm_INT
CASUCCS0	CASUCCS0E	CASUCCS0C	
CAFAILCS1	CAFAILCS1E	CAFAILCS1C	XSPIm_INTERR
CAFAILCS0	CAFAILCS0E	CAFAILCS0C

PATCMP	PATCMPE	PATCMPC	XSPIm_INT
CMDCMP	CMDCMPE	CMDCMPC	XSPIm_INT

36.3.7 Flows of Operations

36.3.7.1 Flow of Configuration

The figure below shows flow of configuration.

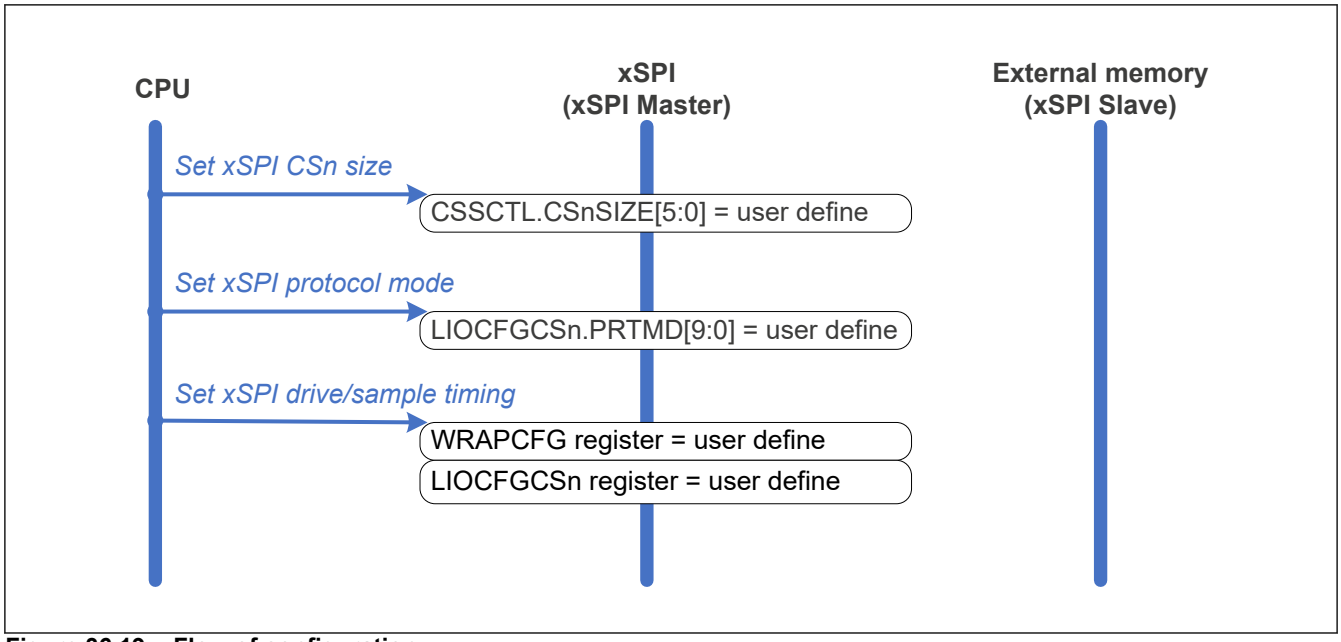

Figure 36.19 Flow of configuration

36.3.7.2 Flow of Communication Stop

The figure below shows flow of communication stop.

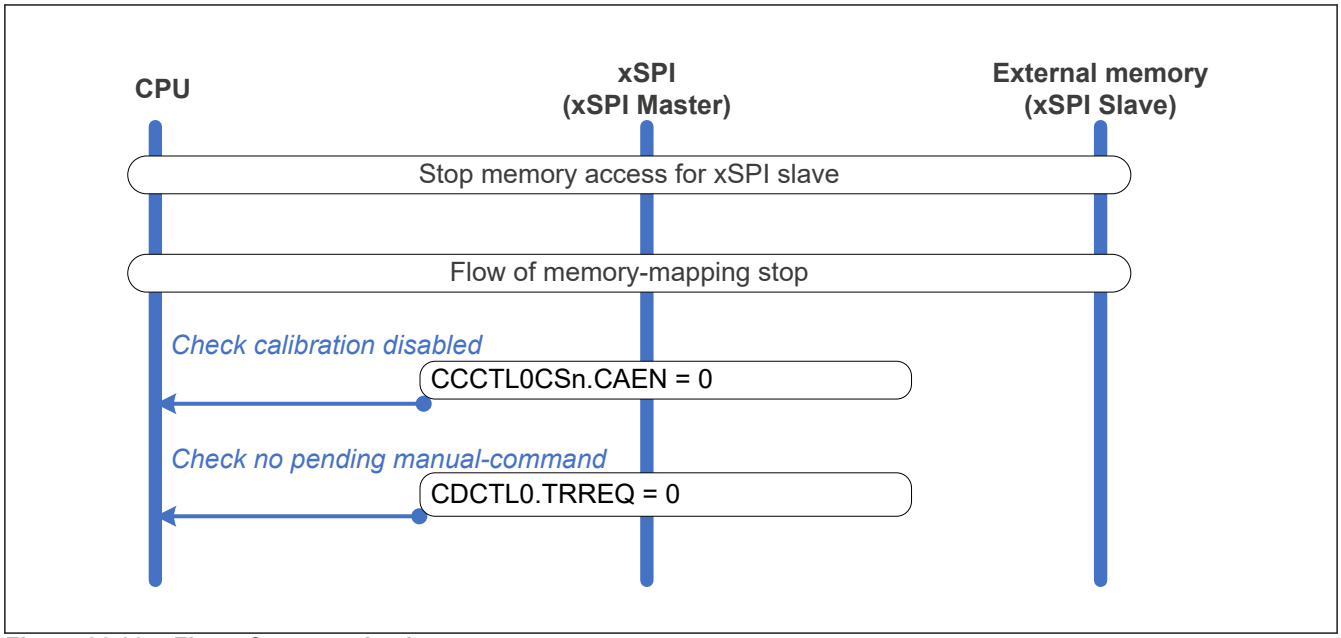

Figure 36.20 Flow of communication stop

Note: In case of re-config of any configuration register, all communication with xSPI slave shall be stopped completely. It means that the automatic calibration is disabled, and there is no pending manual-command and memory-mapping access.

36.3.7.3 Flow of Automatic Calibration

The figure below shows flow of automatic calibration.

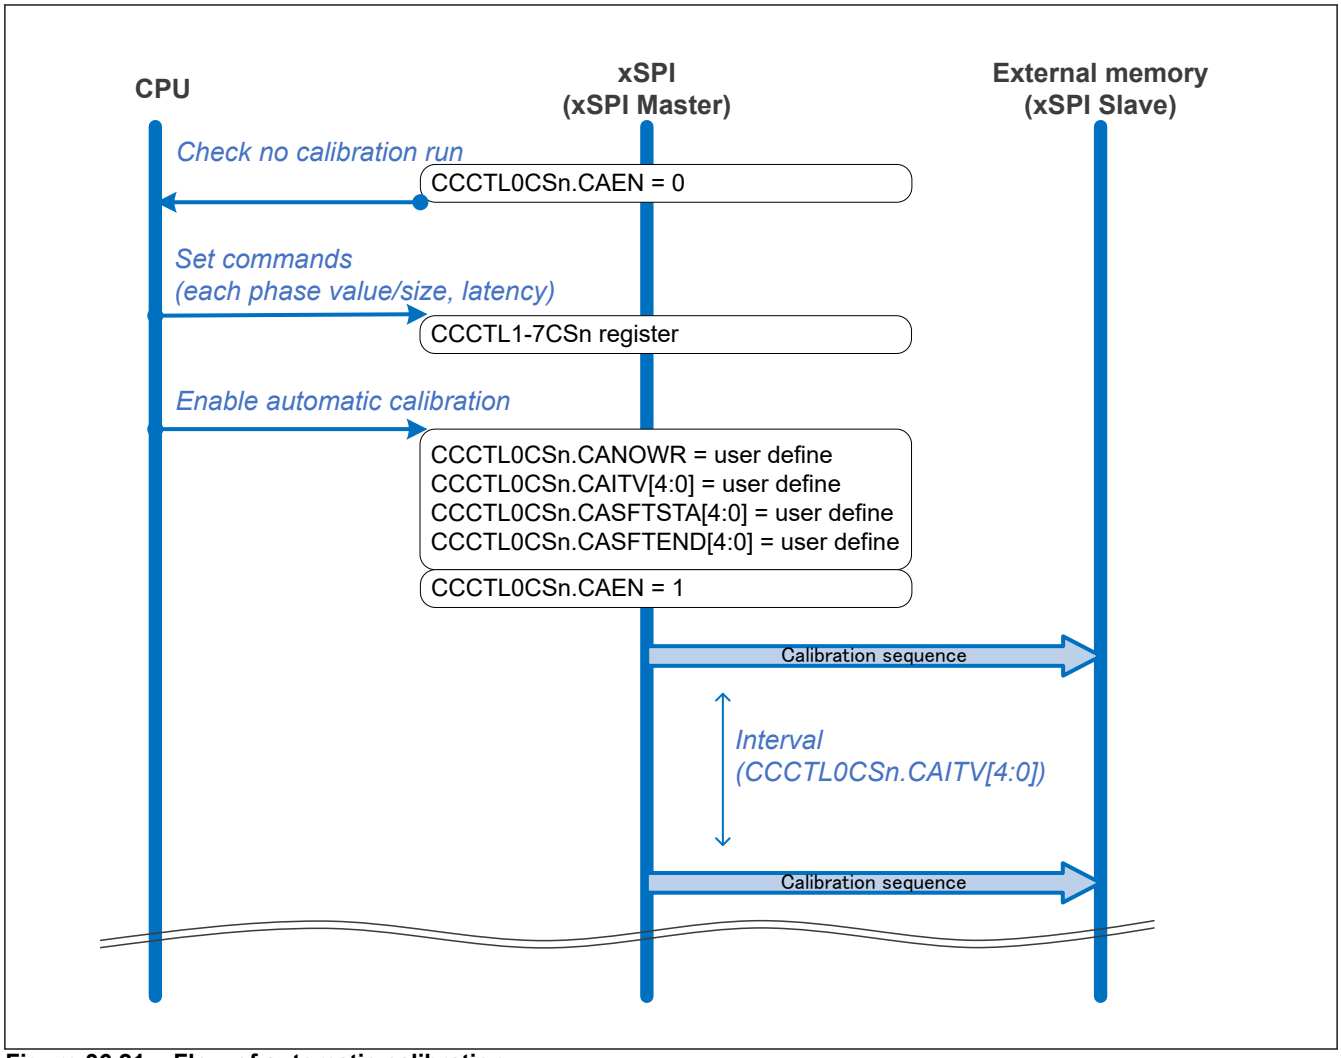

Figure 36.21 Flow of automatic calibration

36.3.7.4 Flow of Manual-command Procedure

The figure below shows manual-command procedure for direct mode.

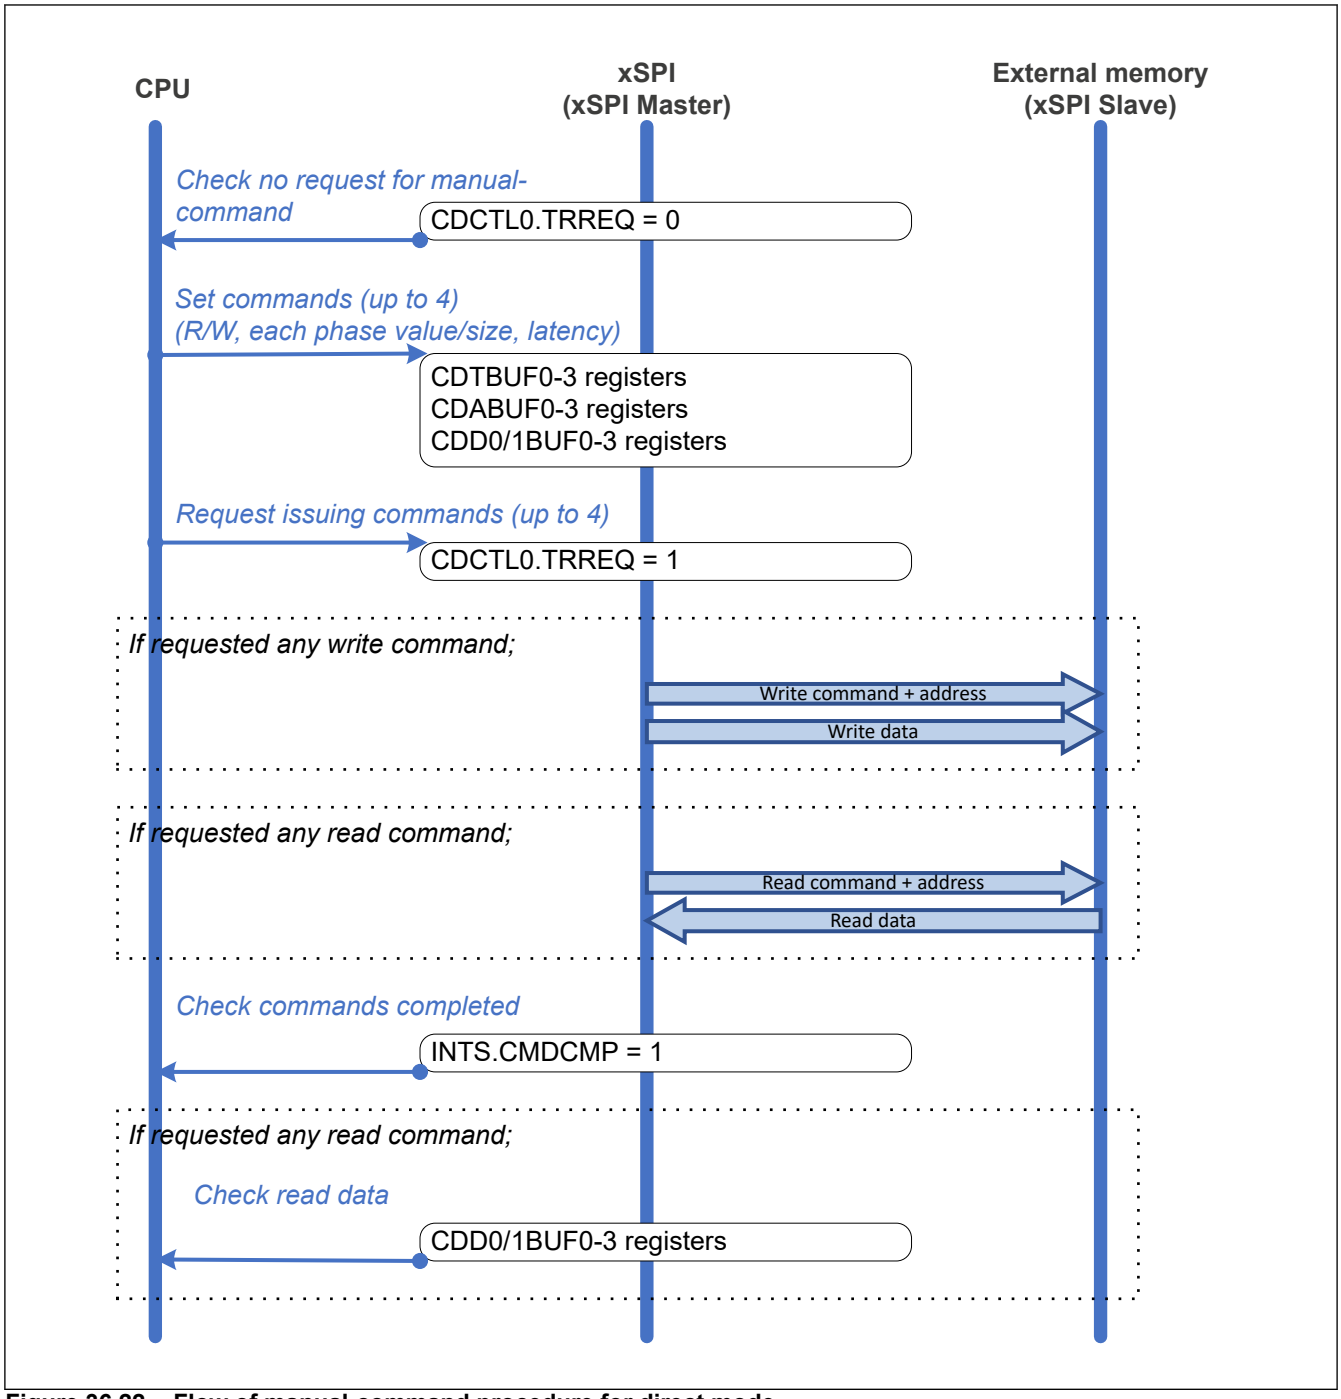

Figure 36.22 Flow of manual-command procedure for direct mode

The figure below shows manual-command procedure for periodic mode.

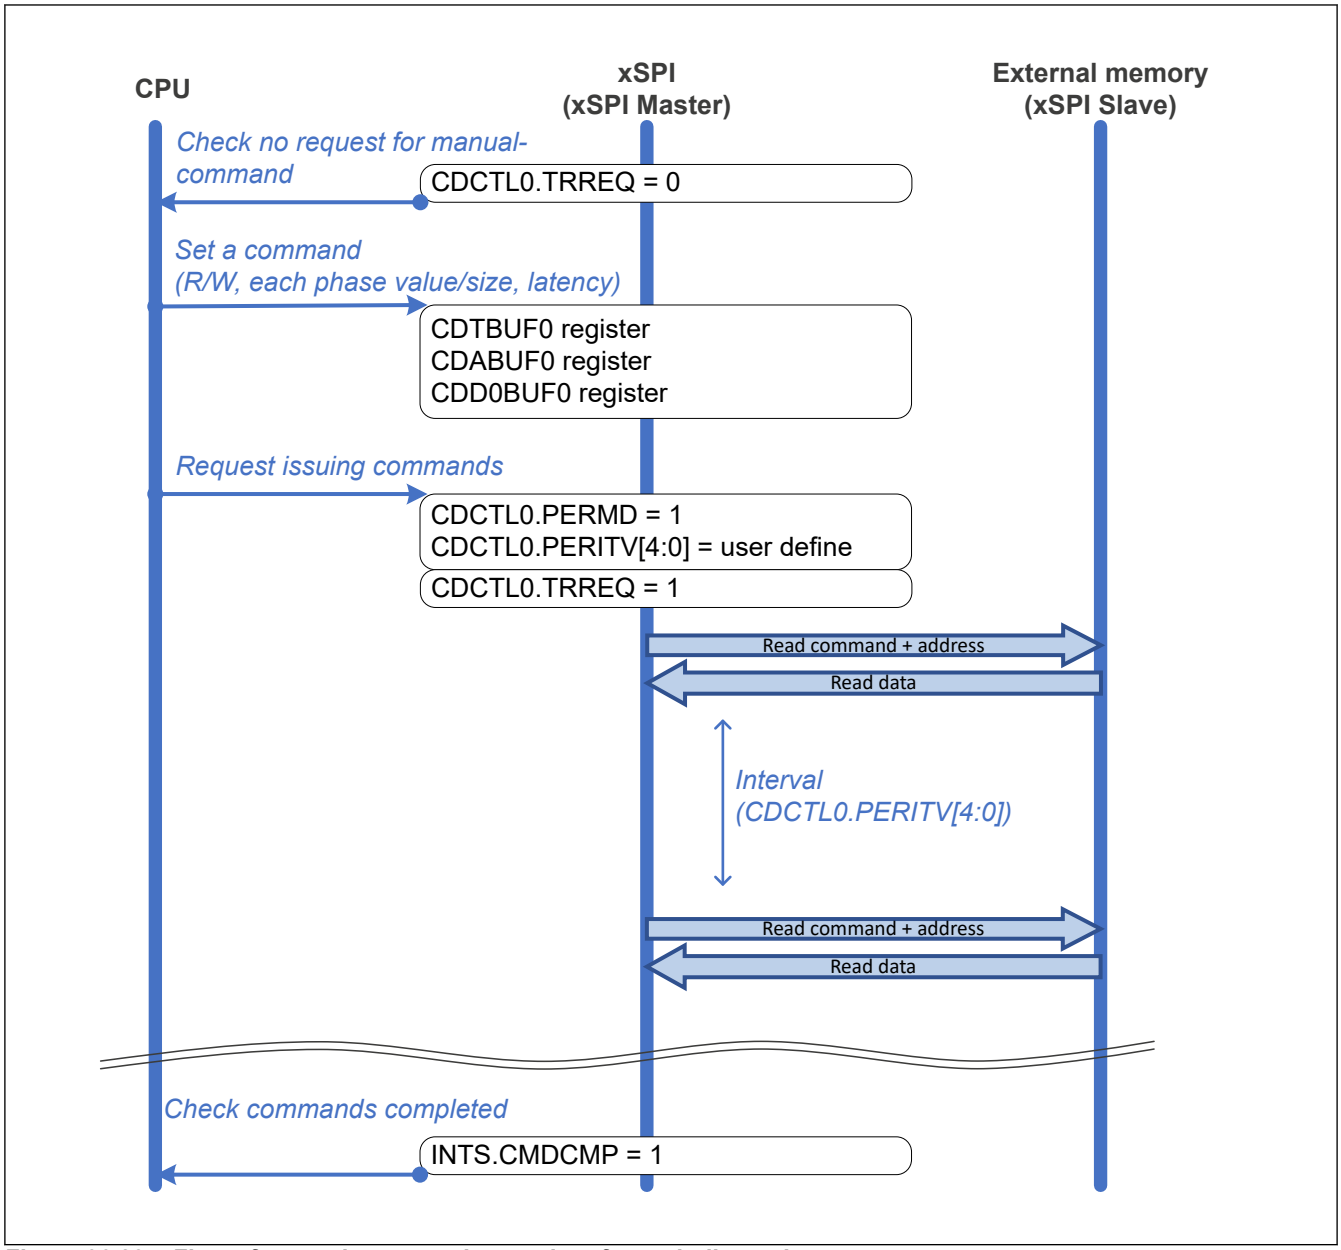

Figure 36.23 Flow of manual-command procedure for periodic mode

36.3.7.5 Flow of Memory-mapping

The figure below shows flow of memory-mapping.

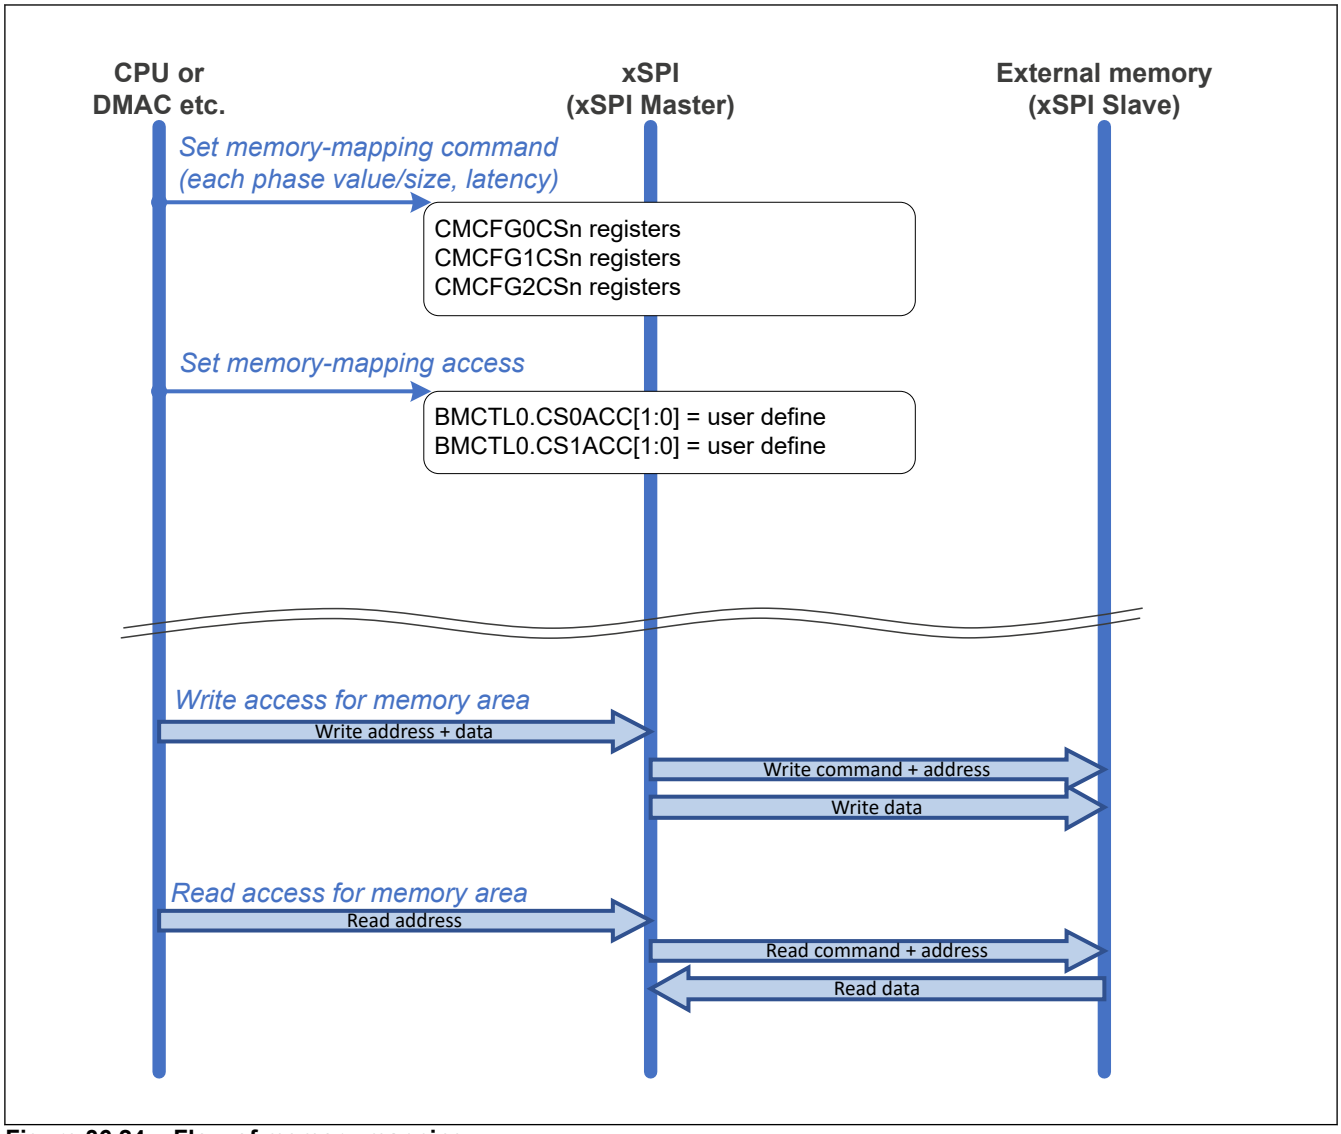

Figure 36.24 Flow of memory-mapping

36.3.7.6 Flow of Memory-mapping Stop

The figure below shows flow of memory-mapping stop.

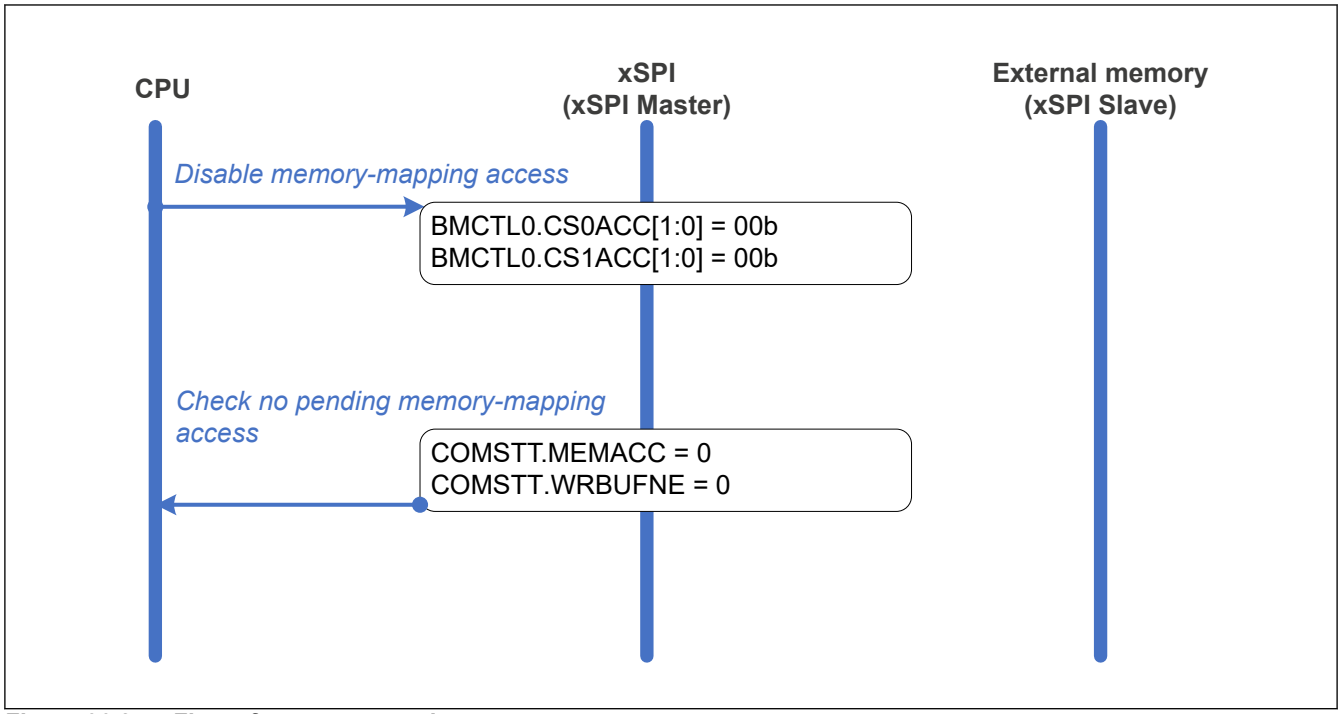

Figure 36.25 Flow of memory-mapping stop

36.3.7.7 Flow of Pattern Request

The figure below shows flow of pattern request. Before requesting any pattern, any ongoing commands should be completed or canceled.

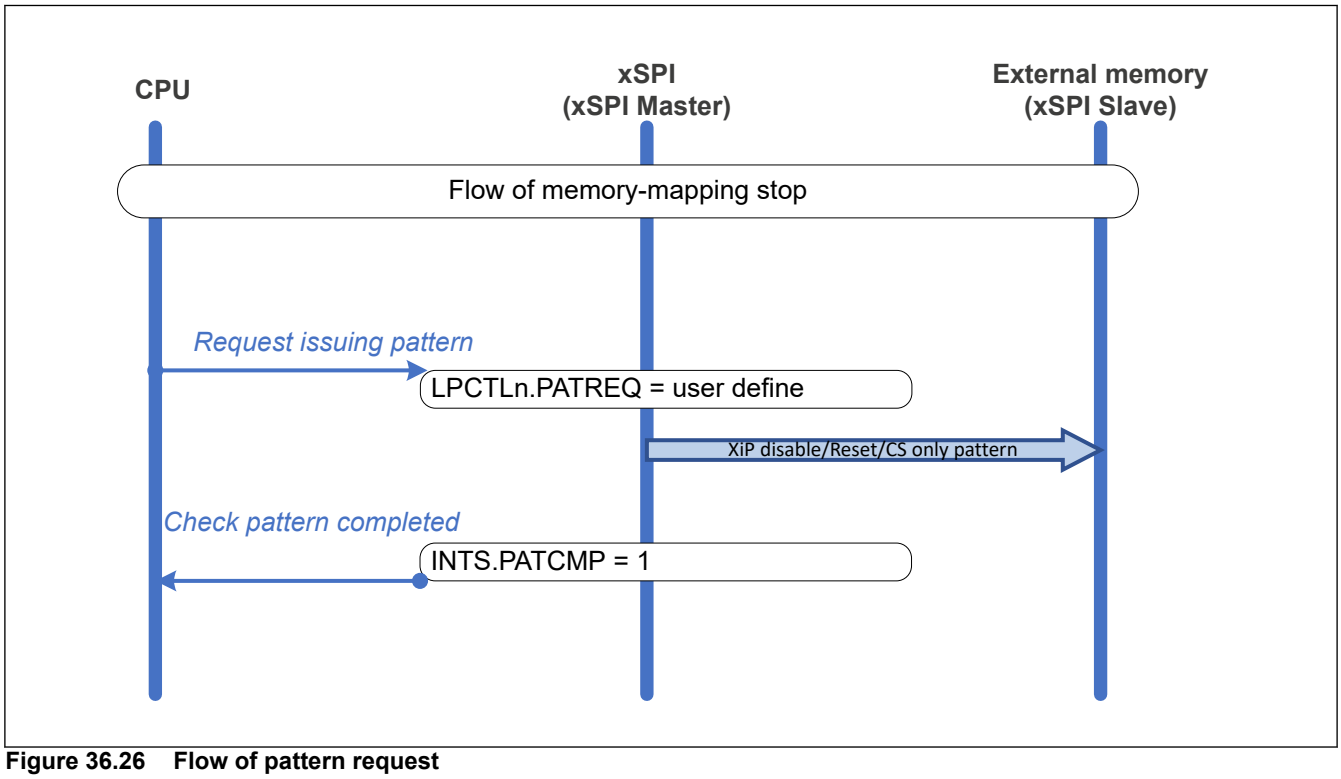

Figure 36.26 Flow of pattern request

36.3.7.8 Flow of XiP Mode

The figure below shows flow of XiP mode enable/disable.

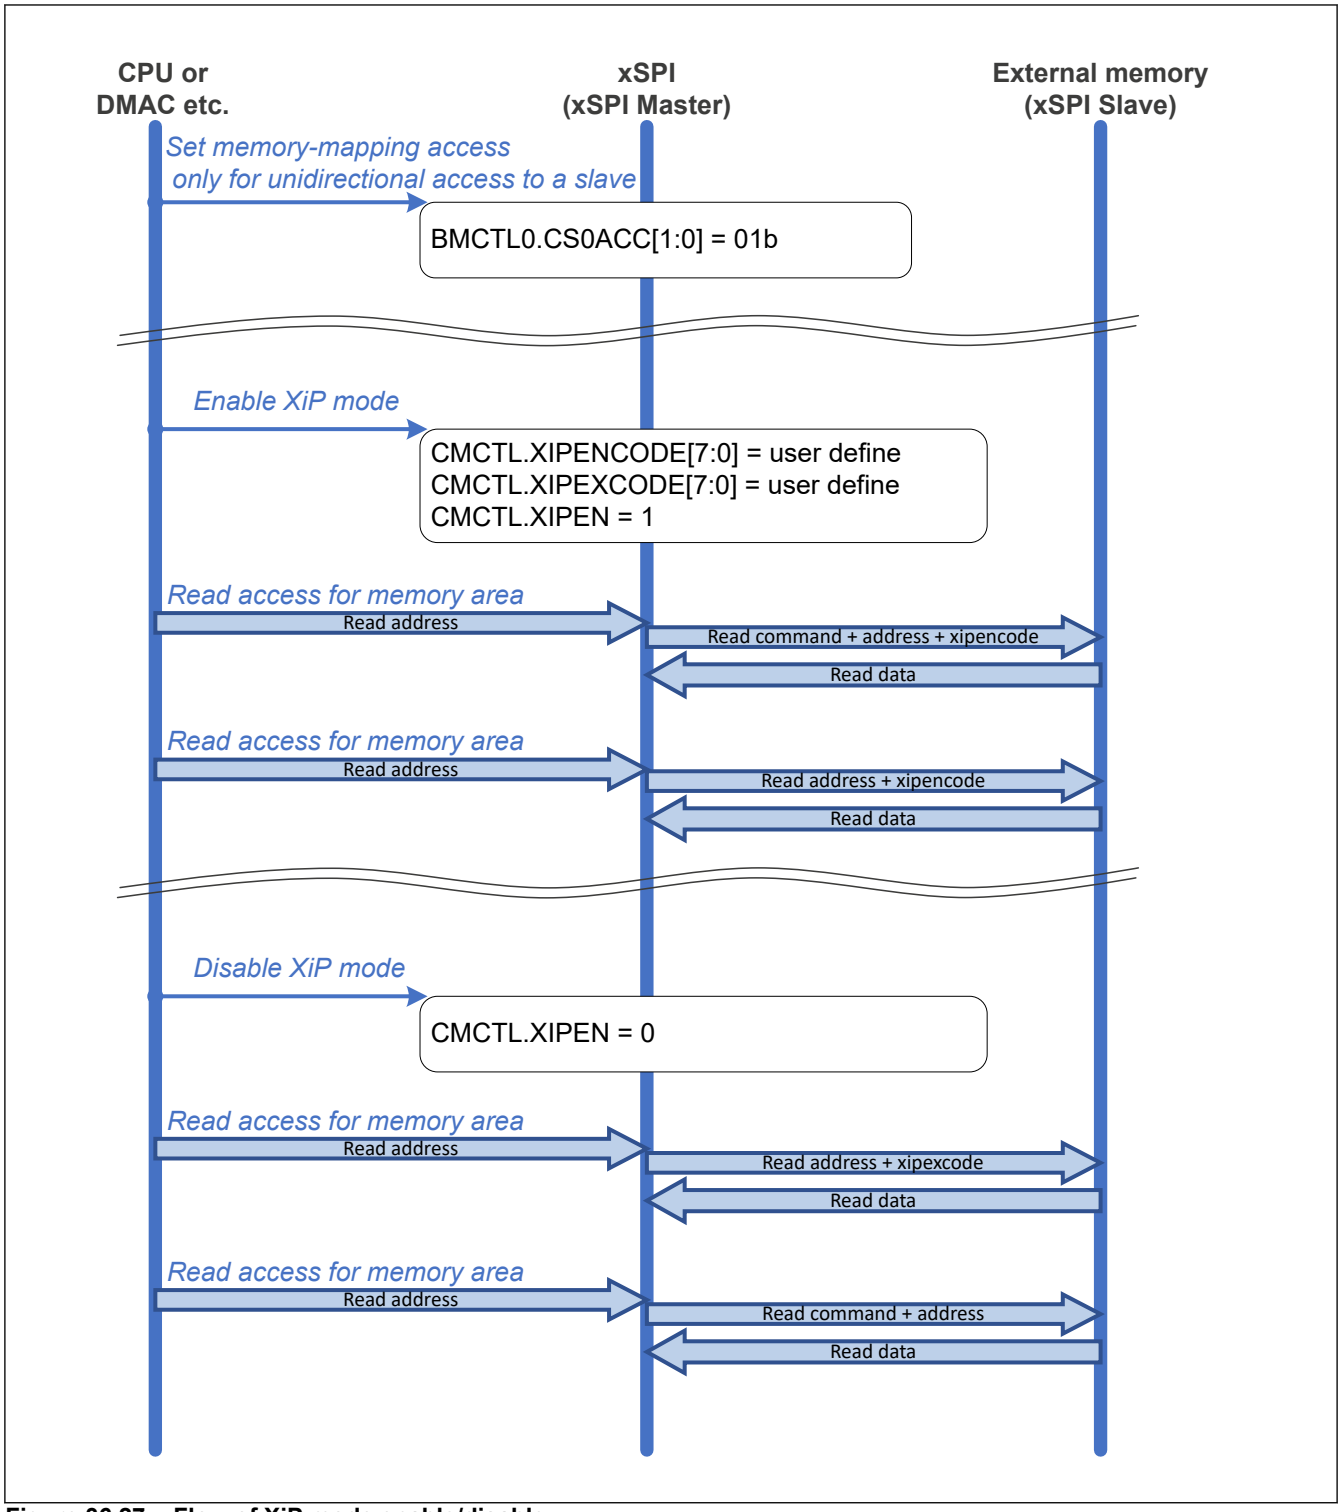

Figure 36.27 Flow of XiP mode enable/disable

36.3.8 Usage Notes

- If prefetch function is enabled and CS size control register (CSSCTL) is not set correctly compared to size of connected slave device, xSPI master may access outside of the slave device address. It may cause DS timeout in case of 8D-8D-8D. Make sure to set the correct slave device size to CSSCTL register.
- DDR access without DS is not supported.

37. CRC Operation Unit (CRC)

37.1 Overview

Cyclic redundancy check (CRC) operation units generate CRC codes. Table 37.1 lists the specifications of the CRC operation unit, and Figure 37.1 shows a block diagram of the CRC operation unit.

Table 37.1 CRC specifications

Parameter	Description	
Number of channels	2 channels	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a natural number)	CRC codes are generated for any desired data in 32n-bit units (where n is a natural number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ (CRC-8) • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ (CRC-16) $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
Low power consumption	Module-stop state can be set.	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.

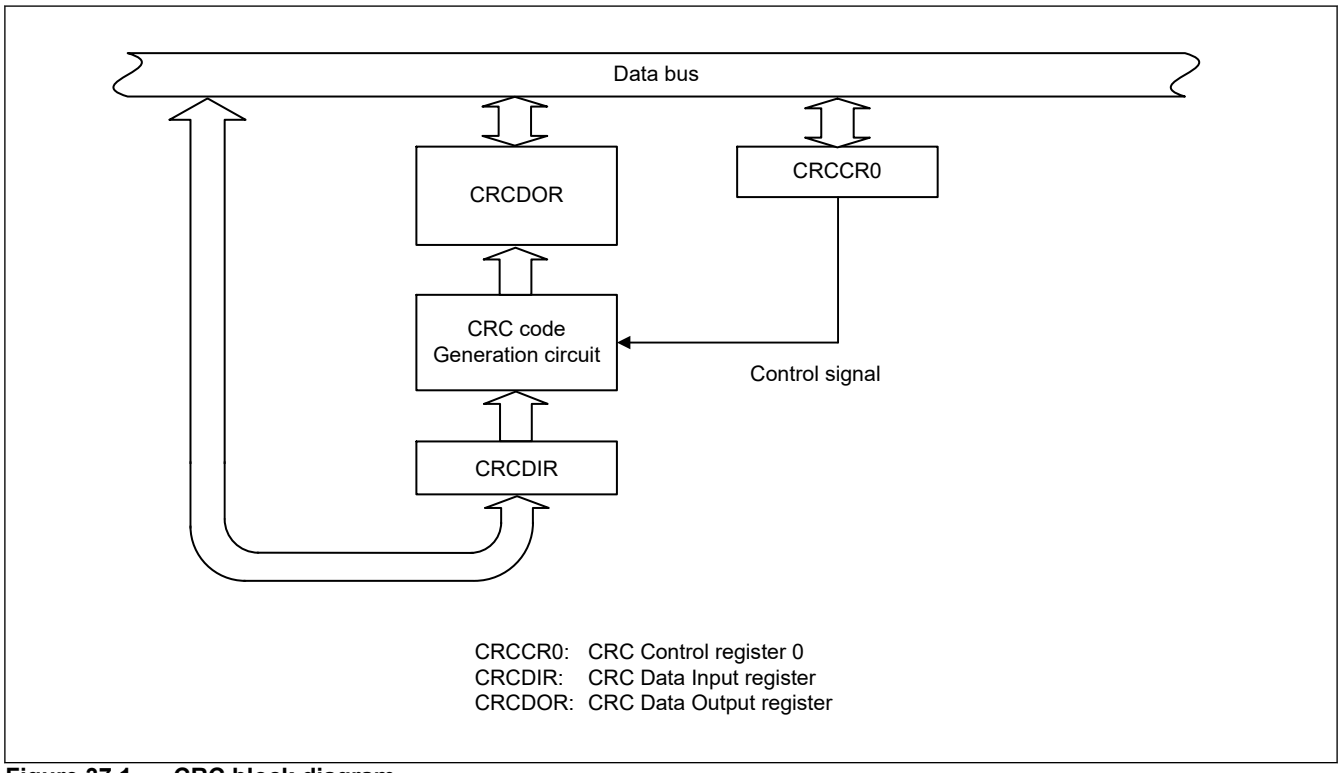

Figure 37.1 CRC block diagram

37.2 Register Descriptions

37.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_3000

Offset address: 0x0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 0: No calculation is executed. 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed.	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
7	DORCLR	CRCDOR Register Clear 0: No effect 1: Clears the CRCDOR register	W

GPS[2:0] bits (CRC Generating Polynomial Switching)

Set these bits to select the CRC Generating Polynomial.

LMS bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, see section 37.3. Operation.

DORCLR bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0x00000000.

37.2.2 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_3000

Offset address: 0x4

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	CRC Data Input	R/W

CRCDIR or CRCDIR_BY is written with data for the CRC calculation.

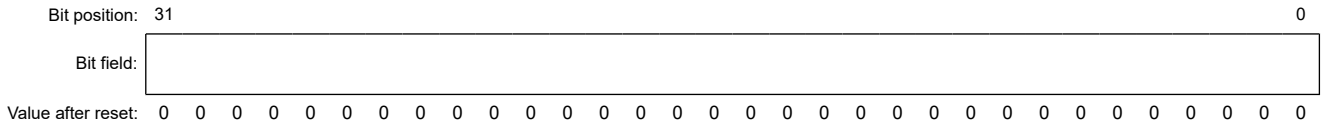
CRCDIR is the register symbol for R/W access in 32-bit units. When generating a 32-bit CRC code, the input data should be written to CRCDR.

CRCDIR_BY is the register symbol for R/W access in 8-bit units. When generating an 8- or 16-bit CRC code, the input data should be written to CRCDID_BY.

37.2.3 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_3000

Offset address: 0x8



Bit	Symbol	Function	R/W
31:0	n/a	CRC Data Output	R/W

When calculating with the initial value set to a value other than 0x00000000, rewrite the CRCDOR register.

The CRC code should be written to the CRCDIR register following the communication data. If the calculation result is 0x00000000, there is no error in the communication data.

If a 32-bit CRC is selected, the CRCDOR register should be accessed. If a 16-bit CRC is selected, the CRCDOR_HA register should be accessed. If an 8-bit CRC is selected, the CRCDOR_BY register should be accessed.

37.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.

The following shows examples of generating the CRC code for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before the CRC calculation (when a 16-bit CRC is in use, bits [31:16] of CRCDOR are not updated).

When an 8-bit CRC is in use, the valid bits of the CRC code is obtained in the lower-order byte of CRCDOR. When a 32-bit CRC is in use, the valid bits of the CRC code is obtained in bits [31:0] of CRCDOR.

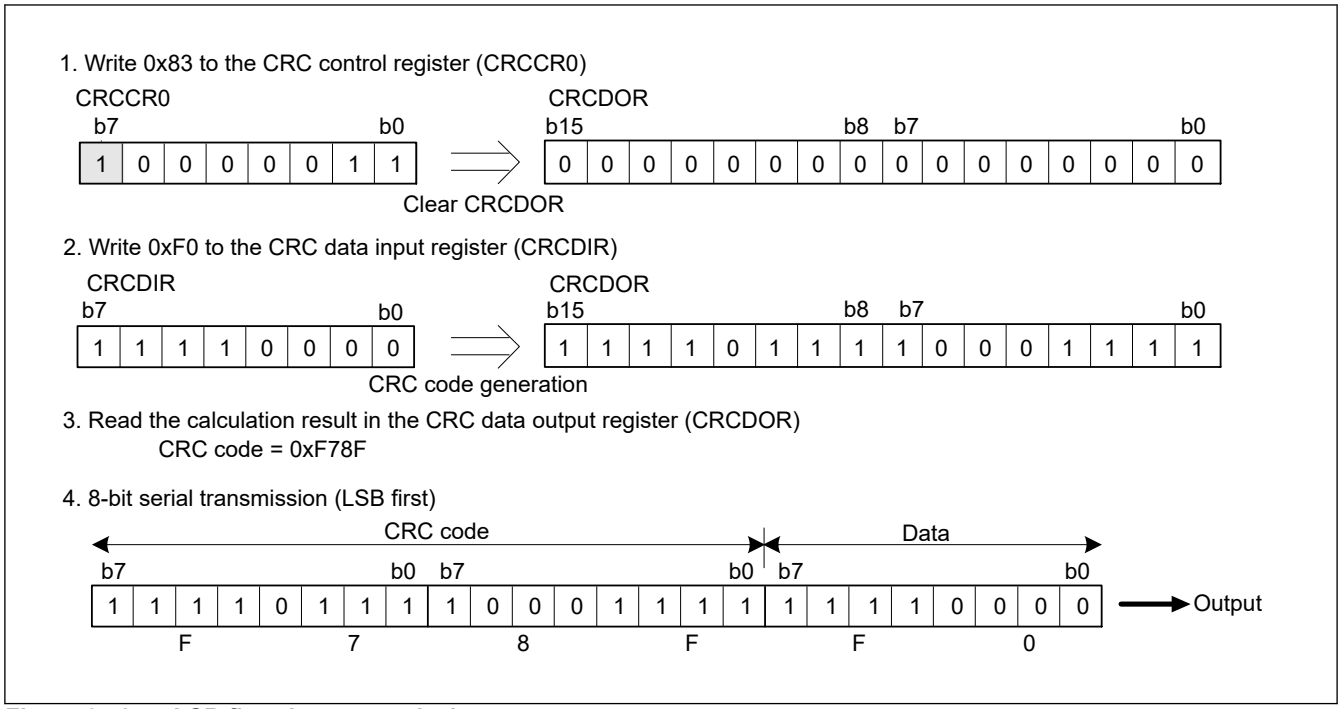


Figure 37.2 LSB first data transmission

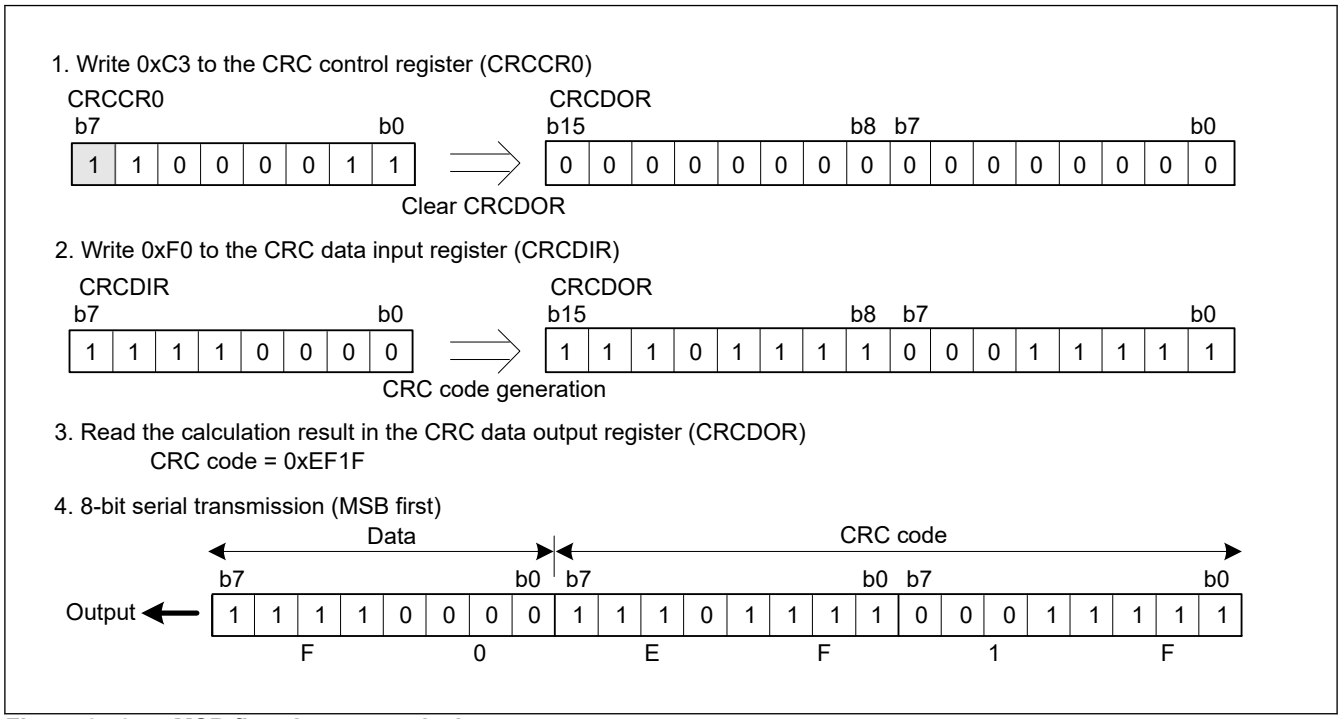

Figure 37.3 MSB first data transmission

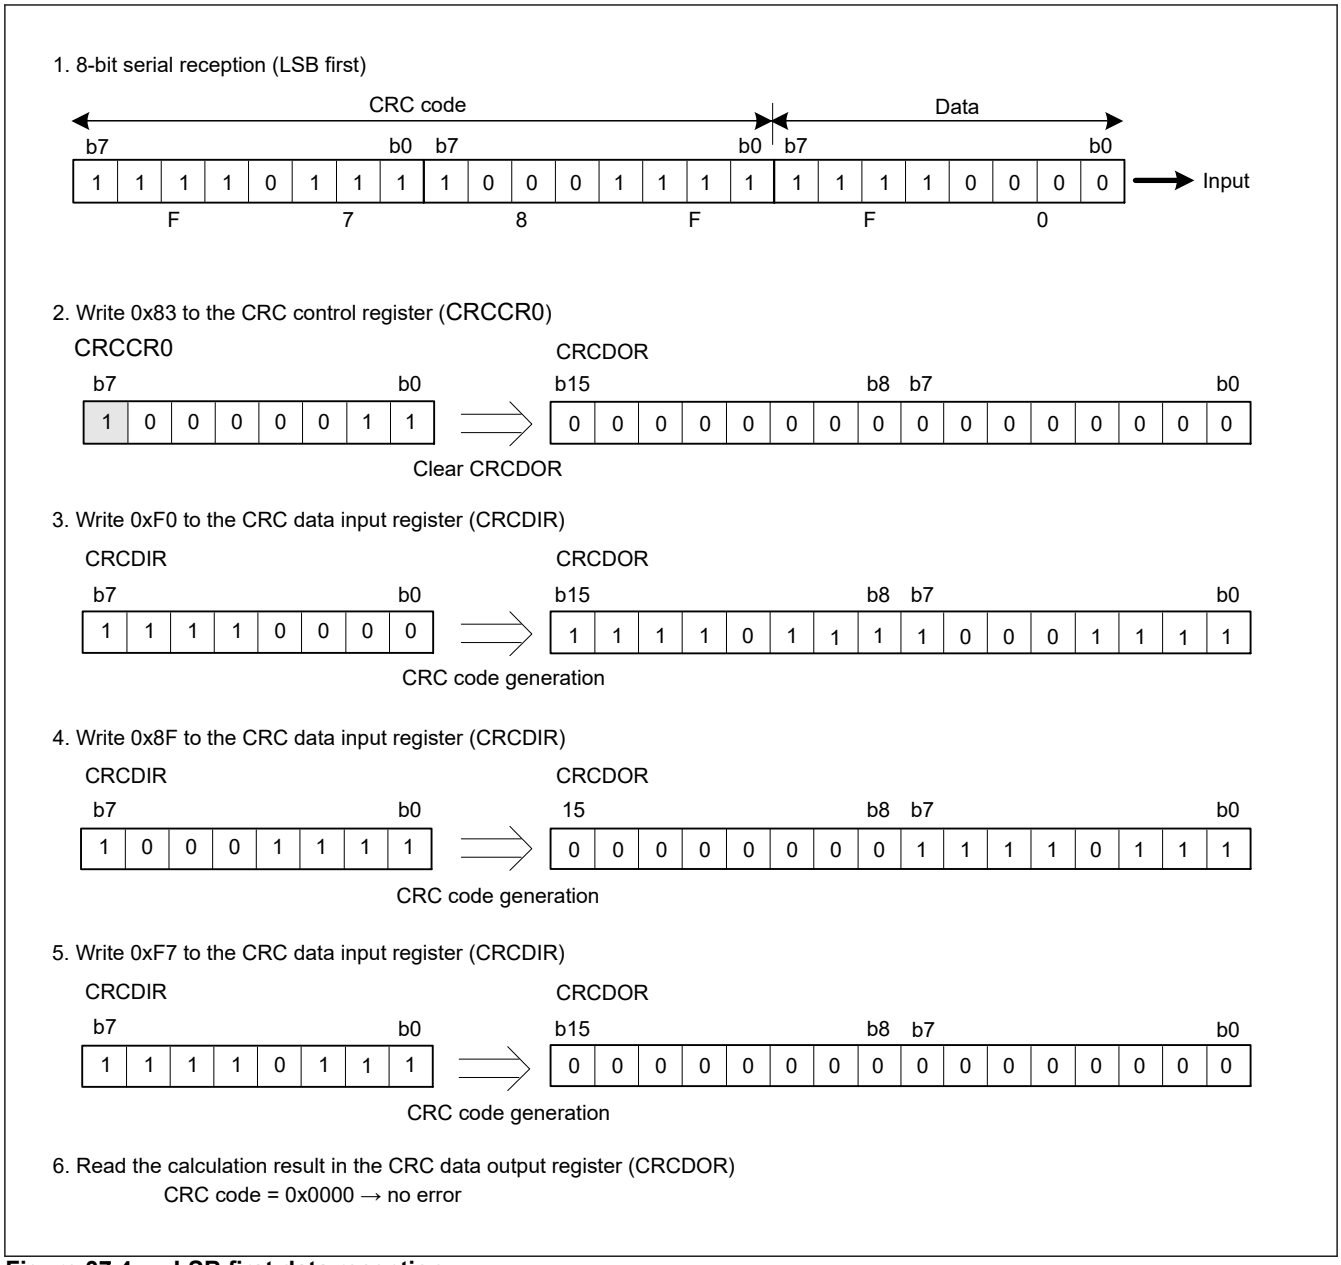

Figure 37.4 LSB first data reception

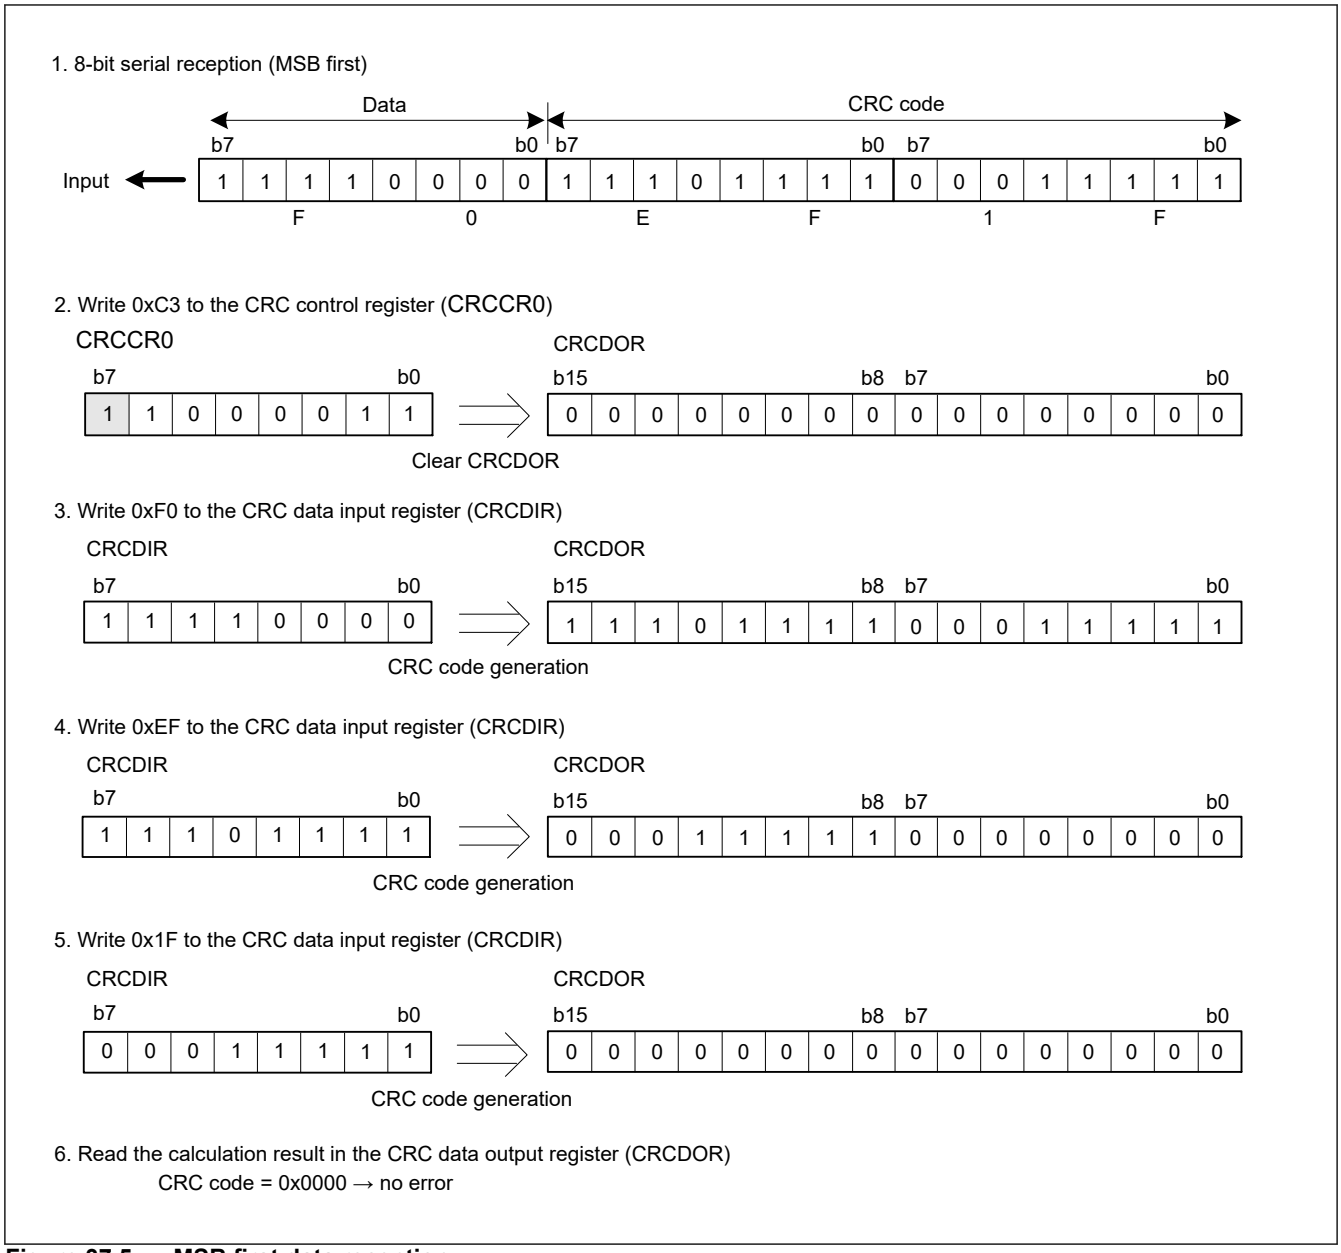

Figure 37.5 MSB first data reception

37.4 Usage Notes

37.4.1 Module-Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the Module Stop Control Register D and G (MSTPCRD and MSTPCRG). After a reset, the CRC is in the module-stop state. Register access is enabled by releasing the module-stop state.

For details, see section 8, Low-Power Consumption Function.

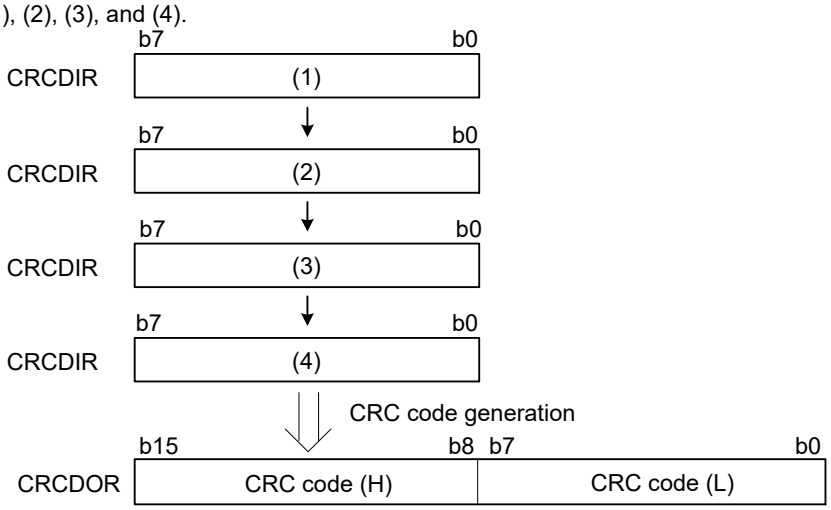
37.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

When transmitting 32-bit data (in case operation executed on 8 bits in parallel)

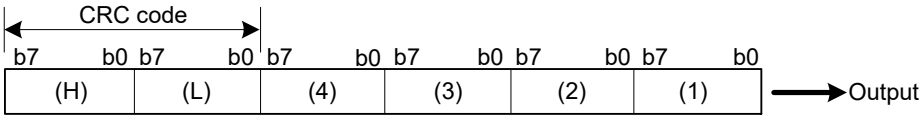
1. CRC code

After specifying the method for generation calculation, write data to the CRCDIR register in the order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB first



(ii) When transmission is MSB first

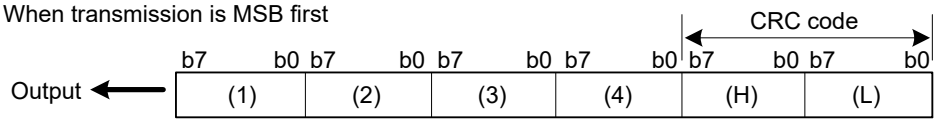


Figure 37.6 LSB first and MSB first data transmission

38. Boundary Scan

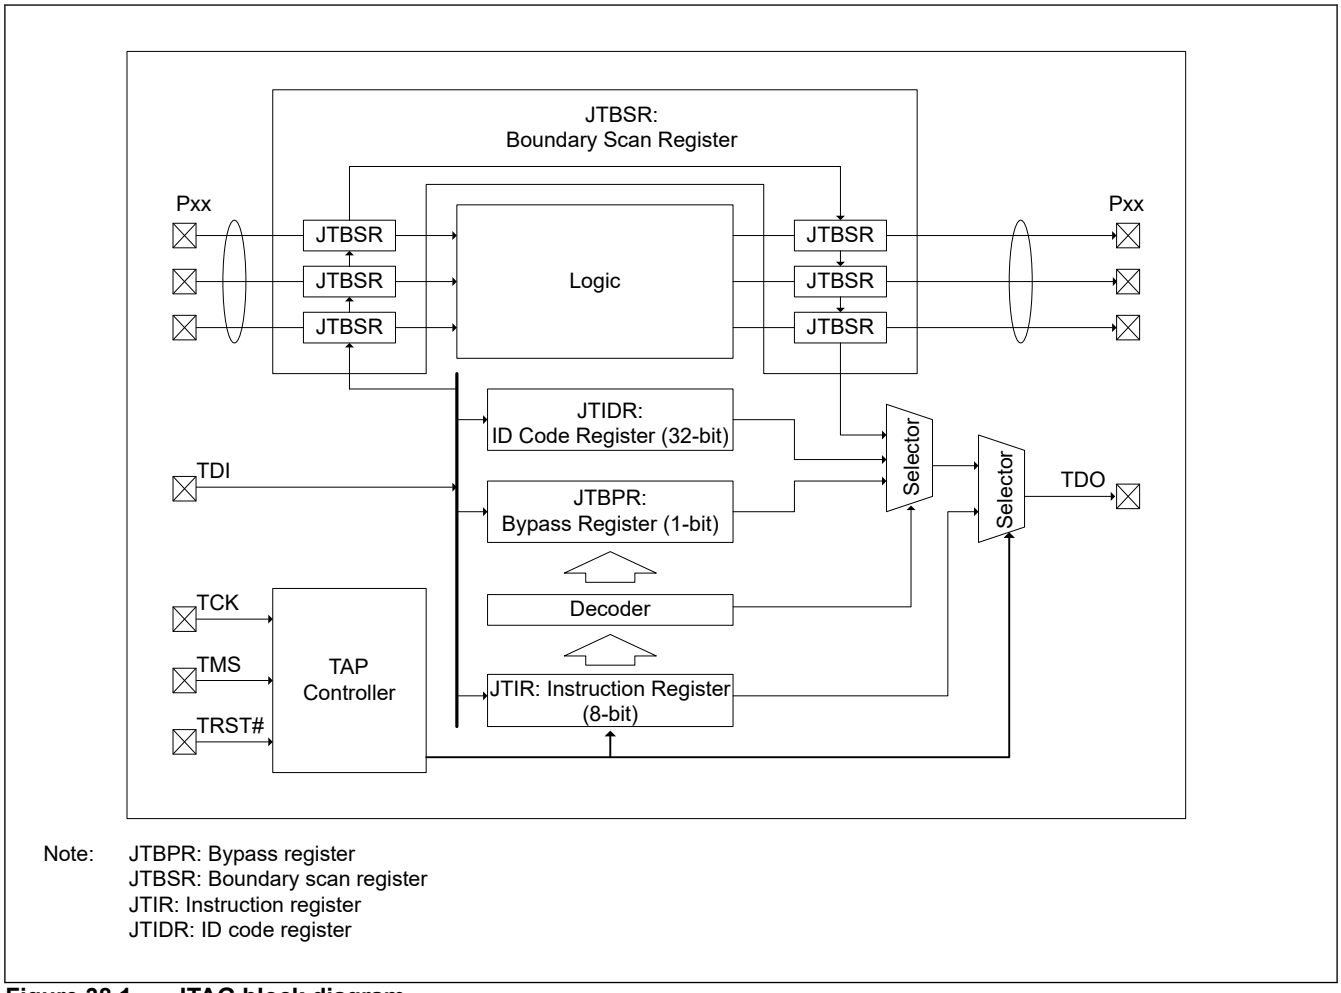
38.1 Overview

The LSI has a boundary scan function. The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary-Scan Architecture.

Table 38.1 lists the specifications of boundary scan and Figure 38.1 shows a block diagram of the boundary scan function.

Table 38.1 Boundary scan specifications

Parameter	Specifications
Boundary scan enabled/disabled	Boundary scan function is enabled when the BSCANP pin is driven high.
Dedicated boundary scan pins	The TDO, TCK, TDI, TMS, and TRST# pins are dedicated for the JTAG when the boundary scan function is enabled.
Six test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode



Note: JTBPR: Bypass register
JTBSR: Boundary scan register
JTIR: Instruction register
JTIDR: ID code register

Figure 38.1 JTAG block diagram

Table 38.2 shows the I/O pins used in the boundary scan function.

Table 38.2 Pin configuration of JTAG

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50% when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin
TRST#	Input	Test reset input pin

38.2 Register Descriptions

Instructions can be input to the instruction register via the TDI pin by serial transfer.

The bypass register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.

The boundary scan register, which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data are being shifted in.

None of the registers is accessible from the CPU. Table 38.3 shows the availability of serial transfer for the registers.

Table 38.3 Serial transfer for the registers

Register	Serial input	Serial output
Instruction register	Available	Available
ID code register	Available	Available
Bypass register	Available	Available
Boundary scan register	Available	Available

Note: Any serial transfer is available if standards for the boundary scan function are satisfied.

38.2.1 JTIR : Instruction Register

Base address: —

Offset address: —

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TS[7:0]							
Value after reset:	0	1	0	1	0	1	0	1

Bit	Symbol	Function	R/W
7:0	TS[7:0]	Test Bit Set The command configuration is as shown in Table 38.4.	—

The JTIR register is an 8-bit register.

Boundary scan instructions can be transferred to the instruction register by serial input from the TDI pin.

The instruction register is initialized when the TRST# pin is driven to the low level or when the TAP controller is in the Test-Logic-Reset state.

Table 38.4 Command configuration (1 of 2)

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (value after reset)

Table 38.4 Command configuration (2 of 2)

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

38.2.2 JTIDR : ID Code Register

Base address: —

Offset address: —

Bit position:	31																												0
Bit field:	DID[31:0]																												
Value after reset:	0	0	0	0	1	0	0	0	0	1	0	0	0	1	0	1	0	1	0	0	0	1	0	0	0	1	0	0	0	1	1	1

Bit	Symbol	Function	R/W
31:0	DID[31:0]	This register has the fixed value that indicates the device IDCODE.	—

The JTIDR register is a 32-bit register.

ID code register data is output from the TDO pin when the IDCODE instruction is executed.

38.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register.

This register is connected between the TDI and TDO pins when BYPASS mode is set.

The JTBPR register cannot be read from or written to by the CPU.

38.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register to control the external input and output pins of this LSI and is distributed across the pad.

The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions are issued to apply the JTBSR register in boundary-scan testing.

Refer to the BSDL file for the correspondences between the pins of this LSI and the bits of the boundary scan register.

The value is undefined after a reset.

38.3 Operation

The boundary scan function is valid when the RES# and BSCANP pins are driven high.

38.3.1 TAP Controller

Figure 38.2 shows the state transition diagram of the TAP controller. Table 38.5 describes each state.

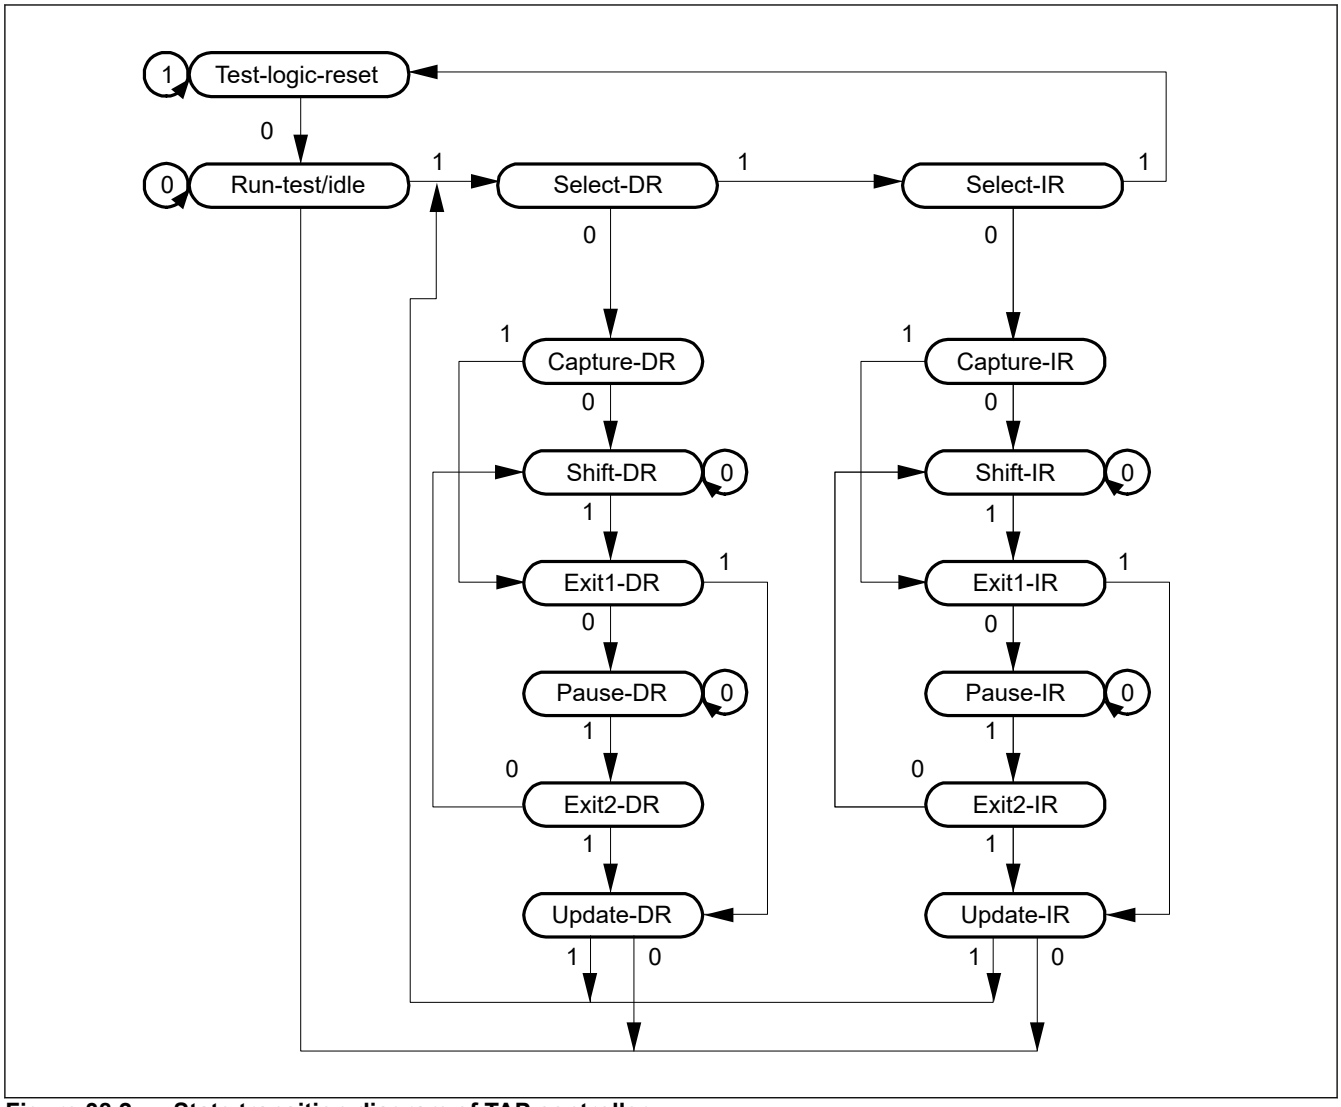


Figure 38.2 State transition diagram of TAP controller

Table 38.5 Explanation of states (1 of 2)

State	Explanation
Test Logic Reset	Reset state of the TAP controller The LSI is in this state during normal operation.
Run Test/Idle	Test execution state
Select DR Scan	Temporary state used for selecting a data register
Select IR Scan	Temporary state used for selecting an instruction register
Capture DR	Data of the test data register corresponding to the current instruction is captured in parallel.
Shift DR	The test data register corresponding to the current instruction is connected between the TDI and TDO pins, and data is transferred serially.
Exit DR	Temporary state
Pause DR	Clocks are applied while the value input in the Shift DR state is retained.
Exit2 DR	Temporary state
Update DR	Output latches of the test data register corresponding to the current instruction are updated.
Capture IR	A fixed value is input to the instruction register.
Shift IR	The instruction register is connected between the TDI and TDO pins, and data is transferred serially.
Exit IR	Temporary state

Table 38.5 Explanation of states (2 of 2)

State	Explanation
Pause IR	Clocks are applied while the value input in the Shift IR state is retained.
Exit2 IR	Temporary state
Update IR	The current instruction is updated to the instruction input in the Shift IR state.

38.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction drives the bypass register. This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit does not affect the system circuit.

The bypass register is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is set to 0 in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result to the boundary scan register from the print circuit board.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from this LSI's internal circuits to the boundary scan register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this LSI and output signals are also directly output to the external circuits. The system circuit of this LSI is not affected by this instruction.

In SAMPLE operation, the boundary scan register latches the snapshot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snapshot at the rising edge of the TCK in Capture-DR state. The scan register latches snapshots without affecting the LSI normal operation.

In PRELOAD operation, the value after reset is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, the ID code register value is output from the TDO in LSB-first order in Shift-DR state of the TAP controller. While this instruction is being executed, the test circuit does not affect the system circuit. The instruction register is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state.

The bypass register is connected between the TDI and TDO pins, leading to the same operation as when BYPASS mode has been selected.

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state. The bypass register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

38.4 Usage Notes

1. For serial transfer, data are input or output in LSB-first order. See Figure 38.3.
2. Pins of the boundary scan (TDI, TMS, and TRST#) have to be pulled up by pull-up resistors.
   However, if an on-chip emulator is in use, handle the TRST# pin according to the manual for the given on-chip emulator.
3. Power supply pins (VDD, VSS, VCC1833_n, VCC33, VCC18_PLL0, VCC18_PLL1, AVCC18_TSU, VCC33_USB, VCC18_USB, VSS_USB, AVCC18_USB, VCC18_ADC0, VCC18_ADC1) cannot be boundary-scanned.
4. Analog reference pins (VREFH0, VREFH1, and USB_RREF) cannot be boundary-scanned.
5. Analog input pins (AN000 to AN003 and AN100 to AN107) cannot be boundary-scanned.
6. Clock pins (EXTAL, XTAL, and EXTCLKIN) cannot be boundary-scanned.
7. The reset pin (RES#) cannot be boundary-scanned.
8. The operating mode input pin (MDX) cannot be boundary-scanned.
9. USB dedicated pins (USB_DP and USB_DM) cannot be boundary-scanned.
10. The boundary-scan pin (BSCANP) cannot be boundary-scanned.
11. The boundary-scan pins (TCK, TMS, TRST#, TDI, and TDO) cannot be boundary-scanned.
12. The boundary scan function is not available when the chip is in the reset state.
13. For a pin that incorporates open-drain functionality and for which the open-drain function is enabled, if the boundary-scan function sets the corresponding bit in the output scan register and output enable register to 1, executing an EXTEST, CLAMP, or SAMPLE/PRELOAD instruction makes the pin output the high level rather than placing it in the high-impedance state.*1

Note 1. For details on boundary-scan target pins, refer to the BSDL file. Boundary-scan is not applicable to some pins and power pins.

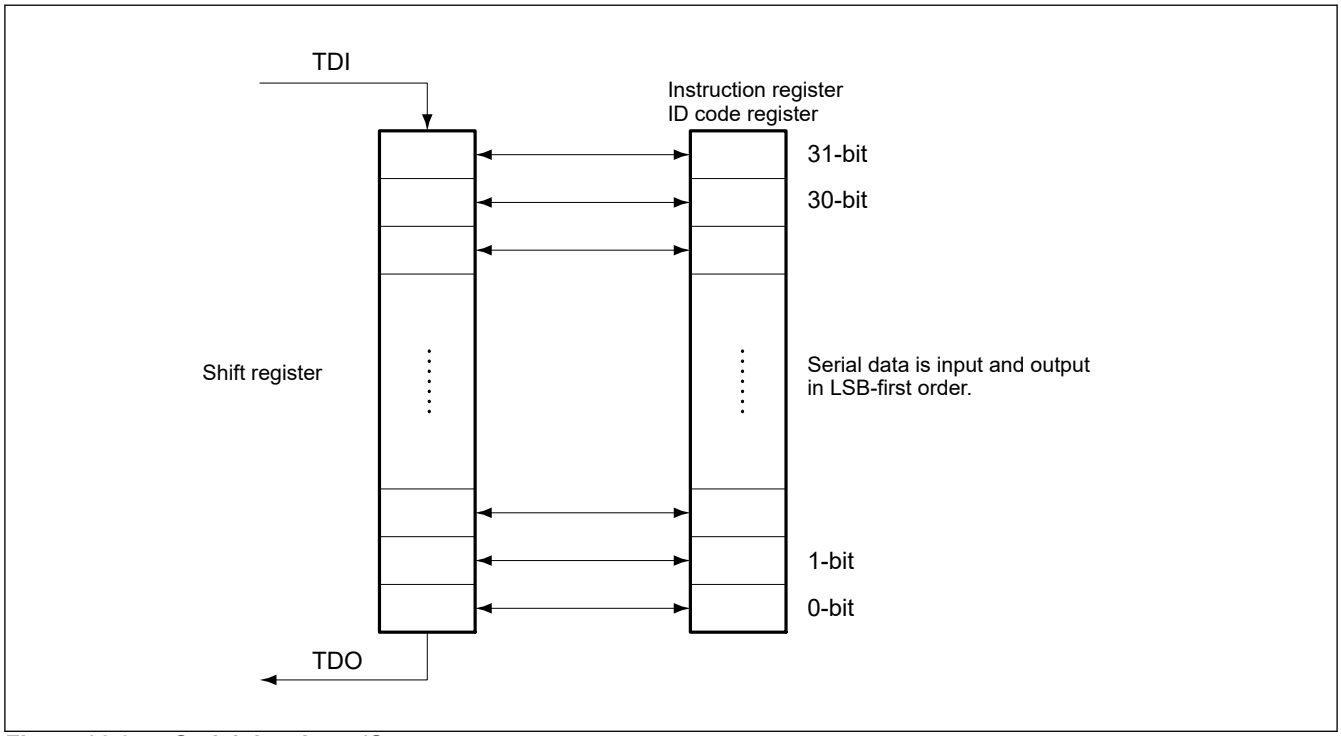

Figure 38.3 Serial data Input/Output

39. ΔΣ Interface (DSMIF)

39.1 Overview

The ΔΣ interfaces (DSMIF) can be connected with up to three external ΔΣ modulators. It is capable of filtering delta-sigma modulated 1-bit digital input data and converting it into 16-bit digital data.

Table 39.1 lists the specifications of DSMIF and Table 39.2 lists the functions of DSMIF. Figure 39.1 shows a block diagram of DSMIF.

Table 39.1 DSMIF specifications

Parameter	Description
Number of units	2 units
Number of channels	3 channels per unit for a total of 6 channels
Decimation filter characteristics	Filter are selectable as Sinc 1st order, Sinc 2nd order, Sinc 3rd order Can select each channel.
Over-sampling rate (decimation rate)	Selectable from 4 to 256 Can select each channel.
Interface clock	Support Master mode (MCLK is used as output)/Slave mode (MCLK is used as input) by channel Master mode supports the following output clock: ● 25/20/12.5/10/6.25/5 MHz (PCLKH 200 MHz) ● 25/18.75/12.5/9.375/6.25/5 MHz (PCLKH 150 MHz) Filter received clock inversion function.
Data capture	Crests and troughs can trigger capture, allowing capture of values for current with the same timing. Can select one capture trigger from six triggers for each trigger input by channel.
Unit synchronization	Not supported
Reset function of differential filter clock divider	Support channel by channel. Can select one from three triggers.
Error source ouput (interrupt)	Error signals are output under the following conditions: ● Abnormal-overcurrent detection ● Short-circuit detection ● Total-current error detection
Low-power consumption function	The module-stop state can be set (clock gating function is implemented)

Table 39.2 DSMIF functions (1 of 2)

Parameter			Unit 0 (DSMIF0)	Unit 1 (DSMIF1)
I/O pin	Clock	Clock I/O pin DSMIF0: ch0-2 DSMIF1: ch3-5	MCLK0 MCLK1 MCLK2	MCLK3 MCLK4 MCLK5
	Data	DATA input pin DSMIF0: ch0-2 DSMIF1: ch3-5	MDAT0 MDAT1 MDAT2	MDAT3 MDAT4 MDAT5

Table 39.2 DSMIF functions (2 of 2)

Parameter			Unit 0 (DSMIF0)	Unit 1 (DSMIF1)
Interrupt source	Normal	Current data register update (Combined with ch0 to ch2 for DSMIF0, combined with ch3 to ch5 for DSMIF1)	DSMIF0_CDRUI	DSMIF1_CDRUI
	Error*1	Lower threshold current sum error	DSMIF0_LTCSE	DSMIF1_LTCSE
		Upper threshold current sum error	DSMIF0_UTCSE	DSMIF1_UTCSE
		Lower threshold overcurrent detection 0	DSMIF0_LTODE0	DSMIF1_LTODE0
		Lower threshold overcurrent detection 1	DSMIF0_LTODE1	DSMIF1_LTODE1
		Lower threshold overcurrent detection 2	DSMIF0_LTODE2	DSMIF1_LTODE2
		Upper threshold overcurrent detection 0	DSMIF0_UTODE0	DSMIF1_UTODE0
		Upper threshold overcurrent detection 1	DSMIF0_UTODE1	DSMIF1_UTODE1
		Upper threshold overcurrent detection 2	DSMIF0_UTODE2	DSMIF1_UTODE2
		Short-circuit detection 0	DSMIF0_SCDE0	DSMIF1_SCDE0
		Short-circuit detection 1	DSMIF0_SCDE1	DSMIF1_SCDE1
		Short-circuit detection 2	DSMIF0_SCDE2	DSMIF1_SCDE2
Trigger input ELC destination	Capture	Current data capture trigger 0	DSMIF0 CAP_TRG0	DSMIF1 CAP_TRG0
		Current data capture trigger 1	DSMIF0 CAP_TRG1	DSMIF1 CAP_TRG1
		Current data capture trigger 2	DSMIF0 CAP_TRG2	DSMIF1 CAP_TRG2
		Current data capture trigger 3	DSMIF0 CAP_TRG3	DSMIF1 CAP_TRG3
		Current data capture trigger 4	DSMIF0 CAP_TRG4	DSMIF1 CAP_TRG4
		Current data capture trigger 5	DSMIF0 CAP_TRG5	DSMIF1 CAP_TRG5
	Counter Reset	Decimation dividing counter initialization trigger 0	DSMIF0 CDCNT_INT_TRG0	DSMIF1 CDCNT_INT_TRG0
		Decimation dividing counter initialization trigger 1	DSMIF0 CDCNT_INT_TRG1	DSMIF1 CDCNT_INT_TRG1
		Decimation dividing counter initialization trigger 2	DSMIF0 CDCNT_INT_TRG2	DSMIF1 CDCNT_INT_TRG2

Note 1. binded unit error signal connect to POE3 and POEG

39.2 Register Descriptions

39.2.1 DSMIF Common Control Registers

39.2.1.1 DSSEICR : Overcurrent Sum Error Detect Interrupt Control Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISEH	ISEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ISEL	Overcurrent sum error lower limit detection interrupt enable bit 0: Do not output overcurrent sum error lower limit detection interrupt 1: Overcurrent sum error lower limit detection interrupt can be output	R/W
1	ISEH	Overcurrent sum error upper limit detection interrupt enable bit 0: Do not output overcurrent sum error upper limit detection interrupt 1: Overcurrent sum error lower upper detection interrupt can be output	R/W

Bit	Symbol	Function	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.2 DSSECSR : Overcurrent Sum Error Detect Channel Setting Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SEDM[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SEDM[2:0]	Overcurrent sum error detect mode setting bit 0 0 0: Detects error of sum value of overcurrent data of CH0, CH1, CH2 0 0 1: Detects error of sum value of overcurrent data of CH0, CH1 0 1 0: Detects error of overcurrent data of CH0 0 1 1: Detects error of overcurrent data of CH1 1 0 0: Detects error of overcurrent data of CH2 Others: Setting prohibited (detects error of sum value of overcurrent data of CH0, CH1, CH2)	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.3 DSSELTR : Overcurrent Sum Error Detect Low Threshold Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x048

Bit position:	31														17																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCMPTBL[17:0]																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	SCMPTBL[17:0]	Overcurrent sum error detect lower limit These bits set the lower limit of the active current value for overcurrent sum error detection. Set these bits to the lower limit of the sum value of the overcurrent data for each channel.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.4 DSSEHTR : Overcurrent Sum Error Detect High Threshold Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x04C

Bit position:	31														17																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCMPTBH[17:0]																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	SCMPTBH[17:0]	Overcurrent sum error detect upper limit These bits set the upper limit of the active current value for overcurrent sum error detection. Set these bits to the upper limit of the sum value of the overcurrent data for each channel.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.5 DSSECR : Overcurrent Sum Error Detect Control Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x050

Bit position:	31																												1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEEH	SEEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEEL	Overcurrent sum error lower limit detection enable bit 0: The lower limit exceeded detection function of overcurrent sum error detection is invalid 1: The lower limit exceeded detection function of overcurrent sum error detection is valid	R/W
1	SEEH	Overcurrent sum error upper limit detection enable bit 0: The upper limit exceeded detection function of overcurrent sum error detection is invalid 1: The upper limit exceeded detection function of overcurrent sum error detection is valid	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.6 DSSECDRn : Overcurrent Sum Error Detect Capture Data Register n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x060 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SECDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SECDR[15:0]	Overcurrent sum error detect capture data n Captures the overcurrent data of the target channel when the upper limit error or the lower limit error of the over sum current error detection occurs. See Table 39.7 for details of the data to be captured.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.7 DSCSTRTR : Channel Software Start Trigger Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG2	STRTRG1	STRTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STRTRG0	Channel 0 start trigger 0: Do nothing 1: Start channel	R/W
1	STRTRG1	Channel 1 start trigger 0: Do nothing 1: Start channel	R/W
2	STRTRG2	Channel 2 start trigger 0: Do nothing 1: Start channel	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.8 DSCSTPTR : Channel Software Stop Trigger Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG2	STPTRG1	STPTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STPTRG0	Channel 0 stop trigger 0: Do nothing 1: Stop channel	R/W
1	STPTRG1	Channel 1 stop trigger 0: Do nothing 1: Stop channel	R/W
2	STPTRG2	Channel 2 stop trigger 0: Do nothing 1: Stop channel	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

39.2.1.9 DSCESR : Channel Error Status Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SUMERRH	SUMERRL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SCF2	SCF1	SCF0	—	OCFH2	OCFH1	OCFH0	—	OCFL2	OCFL1	OCFL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OCFL0	Channel 0 overcurrent lower limit detection flag 0: Indicates that the overcurrent data is not less than the lower limit 1: Indicates that the overcurrent data is less than the lower limit	R
1	OCFL1	Channel 1 overcurrent lower limit detection flag 0: Indicates that the overcurrent data is not less than the lower limit 1: Indicates that the overcurrent data is less than the lower limit	R
2	OCFL2	Channel 2 overcurrent lower limit detection flag 0: Indicates that the overcurrent data is not less than the lower limit 1: Indicates that the overcurrent data is less than the lower limit	R
3	—	This bit is read as 0.	R
4	OCFH0	Channel 0 overcurrent upper limit detection flag 0: Indicates that the overcurrent data is not more than the upper limit 1: Indicates that the overcurrent data is more than the upper limit	R
5	OCFH1	Channel 1 overcurrent upper limit detection flag 0: Indicates that the overcurrent data is not more than the upper limit 1: Indicates that the overcurrent data is more than the upper limit	R
6	OCFH2	Channel 2 overcurrent upper limit detection flag 0: Indicates that the overcurrent data is not more than the upper limit 1: Indicates that the overcurrent data is more than the upper limit	R
7	—	This bit is read as 0.	R
8	SCF0	Channel 0 short circuit detection flag 0: Indicates that the MDAT0 pin short circuit is not detected 1: Indicates that a short circuit on the MDAT0 pin has been detected	R
9	SCF1	Channel 1 short circuit detection flag 0: Indicates that the MDAT1 pin short circuit is not detected 1: Indicates that a short circuit on the MDAT1 pin has been detected	R
10	SCF2	Channel 2 short circuit detection flag 0: Indicates that the MDAT2 pin short circuit is not detected 1: Indicates that a short circuit on the MDAT2 pin has been detected	R
15:11	—	These bits are read as 0.	R
16	SUMERRL	Overcurrent sum error lower limit detection flag 0: Indicates that the sum value of overcurrent data is not less than the lower limit 1: Indicates that the sum value of overcurrent data is less than the lower limit	R
17	SUMERRH	Overcurrent sum error upper limit detection flag 0: Indicates that the sum value of overcurrent data is not more than the upper limit 1: Indicates that the sum value of overcurrent data is more than the upper limit	R
31:18	—	These bits are read as 0.	R

39.2.1.10 DSCSR : Channel Status Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x118

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	DUF2	DUF1	DUF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DUF0	Channel 0 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This register becomes 0 when DUF0 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF0/ DSCSCRCH0.CLRDUF) or when the Current Data Register Channel 0 (DSCDRCH0) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R
1	DUF1	Channel 1 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This register becomes 0 when DUF1 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF1/ DSCSCRCH1.CLRDUF) or when the Current Data Register Channel 1 (DSCDRCH1) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R
2	DUF2	Channel 2 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This register becomes 0 when DUF2 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF2/ DSCSCRCH2.CLRDUF) or when the Current Data Register Channel 2 (DSCDRCH2) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R
31:3	—	These bits are read as 0.	R

39.2.1.11 DSCSSR : Channel State Status Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x11C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CHSTATE2	—	—	—	CHSTATE1	—	—	—	CHSTATE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CHSTATE0	Channel 0 state 0: Channel stop 1: Channel in operation	R

Bit	Symbol	Function	R/W
3:1	—	These bits are read as 0.	R
4	CHSTATE1	Channel 1 state 0: Channel stop 1: Channel in operation	R
7:5	—	These bits are read as 0.	R
8	CHSTATE2	Channel 2 state 0: Channel stop 1: Channel in operation	R
31:9	—	These bits are read as 0.	R

39.2.1.12 DSCESCR : Channel Error Status Clear Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRSUMERRH	CLRSUMERRL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CLRSCF2	CLRSCF1	CLRSCF0	—	CLROCFH2	CLROCFH1	CLROCFH0	—	CLROCFL2	CLROCFL1	CLROCFL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLROCFL0	Channel 0 Overcurrent Lower Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFL0 / DSCSRCH0.OCFL	W
1	CLROCFL1	Channel 1 Overcurrent Lower Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFL1 / DSCSRCH1.OCFL	W
2	CLROCFL2	Channel 2 Overcurrent Lower Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFL2 / DSCSRCH2.OCFL	W
3	—	The write value should be 0.	W
4	CLROCFH0	Channel 0 Overcurrent Upper Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFH0 / DSCSRCH0.OCFH	W
5	CLROCFH1	Channel 1 Overcurrent Upper Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFH1 / DSCSRCH1.OCFH	W
6	CLROCFH2	Channel 2 Overcurrent Upper Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.OCFH2 / DSCSRCH2.OCFH	W
7	—	The write value should be 0.	W
8	CLRSCF0	Channel 0 Short Circuit Detection Flag Clear 0: No effect 1: Clear DSCESR.SCF0 / DSCSRCH0.SCF	W
9	CLRSCF1	Channel 1 Short Circuit Detection Flag Clear 0: No effect 1: Clear DSCESR.SCF1 / DSCSRCH1.SCF	W

Bit	Symbol	Function	R/W
10	CLRSCF2	Channel 2 Short Circuit Detection Flag Clear 0: No effect 1: Clear DSCESR.SCF2 / DSCSRCH2.SCF	W
15:11	—	The write value should be 0.	W
16	CLRSUMERRL	Overcurrent Sum Error Lower Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.SUMERRL	W
17	CLRSUMERRH	Overcurrent Sum Error Upper Limit Detection Flag Clear 0: No effect 1: Clear DSCESR.SUMERRH	W
31:18	—	The write value should be 0.	W

39.2.1.13 DSCSCR : Channel Status Clear Register

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x128

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRDUF2	CLRDUF1	CLRDUF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLRDUF0	Channel 0 Data Update Flag Clear 0: No effect 1: Clear DSCSR.DUF0 / DSCSRCH0.DUF	W
1	CLRDUF1	Channel 1 Data Update Flag Clear 0: No effect 1: Clear DSCSR.DUF1 / DSCSRCH1.DUF	W
2	CLRDUF2	Channel 2 Data Update Flag Clear 0: No effect 1: Clear DSCSR.DUF2 / DSCSRCH2.DUF	W
31:3	—	The write value should be 0.	W

39.2.2 DSMIF Channel Control Registers

39.2.2.1 DSICRCHn : Interrupt Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x180 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IUE	ISE	IOEH	IOEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IOEL	Overcurrent lower limit detection interrupt enable 0: Do not output overcurrent lower limit detection interrupt 1: Overcurrent lower limit detection interrupt can be output	R/W
1	IOEH	Overcurrent upper limit exceeded output interrupt enable 0: Do not output overcurrent upper limit detection interrupt 1: Overcurrent upper limit exceeded detection interrupt can be output	R/W
2	ISE	Short circuit detection error interrupt enable 0: Do not output short circuit detection interrupt 1: Short circuit detection interrupt can be output	R/W
3	IUE	Current data register update interrupt enable 0: Do not output current data register update interrupt 1: Current data register update interrupt can be output	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.2 DSCMCCRCHn : Current Measurement Clock Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x184 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CKDIV[5:0]						SEDGE	—	—	—	—	—	—	CKDIR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CKDIR	A/D conversion clock master/slave switching 0: MCLKn pin is input (slave operation) 1: MCLKn pin is output (master operation)	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	SEDGE	Sampling edge selection 0: Capture MDATn at the negative edge of MCLKn 1: Capture MDATn at the positive edge of MCLKn	R/W
13:8	CKDIV[5:0]	A/D conversion clock division ratio Set the division ratio in clock master mode. Set to a division ratio of 2 × (CKDIV[5:0] + 1) with the core clock	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.3 DSCMFCRCHn : Current Measurement Filter Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x188 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	CMSH[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDEC[7:0]								—	—	—	—	—	—	CMSINC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMSINC[1:0]	Current measurement filter order setting 0 0: Sinc3 (3rd order) 0 1: Sinc1 (1st order) 1 0: Sinc2 (2nd order) 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	CMDEC[7:0]	Decimation ratio selection for current measurement M indicates the decimation ratio. Decimation ratio M is set as follows: M = CMDEC + 1 The decimation ratio M can be set within the following range. 4 ≤ M ≤ 256 (0x3 ≤ CMDEC ≤ 0xFF) Setting less than M = 4 is prohibited. When these value is set, Sinc filter operation is not guaranteed.	R/W
20:16	CMSH[4:0]	Data shift setting for current measurement*1 0x00: [23:8] 0x01: [22:7] 0x02: [21:6] 0x03: [20:5] 0x04: [19:4] 0x05: [18:3] 0x06: [17:2] 0x07: [16:1] 0x08: [15:0] 0x09: [14:0]<<1 0x0A: [13:0]<<2 0x0B: [12:0]<<3 0x0C: [11:0]<<4 0x0D: [10:0]<<5 0x0E: [9:0]<<6 0x0F: [8:0]<<7 0x10: [7:0]<<8 0x11: [6:0]<<9 0x12: [5:0]<<10 0x13: [4:0]<<11 Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. In CMSH[4:0] = 0x09 to 0x13, the lower bits are filled with 0s.

39.2.2.4 DSCMCTCRCHn : Current Measurement Capture Trigger Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x18C + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DEDGE	—	—	—	—	—	DITSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CTSELB[2:0]			—	—	—	—	—	CTSELA[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTSELA[2:0]	Current capture trigger A selection bit 0x0: Do not capture 0x1: Select current data capture trigger 0 0x2: Select current data capture trigger 1 0x3: Select current data capture trigger 2 0x4: Select current data capture trigger 3 0x5: Select current data capture trigger 4 0x6: Select current data capture trigger 5 0x7: Setting prohibited (do not capture)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	CTSELB[2:0]	Current capture trigger B selection bit 0x0: Do not capture 0x1: Select current data capture trigger 0 0x2: Select current data capture trigger 1 0x3: Select current data capture trigger 2 0x4: Select current data capture trigger 3 0x5: Select current data capture trigger 4 0x6: Select current data capture trigger 5 0x7: Setting prohibited (do not capture)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
17:16	DITSEL[1:0]	Current measurement filter initialization trigger selection bit for frequency division counter for decimation. 0 0: Do not initialize 0 1: Select decimation dividing counter initialization trigger 0 1 0: Select decimation dividing counter initialization trigger 1 1 1: Select decimation dividing counter initialization trigger 2	R/W
22:18	—	These bits are read as 0. The write value should be 0.	R/W
23	DEDGE	Current measurement filter initialization trigger for division counter for decimation edge selection bit. The trigger from ELC is usually used positive edge. Change from the initial value if necessary. 0: The frequency division counter for decimation is initialized at the negative edge of initialization trigger 1: The frequency division counter for decimation is initialized at the positive edge of initialization trigger	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.5 DSEDCRCHn : Error Detect Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x190 + 0x90 × n

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SDE	Short circuit detection enable bit 0: Short circuit detection is invalid 1: Short circuit detection is valid	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.6 DSOCFCRCHn : Overcurrent Detect Filter Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x194 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	OCSH[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OCDEC[7:0]								—	—	—	—	—	—	OCSINC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OCSINC[1:0]	Overcurrent detection filter order setting 0 0: Sinc3 (3rd order) 0 1: Sinc1 (1st order) 1 0: Sinc2 (2nd order) 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	OCDEC[7:0]	Decimation ratio selection for overcurrent detection M indicates the decimation ratio. Decimation ratio M is set as follows: M = OCDEC + 1 The decimation ratio M can be set within the following range. 4 ≤ M ≤ 256 (0x3 ≤ OCDEC ≤ 0xFF) Setting less than M = 4 is prohibited. When these value is set, Sinc filter operation is not guaranteed.	R/W

Bit	Symbol	Function	R/W
20:16	OCSH[4:0]	Data shift setting for overcurrent detection*1 0x00: [23:8] 0x01: [22:7] 0x02: [21:6] 0x03: [20:5] 0x04: [19:4] 0x05: [18:3] 0x06: [17:2] 0x07: [16:1] 0x08: [15:0] 0x09: [14:0]<<1 0x0A: [13:0]<<2 0x0B: [12:0]<<3 0x0C: [11:0]<<4 0x0D: [10:0]<<5 0x0E: [9:0]<<6 0x0F: [8:0]<<7 0x10: [7:0]<<8 0x11: [6:0]<<9 0x12: [5:0]<<10 0x13: [4:0]<<11 Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. In OCSH[4:0] = 0x09 to 0x13, the lower bits are filled with 0s.

39.2.2.7 DSOCLTRCHn : Overcurrent Low Threshold Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x198 + 0x90 × n

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OCMPTBL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	OCMPTBL[15:0]	Overcurrent detection lower limit This bit sets the lower limit of the active current value for overcurrent detection.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.8 DSOCHTRCHn : Overcurrent High Threshold Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x19C + 0x90 × n

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OCMPTBH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	OCMPTBH[15:0]	Overcurrent detection upper limit This bit sets the upper limit of the active current value for overcurrent detection.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.9 DSSCTSRCHn : Short Circuit Threshold Setting Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1A0 + 0x90 × n

Bit position:	31			28												16			12												0
Bit field:	—	—	—	SCNTH[12:0]												—	—	—	SCNTL[12:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	SCNTL[12:0]	Short circuit detection low continuous detection count Set the upper limit for the number of times 0 is input continuously to the MDATn pin.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	SCNTH[12:0]	Short circuit detection high continuous detection count Set the upper limit for the number of times 1 is input continuously to the MDATn pin.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.10 DSODCRCHn : Overcurrent Detect Control Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1A4 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ODEH	ODEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ODEL	Overcurrent lower limit detection enable bit 0: Overcurrent lower limit detection is invalid 1: Overcurrent lower limit detection is valid	R/W
1	ODEH	Overcurrent upper limit exceeded detection enable bit 0: Overcurrent upper limit exceeded detection is invalid 1: Overcurrent upper limit exceeded detection is valid	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.11 DSCSTRTRCHn : Software Start Trigger Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1C0 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STRTRG	Channel start trigger Mirror register of DSCSTRTR.STRTRGn 0: Do nothing 1: Start channel n	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.12 DSCSTPTRCHn : Software Stop Trigger Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1C4 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STPTRG	Channel stop trigger Mirror register of DSCSTRTR.STPTRGn 0: Do nothing 1: Stop channel n	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

39.2.2.13 DSCDRCHn : Current Data Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1D0 + 0x90 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADDR[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR[15:0]	Current data Stores the current value generated by the current measurement data block.	R
31:16	—	These bits are read as 0.	R

39.2.2.14 DSCCDRACHn : Capture Current Data Register A Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1D4 + 0x90 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CDRA[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CDRA[15:0]	Capture current data A The current data value when the capture trigger A is input is stored.	R
31:16	—	These bits are read as 0.	R

39.2.2.15 DSCCDRBCHn : Capture Current Data Register B Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1D8 + 0x90 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CDRB[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CDRB[15:0]	Capture current data B The current data value when the capture trigger B is input is stored.	R
31:16	—	These bits are read as 0.	R

39.2.2.16 DSOCDRCHn : Overcurrent Data Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1DC + 0x90 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ODR[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ODR[15:0]	Overcurrent data Stores the current value generated by the overcurrent data block.	R
31:16	—	These bits are read as 0.	R

39.2.2.17 DSCOCDRCHn : Capture Overcurrent Data Register Channel n (n = 0 to 2)

Base address: DSMIFm = 0x9000_8000 + 0x0400 × m (m = 0, 1)

Offset address: 0x1E0 + 0x90 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

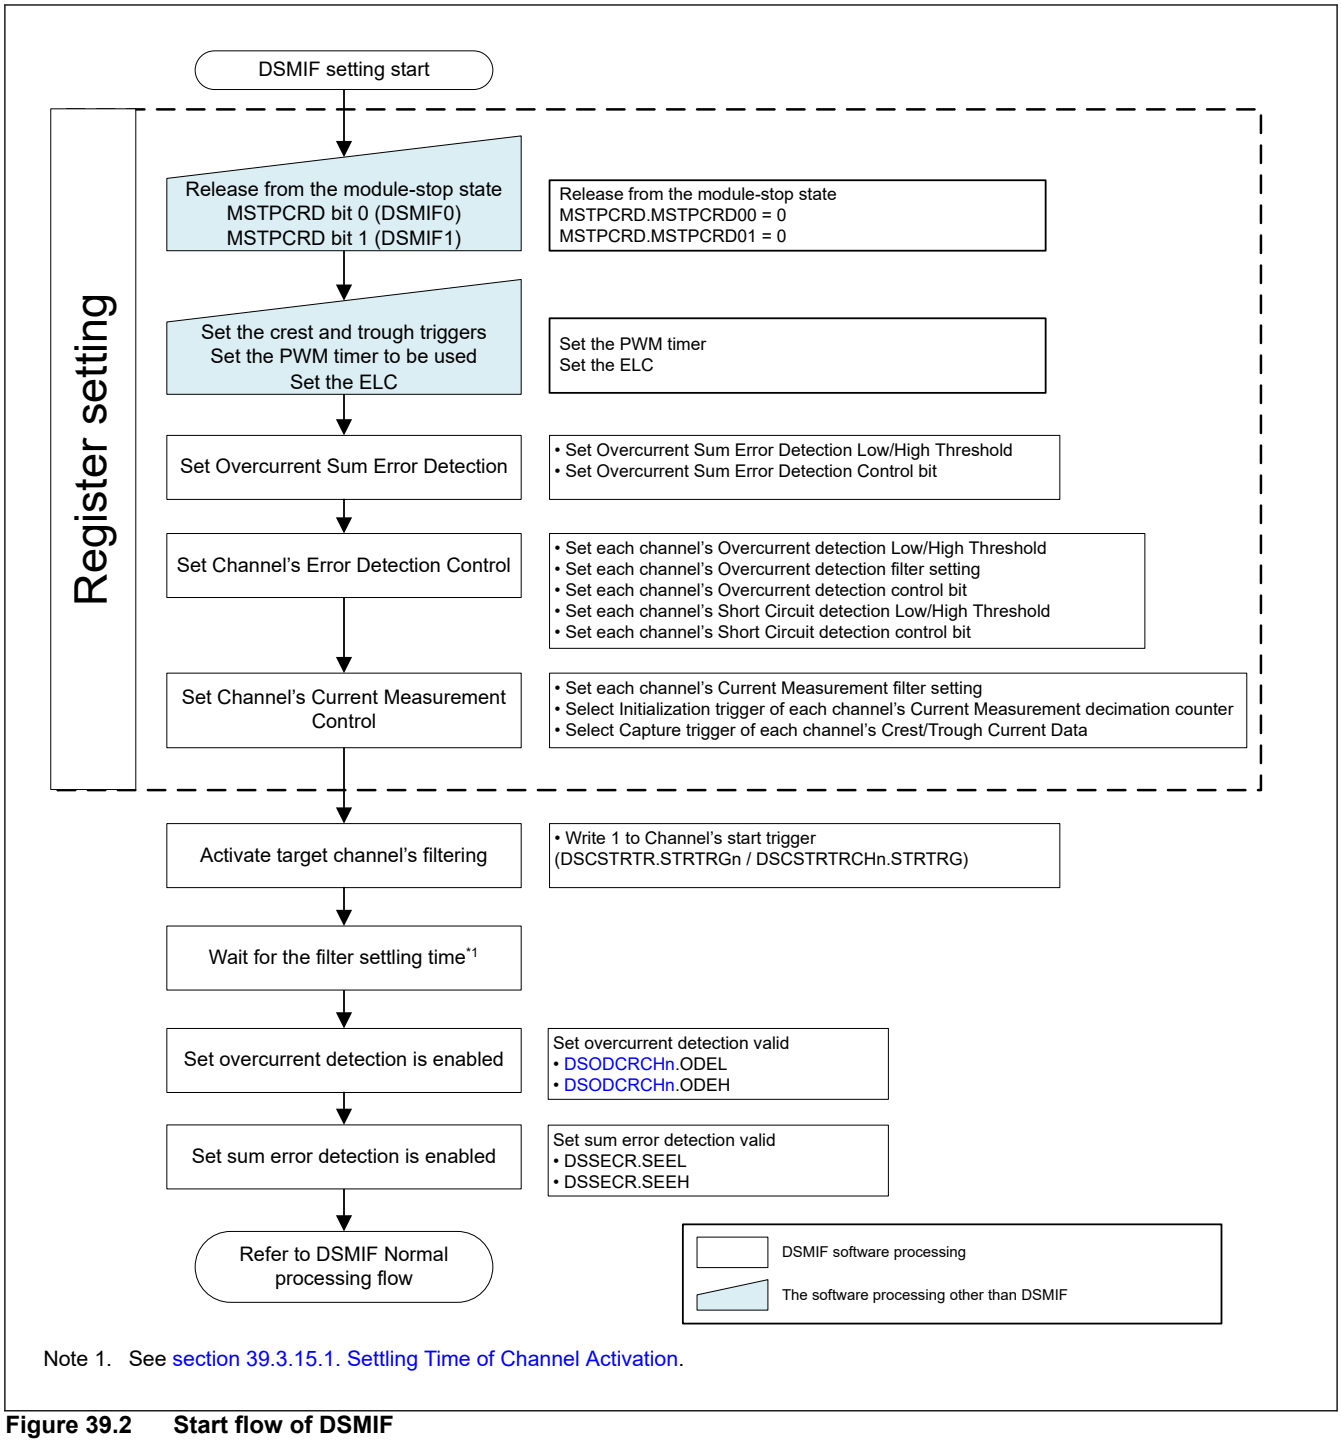
39.3 Operation

39.3.1 Start Flow

Figure 39.2 shows an example of a start procedure for DSMIF.

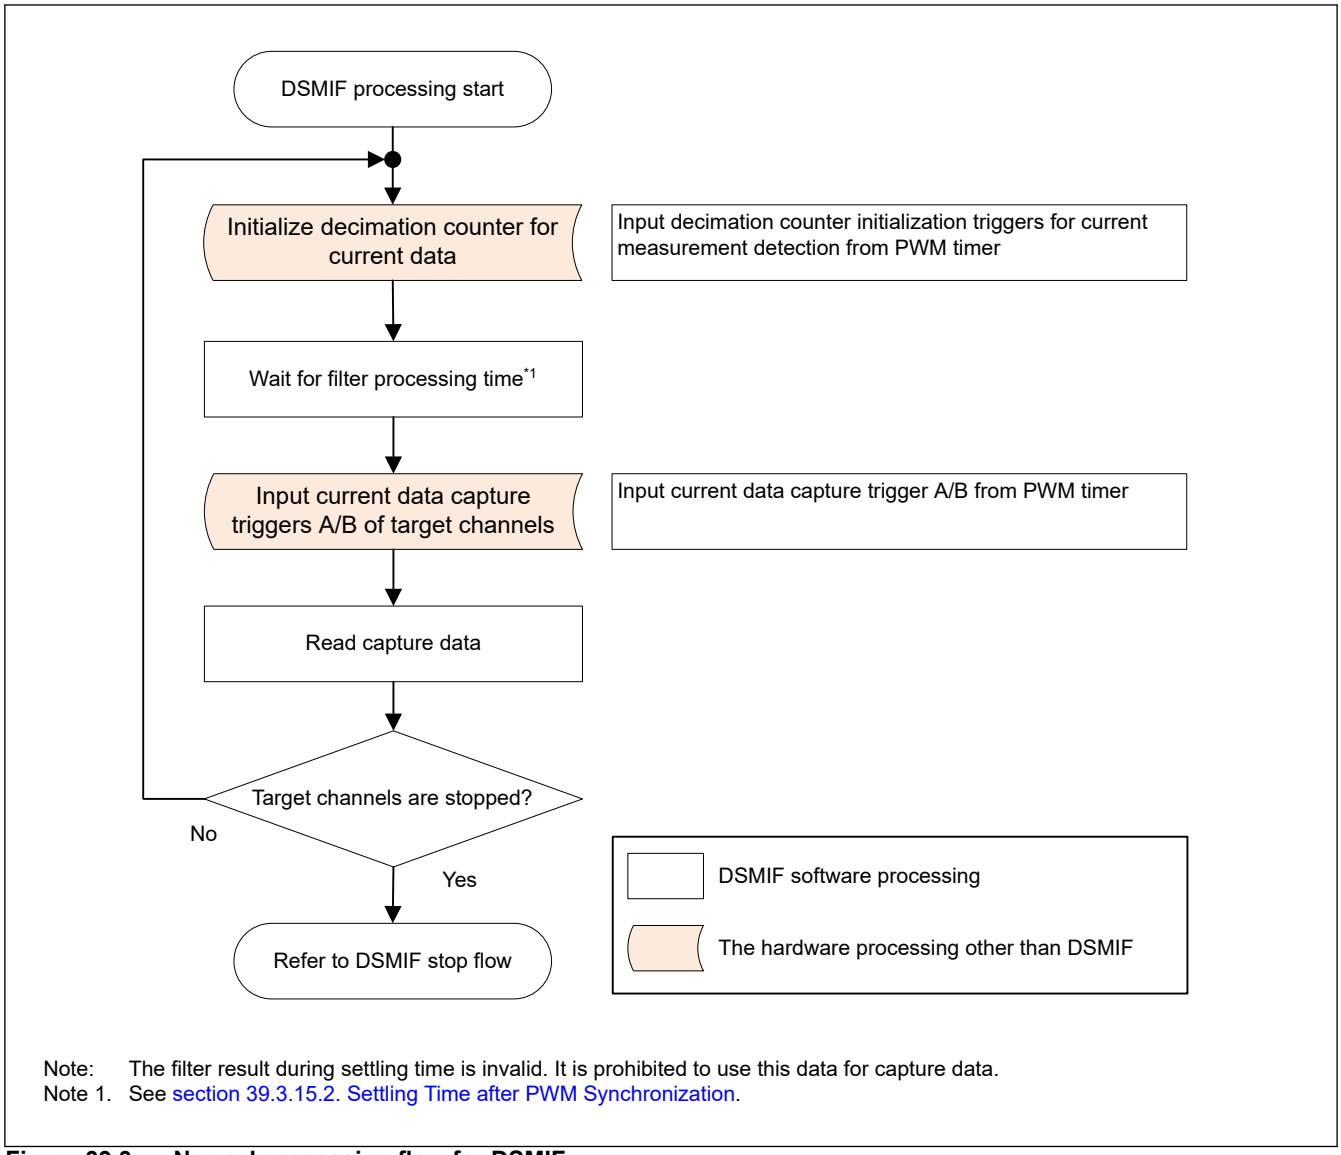


Note 1. See section 39.3.15.1. Settling Time of Channel Activation.

Figure 39.2 Start flow of DSMIF

39.3.2 Normal Processing Flow

Figure 39.3 shows an example of a normal processing procedure for DSMIF.



Note: The filter result during settling time is invalid. It is prohibited to use this data for capture data.
Note 1. See section 39.3.15.2. Settling Time after PWM Synchronization.

Figure 39.3 Normal processing flow for DSMIF

39.3.3 Stop Flow

Figure 39.4 shows an example of a stop procedure in channel synchronization control mode for DSMIF. Figure 39.5 shows the example of the stop procedure in channel individual control mode of DSMIF.

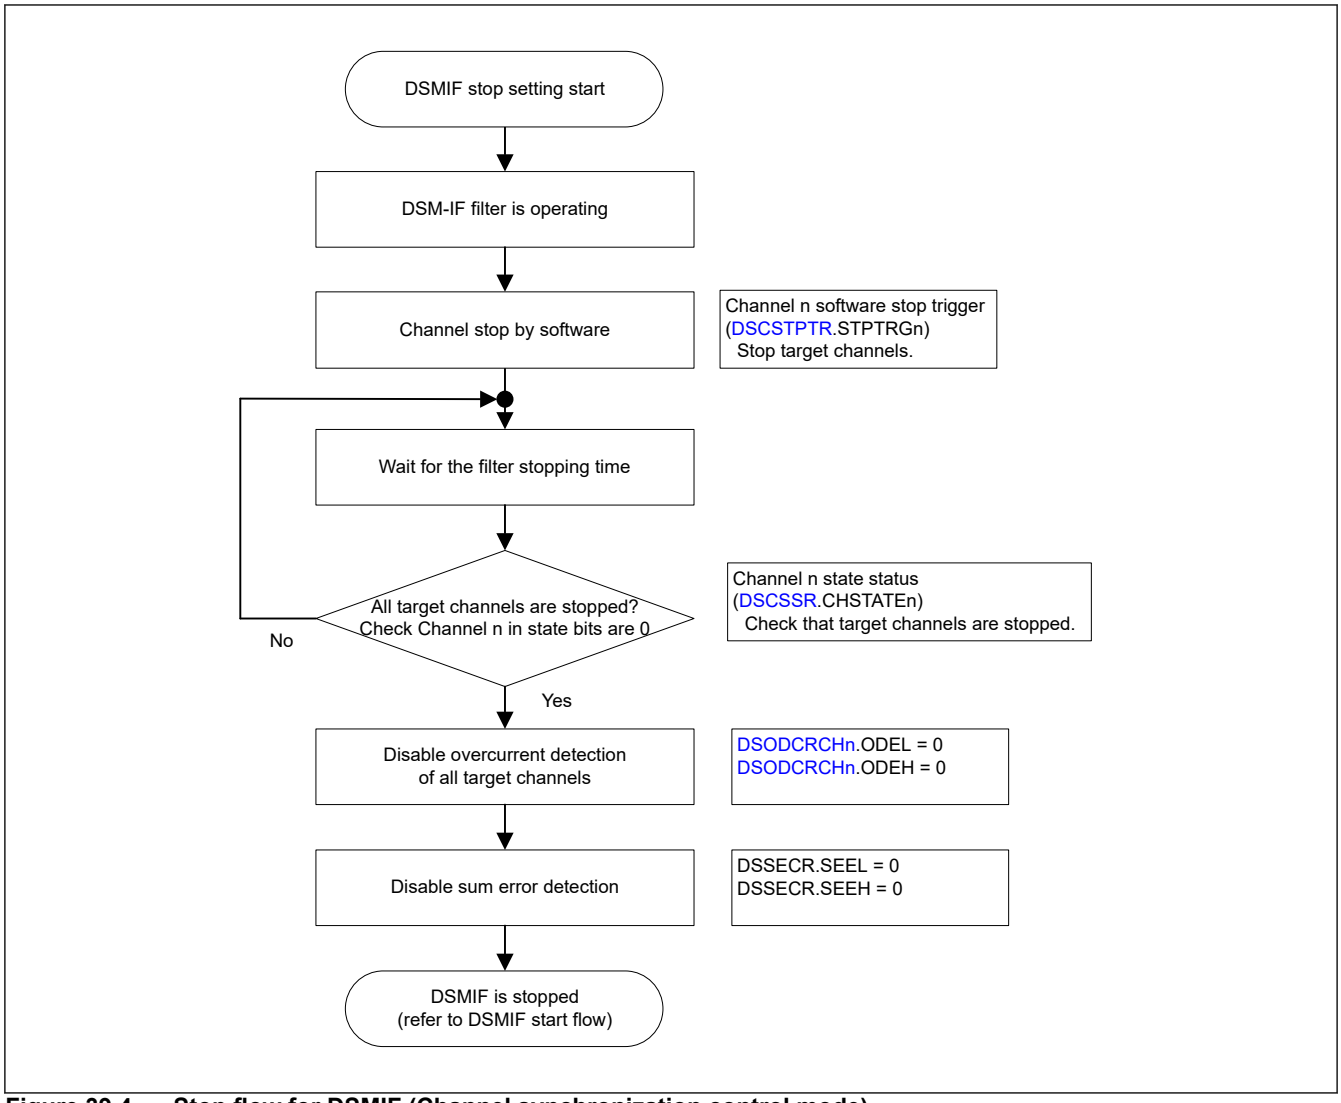


Figure 39.4 Stop flow for DSMIF (Channel synchronization control mode)

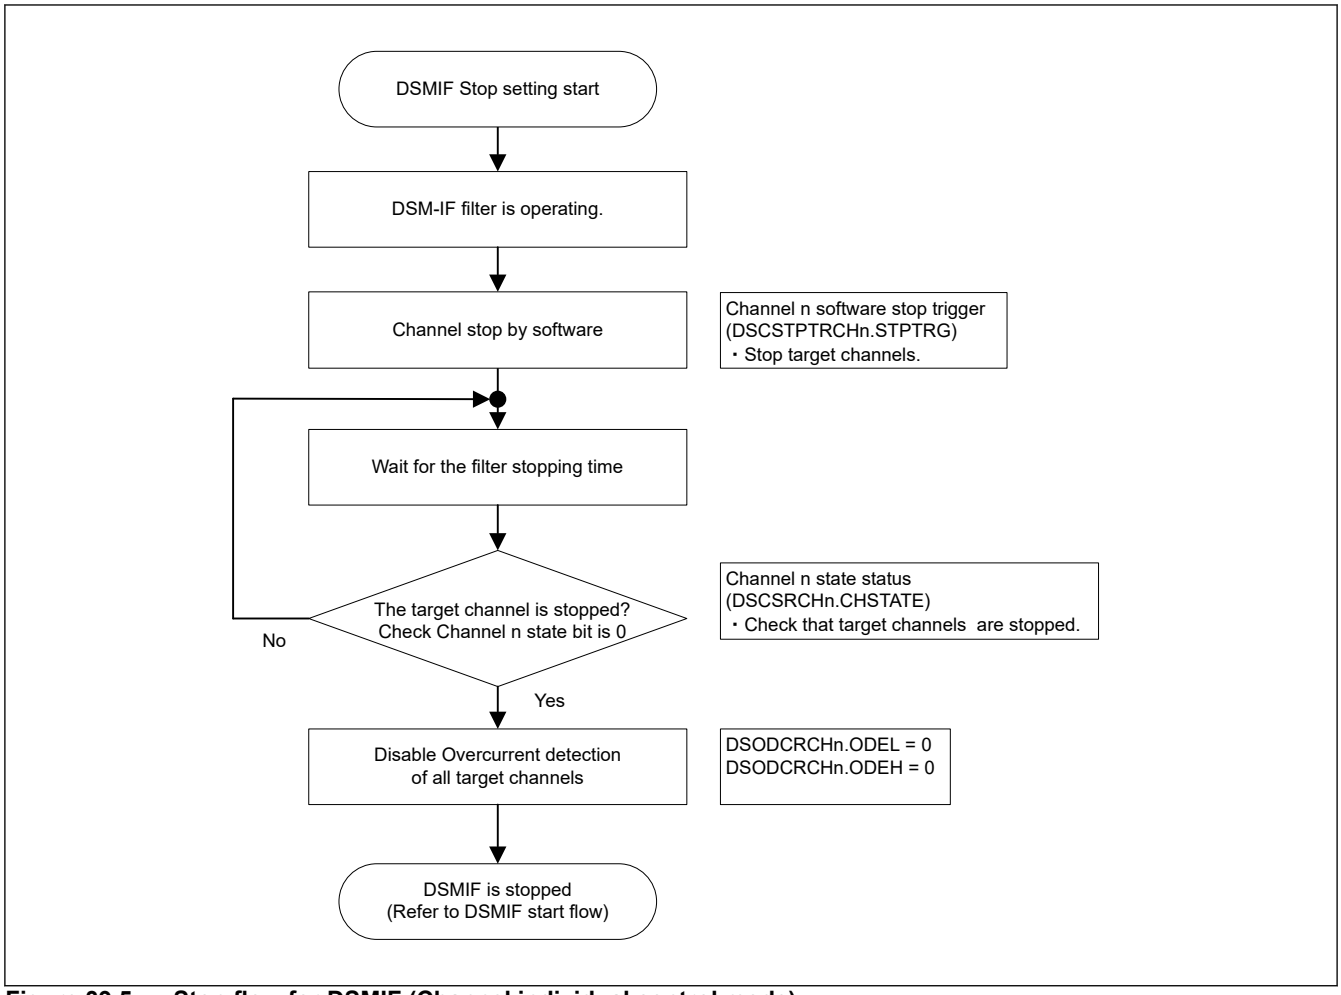

Figure 39.5 Stop flow for DSMIF (Channel individual control mode)

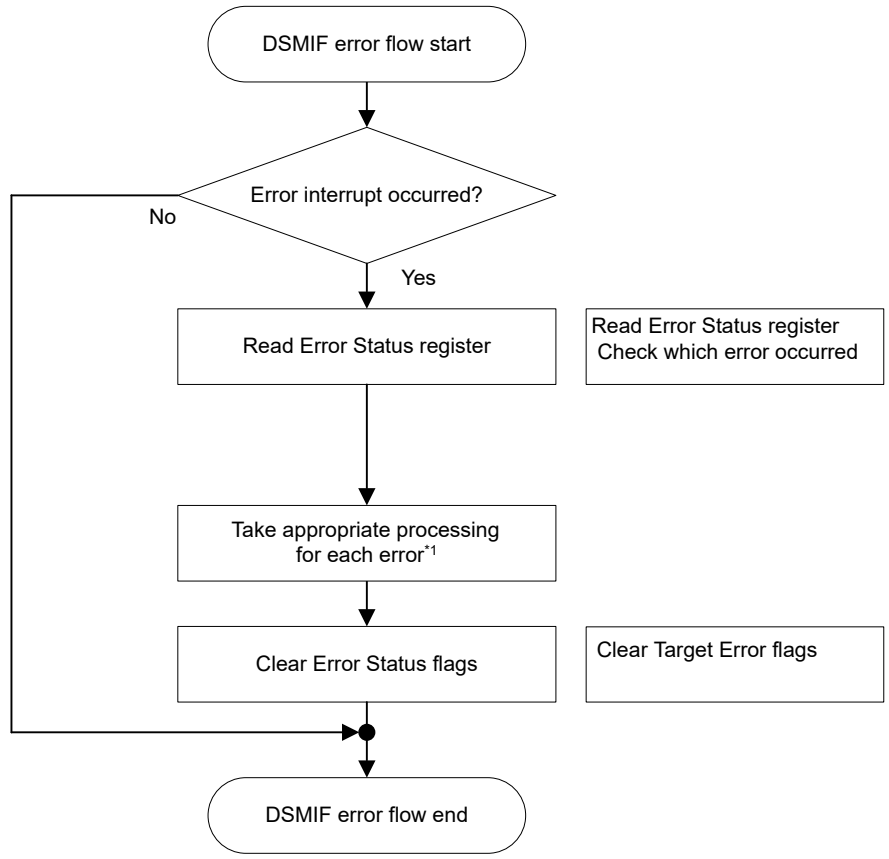
39.3.4 Error Flow

Figure 39.6 shows an example of an error procedure for DSMIF.



Note 1. The processing after each error detection depends on the user's system. Therefore, execute the error processing after the error detection according to each system.

Figure 39.6 Error flow for DSMIF

39.3.5 Clock Specification

When DSCMCCRCHn.CKDIR is set to 0 (clock slave mode), an external delta-sigma modulator clock is input to MCLKn. When DSCMCCRCHn.CKDIR is set to 1 (clock master mode), the frequency-divided core clock is output to MCLKn.

The frequency of the MCLKn can be selected by the DSCMCCRCHn.CKDIV[5:0] bits.

Table 39.3 shows the clock division ratio of master mode in DSMIF.

Table 39.3 Clock division ratio of Master mode in DSMIF

No.	Core clock (MHz)	MCLKn (MHz)	Supported core clock division ratio	Setting value (DSCMCCRCHn.CKDIV[5:0])
1	200	25	8	00_0011b
2		20	10	00_0100b
3		12.5	16	00_0111b
4		10	20	00_1001b
5		6.25	32	00_1111b
6		5	40	01_0011b

39.3.6 Channel Start and Channel Stop

The channel start and channel stop are controlled by the register in Table 39.4. Set the channels to be synchronized to 1 simultaneously. Set the channel start according to section 39.3.1. Start Flow. Set the channel stop according to section 39.3.3. Stop Flow.

Table 39.4 Channel start trigger and channel stop trigger

Channel mode	Category	Register bit name
Channel synchronization control mode	Channel start	DSCSTRTR.STRTRG0
		DSCSTRTR.STRTRG1
		DSCSTRTR.STRTRG2
	Channel stop	DSCSTPTR.STPTRG0
		DSCSTPTR.STPTRG1
		DSCSTPTR.STPTRG2
Channel individual control mode	Channel start	DSCSTRTRCHn.STRTRG
	Channel stop	DSCSTPTRCHn.STPTRG

39.3.7 Channel Synchronization

To synchronize the Sinc filters of multiple channels, use the following procedure. To allow for multiple channels to be synchronized, follow the procedure in section 39.3.1. Start Flow.

1. Set the same clock settings.
2. Select the same trigger for division counter initialization trigger.
   Set the same value to Division counter initialization trigger select bits (DSCMCTCRCHn.DITSEL[1:0]).
3. Select the same trigger for capture trigger A and B.
   (a) Set the same value to the Current Capture Trigger A Select bits (DSCMCTCRCHn.CTSELA[2:0]).
   (b) Set the same value to the Current Capture Trigger B Select bits (DSCMCTCRCHn.CTSELB[2:0]).
4. Activate the channels simultaneously
   Write 1 to Channel n start trigger (DSCSTRTR.STRTRGn) at the same time.

39.3.8 Data Input Control

By using the DSCMCCRCHn.SEDGE bit, data receive can be selected to receive on the falling edge of MCLKn or the rising edge of MCLKn. Data input control receives clock and data from DSM. Synchronized data and clock are output to the sinc filter and short-circuit detection.

39.3.9 Sinc Filter

The differentiation stage is operated by decimation clock (the frequency is 1/M of MCLKn). M is the decimation ratio and is set in the DSCMFCRCHn.CMDEC[7:0] bits for current measurement or in the DSOCFCRCHn.OCDEC[7:0] bits for overcurrent detection. The filter result is stored in register every decimation clock. In the case of current data, an interrupt is output at the same time when the filter result is stored.

Figure 39.7 shows a block diagram for the Sinc Filter.

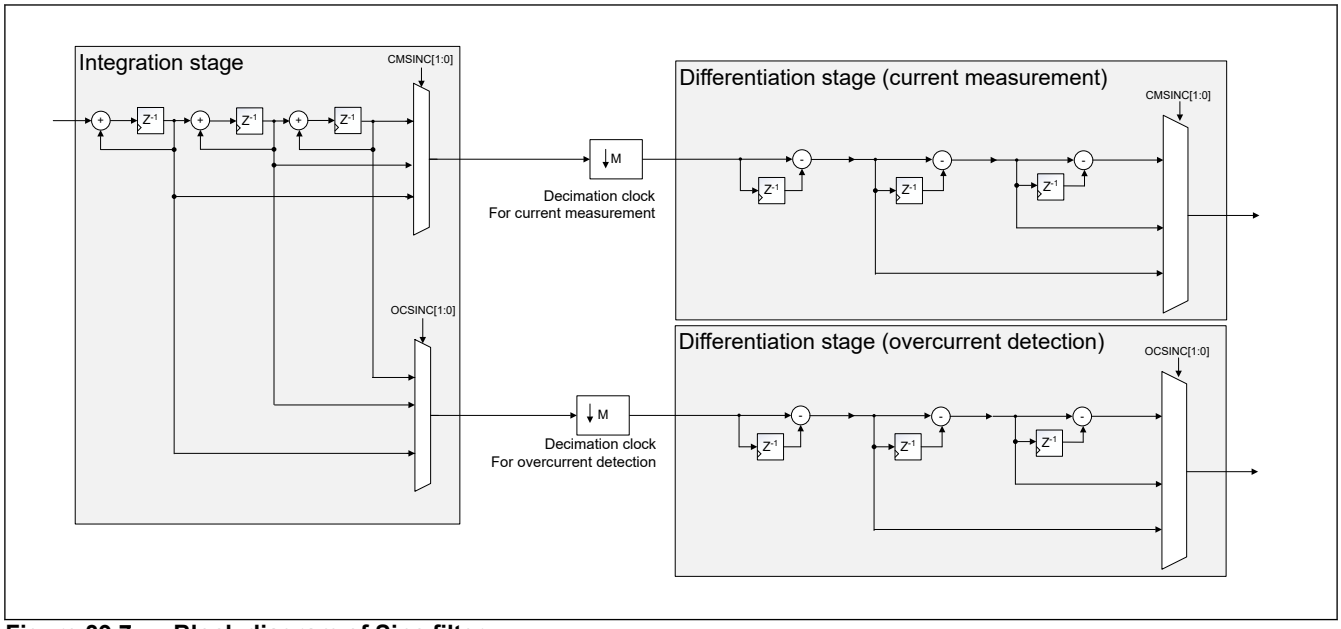


Figure 39.7 Block diagram of Sinc filter

39.3.10 Available Settings of Sinc Filter

Table 39.5 lists the available settings of the sinc filter and data shifting.

Table 39.5 Available settings of Sinc filter (1 of 2)

Sinc filter order	Decimation ratio	Effective bits	Peak value (Decimal)	Peak value (Hexadecimal)	Stored data	CMSH[4:0] OCSH[4:0]	Resolution

Figure 39.8 shows the relationship between the filter settings and the stored values.

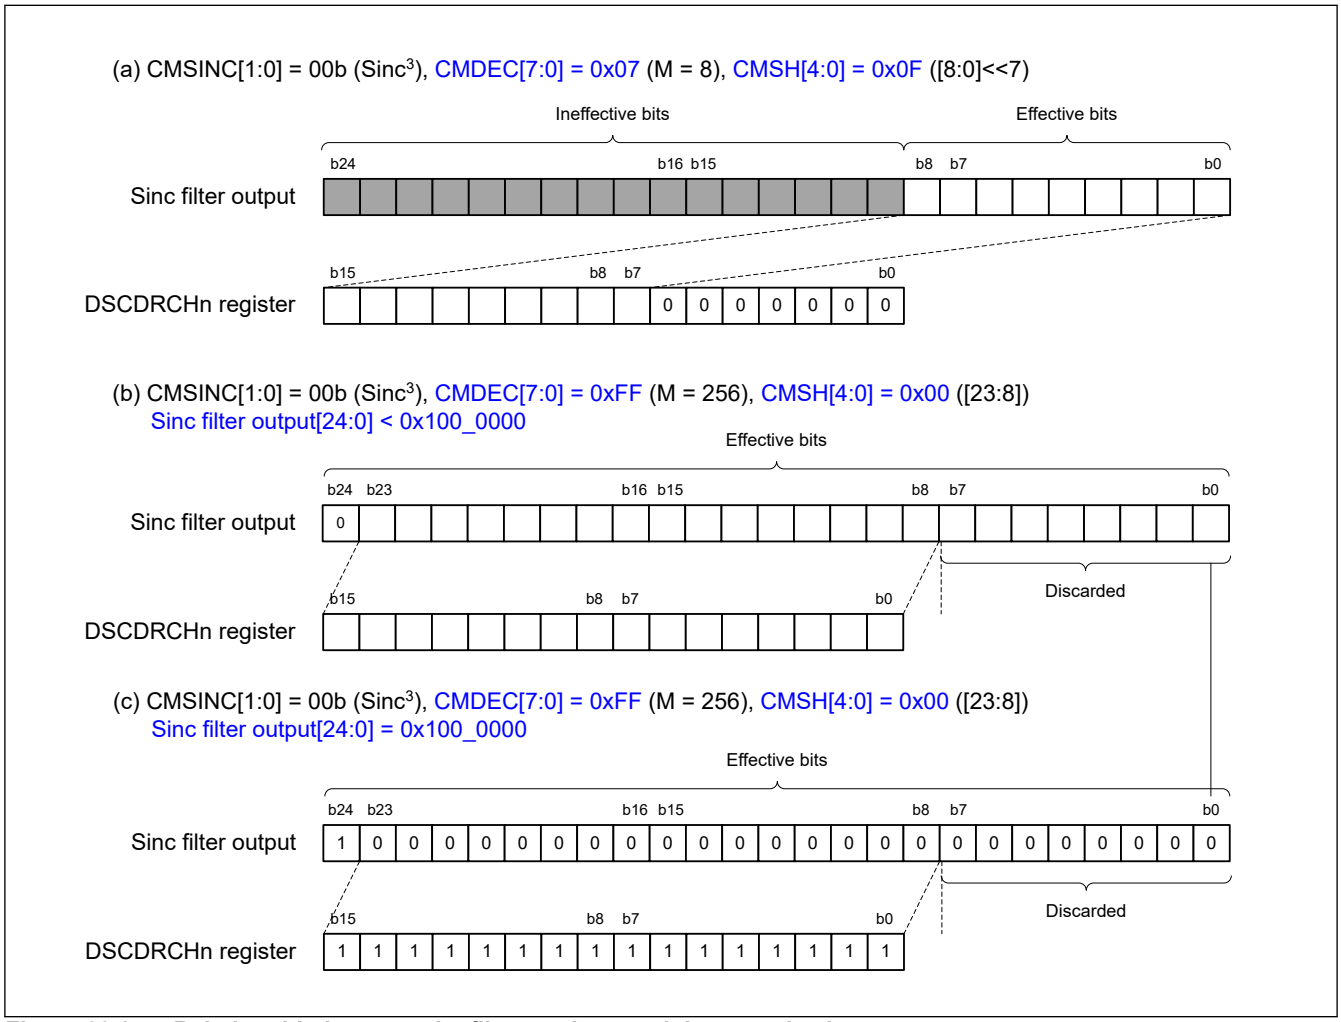

Figure 39.8 Relationship between the filter settings and the stored values

39.3.11 Current Measurement Data Processing

Each channel of DSMIF has the data registers specified in Table 39.6. Capture trigger A is selected by DSCMCTCRCHn.CTSELA[2:0] and capture trigger B is selected by DSCMCTCRCHn.CTSELB[2:0].

The trigger capturing function allows the capture of the values for current at the time of capture trigger A and capture trigger B using the event link controller (ELC) to set the capture trigger A or capture trigger B.

Table 39.6 Current measurement data list

No.	Register name	Symbol	Stored data
1	Current Data register	DSCDRCHn	The measured values for current
2	Capture Current Data Register A	DSCCDRACHn	The captured value of Current Data register by capture trigger A from the internal timer module
3	Capture Current Data Register B	DSCCDRBCHn	The captured value of Current Data register by capture trigger B from the internal timer module

39.3.12 Overcurrent Detection

When the overcurrent upper limit detection enable (DSODCRCHn.ODEH) is valid, the overcurrent upper limit detection can operate. And when the overcurrent lower limit detection enable (DSODCRCHn.ODEL) is valid, the overcurrent lower limit detection can operate. The current data is stored in the DSOCDRCHn as a 16-bit data shifted from 25-bit data output from sinc filter for overcurrent detection in accordance with the setting of the DSOCFCRCHn.OCSH[4:0] bits. An overcurrent upper limit detection interrupt is requested when the value in the DSOCDRCHn register is upper than the value of OCMPTBH. An overcurrent lower limit detection interrupt is requested when the value in the DSOCDRCHn register is lower than the value of OCMPTBL.

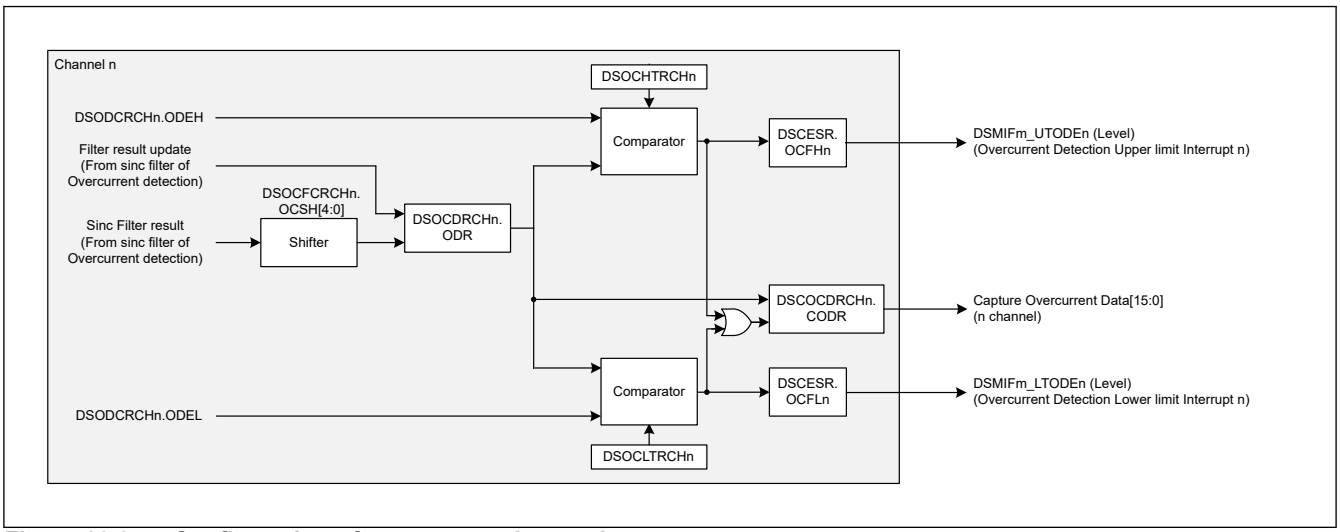

Figure 39.9 Configuration of overcurrent data registers

39.3.13 Short-circuit Detection

When the short-circuit detection enable (DSEDCRCHn.SDE) is valid, the short-circuit detection can operate. A dedicated 13-bit counter counts consecutive 0's or 1's input from dsmdata n (n = 0 to 2). When the number of consecutive 0's exceeds the value set in the DSSCTSRCHn.SCNTL[12:0] register or the number of consecutive 1's exceeds the value set in the DSSCTSRCHn.SCNTH[12:0] register, a short-circuit detection interrupt request is generated.

39.3.14 Overcurrent Sum Error Detection

When the overcurrent sum error upper limit detection enable (DSSECR.SEEH) is valid, the overcurrent sum error upper limit detection can operate. When the overcurrent sum error lower limit detection enable (DSSECR.SEEL) is valid, the overcurrent sum error lower limit detection can operate. An overcurrent upper limit sum error detection interrupt is requested when the sum of the values for each mode (see Table 39.7) is higher than the value of SCMPTBH.

An overcurrent lower limit sum error detection interrupt is requested when the sum of the values for each mode is lower than the value of SCMPTBL.

Table 39.7 List of sum error mode detect mode and capture data (1 of 2)

SEDM[2:0]	Sum error detect mode	CH0	CH1	CH2	DSSECDR0	DSSECDR1	DSSECDR2
000b	Three value sum error detect	✓	✓	✓	DSOCDRCH0	DSOCDRCH1	DSOCDRCH2
001b	Two value sum error detect	✓	✓	—	DSOCDRCH0	DSOCDRCH1	—*1

Table 39.7 List of sum error mode detect mode and capture data (2 of 2)

SEDM[2:0]	Sum error detect mode	CH0	CH1	CH2	DSSECDR0	DSSECDR1	DSSECDR2
010b	One channel error detect	✓	—	—	DSOCDRCH0	—	—
011b		—	✓	—	DSOCDRCH1	—	—
100b		—	—	✓	DSOCDRCH2	—	—

Note 1. Do not store data, hold previous value.

39.3.15 Settling Time

39.3.15.1 Settling Time of Channel Activation

Settling time of channel activation is the time from when the channel is activated until the filter result is stable and output.

The settling time is calculated as follows.

Table 39.8 Settling time of channel activation

Sinc order	Processing time of settling time of channel activation
Sinc[1]	(MCLK period × Decimation ratio) × sinc order + MCLK period × 1 cycle + PCLKH period × 18 cycles
Sinc[3] Sinc[2]	(MCLK period × Decimation ratio) × (sinc order + 1) + MCLK period × 1 cycle + PCLKH period × 18 cycles

39.3.15.2 Settling Time after PWM Synchronization

Settling time after PWM synchronization is the time from the input of the decimation dividing counter initialization trigger to the stable output of the filter result.

Table 39.9 Settling time after PWM synchronization

Processing time of settling time of PWM synchronization
(MCLK period × Decimation ratio) × sinc order + PCLKH period × 13 cycles

40. 12-Bit A/D converter (ADC12)

40.1 Overview

This LSI incorporates two unit of a 12-bit successive approximation A/D converter. Analog inputs of up to 4 channels are selectable for unit0 (LLPP of CPU), analog inputs of up to 8 channels are selectable for unit1 (NONSAFETY).

The 12-bit A/D converter converts analog inputs of up to 4/8 selected channels to a 12-bit digital value through successive approximation.

The 12-bit A/D converter has three operating modes: single scan mode in which analog inputs selected arbitrarily are converted only once in ascending order of channel number; continuous scan mode in which analog inputs selected arbitrarily are continuously converted in ascending order of channel number; and group scan mode in which analog inputs are arbitrarily selected and divided into two groups (group A and group B) or three groups (group A, group B and group C), and then analog inputs of channels selected for each group are converted in ascending order of channel number.

In group scan mode, the conditions for scanning start of each groups (A, B or A, B, C) (synchronous trigger) can be independently selected, thus allowing A/D conversion of each groups to be started independently. In addition to the above actions, the group priority operation in group scan mode accepts the start of scanning the priority group during the scan of the low priority group, interrupts the scan of the low priority group, and starts the scan of the priority group. The priority of group priority operations is group A > group B > group C. In group priority operation, if the scan start of group B is accepted during the scan of group C, the scan of group C is interrupted and the scan of group B is started. If the scan start of group A is accepted during the scan of group C, the scan of group A is started. The scan of Group C is interrupted and the scan of Group A is started. Similarly, if the scan start of Group A is accepted during the scan of Group B, the scan of Group B is interrupted and the scan of Group A is started. The interrupted group scan is able to resume after the priority group scan is complete also.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

The compare function is a function that outputs an interrupt (ADCn_CMPAI/ADCn_CMPBI) when the A/D conversion value of the selected channel by specifying the upper and lower reference values for each window A/B matches the comparison conditions. The event (ADCn_WCMPM/ADCn_WCMPUM) is output according to the event conditions (A or B, A and B, A exor B). In addition, a comparator operation that compares the A/D conversion value with the lower reference value is also possible.

Table 40.1 lists the specifications of the 12-bit A/D converter and Table 40.2 indicates the functions of the 12-bit A/D converter. Figure 40.1 shows a block diagram of the 12-bit A/D converter.

Table 40.1 ADC12 specifications (1 of 2)

Item	Description
Number of units	Two units, 0 and 1
Input channels	• Unit 0: Up to 4 channels in LLPP of CPU0 • Unit 1: Up to 8 channels in NONSAFETY
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	0.84 µs: Channel-dedicated sample-and-hold circuits not in use 1.52 µs: Channel-dedicated sample-and-hold circuits in use At PCLKADC in the 12-bit A/D converter: 25 MHz
A/D conversion clock	PCLKADC (25 MHz or 18.75 MHz)

Table 40.1 ADC12 specifications (2 of 2)

Item	Description
Operating modes	• Single scan mode: A/D conversion is performed only once on the analog inputs of arbitrarily selected channels • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of arbitrarily selected channels • Group scan mode: Two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used. Only the combination of groups A and B can be selected when the number of the groups is two. Analog inputs that are arbitrarily selected are divided into two groups (group A and B) or three groups (group A, B, and C), and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of groups A, B, and C (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently. • Group scan mode (when Group A is given priority): If a priority-group trigger is input during scanning of the low-priority group, scan of the low-priority group is stopped and scan of the priority group is started. The priority order is group A (highest) > group B > group C (lowest). Whether or not to restart scanning of the low-priority group after processing for the high-priority group completes, is selectable. Rescan can also be set to start either from the beginning of the selected channel or the channel on which A/D conversion is not completed.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers Trigger by the multi-function timer pulse unit (MTU3) and event link controller (ELC) • Asynchronous trigger A/D conversion can be triggered by the external trigger ADTRG0# (unit 0) and ADTRG1# (unit1).
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in unit 0 • Variable sampling state count • Selectable A/D-converted value addition mode or average mode • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison and data registers, and between values in the data registers • Overwrite checking function of the A/D data register
Interrupt sources and ELC events	• ADCn_ADI (for ELC, trigger of interrupt is slightly different for CPU SPI) • ADCn_GBADI: A/D scan end interrupt for Group B • ADCn_GCADI: A/D scan end interrupt for Group C • ADCn_CMPAI: Window A compare match • ADCn_CMPBI: Window B compare match • ADCn_WCMPM: compare match • ADCn_WCMPUM: compare mismatch
ELC interface	• An ELC event is generated upon completion of all scans • Able to start scanning by a trigger from the ELC
Module-stop function	Module-stop state can be set to reduce power consumption

Table 40.2 Function of ADC12 (1 of 2)

Parameter	Unit 0 (ADC120)	Unit 1 (ADC121)
Analog input channel	AN000 to AN003	AN100 to AN107

Note 1. Trigger of event is slightly different from normal interrupt for CPU SPI.

Table 40.3 ADC12 interrupt sources

Name	Interrupt sources	CPU0 GIC request	DMAC activation
ADCn_ADI	A/D scan end interrupt	Possible	Possible*1
ADCn_GBADI	A/D scan end interrupt for Group B	Possible	Possible
ADCn_GCADI	A/D scan end interrupt for Group C	Possible	Possible
ADCn_CMPAI	Window A compare match	Possible	Not possible
ADCn_CMPBI	Window B compare match	Possible	Not possible
ADCn_WCMPM	Compare match	Not possible	Possible
ADCn_WCMPUM	Compare mismatch	Not possible	Possible

Note: n = 0 to 1.
Note 1. Trigger of event is slightly different from normal interrupt for CPU SPI.

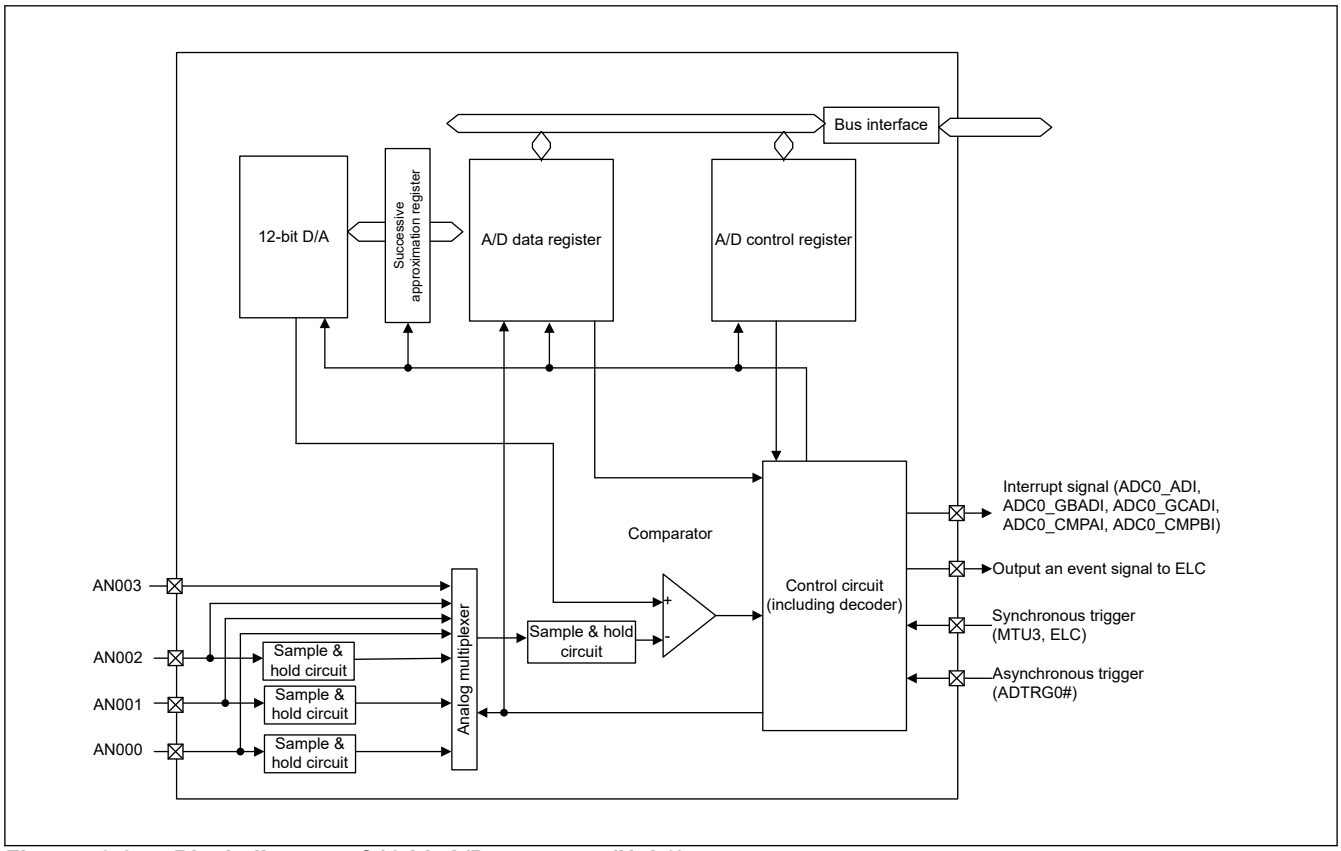

Figure 40.1 Block diagram of 12-bit A/D converter (Unit0)

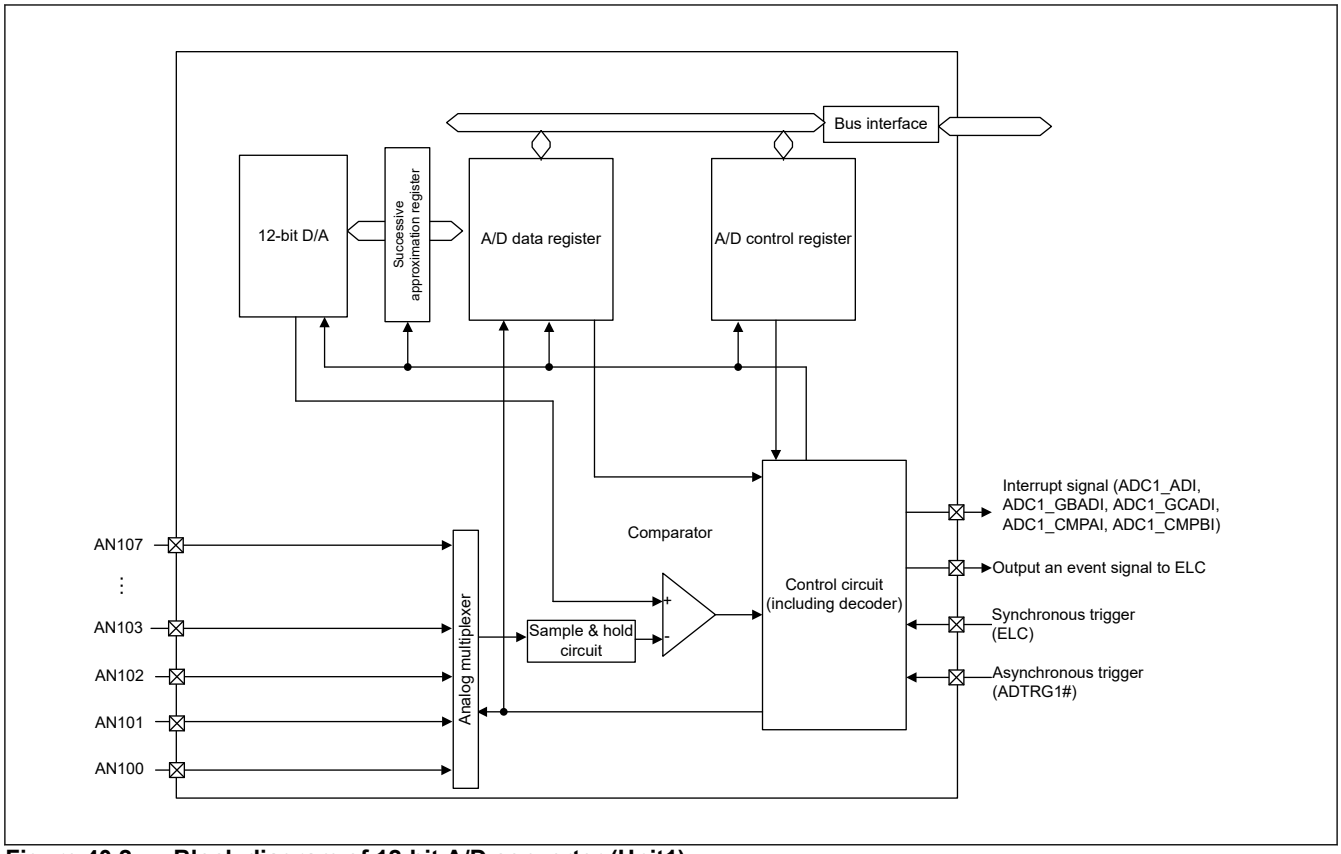

Figure 40.2 Block diagram of 12-bit A/D converter (Unit1)

40.2 Register Descriptions

40.2.1 ADCSR : A/D Control Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]		ADIE	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double triggered operation. The setting is only valid while double trigger mode is selected.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt Enable 0: Disables ADCn_GBADI interrupt generation upon group B scan completion 1: Enables ADCn_GBADI interrupt generation upon group B scan completion	R/W
7	DBLE	Double Trigger Mode Select 0: Deselects double trigger mode 1: Selects double trigger mode	R/W
8	EXTRG	Trigger Select 0: A/D conversion is started by a synchronous trigger (MTU3, ELC) 1: A/D conversion is started by the asynchronous trigger (ADTRGn#)	R/W

Bit	Symbol	Function	R/W
9	TRGE	Trigger Start Enable 0: Disables A/D conversion to be started by the synchronous or asynchronous trigger 1: Enables A/D conversion to be started by the synchronous or asynchronous trigger	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	ADIE	Scan End Interrupt Enable 0: Disables ADCn_ADI interrupt generation upon scan completion 1: Enables ADCn_ADI interrupt generation upon scan completion	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D conversion Start 0: Stops A/D conversion process 1: Starts A/D conversion process	R/W

40.2.2 ADANSA0 : A/D Channel Select Register A0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ANSA0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ANSA0[7:0]	A/D conversion Analog input Channel Select ANSA0[0] bit corresponds to ch0 and ANSA0[7] corresponds ch7. 0: ch0-ch7 are not subjected to conversion. 1: ch0-ch7 are subjected to conversion.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.3 ADADS0 : A/D-Converted Value Addition/Average Function Channel Select Register 0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x08

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ADS0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ADS0[7:0]	A/D-Converted Value Addition/Average Channel Select 0: A/D-converted value addition/average mode for ch0-ch7 is not selected 1: A/D-converted value addition/average mode for ch0-ch7 is selected	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.4 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition Count Select 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2-time conversion (addition once) 0 1 0: 3-time conversion (addition twice)*1 0 1 1: 4-time conversion (addition three times) 1 0 1: 16-time conversion (addition 15 times)*1 Others: Setting is prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Enable 0: Addition mode is selected 1: Average mode is selected	R/W

Note 1. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the Addition count to 3 times and 16times (ADADC.ADC[1:0] = 010b, 101b).

40.2.5 ADCER : A/D Control Extended Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADRFMT	—	—	—	—	—	—	—	—	—	ACE	—	—	ADPRC[1:0]		—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
2:1	ADPRC[1:0]	A/D Conversion Accuracy Specify 0x00: A/D conversion is performed with 12-bit accuracy Others: Setting prohibited	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	ACE	A/D Data Register Automatic Clearing Enable 0: Disables automatic clearing 1: Enables automatic clearing	R/W
14:6	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Right-alignment is selected for the A/D data register format 1: Left-alignment is selected for the A/D data register format	R/W

40.2.6 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode. See Table 40.4 for details.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected. See Table 40.5 for details.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Table 40.4 Selection of A/D activation sources by the TRSB[5:0] bits (for group B only) (1 of 2)

Module	Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]
Trigger source de-selection state			1	1	1	1	1	1
MTU3	TRGA0N	Compare match with or input capture to MTU0.TGRA	0	0	0	0	0	1
MTU3	TRGA1N	Compare match with or input capture to MTU1.TGRA	0	0	0	0	1	0
MTU3	TRGA2N	Compare match with or input capture to MTU2.TGRA	0	0	0	0	1	1
MTU3	TRGA3N	Compare match with or input capture to MTU3.TGRA	0	0	0	1	0	0
MTU3	TRGA4N	Compare match with or input capture to MTU4.TGRA, or an underflow of MTU4.TCNT (in the trough) in complementary PWM mode	0	0	0	1	0	1
MTU3	TRGA6N	Compare match with MTU6.TGRA	0	0	0	1	1	0
MTU3	TRGA7N	Compare match with MTU7.TGRA	0	0	0	1	1	1
MTU3	TRG0N	Compare match with MTU0.TGRE	0	0	1	0	0	0
MTU3	TRG4AN	Compare match between MTU4.TADCORA and MTU4.TCNT	0	0	1	0	0	1

Note: Trigger source from MTU3 is not available in ADC12 unit 1.

40.2.7 ADANSB0 : A/D Channel Select Register B0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x14

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ANSB0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ANSB0[7:0]	A/D Conversion Analog Input Channel Select ANSB0[0] bit corresponds to ch0 and ANSB0[7] corresponds ch7. 0: ch0-ch7 are not subjected to conversion 1: ch0-ch7 are subjected to conversion	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.8 ADDBLDR : A/D Data Duplication Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x18

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDR[15:0]	The result of A/D conversion in response to the second trigger in double trigger mode.	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

40.2.9 ADDRn : A/D Data Register n (n = 0 to 3 for unit 0, n = 0 to 7 for unit1)

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x020 + 0x002 × n (ADC120: n = 0 to 3, ADC121: n = 0 to 7)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DR[15:0]	The result of A/D conversion (n: Number of channel)	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

40.2.10 ADSHCR : A/D Sample and Hold Control Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x66

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Sample and hold period setting These bits set the sample and hold period in the range from 4 to 255 states. S/H period is set 13 + this register value.	R/W
10:8	SHANS[2:0]	Sample and hold use or bypass select for ch0-2 SHANS[2] corresponds to ch2, SHANS[0] corresponds to ch0. 0: Bypass S/H 1: Use S/H	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

40.2.11 ADELCCR : A/D Event Link Control Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x7D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GCELC	ELCC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ELCC[1:0]	Event link control bits Control the end of scan event (ADCn_ADI). To enable the ELCC[1:0] setting, set GCELC to 0. 0 0: Output event signal at the end of scan except the end of group scan of group A, B 0 1: Output event signal at the end of group scan of group B 1 x: Output event signal at the end of scan	R/W
2	GCELC	Event control bit for Group C 0: Enable the setting of ELCC[1:0] 1: Disable the setting of ELCC[1:0] and output event signal at the end of group scan of group C	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

40.2.12 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x80

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Control Setting*1 0: Operation is without group priority control 1: Operation is with group priority control	R/W
1	GBRSCN	Group B Restart Setting (Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Scanning for group is not restarted when priority control is performed 1: Scanning for group is restarted when priority control is performed	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select (Enabled only when PGS = 1 and GBRSCN = 1, Set 0 when PGS = 0.) 0: Restart scan with first channel 1: Restart scan with suspended channel	R/W
15	GBRP	Group B Single Scan Continuous Start*2 (Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Single scan for group B is not continuously activated 1: Single scan for group B is continuously activated	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.
Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for low priority group regardless of the setting of the GBRSCN bit.

40.2.13 ADDBLDRA : A/D Data Duplication Register A

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDRA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDRA[15:0]	The result of A/D conversion during extended operation in double trigger mode	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

40.2.14 ADDBLDRB : A/D Data Duplication Register B

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x86

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDRB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDRB[15:0]	The result of A/D conversion during extended operation in double trigger mode	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

40.2.15 ADWINMON : A/D Compare Function Window A/B Status Monitoring Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x8C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination result monitor 0: Window A/B combination condition does not match. 1: Window A/B combination condition match.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparing result monitor for window A 0: Window A comparing condition does not match. 1: Window A comparing condition match.	R
5	MONCMPB	Comparing result monitor for window B 0: Window B comparing condition does not match. 1: Window B comparing condition match.	R
7:6	—	These bits are read as 0.	R

40.2.16 ADCMPCR : A/D Compare Function Control Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x90

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B combination condition setting This bit is valid when both windows A/B are valid (CMPAE = 1 and CMPBE = 1). 0 0: Output ADCn_WCMPM when window A comparison condition match OR window B comparison condition match, otherwise output ADCn_WCMPUM 0 1: Output ADCn_WCMPM when window A comparison condition match EXOR window B comparison condition match, otherwise output ADCn_WCMPUM 1 0: Output ADCn_WCMPM when window A comparison condition match AND window B comparison condition match, otherwise output ADCn_WCMPUM 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Window B operation permission 0: Window B is not in operation. Output of ADCn_WCMPM/ADCn_WCMPUM is not parmitted. 1: Window B is in operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Window A operation permission 0: Window A is not in operation. Output of ADCn_WCMPM/ADCn_WCMPUM is not permitted. 1: Window A is in operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
13	CMPBIE	Compare window B Interrupt Enable 0: Generation of an ADCn_CMPBI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an ADCn_CMPBI interrupt in response to matches with a condition for comparison is enabled.	R/W
14	WCMPE	Window Function enable 0: Window function disabled 1: Window function enabled	R/W
15	CMPAIE	Compare window A Interrupt Enable 0: Generation of an ADCn_CMPAI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an ADCn_CMPAI interrupt in response to matches with a condition for comparison is enabled.	R/W

40.2.17 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x94

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CMPCHA0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CMPCHA0[7:0]	Window A Channel Select Set the CMPCHA0[7:0] bits when DCSR.ADST = 0. 0: Channel is not target 1: Channel is target	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.18 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x98

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CMPLCHA0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CMPLCHA0[7:0]	Window A comparison condition for target channel (ch0-7) setting CMPLCHA0[7] corresponds channel 7 and CMPLCHA0[0] corresponds channel 0. When the comparison result of each channel input matches the set condition, the ADCMPSR0.CMPSTCHA0n bit is set to 1 and a compare interrupt (ADCn_CMPAI) is generated. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 register value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 register value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.19 ADCMPDR0 : A/D Comparison Function Window A Lower Level Setting Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x9C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPLLA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLLA[15:0]	Reference data setting when using the compare function window A	R/W

40.2.20 ADCMPDR1 : AD Comparison Function Window A Upper Level Setting Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0x9E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPULA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPULA[15:0]	Reference data setting when using the compare function window A	R/W

40.2.21 ADCMPSR0 : A/D Comparison Function Window A Channel Status Register 0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CMPSTCHA0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CMPSTCHA0[7:0]	Window A Status Flag This flag shows the comparison result of each targeted channel, when window A is operating (ADCMPCR.CMPAE = 1b). If this flag is set while ADCMPCR.CMPAIE = 1, a compare interrupt (ADCn_CMPAI) request is generated. 0: Condition does not match 1: Condition matches	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.22 ADWINLLB : A/D Compare Function Window B Lower-Side Level Setting Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xA8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPLLB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLLB[15:0]	Reference lower data setting when using the compare function window B	R/W

40.2.23 ADWINULB : A/D Compare Function Window B Upper-Side Level Setting Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xAA

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPULB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPULB[15:0]	Reference upper data setting when using the compare function window B	R/W

40.2.24 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xAC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Window B Flag When window B operation is enabled (ADCMPCR.CMPBE = 1b), this bit indicates the comparison result of channels to which window B comparison conditions are applied. 0: Comparison conditions are not met 1: Comparison conditions are met	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

40.2.25 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xA6

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMPCHB[5:0]	Window B Channel Select Select channels for comparing with window B condition. Set the CMPCHB[5:0] bits when the ADCSR.ADST bit is 0. 0x00: ch0 0x01: ch1 0x02: ch2 ⋮ 0x07: ch7 0x3F: No channel is selected Others: Setting prohibited	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	CMPLB	Window B Comparison Condition Setting When the comparison result of target input matches the set condition, the ADCMPBSR.CMPSTB bit is set to 1 and a compare interrupt (ADCn_CMPBI) is generated. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB register value > A/D-converted value. When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value. 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB register value < A/D-converted value. When window function is enabled (ADCMPCR.WCMPE = 1): ADWINLLB register value < A/D-converted value < ADWINULB register value.	R/W

40.2.26 ADANSC0 : A/D Channel Select Register C0

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xD4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ANSC0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ANSC0[7:0]	A/D-Converted Channel Select for Group C in Group Scan Mode ANSC0[7] corresponds ch7, and ANSC0[0] corresponds ch0. 0: Channel is not target 1: Channel is target	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

40.2.27 ADGCTRGR : A/D Group C Trigger Select Register

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xD9

Bit position:	7	6	5	4	3	2	1	0
Bit field:	GRCE	GCADIE	TRSC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSC[5:0]	Group C A/D Conversion Start Trigger Select Select starting trigger for A/D conversion of group C in group scan mode. See Table 40.6 for more details.	R/W
6	GCADIE	Group C Scan Completion Interrupt Enable 0: Group C scan completed interrupt (ADCn_GCADI) is disabled 1: Group C scan completed interrupt (ADCn_GCADI) is enabled	R/W
7	GRCE	Group C A/D Conversion Enable 0: Group C A/D conversion is disabled 1: Group C A/D conversion is enabled	R/W

Table 40.6 A/D conversion start trigger for Group C in group scan mode (1 of 2)

Module	Trigger	Description	TRSC					
			[5]	[4]	[3]	[2]	[1]	[0]

40.2.28 ADSSTRn : A/D Sampling State Register n (n = 0 to 3 for unit 0, n = 0 to 7 for unit1)

Base address: ADC120 = 0x9000_4000
ADC121 = 0x8004_5000

Offset address: 0xE0 + 0x01 × n (ADC120: n = 0 to 3, ADC121: n = 0 to 7)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SST[7:0]							
Value after reset:	0	0	0	0	1	0	1	1

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 8 to 255 states.	R/W

40.3 Operation

40.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

There are three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1. In group scan mode, the selected channels of group A and the selected channels of group B (and the selected channels of group C) are scanned once after starting to be scanned according to the respective synchronous triggers (MTU3, ELC).

In single scan mode and continuous scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register, starting from the pin with the smallest number n. In group scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register for group A, and performed for ANn pins selected by the ADANSB0 register for group B and performed for ANn pins selected by the ADANSC0 register for group C, respectively, starting from the pin with the smallest number n.

Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by any of the synchronous triggers (MTU3, ELC) selected by the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use the double trigger.

To enable double trigger extended mode, select double trigger mode, and then select the synchronous trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 001011b
  TRG4AN or TRG4BN
- ADSTRGR.TRSA[5:0] = 001111b
  TRG7AN or TRG7BN

In the double trigger extended mode, in addition to the normal double trigger mode operation, the A/D conversion data activated by the odd number trigger (TRG4AN, TRG7AN) is stored in the A/D data duplex register A (ADDBLDRA), and the A/D conversion data activated by the even number trigger (TRG4BN, TRG7BN) is stored in the A/D Data Duplication register B (ADDBLDRB).

If two types of trigger source occur at the same time, the data is not sorted by the trigger factor and the A/D conversion data is stored in the Data Duplication register B (ADDBLDRB). If one trigger is performing A/D conversion and the other trigger is input, the other trigger will be ignored.

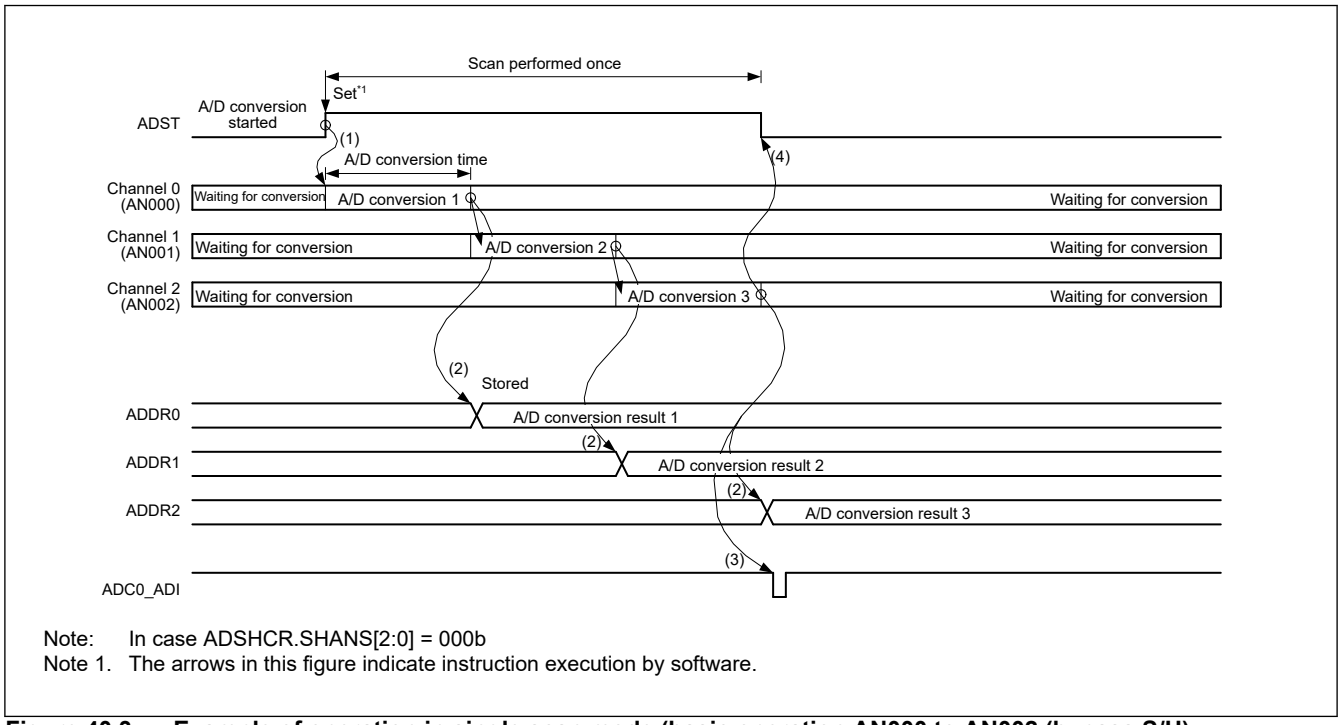
Analog input AN000 to AN002 can use the S/H circuit by setting of ADSHCR.SHANS[2:0].

40.3.2 Single Scan Mode

40.3.2.1 Basic Operation (Not use S/H circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) due to software or synchronous trigger (MTU3, ELC) input, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated.
4. ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion and is automatically cleared when A/D conversion of all selected channels is completed, and the 12-bit A/D converter goes into a standby state.



Note: In case ADSHCR.SHANS[2:0] = 000b
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 40.3 Example of operation in single scan mode (basic operation AN000 to AN002 (bypass S/H) selected)

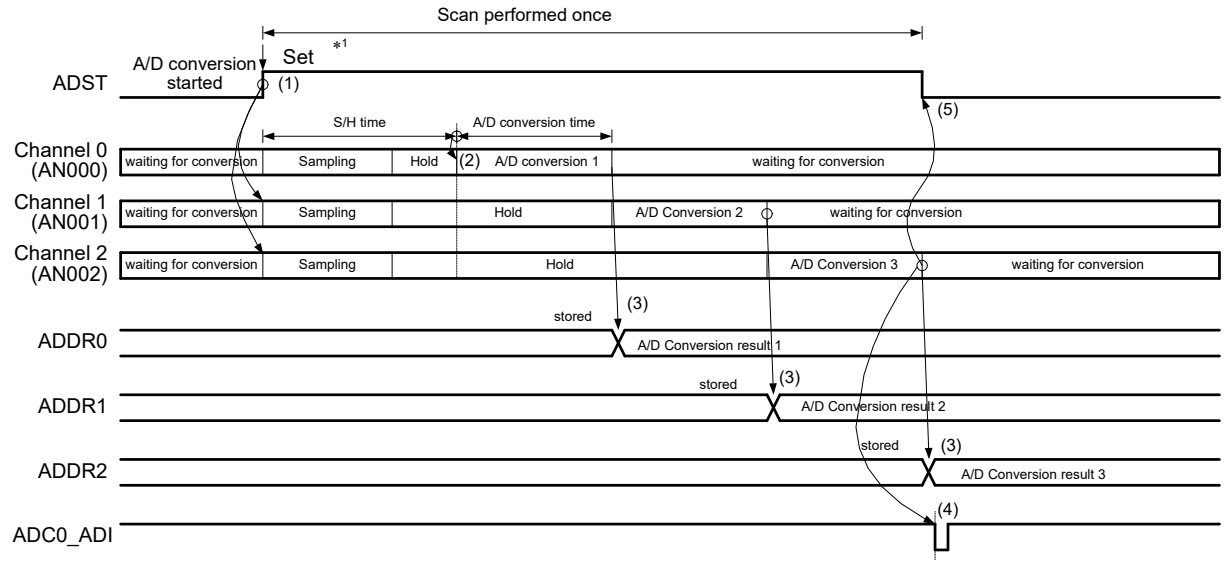
40.3.2.2 Basic Operation (Use S/H circuits)

The S/H circuit is used to A/D Convert the analog inputs of all selected channels after S/H is performed only once.

The channel that uses the S/H circuit is selected with the ADSHCR.SHANS[2:0] bits.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software or synchronization trigger (MTU3, ELC), all channels using the S/H circuit start sampling analog inputs.

2. After sampling and holding, A/D conversion is started in ascending order of n of the channel ANn selected in the ADANSA0 register.
3. When the A/D conversion of the channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
4. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated.
5. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion and is automatically cleared when A/D conversion of all selected channels is completed, and the 12-bit A/D converter goes into a standby state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 40.4 Example of operation in single scan mode (basic operation with S/H, AN000 to AN002 selected)

40.3.2.3 A/D conversion in Double Trigger Mode

When double trigger mode is selected in single scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU3, ELC).

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1. When ADCSR.DBLE is set to 1, the channel selection of the ADANSA0 register is disabled.

To select the double trigger mode, use ADSTRGR.TRSA[5:0] to select the synchronous trigger (MTU3, ELC), set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Also, do not use software trigger.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) due to the synchronous trigger (MTU3, ELC) input, the A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ADC0_ADI interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ADC0_ADI interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by the second synchronous trigger input, A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) dedicated to the double trigger mode.

6. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning), an ADC0_ADI interrupt request (pulse output) is generated.
7. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

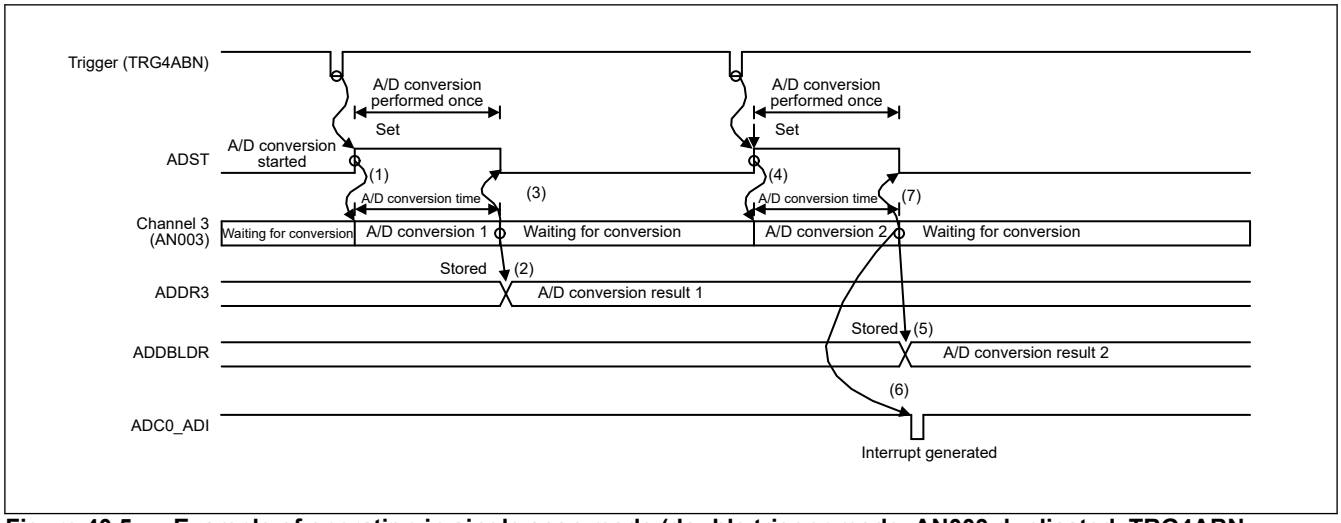


Figure 40.5 Example of operation in single scan mode (double trigger mode, AN003 duplicated, TRG4ABN is selected as the trigger)

40.3.2.4 Extended Operations When Double Trigger Mode is Selected

When double trigger mode is selected in single scan mode, single scan is performed twice.

To enable double trigger extended mode, and then select the following synchronous trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 001011b
  TRG4AN or TRG4BN
- ADSTRGR.TRSA[5:0] = 001111b
  TRG7AN or TRG7BN

And set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Also, do not use software trigger.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1. When ADCSR.DBLE is set to 1, the channel selection of the ADANSA0 register is disabled.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by TRG4AN, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy) and A/D Data Duplication register A (ADDBLDRA).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ADC0_ADI interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ADC0_ADI interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by TRG4BN input, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) and the A/D Data Duplication register B (ADDBLDRB).
6. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning), an ADC0_ADI interrupt request (pulse output and level output) is generated.
7. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

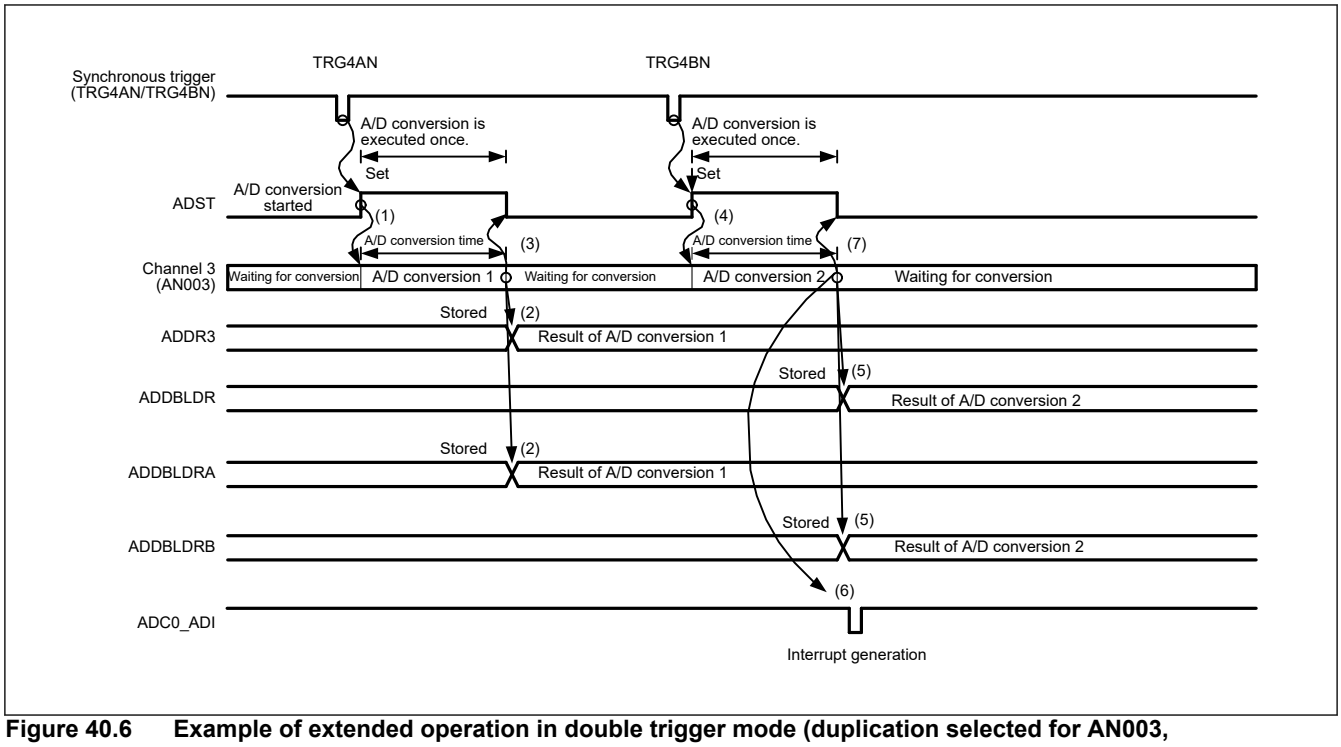

Figure 40.6 Example of extended operation in double trigger mode (duplication selected for AN003, TRG4AN, TRG4BN selected)

40.3.3 Continuous Scan Mode

40.3.3.1 Basic Operation (Not use S/H circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the channels selected by the ADANSA0 register.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronous trigger (MTU3, ELC), or asynchronous trigger, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated. In addition, the 12-bit A/D converter continuously starts A/D conversion in ascending order of n of ANn selected in the ADANSA0 register.
4. The ADCSR.ADST bit is not cleared automatically, and (2) to (3) are repeated during 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stopped), A/D conversion is stopped and the 12-bit A/D converter is in the standby state.
5. After that, when the ADCSR.ADST bit becomes 1 (A/D conversion starts), A/D conversion starts again in ascending order of n of ANn selected in the ADANSA0 register.

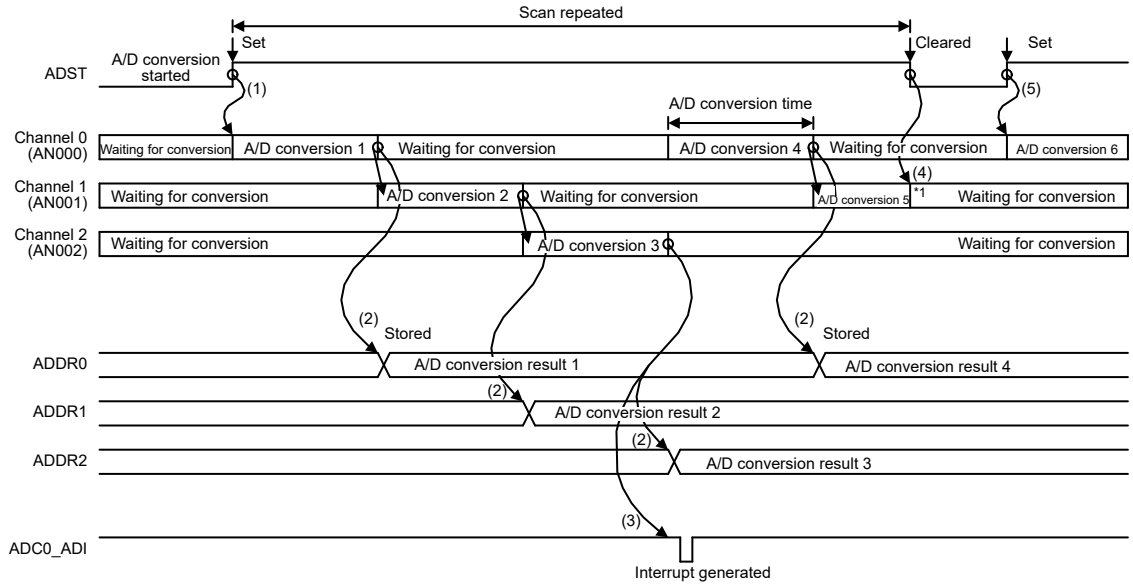

Figure 40.7 Example of operation in continuous scan mode (basic operation AN000 to AN002 selected)

40.3.3.2 Basic Operation (Use S/H circuits)

When the S/H circuit is used, the operation of A/D conversion of the analog inputs of all the selected channels is repeated after the sample and hold is performed. The channel that uses the S/H circuit is selected with the ADSHCR.SHANS[2:0] bits.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronization trigger (MTU3, ELC), or asynchronization trigger, all channels using the S/H circuit start sampling analog inputs.
2. After sampling and holding, A/D conversion is started in ascending order of n of the channel ANn selected in the ADANSA0 register.
3. When the A/D conversion of the channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
4. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, ADC0_ADI interrupt request (pulse output) is generated. It also begins sampling the analog inputs of all channels that use the S/H circuitry.
5. The ADCSR.ADST bit is not cleared automatically, and (2) to (4) are repeated while it is set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stopped), A/D conversion is stopped and the 12-bit A/D converter is in the standby state.
6. After that, when the ADCSR.ADST bit becomes 1 (A/D conversion starts), sampling of analog inputs of all channels using the S/H circuit starts again.

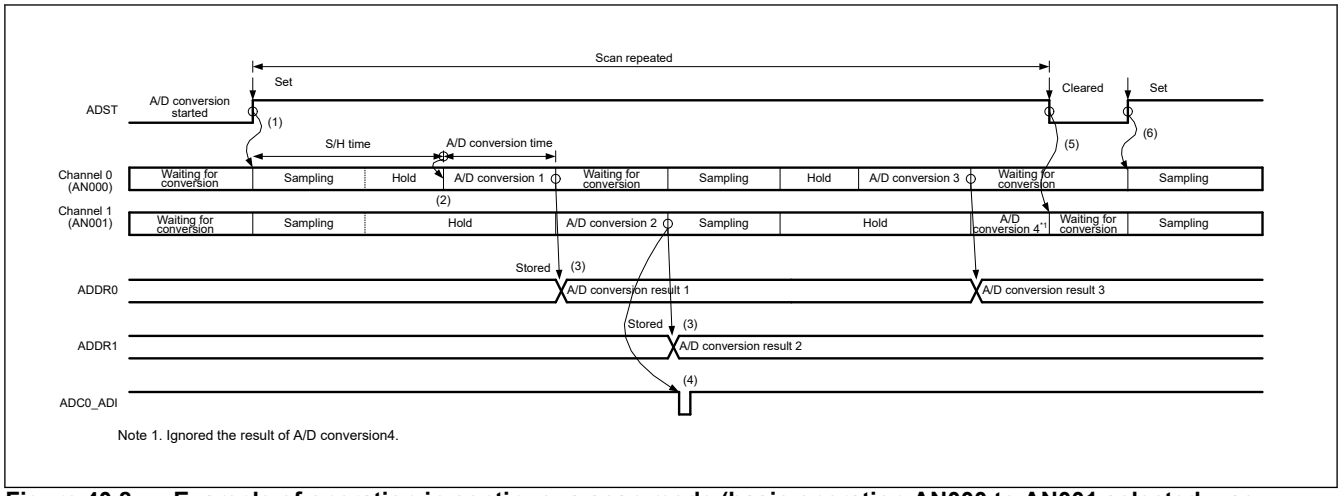

Figure 40.8 Example of operation in continuous scan mode (basic operation AN000 to AN001 selected, use S/H circuit)

40.3.4 Group Scan Mode

40.3.4.1 Basic Operation

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in each group (A and B or A, B and C) after scanning is started by a synchronous trigger (MTU3, ELC). Scan operation of each group is similar to the scan operation in single scan mode.

To set the trigger for group scan mode, select the trigger for group A with the ADSTRGR.TRSA[5:0] bits, select the trigger for group B with the ADSTRGR.TRSB[5:0] bits, and select the trigger for group C with the ADGCTRGR.TRSC[5:0] bits. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers. For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

The following is an example of the operation of the group scan mode by the synchronous trigger from the MTU3. Group A is set to start conversion with a TRG4AN trigger from MTU3, Group B is set to start conversion with a TRG4BN trigger from MTU3, and Group C is set to start conversion with a TRG4ABN trigger from MTU3.

1. Start scanning of group A with TRG4AN trigger from MTU3.
2. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled) at the end of group A scanning, the ADC0_ADI interrupt is output.
3. Start scanning Group B with TRG4BN trigger from MTU3.
4. If the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled) at the end of Group B scanning, an ADC0_GBADI interrupt is output.
5. Trigger TRG4ABN from MTU3 to start scanning for Group C.
6. If the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled) at the end of Group C scanning, an ADC0_GCADI interrupt is output.

In group scan mode, different channels and triggers should be selected for group A and group B.

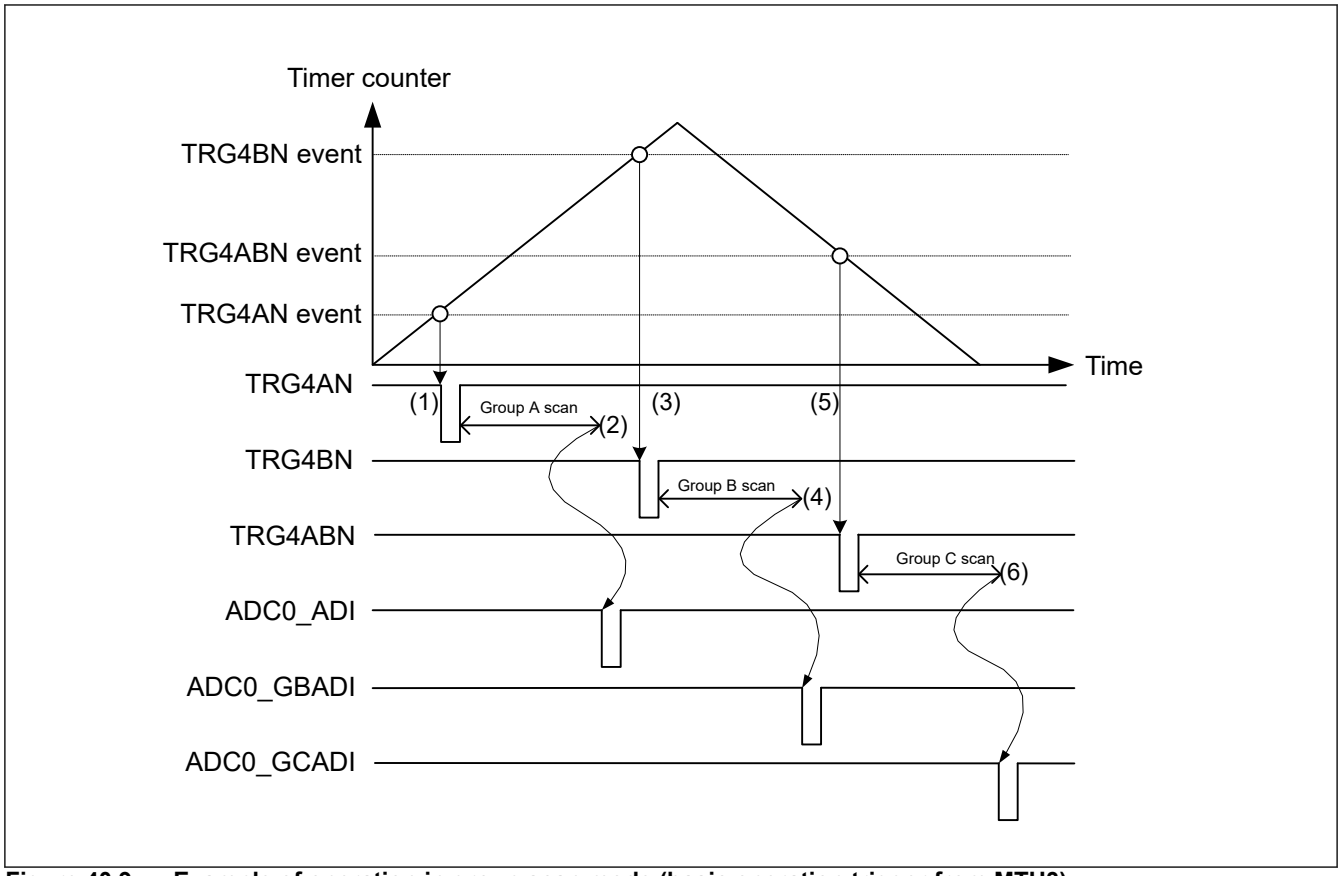

Figure 40.9 Example of operation in group scan mode (basic operation trigger from MTU3)

40.3.4.2 A/D conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, group A controls two single scan mode executions starting with a synchronous trigger (MTU3, ELC) as a series of operations. Group B and Group C behave in the same way as single scan mode started with a synchronous trigger (MTU3, ELC).For group scan mode trigger settings, the ADSTRGR.TRSA[5:0] bits select the trigger for group A, the ADSTRGR.TRSB[5:0] bits select the trigger for group B, and ADGCTRGR.TRSC[5:0] bits selects the trigger for Group C. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers.

If you select "TRG4AN" or "TRG4BN", "TRG7AN" or "TRG7BN" as the trigger for group A in the ADSTRGR.TRSA[5:0] bits, it operates in double trigger extended mode.

For the channels to be scanned, select the group A channel with the ADCSR.DBLANS[4:0] bits, select the group B channel with the ADANSB0 register, and select the group C channel with the ADANSC0 register.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following shows an operation example when the group scan mode and double trigger mode are set by the synchronous trigger from the MTU3. Group A is set to start conversion with a TRG4ABN trigger from MTU3, Group B is set to start conversion with a TRGA0N trigger from MTU3, and Group C is set to start conversion with a TRGA1N trigger from MTU3.

1. Start scanning Group C with the TRGA1N trigger from the MTU3.
2. If the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled) at the end of Group C scanning, the ADC0_GCADI interrupt is output.
3. The TRGA0N trigger from the MTU3 starts scanning for group B.
4. If the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled) at the end of Group B scanning, an ADC0_GBADI interrupt is output.
5. The first TRG4ABN trigger from the MTU3 will start the first scan of Group A.

6. At the end of the first scan of Group A, the converted data is stored in ADDRy, and the ADC0_ADI interrupt request does not occur regardless of the setting of the ADCSR.ADIE bit.
7. The second TRG4ABN trigger from the MTU3 will start the second scan of Group A.
8. At the end of the second scan of group A, the conversion data is stored in ADDBLDR, and if the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled), the ADC0_ADI interrupt is output.
9. The second TRGA0N trigger from the MTU3 starts the second scan of group B.
10. At the end of the second scan of Group B, if the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled), an ADC0_GBADI interrupt is output.
11. The second TRGA1N trigger from the MTU3 starts the second scan of Group C.
12. At the end of the second scan of Group C, if the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled), an ADC0_GCADI interrupt is output.

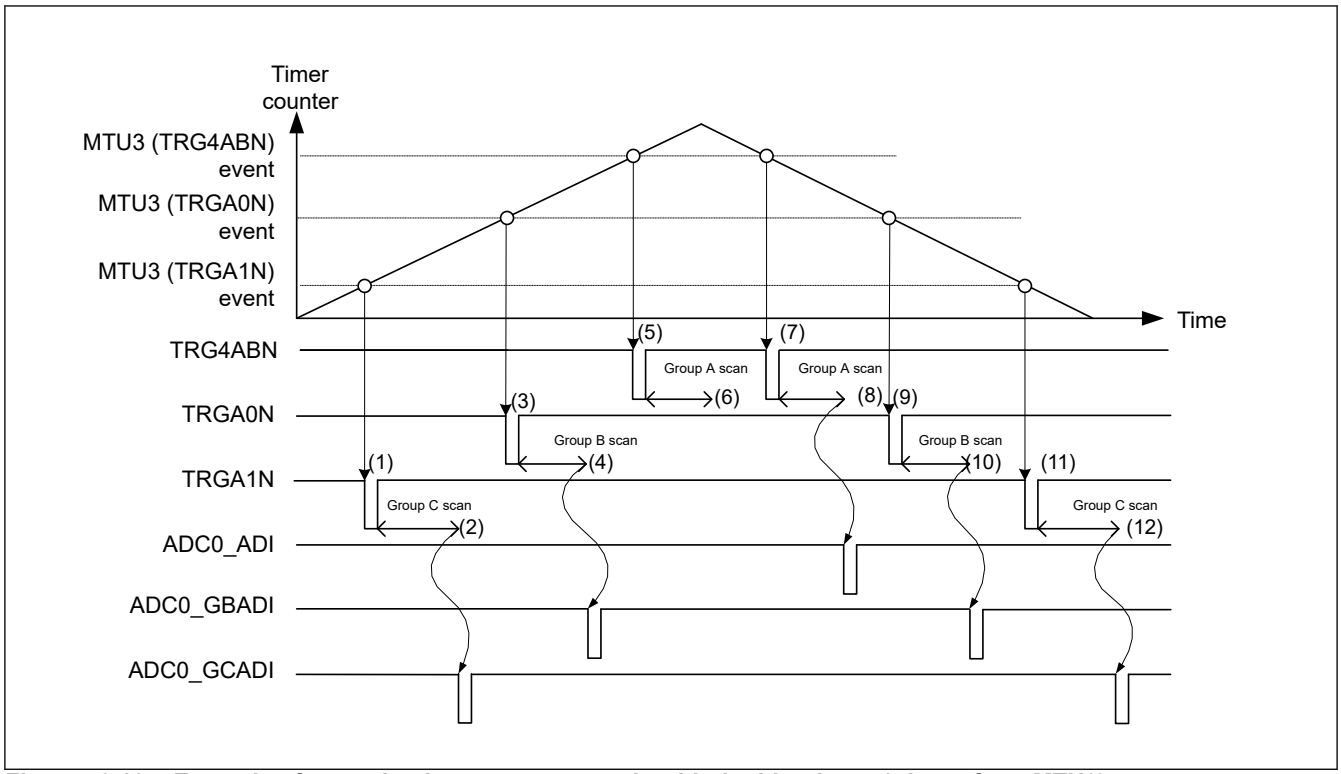

Figure 40.10 Example of operation in group scan mode with double trigger (trigger from MTU3)

40.3.4.3 Operation under Group Priority Control

When the ADGSPCR.PGS bit is set to 1 in group scan mode, group priority operation is performed. Group priority is in the order of group A > group B > group C. The number of groups used in group scan mode can be selected from either 2 (Groups A, B) or 3 (Groups A, B, C) depending on the setting of ADGCTRGR.GRCE. When setting the PGS bit in the ADPGSCR register to 1, follow the procedure in Figure 40.11 to set the relevant registers. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

In the basic operation of group scan mode, the trigger input generated during scanning of groups A, B, and C is ignored, and the scanning operation of groups A, B, and C is the same as that of single scan mode.

In the group priority operation, if there is a trigger input of the priority group during the scan of the low priority group, the scan of the low priority group is interrupted and the priority group is scanned.

When the ADGSPCR.GBRSCN bit is 0, the low priority group is in the standby state after the priority group scan is completed. Also, the low priority group trigger input that occurs during the scan is ignored.

When the ADGSPCR.GBRSCN bit is 1, the scan of the low priority group is automatically re-executed after the scan of the priority group is completed. In addition, the trigger input of the low priority group that occurred during the scan of the

priority group is valid, and the scan of the low priority group is automatically executed after the scan of the priority group is completed.

When the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS is 0, the scan of the low priority group is restarted from the beginning. Also, when ADGSPCR.LGRRS is 1, the scan of the low priority group is re-executed from the interrupted channel.

Table 40.7 shows the setting of the ADGSPCR.GBRSCN bit and the operation when a trigger is input during scanning.

When the ADGSPCR.GBRP bit is set to 1, the scan operation of the lowest priority group is the operation of executing a single scan continuously.

For the trigger setting in group scan mode, select the group A synchronous trigger with the ADSTRGR.TRSA[5:0] bits, and set the group B synchronous trigger different from the group A trigger with the ADSTRGR.TRSB[5:0] bits. Select a Group C synchronous trigger that is different from the Group A and B triggers on the ADGCTRGR.TRSC[5:0] bits.

When the group scan mode is set to 2 groups (ADGCTRGR.GRCE bit is set to 0) and the ADGSPCR.GBRP bit is set to 1, the ADSTRGR.TRSB[5:0] bits is set to 0x3F.

If the group scan mode is set to 3 groups (ADGCTRGR.GRCE bit is set to 1) and the ADGSPCR.GBRP bit is set to 1, set the ADGCTRGR.TRSC[5:0] bits to 0x3F.

For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

Table 40.8 shows Group priority operation setting and operation mode of 2 groups, and Table 40.9 shows Group priority operation setting and operation mode of 3 groups.

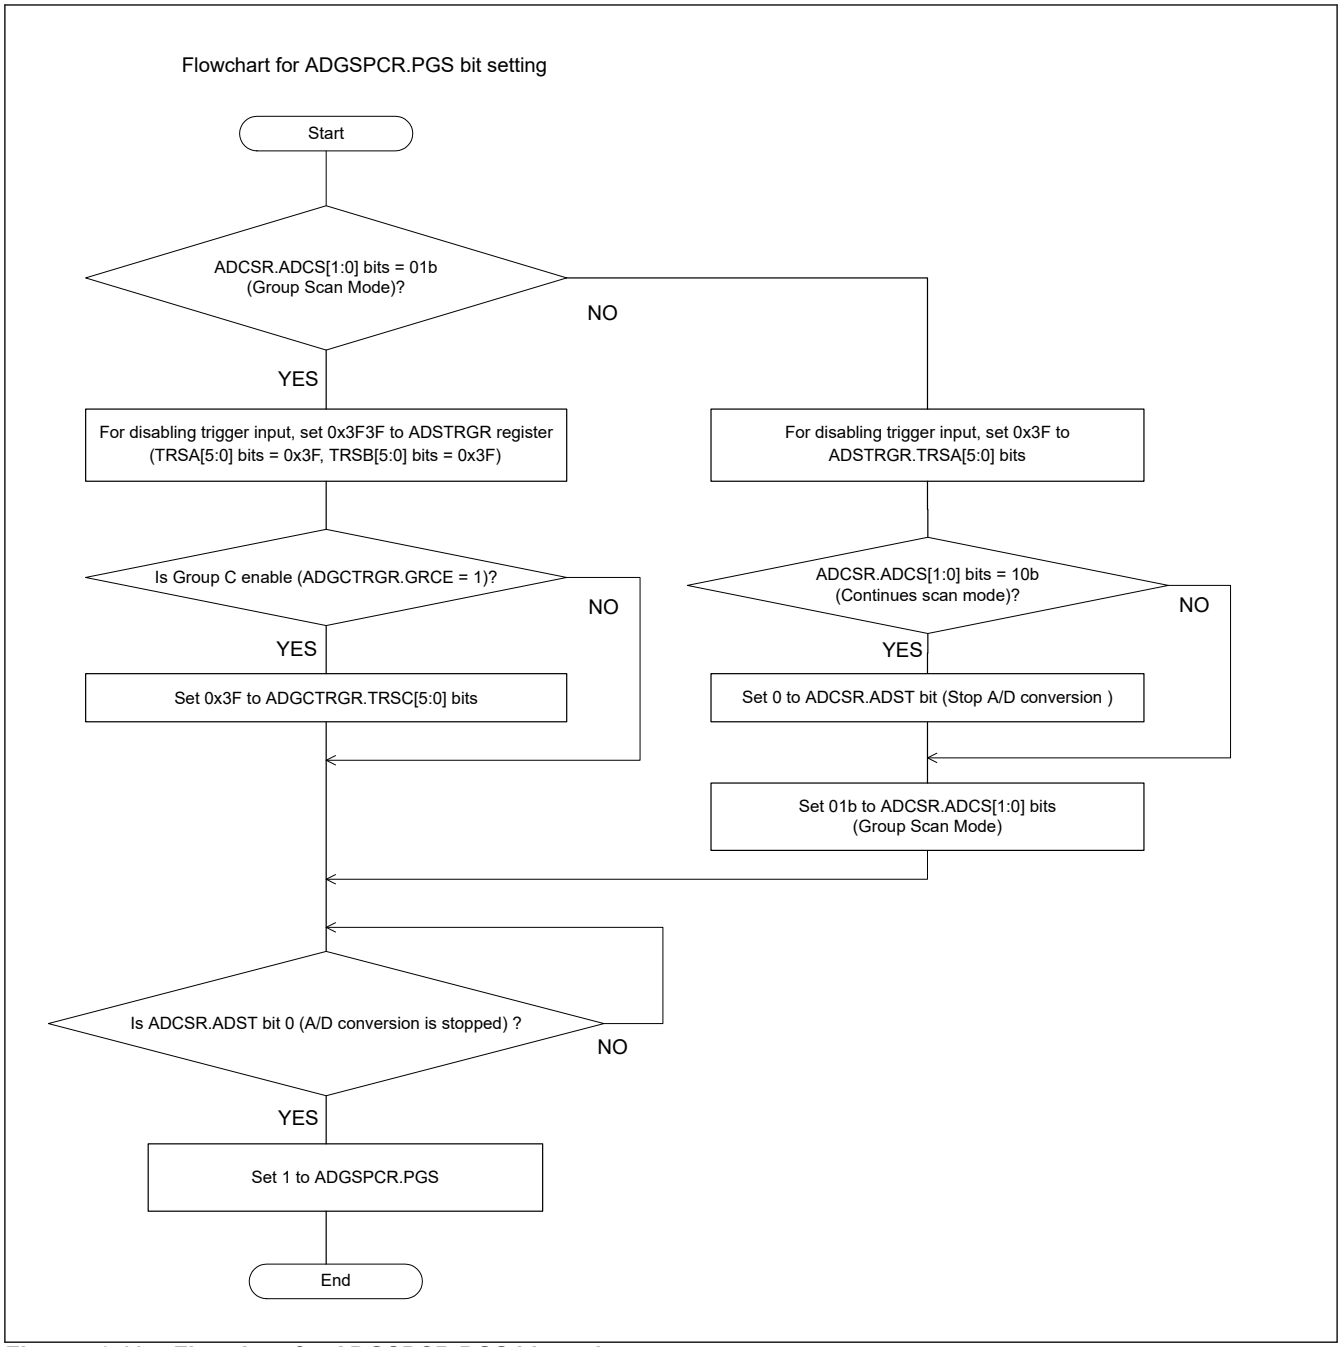

Figure 40.11 Flowchart for ADGSPCR.PGS bit setting

Table 40.7 Control of A/D conversion operations according to the settings of the ADGSPCR.GBRSCN bit (1 of 2)

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group A is completed.

Table 40.7 Control of A/D conversion operations according to the settings of the ADGSPCR.GBRSCN bit (2 of 2)

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group B is in progress	Input of trigger for group A	Conversion for group B that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group B is discontinued and conversion for group A starts. • Conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group B is completed.
When A/D conversion for group C is in progress	Input of trigger for group A	Conversion for group C that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group C is discontinued and conversion for group A starts. • Conversion for group C starts after conversion for group A is completed.
	Input of trigger for group B	Conversion for group C that is in progress is discontinued and conversion for group B starts.	• Conversion in progress for group C is discontinued and conversion for group B starts. • Conversion for group C starts after conversion for group B is completed.
	Input of trigger for group C	Trigger input is ineffective.	Trigger input is ineffective.

Table 40.8 Group priority operation setting and operation mode for 2 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

ADGSPCR			Operation mode
GBRSCN	LGRRS	GBRP	
0	—	0	Group priority operation of 2 groups (groups A and B). When the trigger of group A is input, the scan of group B ends (does not re-execute).
1	0	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B restarts the scan from the beginning of the channel specified by ADANSB0 after the scan of group A is completed.
1	1	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B resumes the scan from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.
—	0	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the group B scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSB0 after the group A scan is completed.
1	1	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the scan of group B is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.

Table 40.9 Group priority operation setting and operation mode for 3 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1) (1 of 2)

ADGSPCR			Operation mode
GBRSCN	LGRRS	GBRP	
0	—	0	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). When the trigger of group A or group B is input, the scan of group C ends (does not re-execute).

Table 40.9 Group priority operation setting and operation mode for 3 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1) (2 of 2)

ADGSPCR			
GBRSCN	LGRRS	GBRP	Operation mode
0	—	1	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	0	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the top channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the top channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	1	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	0	1	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is interrupted, the scan is restarted from the beginning of the channel specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	1	1	Group priority operation of 3 groups (groups A, B, C). After the A/D conversion process of group B is interrupted, the interrupted channel is restarted from the channels specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSC0 after the group A/B scan is completed.

40.3.5 Compare Function (Window A, Window B)

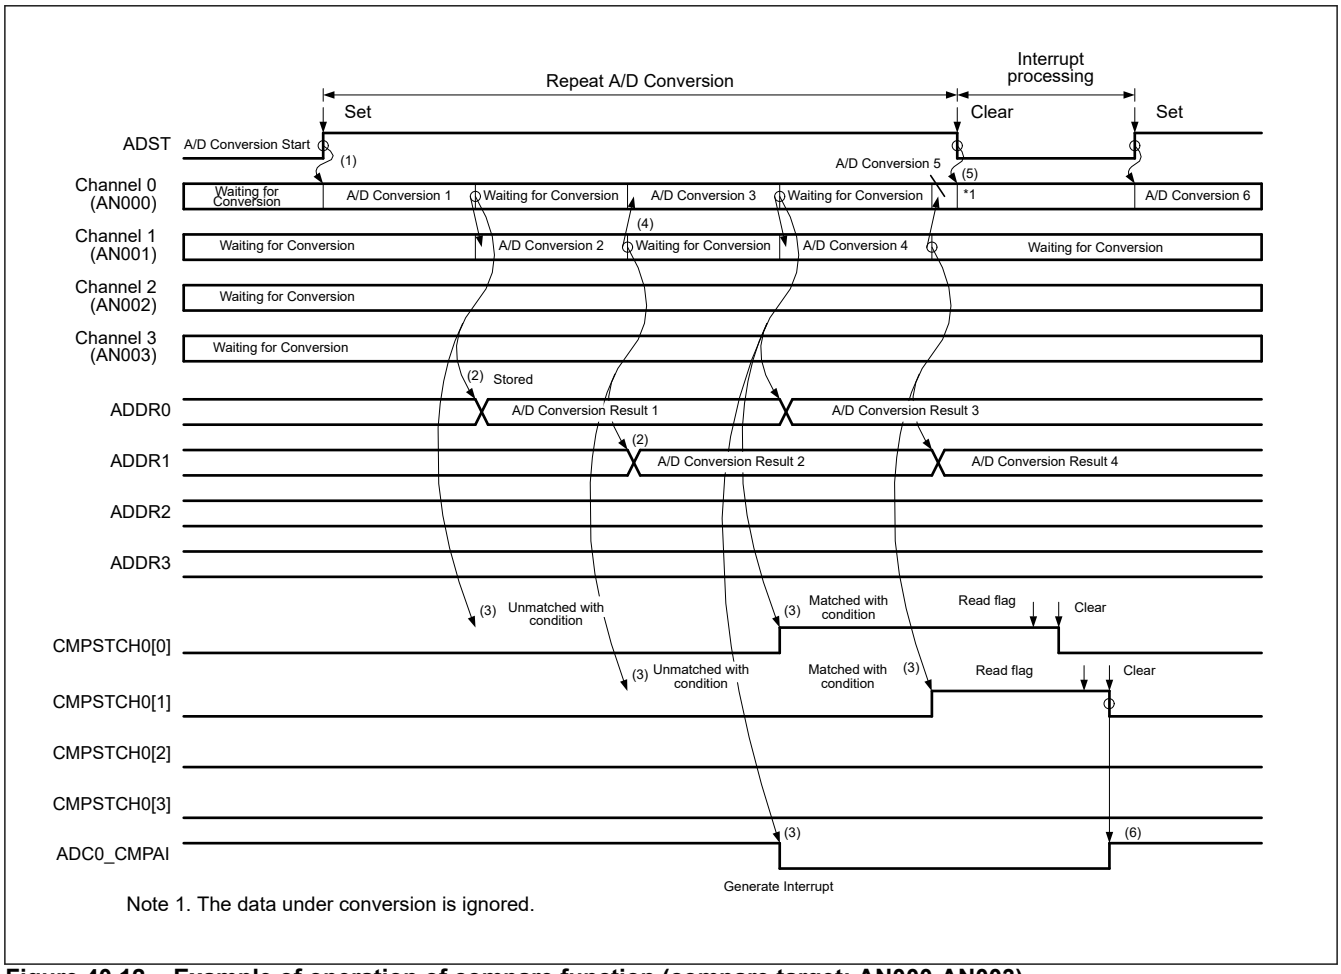
40.3.5.1 Compare Function Window A/B

The compare function is a function that compares the reference value set in the register with the A/D conversion result, and the reference value can be set for each window (A/B). Double trigger mode cannot be used when using the compare function. The major difference between window A and window B is that window B has one selectable channel and different interrupt output signals.

Operation using compare function in combination with continuous scan mode is described below.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronous trigger (MTU3, ELC), or asynchronous trigger, A/D conversion of the selected channel is started.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy). When ADCMPCR.CMPAE = 1b, if it is set for window A in the ADCMPANSR0 register, it is compared with the ADCMPDR0 register setting value. When ADCMPCR.CMPBE = 1b, if the ADCMPBNSR register is set for window B, it will be compared with the ADWINULB/ADWINLLB register setting value.
3. As a result of comparison, when the condition set in ADCMPLR0 is matched in window A, the flag (ADCMPSR0. CMPSTCHA0n) bit of the compare function window A is set to 1. At this time, if the ADCMPCR.CMPAIE bit is set to 1, an ADC0_CMPAI interrupt request (level) is generated. Similarly, when window B matches the conditions set in ADCMPBNSR.CMPLB, the compare function window B flag (ADCMPBSR.CMPSTB) bit is set to 1. At this time, if the ADCMPCR.CMPBIE bit is set to 1, an ADC0_CMPBI interrupt request (level) is generated.
4. When all the selected A/D conversions and comparisons are completed, scanning is performed again.
5. After accepting the ADC0_CMPAI/ADC0_CMPBI interrupt, set the ADCSR.ADST bit to 0 (A/D conversion stopped) and execute processing for the channel for which the compare flag is set.

6. When all the compare flags in window A are cleared, the ADC0_CMPAI interrupt request is canceled. Similarly, clearing the compare window B flag cancels the ADC0_CMPBI interrupt request. If you want to perform the compare again, start the A/D conversion again.



Note 1. The data under conversion is ignored.

Figure 40.12 Example of operation of compare function (compare target: AN000-AN003)

40.3.5.2 Event output in Compare Function

For the event output of the compare function, specify the upper and lower reference values for each of windows A/B, compare the A/D conversion value of the selected channel with the upper/lower reference values, and then the event (ADCn_WCMPM/ADCn_WCMPUM) is output according to the event condition (A or B, A and B, A exor B) from the result of satisfying/failing the comparison condition of windows A and B. When using this function, perform A/D conversion in single scan mode.

In window A, any channel of ANn00-ANn07 can be selected. When multiple channels are selected in window A and the comparison condition is satisfied in one of the channels, the comparison condition is satisfied in window A. In window B, one channel of ANn00-ANn07 can be selected.

The setting procedure and setting example when using the event output of the compare function are shown below.

1. ADCSR.ADCS bit must be 00b (single scan mode).
2. Select the channel to be used for window A in the ADCMPANSR0 register, set the comparison condition of the compare function window in the ADCMPLR0 register, and set the upper/lower reference value in the ADCMPDR0/1 register.
3. Select the channel to be used for window B and the comparison condition in the ADCMPBNSR register, and set the upper/lower reference values in the ADWINULB/ADWINLLB registers.
4. In the ADCMPCR register, set the window A/B compound condition, window A/B operation permission, and interrupt output permission.

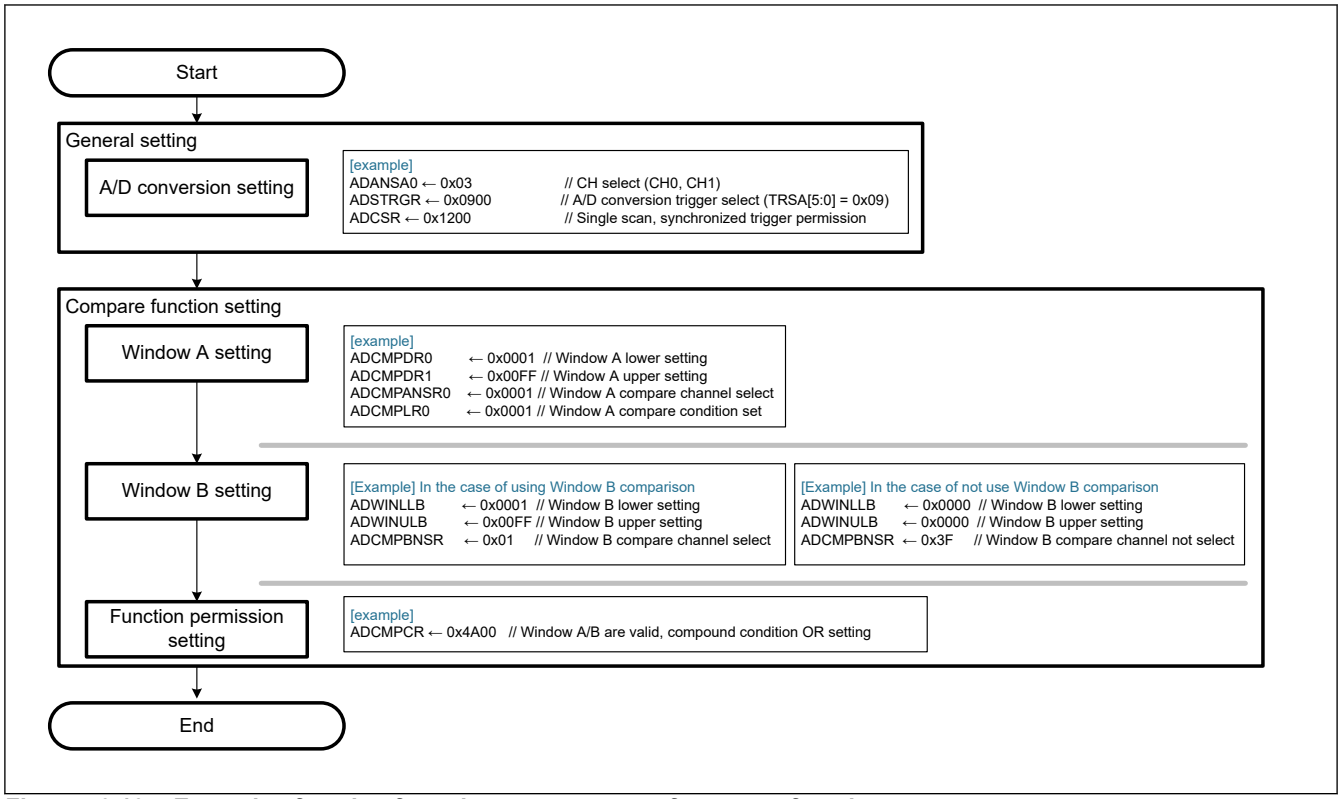


Figure 40.13 Example of setting for using event output of compare function

Precautions when using event output using only window A of the compare function

- Enable both windows A and B. (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition setting for windows A and B to "OR condition". (ADCMPCR.CMPAB[1:0] = 00b)
- Set the comparison target channel in window B to "Unselected". (ADCMPBNSR.CMPCHB[5:0] = 111111b).
- Set the comparison condition of window B to 0 < conversion result < 0, which is "always inconsistent". (ADCMPCR.WCMPE = 1, ADWINLLB.CMPLLB[15:0] = ADWINULB.CMPULB[15:0] = 0x0000, ADCMPBNSR.CMPLB = 1)

Figure 40.14 shows example of event output operation of compare function.

The scan end event is output when one single scan ends. Also, depending on the setting of ADCMPCR.CMPAB[1:0], the match/unmatch event (ADCn_WCMPM/ADCn_WCMPUM) is output with a delay of 1 (Unit 0: PCLKH, Unit 1: PCLKL).

Note: Match/unmatch events are exclusive outputs, and both events are not output at the same time.

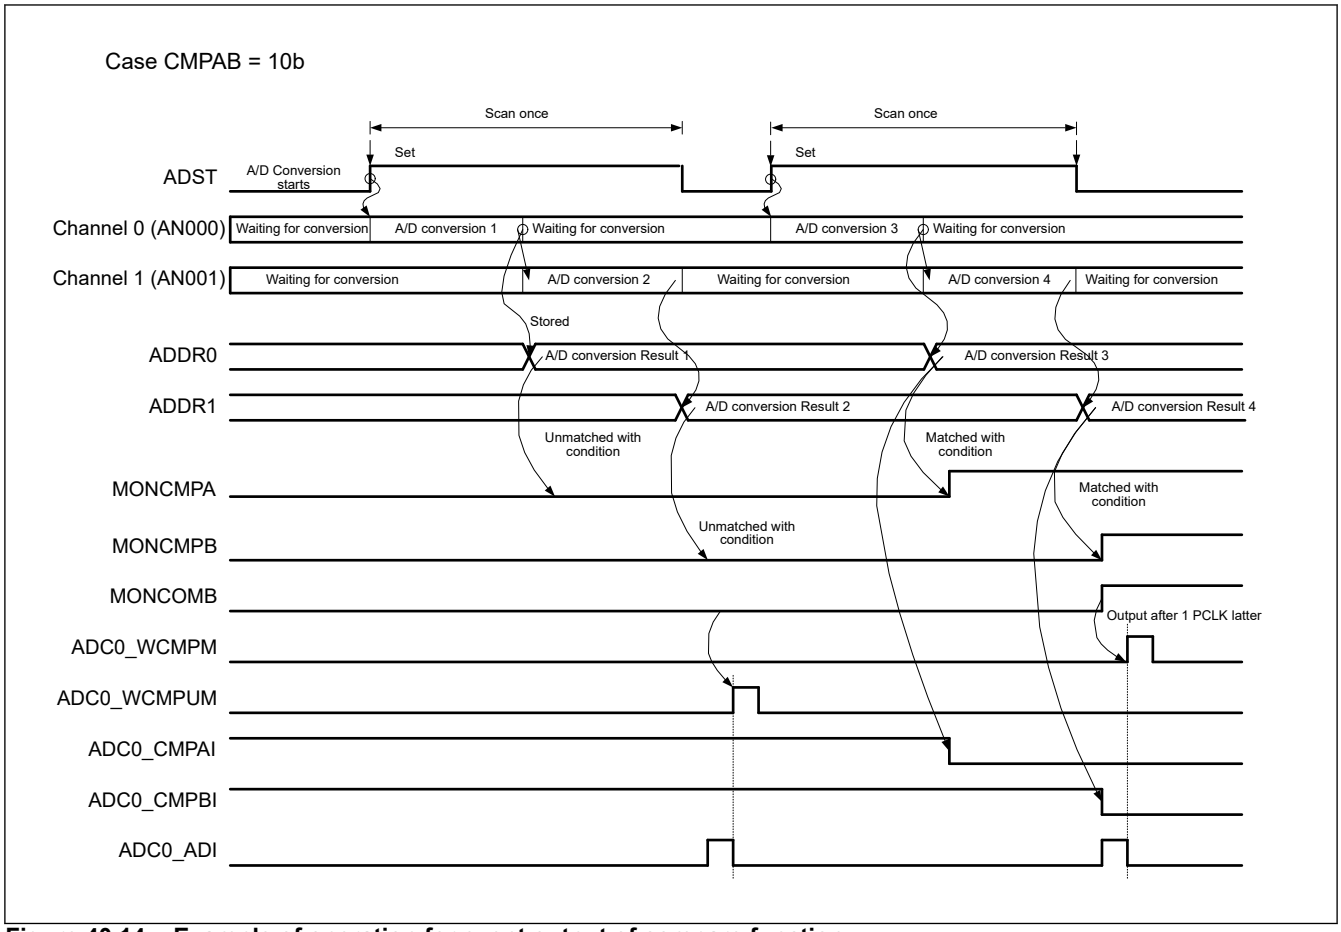

Figure 40.14 Example of operation for event output of compare function

Precautions when using event output of the compare function

The event output of the compare function outputs match/unmatch according to the setting of ADCMPCR.CMPAB[1:0] from the comparison result of window A and the comparison result of window B. The comparison result of window A is the logical sum of the comparison result of the channel to be compared in window A.

The comparison result of window A and the comparison result of window B are updated every A/D conversion of the channel to be compared, and the comparison result is retained even after the single scan is completed. To clear the comparison result (0), set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

40.3.5.3 Compare function constraint

The compare function has the following restrictions.

- Double trigger mode cannot be used together.
  (ADDBLDR, ADDBLDRA, ADDBLDRB are not subject to the compare function.)
- If you want to use match/unmatch event output, set the single scan mode.
- The same CH cannot be set in window A and window B.
- Set so that the upper reference value ≥ the lower reference value.

40.3.6 A/D Data Register Automatic Clearing Function

By setting the ADCER.ACE bit to 1, these are used when the CPU and DMAC read the A/D data registers (ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB). The register can be cleared automatically to 0x0000.

By using this function, it is possible to detect an un-updated failure of the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers. The following is an example when the automatic clear function of the ADDRy register is disabled/ enabled.

When the ADCER.ACE bit is 0 (automatic clearing prohibited), the old data (0x0111) becomes the value of the ADDRy register when the A/D conversion result (0x0222) is not written to the ADDRy register for some reason. Furthermore, when the value of this ADDRy register is read to the general-purpose register by using the A/D conversion end interrupt, the old data (0x0111) can be saved in the general-purpose register. However, when checking for un-updated data, it is necessary to check while holding old data in RAM and general-purpose registers one by one.

When the ADCER.ACE bit is 1 (automatic clearing enabled), the ADDRy register is automatically cleared to 0x0000 when ADDRy = 0x0111 is read by the CPU and DMAC. After that, when 0x0222 of the A/D conversion result cannot be transferred to the ADDRy register for some reason, the cleared data (0x0000) remains as the ADDRy register value. If the value of this ADDRy register is read to a general-purpose register by using the A/D conversion end interrupt, 0x0000 is held in the general-purpose register. By simply checking that the read data value is 0x0000, it can be determined that there was an un-updated failure of the ADDRy register.

40.3.7 A/D-converted Value Addition/Average Function

In A/D-converted value addition function, the same channel is A/D-converted two, three, four or sixteen consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average function, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that affect A/D conversion. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average mode can be specified when A/D conversion of the analog input of the selected channels is selected.

40.3.8 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b and a low-level signal should be input to the asynchronous trigger (ADTRGn#). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1. Figure 40.15 shows a timing of the asynchronous trigger input.

Asynchronous triggers cannot be selected for groups B and C used in group scan mode.

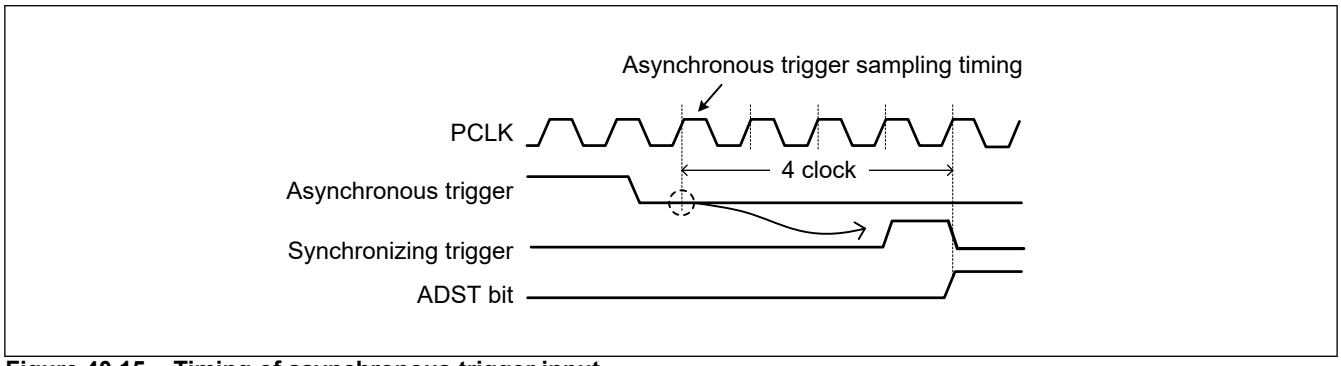

Figure 40.15 Timing of asynchronous trigger input

40.3.9 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

A/D conversion can be started by the synchronization trigger from MTU3 and ELC (1 pulse of "L" in PCLK synchronization). When starting A/D conversion with a synchronous trigger, the ADCSR.TRGE bit is set to 1, the ADCSR.EXTRG bit is set to 0, the ADSTRGR.TRSA[5:0], ADSTRGR.TRSB[5:0], and ADGCTRGR.TRSC[5:0] bits are set to the appropriate trigger factor.

40.3.10 Event Link Function

40.3.10.1 Event output to ELC

ELC can use the ADCn_ADI interrupt request signal as an event signal (ADCn_ADI) to link to a preset module (ADCn_GBADI/ADCn_GCADI interrupt, ADCn_CMPAI/ADCn_CMPBI interrupt cannot be used as an event signal). The event signal can be output regardless of the setting of the corresponding interrupt request permission bit.

The 12-bit A/D converter outputs the scan end event (ADCn_ADI), compare function match event (ADCn_WCMPM), and unmatch event (ADCn_WCMPUM). The scan end event (ADCn_ADI) outputs a "High pulse" for 1 PCLK at the same output timing as the interrupt output (ADCn_ADI) regardless of the setting of ADCSR.ADIE.

The compare match/unmatch event (ADCn_WCMPM/ADCn_WCMPUM) to ELC outputs a "High pulse" for 1 PCLK at a timing delayed by 1 cycle (PCLK) from the interrupt output (ADCn_ADI) regardless of the setting of ADCSR.ADIE. When using the compare match/unmatch event to ELC (ADCn_WCMPM/ADCn_WCMPUM), set it to single scan mode.

40.3.10.2 Starting A/D Conversion with ELC event

The 12-bit A/D converter can start A/D conversion by a preset event by setting ELC_SSEL in ELC.

40.4 Usage Notes

40.4.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, must be read in 16-bit word units, to avoid unmatch from upper value and lower value due to reading by byte units separately.

40.4.2 Notes on Stopping A/D Conversion

40.4.2.1 A/D Conversion Stop Procedure

If using asynchronous or synchronous trigger as the A/D conversion start condition, follow the procedure in the flowchart in Figure 40.16 to stop the A/D conversion.

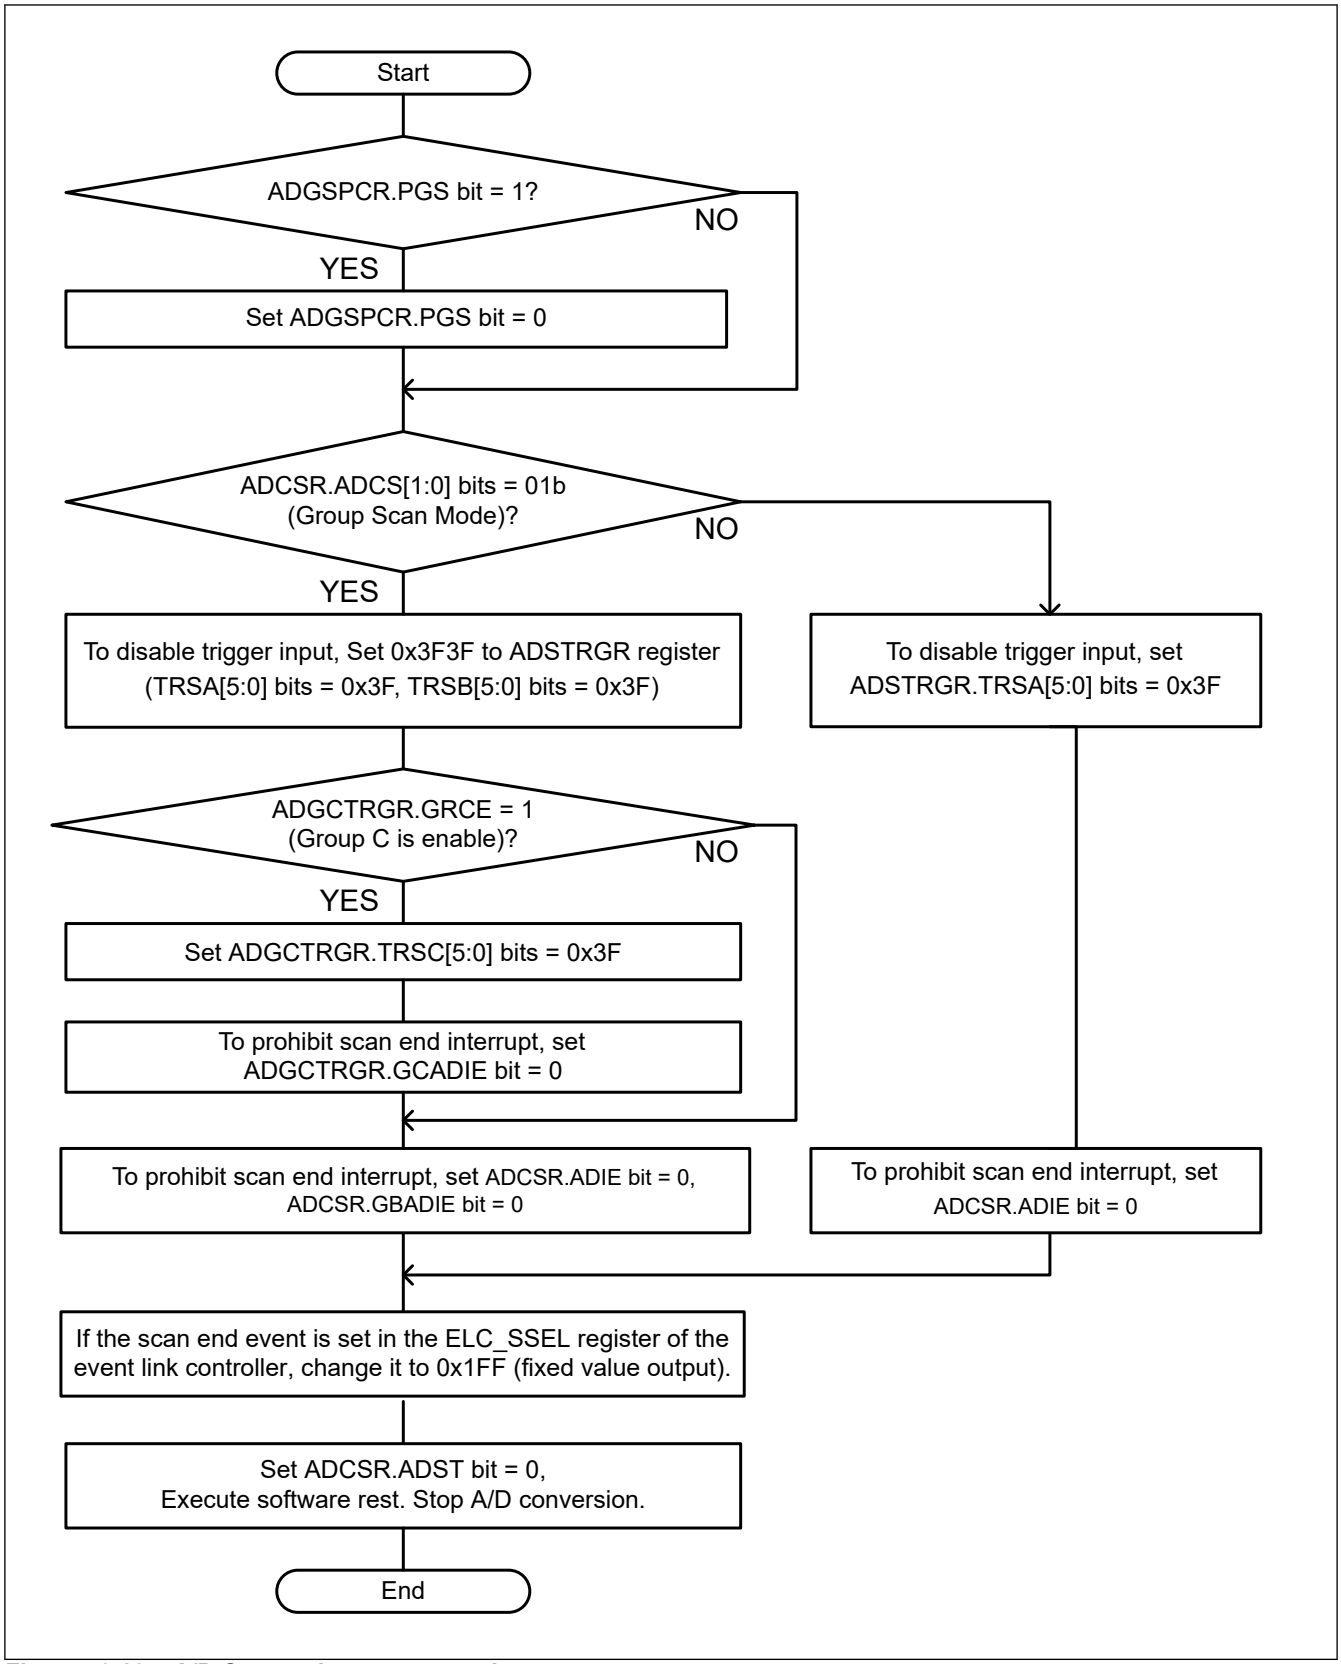

Figure 40.16 A/D Conversion stop procedure

It takes 2 PCLKADC cycles from a software clear until the soft macro stops scanning. If you want to set the following after executing a software clear, enter a wait of 2 PCLKADC cycles or more.

- Scan end interrupt enabled
- Event link controller scan end event valid setting

- Start of A/D conversion by software
- Trigger input valid setting

40.4.2.2 Notes on Mode/Status bits

Initialize or reset the odd/even judgment and monitor bits of the compare function in the double trigger mode as necessary.

- Double trigger mode starts from the first scan operation when ADCSR.DBLE is set from 0 to 1.
- To initialize the monitor bits (MONCMPA, MONCMPB, MONCOMB) of the compare function, set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

40.4.3 A/D conversion forced stop and operation timing at starts

Up to 6 PCLKADCs time is necessary that the A/D converter starts by ADCSR.ADST bit = 1 from stopped status.

When the ADCSR.ADST bit is set to 0 and the A/D conversion is forcibly stopped, the analog part of the 12-bit A/D converter requires a maximum of 2 PCLKADCs to stop operating.

40.4.4 Notes on Scan End Interrupt Processing

When scanning the same analog input twice using any trigger, if the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated, the first A/D-converted data is overwritten with the second A/D-converted data and an overwrite error occurs.

40.4.5 Module-Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled using the Module Stop Control register. The initial setting is for operation of the 12-bit A/D converter to be halted. Releasing the module-stop state enables access to the registers. After release from the module-stop state, wait for at least 15 us before starting A/D conversion.

40.4.6 Notes on Entering Low Power Consumption States

When transitioning to module stop mode, stop A/D conversion. When stopping the A/D conversion, it is necessary to secure the time until the analog part of the 12-bit A/D converter stops after setting the ADCSR.ADST bit to 0.

41. Temperature Sensor Unit (TSU)

41.1 Overview

The temperature sensor unit (TSU) indicates the junction temperature as a 12-bit binary digital output code. A temperature sensor unit is used to monitor the LSI junction temperature.

Figure 41.1 shows a block diagram of a temperature sensor unit.

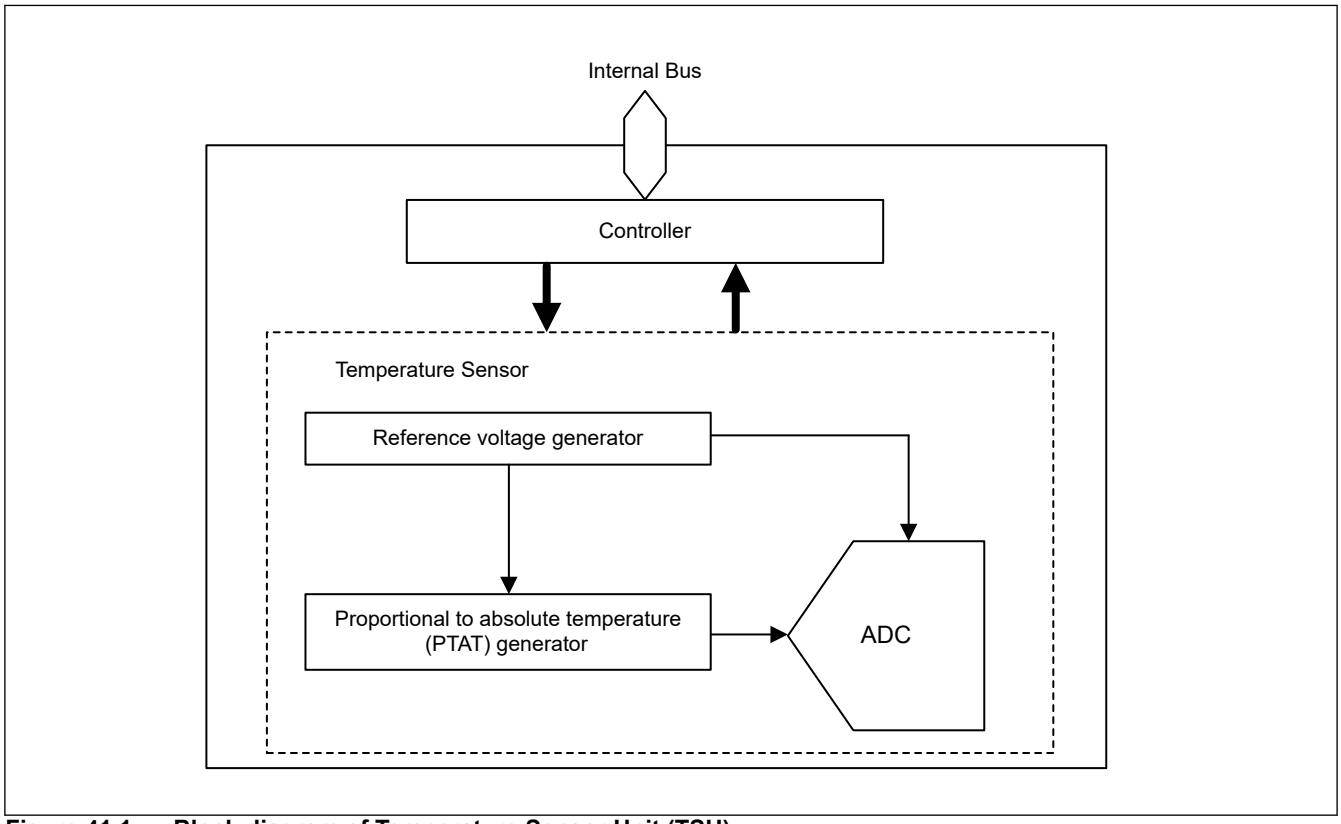

Figure 41.1 Block diagram of Temperature Sensor Unit (TSU)

41.2 Register Descriptions

41.2.1 TSUSM : Sensor Mode Register

Base address: TSU = 0x8004_6000

Offset address: 0x00

Bit position:	31																														1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADCEN	TSEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSEN	Temperature Sensor Enable 0: Disabled 1: Enabled	R/W
1	ADCEN	ADC Enable 0: Disabled 1: Enabled	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

41.2.2 TSUST : Sensor Trigger Register

Base address: TSU = 0x8004_6000

Offset address: 0x04

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	START
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	START	A/D Conversion Control 0: Stops A/D conversion*1 1: Starts A/D conversion*2	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The TSUAD value is invalid when START bit is 0. Please read TSUAD before setting START bit to 0.
Note 2. Before the START bit is set to 1, TSUSM register and TSUSCS register settings are required. These registers are set and waits 60 µsec, then the START bit should be set to 1.

The TSUST register controls the temperature sensor unit to turn A/D convert on and off. After A/D conversion started, temperature conversion is executed and conversion data is updated every 960 PCLKL cycles at PCLKL = 50 MHz and every 640 PCLKL cycles at PCLKL = 37.5 MHz.

41.2.3 TSUSCS : Sensor Configuration Setting Register

Base address: TSU = 0x8004_6000

Offset address: 0x08

Bit position:	31																											3		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CKDIV	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CKDIV	Divider Value for PCLKL 0: 24 for PCLKL = 50 MHz 1: 16 for PCLKL = 37.5 MHz	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

The TSUSCS register is used for temperature sensor configuration.

41.2.4 TSUSAD : Sensor ADC Data Register

Base address: TSU = 0x8004_6000

Offset address: 0x0C

Bit position:	31																				11									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DOUT[11:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	DOUT[11:0]	Temperature Sensor Data Output	R
31:12	—	These bits are read as 0.	R

The TSUSAD register is used to read data for A/D conversion.

41.2.5 TSUSS : Sensor Status Register

Base address: TSU = 0x8004_6000

Offset address: 0x10

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CONV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CONV	A/D Conversion Status 0: Stop 1: A/D conversion is running	R
31:1	—	These bits are read as 0.	R

The TSUSS register indicates A/D conversion status.

41.3 Operation

41.3.1 Startup Sequence

This section describes the register operations for power consumption control and initial setting of this module. The startup sequence is as follows:

1. Release the TSU module from stop status.
   (a) Release write protection (PRCRN register).
   (b) Release the TSU module from the stopped state: MSTPCRD07 = 0.
   (c) Set write protection (PRCRN register).
   (d) Set TSUSCS.CKDIV = 0 (PCLKL = 50 MHz) or 1 (PCLKL = 37.5 MHz) depending on PCLK frequency.
2. Change the TSU status to normal operation mode.
   (a) Write to the TSUSM register and set the TSEN and ADCEN bits to 1.
   (b) Wait 60 µsec.
3. Start the conversion.
   (a) Write to the TSUST register and set the START bit to 1.
   A/D converter starts operation and converts the voltage generated by PTAT generator circuit associated temperature to 12-bit data. The CONV bit in the TSUSS register is set to 1.
   - A/D conversion data is stored in a buffer automatically.
   - Update the data every 960 PCLKL cycles (at TSUSCS.CKDIV = 0, PCLKL = 50 MHz : 19.2 µsec.) or 640 PCLKL cycles. (at TSUSCS.CKDIV = 1, PCLKL = 37.5 MHz : 17.1 µsec.)
   - Stored data in the buffer can be read out by TSUSAD register access. Read the data when TSUST.START = 1. When TSUST.START = 0, read data is invalid.

41.3.2 Stop Sequence

1. Stop the conversion.

(a) Clear the START bit in the TSUST register to 0.

(b) After conversion time has passed, A/D converter is stopped and the CONV bit in the TSUSS register is cleared to 0.

(c) Confirm CONV = 0.

2. Disable the TSU.

(a) Write to the TSUSM register and set the TSEN and ADCEN bits to 0. When restarting TSU operation, execute the startup sequence from Step 2 in section 41.3.1. Startup Sequence.

41.3.3 A/D Start and Stop Timing

A/D conversion signal is generated when the START bit in the TSUST register is set to 1.

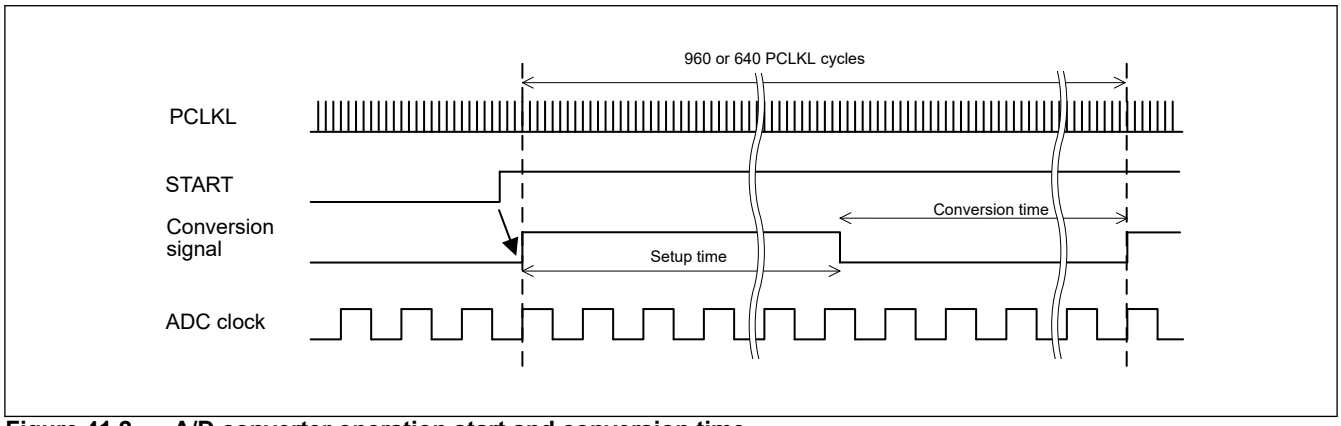

Figure 41.2 A/D converter operation start and conversion time

Even if the START bit in the TSUST register is cleared to 0, A/D converter is still working until the converting cycle is completed. However, do not read the A/D output data after the START bit in the TSUST register is changed to 0.

41.3.4 A/D Output Data Store Timing

When a conversion completion signal is detected, A/D output data is stored in a buffer. Data in the buffer can be read out by read access for TSUSAD register.

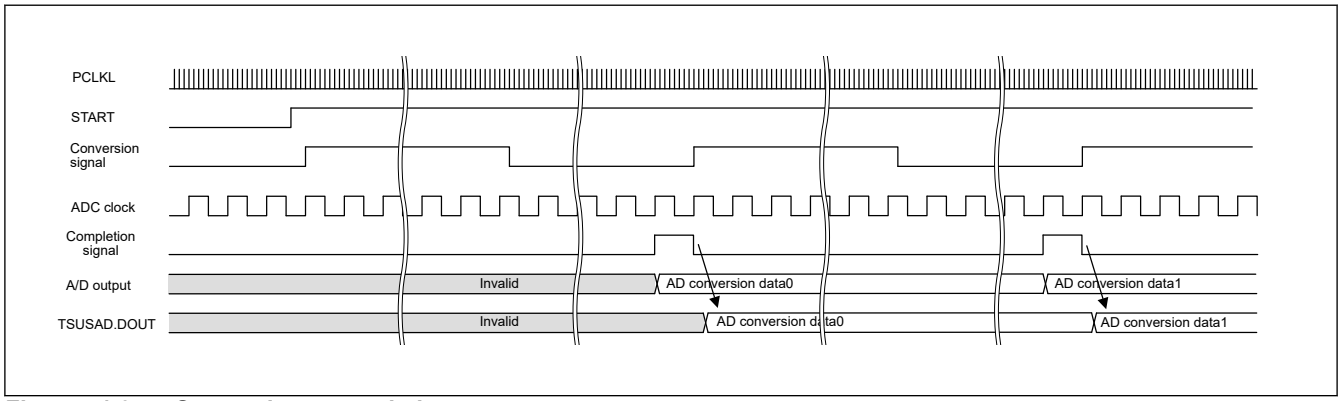

Figure 41.3 Output data store timing

41.3.5 A/D Conversion Status (CONV)

The TSU module enables or disables A/D converter according to the START bit status in the TSUST register. However, conversion completion timing is not the same as the START bit clear point.

In order to confirm the A/D conversion status, TSUSS register is available. When the START bit in TSUST register is set to 1, CONV bit in the TSUSS register is also set to 1. When the START bit in TSUST register is cleared to 0, the CONV bit status in the TSUSS register remains until conversion completion signal is asserted.

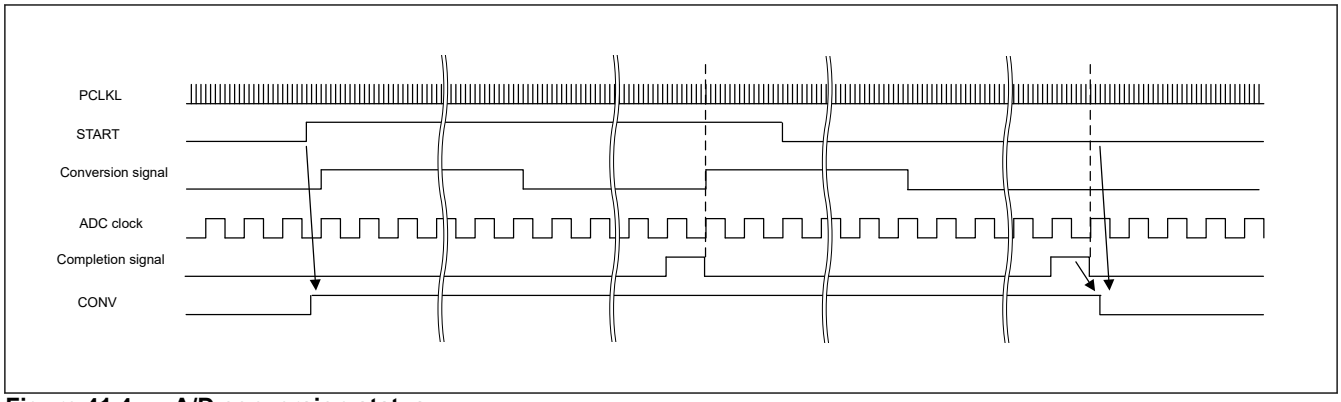

Figure 41.4 A/D conversion status

41.3.6 Using the Temperature Sensor

The temperature sensor outputs 12-bit binary digital output code which varies with the temperature. The user can then obtain the temperature on this LSI by converting the output code value into temperature. To ensure accuracy, 2-point calibration (see section 41.3.6.1. Preparation for Using the Temperature Sensor) and also averaging the data obtained at least 8 times continuously are required.

41.3.6.1 Preparation for Using the Temperature Sensor

The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula (2-point calibration).

Formula for the temperature characteristic:

$T = (Ds - D1) / Slope + T1$ … (1)

T: Measured temperature (°C)

Ds: Code output (TSUSAD.DOUT) by the temperature sensor at the time of temperature measurement

T1 = 25°C: Temperature experimentally measured at one point (°C)

D1: Code output (TSUSAD.DOUT) by the temperature sensor at the time of measurement of T1

T2 = 85°C: Temperature at the experimental measurement of another point (°C)

D2: Code output (TSUSAD.DOUT) by the temperature sensor at the time of measurement of T2

Slope: Temperature gradient by the temperature sensor (digit/°C)

For temperature more than or equal to 25°C (for example, if Ds ≥ D1)

$Slope = (D2 - D1) / (T2 - T1)$ … (2-1)

For temperature below 25°C (for example, if Ds < D1)

$Slope = (D2 - D1) / (T2 - T1) \times 63 / 65$ … (2-2)

Characteristics vary from sensor to sensor. Therefore, the following measurement at two different temperatures (T1 = 25°C and T2 = 85°C) is recommended.

Measure the code D1 output by the temperature sensor at temperature T1 (25°C).

Again, measure the code D2 output by the temperature sensor at a different temperature T2 (85°C). Obtain the temperature gradient (Slope: the formula (2-1) or (2-2) above) from these results.

Subsequently, obtain temperatures by substituting Slope and code output (Ds) into the formula (1) above.

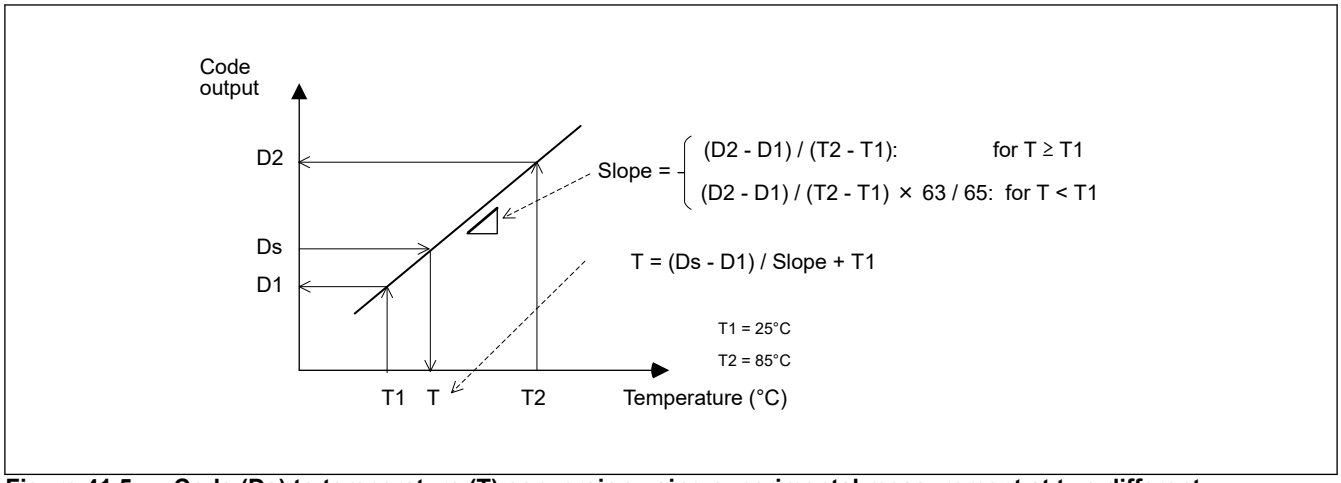

Figure 41.5 Code (Ds) to temperature (T) conversion using experimental measurement at two different temperatures

42. Data Operation Circuit (DOC)

42.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16-bit data.

Table 42.1 lists the data operation circuit specifications and Figure 42.1 shows a block diagram of the data operation circuit.

- 16-bit data is compared and an interrupt can be generated when a selected condition applies.
- 16-bit data can be added.
- 16-bit data can be subtracted.

Table 42.1 DOC specifications

Parameter	Description
Data operation function	16-bit data comparison, addition, and subtraction
Lower power consumption function	Module-stop state can be set.
Interrupts	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than 0xFFFF • The result of data subtraction is less than 0x0000

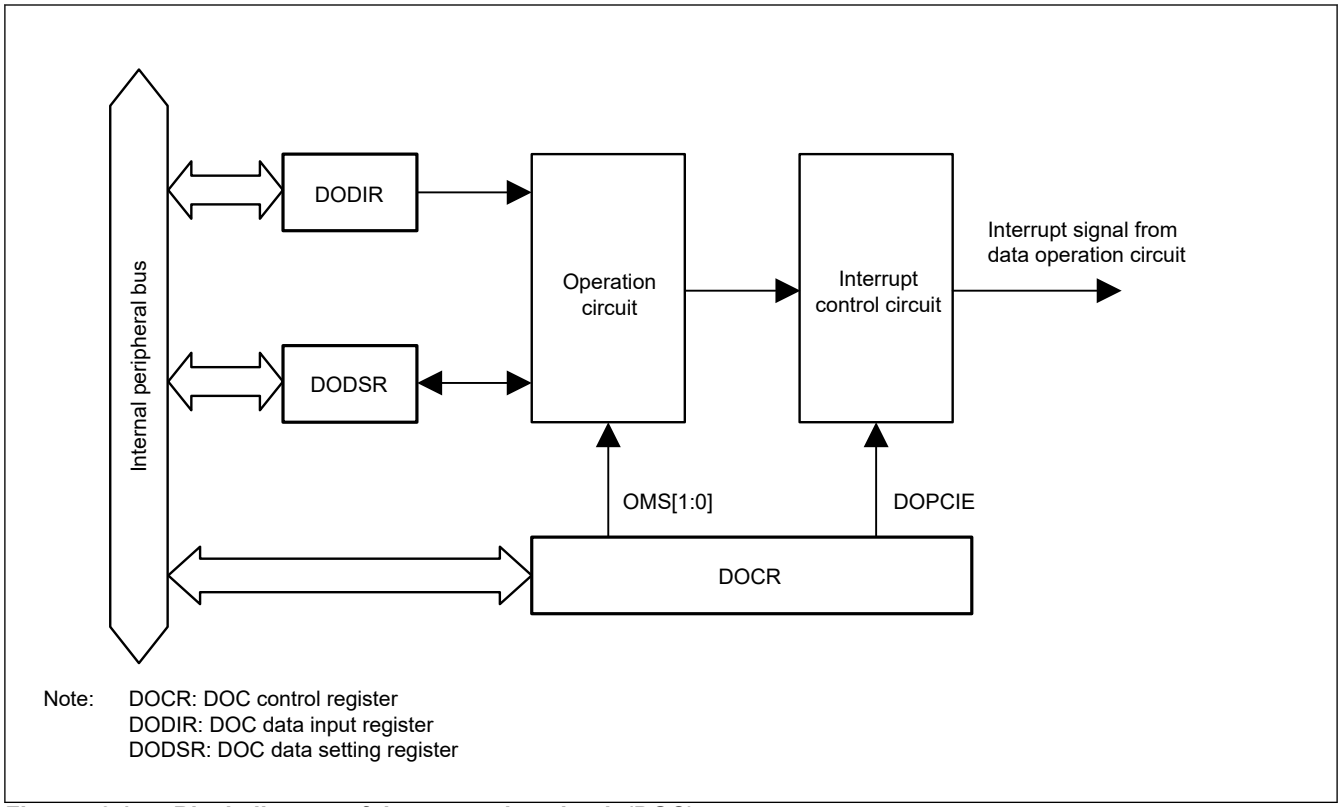

Figure 42.1 Block diagram of data operation circuit (DOC)

42.2 Register Descriptions

42.2.1 DOCR : DOC Control Register

Base address: DOC = 0x8004_4000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DOPCFCL	DOPCF	DOPCIE	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select Selects an operating mode of the data operation circuit. 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	DCSEL	Detection Condition Select Selects a condition for detecting data comparison result. This bit is valid only in the data comparison mode. 0: Data mismatch is detected. 1: Data match is detected.	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	DOPCIE	Data Operation Circuit Interrupt Enable Specifies whether to enable or disable data operation circuit interrupt requests. 0: Disables interrupts from the data operation circuit. 1: Enables interrupts from the data operation circuit.	R/W
5	DOPCF	Data Operation Circuit Flag [Setting conditions] When any of the following is met: ● The condition selected by the DCSEL bit is met. ● A result of data addition is greater than 0xFFFF. ● A result of data subtraction is less than 0x0000. [Clearing condition] Writing 1 to the DOPCFCL bit	R
6	DOPCFCL	DOPCF Flag Clear 0: No effect 1: Clear the DOPCF flag	W
7	—	This bit is read as 0. The write value should be 0.	R/W

42.2.2 DODIR : DOC Data Input Register

Base address: DOC = 0x8004_4000

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	The DODIR register is a 16-bit readable/writable register in which 16-bit data for use in operations are stored.	R/W

42.2.3 DODSR : DOC Data Setting Register

Base address: DOC = 0x8004_4000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	The DODSR register is a 16-bit readable/writable register. This register stores 16-bit data for use as a reference in data comparison mode. This register also stores the results of operations in data addition and data subtraction modes.	R/W

42.3 Operation

42.3.1 Data Comparison Mode

Figure 42.2 shows an example of the steps involved in data comparison mode operation by the data operation circuit. The following is an example of operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison).

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode.
2. The 16-bit reference data is set in DODSR.
3. 16-bit data for comparison is written to DODIR.
4. Writing of 16-bit data continues until all data for comparison have been written to DODIR.
5. If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), the DOCR.DOPCF flag does not change to 1 if a value other than 0x0000 is set in the DODSR register. To perform data comparison, set the DODSR register and write a value to the DODIR register. If the DODSR register is set again after data comparison, the value remaining in the DODIR register will not be compared again with the value set in the DODSR register. That is, comparison proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

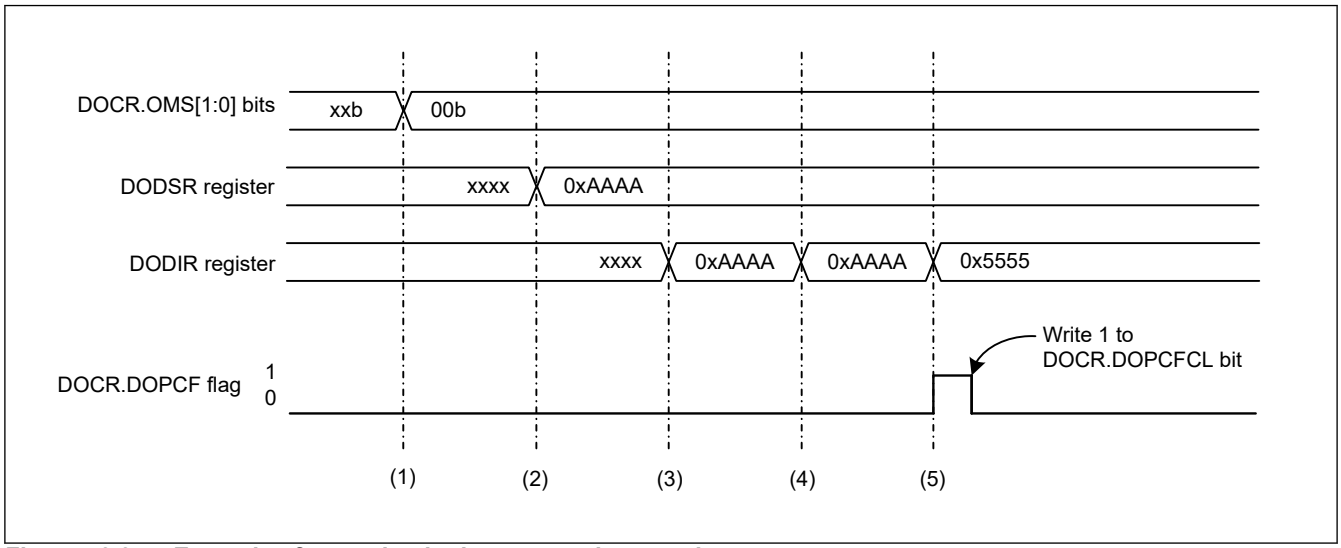

Figure 42.2 Example of operation in data comparison mode

42.3.2 Data Addition Mode

Figure 42.3 shows an example of the steps involved in data addition mode operation by the data operation circuit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 16-bit data is set in the DODSR register as the value after reset.
3. 16-bit data to be added is written to DODIR. The result of the operation is stored in DODSR.
4. Writing of 16-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), data addition is not performed if a value other than 0x0000 is set in the DODSR register. To perform data addition, set the DODSR register and write a value to be added into the DODIR register. If the DODSR register is set again after data addition, the value remaining in the DODIR register will not be added again to the value set in the DODSR register. That is, addition proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

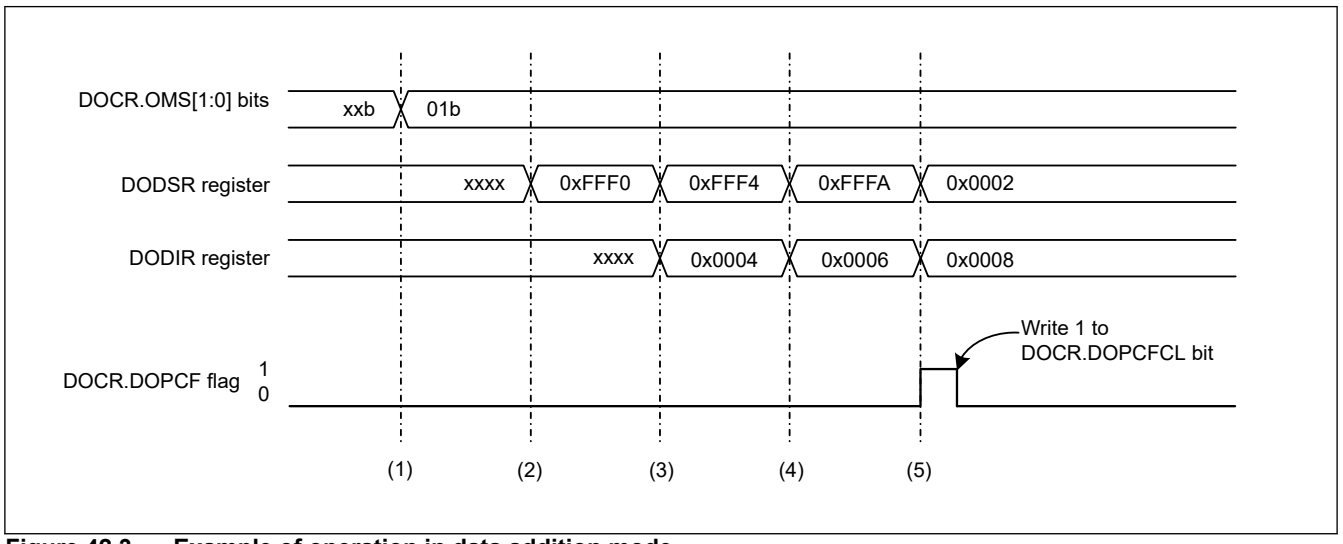

Figure 42.3 Example of operation in data addition mode

42.3.3 Data Subtraction Mode

Figure 42.4 shows an example of the steps involved in data subtraction mode operation by the data operation circuit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 16-bit data is set in the DODSR register as the value after reset.
3. 16-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR.
4. Writing of 16-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), data subtraction is not performed if a value other than 0x0000 is set in the DODSR register. To perform data subtraction, set the DODSR register and write a value to be subtracted into the DODIR register. If the DODSR register is set again after data subtraction, the value remaining in the DODIR register will not be subtracted again from the value set in the DODSR register. That is, subtraction proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

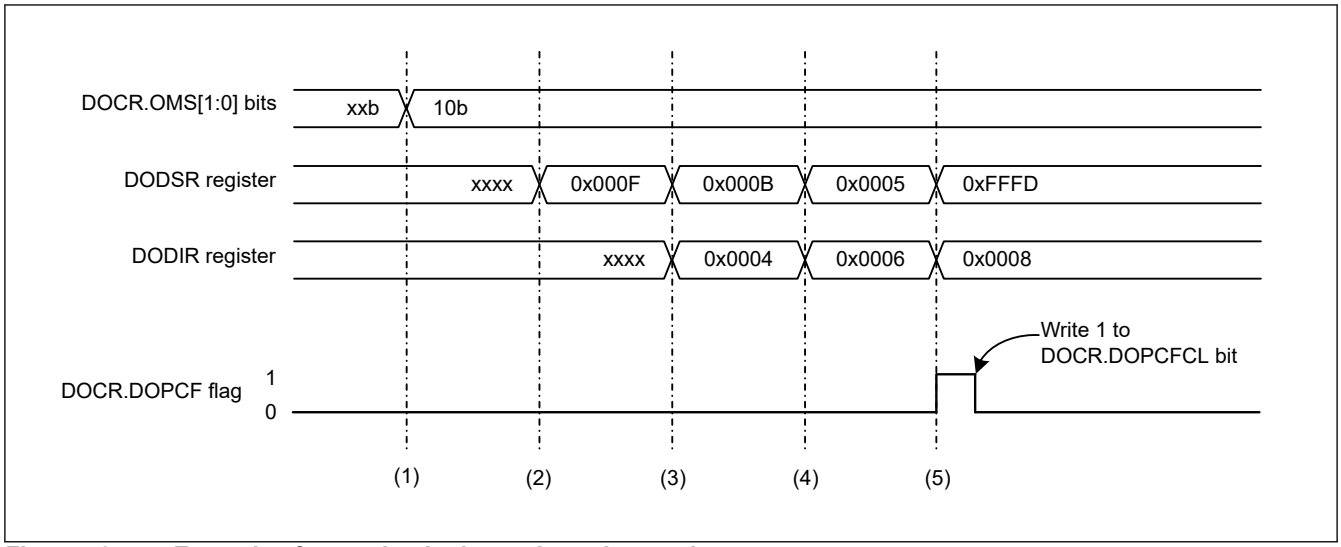

Figure 42.4 Example of operation in data subtraction mode

42.4 Interrupt Requests

The data operation circuit generates the data operation circuit interrupt as an interrupt request. When an interrupt source is generated, the data operation circuit flag (DOCR.DOPCF) corresponding to the interrupt is set to 1. Table 42.2 describes the interrupt request.

Table 42.2 Interrupt request from data operation circuit

Interrupt request	Data operation circuit flag	Interrupt generation timing
Data operation circuit interrupt	DOPCF	• The result of data addition is greater than 0xFFFF • The result of data subtraction is less than 0x0000 • The compared values either match or mismatch

42.5 Usage Note

42.5.1 Module Stop Function Setting

Operation of the data operation circuit can be disabled or enabled using module stop control register D (MSTPCRD). The value after reset indicates that the data operation circuit is in the stop state. Register access is enabled by canceling the module-stop state. For details, see section 8, Low-Power Consumption Function.

43. System SRAM (SYSRAM)

43.1 Overview

The LSI has an on-chip high-speed RAM (with ECC error correction). The RAM, whose capacity is 1.5 MB (512 KB × 3), is installed. Table 43.1 lists the System SRAM (SYSRAM) specifications and Figure 43.1 shows a block diagram of SYSRAM.

Table 43.1 System SRAM specifications

Parameter	Description
RAM capacity	1.5 MB (512 KB × 3)
Operating frequency	150 MHz or 200 MHz (PCLKH)
RAM address	SYSRAM0: 0x1000_0000 to 0x1007_FFFF SYSRAM1: 0x1008_0000 to 0x100F_FFFF SYSRAM2: 0x1010_0000 to 0x1017_FFFF Each RAM module consists of 4 pages of 128 KB
Shortest Latency	• ECC enabled Writing 32/64/96/128-bit transfer: Latency 0 (write to RAM in 1 cycle) 8/16-bit transfer: Latency 2 (write to RAM in 3 cycles) Reading All data transfer: Latency 2 (read from RAM in 3 cycles) • ECC disabled Writing All data transfer: Latency 0 (write to RAM in 1 cycle) Reading All data transfer: Latency 1 (read from RAM in 2 cycles)
Error checking	7-bit ECC data to 32-bit RAM data 1-bit error correction and 2-bit error detection are supported.
Interrupts	3 interrupts are available for each SYSRAMn. They can be used as error events.
Bus error response	SLVERR is returned to the access to the System SRAM. • Write access occurs when write access is disabled by VLWEN bit. • Write or read access occurs when access is disabled by VCEN bit. • Write access occurs when write access is disabled by VRWEN bit to corresponding page. • 2-bit ECC error occurs when read access is done. This response is maskable.
Test function (by error injection)	• Register values can be used as test data to be written to RAM, those in ECEDB[31:0] to the RAM data section and ECERDB[6:0] to the ECC redundancy bit section, respectively. • The ECC redundancy bits included in the RAM data are retained and read as a register value. • The ECC redundancy bits (encoder circuit) generated from the input data and the syndrome code (decoder circuit) can be checked.
Initializing function	Supported

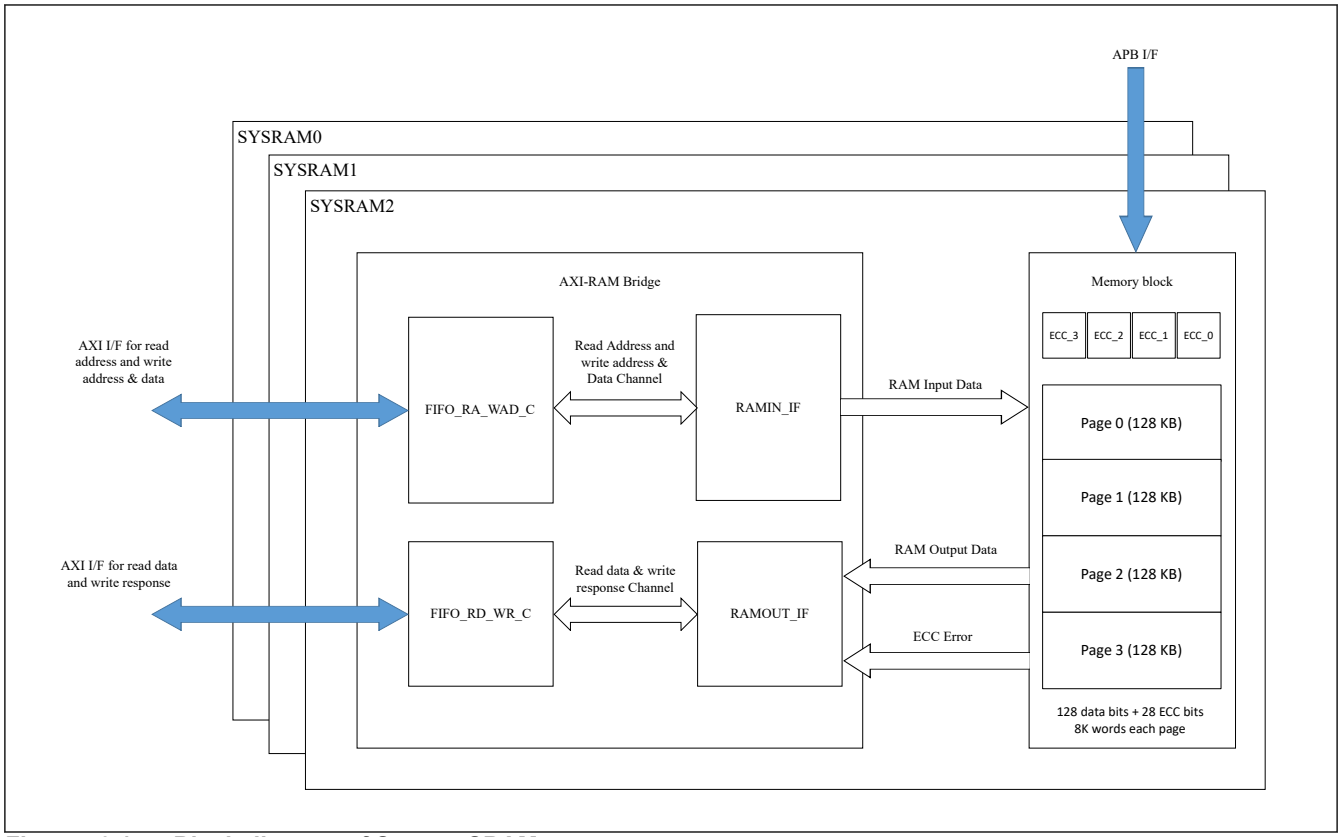

Figure 43.1 Block diagram of System SRAM

43.2 Register Descriptions

43.2.1 SYSRAM_CTRLn : System SRAM Control Register n (n = 0 to 2)

Base address: SYSRAM_CTL = 0x8128_1800

Offset address: 0x000 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MKICCAXIERR	—	—	VLWEN	VCEN	VRWEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	1	0	0	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VECEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	VECEN	Enables or disables error correction with ECC 0: Disabled 1: Enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
19:16	VRWEN[3:0]	Enables write for each page of RAM The bit n corresponds to the page n (n = 0 to 3). 0: Disabled 1: Enabled	R/W

Bit	Symbol	Function	R/W
20	VCEN	Enables access to RAM 0: Disabled 1: Enabled	R/W
21	VLWEN	Enables write for RAM 0: Disabled 1: Enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	MKICCAXIERR	Controls AXI-SLVERR issuance for ECC 2-bit errors 0: Issue AXI-SLEVER 1: Do not issue AXI-SLEVER	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The SYSRAM_CTRLn register is a 32-bit register that controls ECC of the SYSRAMn.

43.2.2 Wn_EC710CTL : ECC Control Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 2)

Offset address: 0x000 + 0x040 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ECEDF7[1:0]		ECEDF6[1:0]		ECEDF5[1:0]		ECEDF4[1:0]		ECEDF3[1:0]		ECEDF2[1:0]		ECEDF1[1:0]		ECEDF0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EMCA[1:0]		—	—	ECOVFF	ECER2C	ECER1C	—	ECTHM	ECERVF	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	ECEMF	ECC Error Indicate Flag Indicates that an error is detected in the current read data. This bit is updated for each 32-bit RAM output data. When ECC error determination is disabled (ECERVF = 0) or the ECC function through mode is set (ECTHM = 1), this bit is always 0. 0: No error is detected in the current read data 1: An error is detected in the current read data	R
1	ECER1F	1-Bit ECC Error Detection/Correction Flag Indicates that a 1-bit error is detected and corrected in the 32-bit read data plus 7 ECC bits (total 39 bits) while the ECC error determination is enabled. 0: 1-bit error has not occurred 1: 1-bit error has occurred*1	R
2	ECER2F	2-Bit ECC Error Detection Flag Indicates that a 2-bit error is detected in the 32-bit read data plus 7 ECC bits (total 39 bits) while the ECC error determination is enabled. 0: 2-bit error has not occurred 1: 2-bit error has occurred*2	R
3	EC1EDIC	1-Bit ECC Error Detection Interrupt Control Enables or disables to output an interrupt signal (SRAMn_IE1) on detection of a 1-bit ECC error. 0: Disables to output an interrupt signal 1: Enables to output an interrupt signal	R/W
4	EC2EDIC	2-Bit ECC Error Detection Interrupt Control Enables or disables to output an interrupt signal (SRAMn_IE2) on detection of a 2-bit ECC error. 0: Disables to output an interrupt signal 1: Enables to output an interrupt signal	R/W

Bit	Symbol	Function	R/W
5	EC1ECP	1-Bit ECC Error Correction Enable Enables or disables error correction when a 1-bit ECC error is detected. 0: Error correction is performed on detection of a 1-bit ECC error 1: Error correction is not performed on detection of a 1-bit ECC error	R/W
6	ECERVF	ECC Error Determination Enable To change this bit, it is necessary to write 01b to bits 15 and 14 at the same time to permit writing. 0: The error determination is disabled 1: The error determination is enabled. The ECC function according to EC1EDIC, EC2EDIC, and EC1ECP bits are enabled.	R/W
7	ECTHM	ECC Function Through Mode Enable Enables or disables ECC function Through mode. If Through mode is enabled, no ECC error determination and no error correction is performed. To change this bit, it is necessary to write 01b to bits 15 and 14 at the same time to permit writing. 0: Disables Through mode 1: Enables Through mode. No effect on encoder. Decoder does not determine the error and does not perform error correction.	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
9	ECER1C	1-Bit ECC Error Detection Clear Clears the 1-bit ECC error detection flag and the error address related flags for the 32-bit read data. Writing 1 to this bit clears the ECER1F, ECOVFF, and ECEDF7[1:0] to ECEDF0[1:0] bits. When a conflict occurs between 1-bit ECC error detection and writing 1 to this bit, writing to this bit is given priority and the 1-bit ECC error detection flag is not set.	R/W
10	ECER2C	2-Bit ECC Error Detection Clear Clears the 2-bit ECC error detection flag and the error address related flags for the 32-bit read data. Writing 1 to this bit clears the ECER2F, ECOVFF, and ECEDF7[1:0] to ECEDF0[1:0] bits. When a conflict occurs between 2-bit ECC error detection and writing 1 to this bit, writing to this bit is given priority and the 2-bit ECC error detection flag is not set.	R/W
11	ECOVFF	ECC Error Address Capture Overflow Flag Indicates that the error address fails to be stored in the ECC error address register when an ECC error occurs. When an ECC error address capture overflow occurs, SRAMn_OVF interrupt is output. If an ECC error address capture overflow occurs again while this flag is 1, SRAMn_OVF interrupt is output again. 0: ECC error address capture overflow has not occurred 1: ECC error address capture overflow has occurred	R
13:12	—	These bits are read as 0. The write value should be 0.	R/W
15:14	EMCA[1:0]	Access Control to ECC Mode Selection Setting these bits to 01b enables writing to bits 7 and 6 of this register. Otherwise, writing to bits 7 and 6 is ignored. These bits are always read as 00b. 0 1: Writing is enabled Others: Writing is disabled	R/W
17:16	ECEDF0[1:0]	ECC Error Address Capture Flag m (m = 0) Indicates the error address register and the error type. When an ECC error occurs and its error type can be identified, the following value is read from these bits. 0 0: ECC error address is not captured in Wn_EC710EADm 0 1: 1-bit ECC error address is captured in Wn_EC710EADm 1 0: 2-bit ECC error address is captured in Wn_EC710EADm	R
19:18	ECEDF1[1:0]	ECC Error Address Capture Flag m (m = 1) This function is the same as ECEDF0.	R
21:20	ECEDF2[1:0]	ECC Error Address Capture Flag m (m = 2) This function is the same as ECEDF0.	R
23:22	ECEDF3[1:0]	ECC Error Address Capture Flag m (m = 3) This function is the same as ECEDF0.	R
25:24	ECEDF4[1:0]	ECC Error Address Capture Flag m (m = 4) This function is the same as ECEDF0.	R

Bit	Symbol	Function	R/W
27:26	ECEDF5[1:0]	ECC Error Address Capture Flag m (m = 5) This function is the same as ECEDF0.	R
29:28	ECEDF6[1:0]	ECC Error Address Capture Flag m (m = 6) This function is the same as ECEDF0.	R
31:30	ECEDF7[1:0]	ECC Error Address Capture Flag m (m = 7) This function is the same as ECEDF0.	R

Note 1. When a 1-bit ECC error is detected while EC1EDIC bit is 1 and ECER1F bit is 0, SRAMn_IE1 interrupt is output. If a 1-bit ECC error is detected while the ECER1F bit is already 1, the SRAMn_IE1 interrupt is not output.

Note 2. When a 2-bit ECC error is detected while EC2EDIC bit is 1 and ECER2F bit is 0, SRAMn_IE2 interrupt is output. If a 2-bit ECC error is detected while the ECER2F bit is already 1, the SRAMn_IE2 interrupt is not output.

The Wn_EC710CTL register indicates operation settings and error status at the time of an ECC error occurrence.

Because RAM block consists of 128-bit data width but ECC is controlled on a 32-bit basis, the highest-order 32 bits are controlled by the W3_EC710CTL register and the lowest-order 32 bits by the W0_EC710CTL register. Do not write to the control bits (bits 7 to 3) of this register while AXI access is in progress.

43.2.3 Wn_EC710TMC : ECC Test Mode Control Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 2)

Offset address: 0x004 + 0x040 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECREIS	ECC Redundancy Bit Input Data Select Selects whether the ECERDB[6:0] bits value or the ECC data in RAM is to be input to the decoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: ECC data read from RAM is input to the decoder 1: The value of the ECERDB[6:0] bits is input to the decoder	R/W
1	ECDCS	ECC Decode Input Select Selects whether the Wn_EC710TED register value or the RAM output data is to be input to the decoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: RAM output data is input to the decoder 1: The value of the Wn_EC710TED register is input to the decoder	R/W
2	ECENS	ECC Encode Input Select Selects whether the input data to RAM or the Wn_EC710TED register value is to be input to the encoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: Data input to RAM is selected 1: The value of the Wn_EC710TED register is selected	R/W

Bit	Symbol	Function	R/W
3	ECREOS	ECC Redundancy Bit Output Data Select Selects whether the ECC encoder output data or the value of the ECERDB[6:0] bits in the Wn_EC710TRC register is to be output as the ECC output. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: The encoded result of the encoder is output 1: The value of the ECERDB[6:0] bits in the Wn_EC710TRC register is output	R/W
4	ECTRRS	RAM Read Test Mode Select If 1 is set, read value of Wn_EC710TED register is 32-bit output data from RAM and read value of the Wn_EC710TRC.ECERDB[6:0] bits is 7 redundancy bits input to RAM. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: Read value is the written value for the Wn_EC710TED register and the Wn_EC710TRC.ECERDB[6:0] bits 1: Read value of Wn_EC710TED register is 32-bit output data from RAM and read value of the Wn_EC710TRC.ECERDB[6:0] bits is 7 redundancy bits input to RAM	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	ECTMCE	Test Mode Enable Enables or disables access to the test register and the test control register. When writing to this bit, it is necessary to set bits 15 and 14 of this register to 10b. If bits 15 and 14 are not 10b, writing to this bit is ignored. 0: Disables access to the test mode register and its bits 1: Enables access to the test mode register and its bits	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W
15:14	ETMA[1:0]	ECTMCE Write Enable When these bits are 10b, writing to the ECTMCE bit is enabled. Any settings other than 10b disables writing to the ECTMCE bit. These bits are always read as 00b. 1 0: Writing is enabled Others: Writing is disabled	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The Wn_EC710TMC register is used to switch over to and control the ECC function test mode. Do not write to this register while AXI access is in progress.

43.2.4 Wn_EC710TRC : ECC Redundancy Bit Data Control Test Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 2)

Offset address: 0x008 + 0x040 × n

Bit position:	31	30						24	22						16	14						8	6						0
Bit field:	—	ECSYND[6:0]							—	ECHORD[6:0]							—	ECECRD[6:0]							—	ECERDB[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	ECERDB[6:0]	ECC Redundancy Bit Input/Output Substitute Buffer Register Handling of this register differs according to the setting of the associated register bits as follows: • Wn_EC710TMC.ECTMCE = 1: This register holds the substitute data for use as the value for the redundancy bit. • Wn_EC710TMC.ECREOS = 1: The value in this register substitutes for the redundancy bit value from the encoder and is written to the RAM. • Wn_EC710TMC.ECREIS = 1: The value in this register substitutes for the redundancy bit value from the RAM and is input to the decoder. • Wn_EC710TMC.ECTRRS = 1: The value read from this register is the input data to be supplied to the RAM. The value written in this register is not read.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
14:8	ECECRD[6:0]	ECC Encode Test Register When Wn_EC710TMC.ECTMCE = 1, the redundancy bit value generated in the encoder circuit is read from this register. Note that the read value is that from the encoder as is, for example, the encoded result of the data which was input to the encoder circuit. On the other hand, the value to be written to the RAM is the data output from the encoder circuit with its lower-order 2 bits inverted.	R
15	—	This bit is read as 0. The write value should be 0.	R/W
22:16	ECHORD[6:0]	ECC 7-Redundancy-Bit Data Retain Test Register When Wn_EC710TMC.ECTMCE = 1, 7 redundancy bits read from the RAM are stored in this register at the next clock cycle for the RAM read access. In addition, ECC 7-Redundancy-Bit Data is stored in the next clock cycle when Wn_EC710TED register is read if Wn_EC710TMC.ECTRRS = 1.	R
23	—	This bit is read as 0. The write value should be 0.	R/W
30:24	ECSYND[6:0]	ECC Decode Syndrome Register When Wn_EC710TMC.ECTMCE = 1, the syndrome code generated in the decoder circuit is read from this register. When Wn_EC710TMC.ECTMCE = 0, all 0s are read. The value of this register varies according to changes of decoder input value.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

The Wn_EC710TRC register controls ECC redundancy bits. The value read from this register is valid only when Wn_EC710TMC.ECTMCE = 1, and always 0s when Wn_EC710TMC.ECTMCE = 0.

43.2.5 Wn_EC710TED : ECC Encode/Decode Input/Output Switchover Test Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 2)

Offset address: 0x00C + 0x040 × n

Bit position:	31																												0
Bit field:	ECEDB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECEDB[31:0]	32-Bit Data Test Register for ECC Encode/Decode In the test mode, the data of this register is used as the input to the encoder/decoder circuit. When Wn_EC710TMC.ECTRRS = 1, the value read from this register is the value of the data output from RAM. This register is readable and writable when Wn_EC710TMC.ECTMCE = 1. When Wn_EC710TMC.ECTMCE = 0, synchronous clearing occurs.	R/W

The Wn_EC710TED register handles ECC redundancy bits.

43.2.6 Wn_EC710EADm : ECC Error Address m Register n (n = 0 to 3, m = 0 to 7)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 2)

Offset address: 0x010 + 0x040 × n + 0x004 × m

Bit position:	31															14													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECEAD[14:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	ECEAD[14:0]	Bit Error Address Retain the address where a 1-bit or 2-bit ECC error was detected.	R
31:15	—	These bits are read as 0.	R

The Wn_EC710EADm registers are read-only registers that retain the values of addresses where ECC errors have occurred.

43.3 Operation

43.3.1 Initialization

RAM initialization function initializes the data and redundancy bit area during reset sequence automatically.

43.3.2 Access Cycle to System SRAM with ECC Function Enabled

Read

Read access cycle when the ECC function is enabled is one cycle longer than the case when the ECC function is disabled regardless of access size.

Write

8/16-bit write access cycle when the ECC function is enabled is two cycles longer than the case when the ECC function is disabled. 32/64/96/128-bit write access cycle when the ECC function is enabled is the same as the case when the ECC function is disabled.

43.3.3 ECC Error Address Calculation Method

An ECC error address is stored as a relative address in the ECC Error Address Register (Wn_EC710EADm). To convert a relative address to an absolute address, follow the calculation formula shown in Table 43.2.

Table 43.2 ECC error address calculation formula

Register	ECC error address calculation formula
W0_EC710EAD0 to W0_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x0
W1_EC710EAD0 to W1_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x4
W2_EC710EAD0 to W2_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x8
W3_EC710EAD0 to W3_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0xC

Note: i = 0 to 2

43.3.4 Notes on ECC Error Address Register

When 1-bit or 2-bit errors occur, up to 8 addresses where such errors have occurred are saved in the Wn_EC710EAD0 to Wn_EC710EAD7 registers in this order.

If the retained error address is detected again due to the same error cause, it is not retained this time. When the same address is detected due to a different error cause, it is saved if there is an empty register.

If a 2-bit error is detected when all the error address registers are filled with addresses of 1-bit errors, the Wn_EC710EAD7 register is overwritten with the error address where the 2-bit error occurred. At this time, the status register indicating the error flag information is not overwritten.

When storage of 8 or more error addresses is attempted, an overflow interrupt occurs. Clear the flag when the overflow interrupt occurs or every time a 1-bit error occurs.

43.3.5 Notes on ECC Error Detection

When a 1-bit or 2-bit error is detected, information of up to 8 errors can be stored in the ECC error information storage registers Wn_EC710CTL.ECEDFm[1:0] (m = 0 to 7), Wn_EC710CTL.ECOVFF, Wn_EC710CTL.ECER2F, Wn_EC710CTL.ECER1F, and Wn_EC710EADm (m = 0 to 7) in the ascending order of register numbers.

Note that operation differs depending on the storage state of ECC error information.

Note: 1. The ECC error information storage state is determined by every 32 bits. When an ECC error occurs in the least significant 32 bits, ECC error storage state is determined by the W0_EC710CTL register bits and the W0_EC710EADm register. When an ECC error occurs in the most significant 32 bits, ECC error storage state is determined by the W3_EC710CTL register bits and the W3_EC710EADm register.
2. When a 2-bit error is detected, immediately conduct the error processing and operate the ECER2C and ECER1C registers to clear error flags and the registers related to error address.
3. When storage of 8 or more error addresses is attempted, an overflow interrupt occurs. When an overflow interrupt occurs, immediately conduct the error processing and operate the ECER2C and ECER1C registers to clear error flags and the registers related to error address.

(1) When there are empty ECC error information storage registers

The error type and error address are stored in an empty register with the smallest number. At this time, the ECC error occurred causes the 1-bit ECC error detection/correction flag (ECER1F) or the 2-bit ECC error detection flag (ECER2F) to change from 0 to 1, and an interrupt signal to be output if the corresponding Interrupt Control register (EC1EDIC or EC2EDIC) enables interrupt output.

Error type:	Error type is stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	ECC error address is stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	When 1-bit ECC error is detected: 1-bit ECC Error Detection/Correction flag (ECER1F) is set to 1. When 2-bit ECC error is detected: 2-bit ECC Error Detection flag (ECER2F) is set to 1.

Note: n = 0 to 3, m = 0 to 7.

(2) When there are no empty ECC error information storage registers (when 1-bit ECC error is detected)

When a 1-bit ECC error is detected, only the ECC Error Address Capture Overflow flag (ECOVFF) is set to 1 in the ECC Error Information Storage register.

At this time, the 1-bit ECC error occurred causes an ECC error address capture overflow interrupt to be generated.

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	ECC error address is not stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	ECC Error Address Capture Overflow flag (ECOVFF) is set to 1

Note: n = 0 to 3, m = 0 to 7.

(3) When there are no empty ECC error information storage registers (when 2-bit ECC error is detected)

When a 2-bit ECC error is detected, operation depends on the state of the 2-bit Error Detection flag (ECER2F) at the detection time.

When ECER2F = 0 on detection of a 2-bit ECC error

If the 2-bit ECC Error Detection flag (ECER2F) is 0 when the error is detected, all ECC error information storage registers are full of 1-bit ECC errors. In this case, only the error address is overwritten in the ECC Error Address register (Wn_EC710EADm).

At this time, the 2-bit ECC error occurred causes the following to occur:

- ECC error capture overflow interrupt
- 2-bit ECC error detection interrupt (EC2EDIC = 1: Interrupt output enabled)

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	2-bit ECC error address is overwritten in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	2-bit ECC Error Detection flag (ECER2F) is set to 1. ECC Error Address Capture Overflow flag (ECOVFF) is set to 1.

When ECER2F = 1 on detection of a 2-bit ECC error

If the 2-bit Error Detection flag (ECER2F) is 1 when the error is detected, only the ECC Error Address Capture Overflow flag (ECOVFF) is set to 1 in the ECC Error Information Storage register.

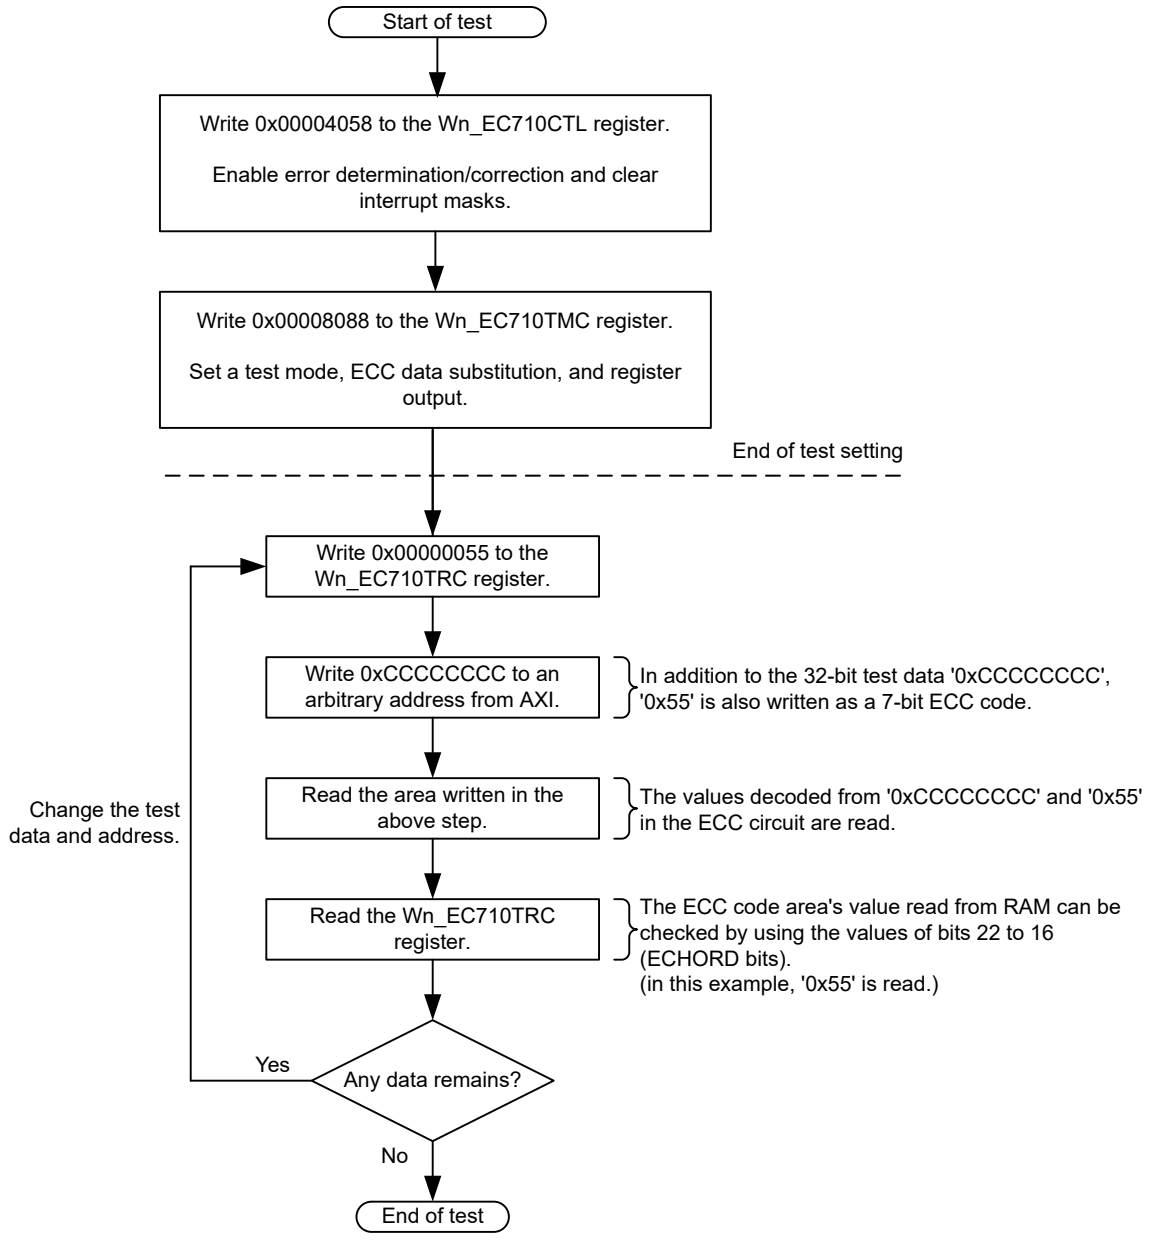
At this time, the 2-bit ECC error occurred causes an ECC error capture overflow interrupt to occur.

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	2-bit ECC error address is not stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	ECC Error Address Capture Overflow flag (ECOVFF) is set to 1

Note: n = 0 to 3, m = 0 to 7.

43.3.6 Test Function (Error Injection)

System SRAM has the error injection function, a facility to test the ECC function. The ECC errors intentionally generated by using the test registers are written to the target RAM area for checking the ECC function without involving the ECC circuit. Figure 43.2 shows an example of test flowchart.



Note: The value of the Wn_EC710CTL register is an example. Use an appropriate value according to the test conditions and purpose.

Figure 43.2 Flowchart example of ECC error injection test

43.3.7 Interrupt

When ECC error occurs, interrupt can be output. Table 43.3 lists the System SRAM interrupt sources. These interrupts are combined to peripheral error interrupts (PERI_ERR0 and PERI_ERR1) as error events with other error interrupts.

Table 43.3 System SRAM interrupt sources

Name	Interrupt sources	CPU0 GIC request	DMAC activation
SRAMn_IE1	System SRAMn ECC 1 bit error	Possible*1	Not possible
SRAMn_IE2	System SRAMn ECC 2 bits error	Possible*1	Not possible
SRAMn_OVF	System SRAMn ECC error address capture overflow	Possible*1	Not possible

Note: n = 0 to 2

Note 1. These are not directly connected to CPU GIC but through peripheral error interrupts (PERI_ERR0 and PERI_ERR1).

43.4 Usage Notes

43.4.1 Release of Register Write Protection

SYSRAM_CTRLn registers are write protected. These registers are used to release write protection, use the following steps.

1. Write 0x0000A508 to PRCRS register (release write protection by PRC3 bit).
2. Write value to protection register.
3. Write 0x0000A500 to PRCRS register (set write protection by PRC3 bit).

43.4.2 Note on Setting the Register

All bus masters must not access System SRAM while a register of this module is being set.

43.4.3 Access in Bit Size Units

This module performs ECC determination process on a 32-bit basis. If access is made on an 8/16-bit basis, the module performs the following operations:

8/16-bit reading

1. After reading 32 bits of data, this module performs ECC determination.
2. To the read requesting bus master, this module returns 8/16-bit data.

8/16-bit writing

1. This module reads 32 bits of data from the write-target address and performs ECC determination.
2. On the read-out 32 bits, this module overwrites new 8/16-bit data.
3. After attaching ECC data to the write-target 32-bit data of step 2., this module writes them to the System SRAM.

44. One-Time Programmable Memory (OTP)

44.1 Overview

This LSI has one-time programmable memory (OTP). Various information is stored or can be additionally stored in OTP. Data written in OTP can't be overwritten. OTP is shared with product configuration parameters which cannot be accessed by user. Then, all the areas are not accessible from CPU.

Table 44.1 lists the OTP specifications and Figure 44.1 shows a block diagram of the OTP.

Table 44.1 OTP Specifications

Item	Description
Number of units	1 unit
Functionality	• Bit width: 16-bit • Word size: 512-word • Register I/F to read or write OTP • WORDLOCK and non WORDLOCK area available – WORDLOCK area protects change of unwritten bit. – Non WORDLOCK area allows additional write to unwritten bit. • Overwrite protection • Redundancy support • Power down mode support
Available information (Non-security support product)	• Unique ID • JTAG authentication ID and setting • SCI/USB boot authentication ID and setting • Anti-rollback counter • Part number • Product Version • RGMII TX clock delay OSC mode clock count • RGMII RX clock delay OSC mode clock count • SHOSTIF boot mode setting • PHOSTIF boot mode setting • User area

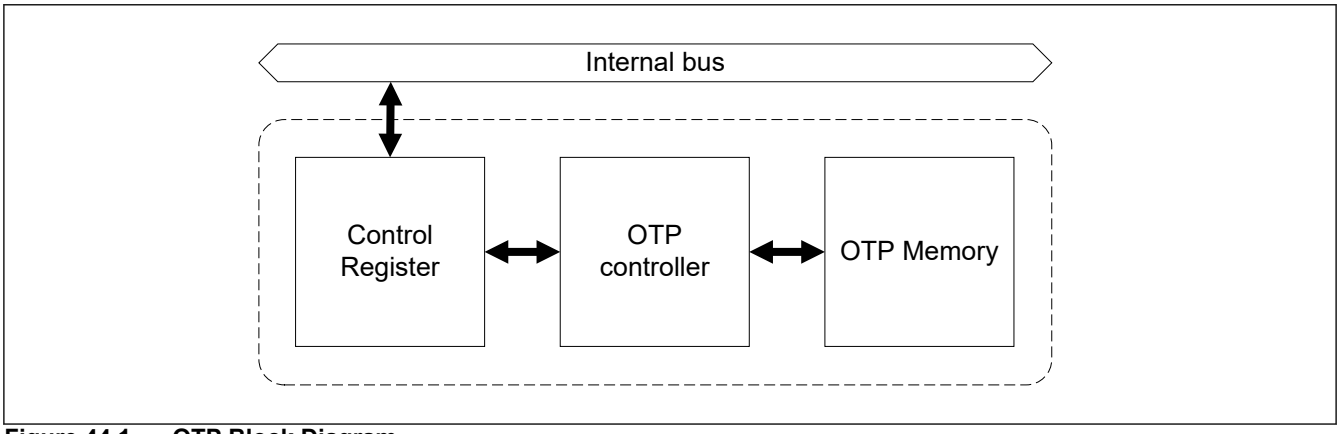


Figure 44.1 OTP Block Diagram

44.2 Register Descriptions

44.2.1 OTPPWR : OTP Power Control Register

Base address: OTP = 0x8102_8000

Offset address: 0x00

Bit position:	31																											4				0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACCL	—	—	—	PWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	PWR	OTP power on/off setting 0: Power off 1: Power on	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	ACCL	Selects OTP access I/F 0: Not selected 1: Selected	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

OTPPWR register controls the power of OTP and provides a valid access path.

If 0 is written to PWR bit during write access to OTP, OTP powers off after write access is complete. PWR bit cannot be changed during read access to OTP.

Change ACCL bit when OTP access is stopped (CNT_ST_IDLE bit in OTPSTR register is 1).

When OTP access is requested while ACCL bit is 0, the access request is ignored and ERR_RP bit in OTPSTR register is asserted.

44.2.2 OTPSTR : OTP Access Status Register

Base address: OTP = 0x8102_8000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CNT_ST_IDLE	—	—	—	—	—	ERR_RDY_RD	ERR_RDY_WR	—	—	—	ERR_RP	ERR_WP	ERR_WR[1:0]		CMD_RDY
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMD_RDY	Indicates whether OTP controller is ready to receive command or not. 0: Not ready 1: Ready	R
2:1	ERR_WR[1:0]	OTP write status 0 0: PASS 0 1: Fail due to overwrites 1 0: Fail due to compare mismatch 1 1: Fail due to overwrites and compare mismatch	R

Bit	Symbol	Function	R/W
3	ERR_WP	Write protection error This bit is set to 1 when OTP write access is issued to the write prohibited area. Cleared at the start of the next OTP write command.	R
4	ERR_RP	Read protection error This bit is set to 1 when OTP read access is issued to the read prohibited area. Cleared at the start of the next OTP read command.	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_RDY_WR	OTP write command ready error This bit is set to 1 when OTP write access is issued during CMD_RDY = 0. Cleared by writing 0 on this bit. Writing 1 is ignored.	R/W
9	ERR_RDY_RD	OTP read command ready error This bit is set to 1 when OTP read access is issued during CMD_RDY = 0. Cleared by writing 0 on this bit. Writing 1 is ignored.	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	CNT_ST_IDLE	Indicates status of OTP controller 0: Busy 1: Idle	R
31:16	—	These bits are read as 0. The write value should be 0.	R/W

OTPSTR register indicates status of command ready and error.

44.2.3 OTPSTAWR : OTP Write Command Register

Base address: OTP = 0x8102_8000

Offset address: 0x08

Bit position:	31																														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STAWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STAWR	OTP write start By writing 1 to this bit, the OTP write command is issued and writing data to OTP is started. This bit is automatically cleared after the OTP write command is completed. Only 1 can be written to this bit. Writing 0 is ignored.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

OTPSTAWR register is used to issue the OTP write command.

If OTPSTAWR register is set to 1 while write prohibited area is set in the OTPADRWR register, the STAWR bit does not change to 1 and no OTP write access occurs. In this case, ERR_WP bit in OTPSTR register is set to 1.

44.2.4 OTPADRWR : OTP Write Address Register

Base address: OTP = 0x8102_8000

Offset address: 0x0C

Bit position:	31																						8								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADRWR[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

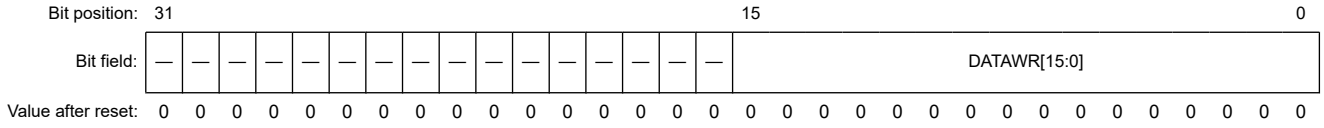
Bit	Symbol	Function	R/W
8:0	ADRWR[8:0]	OTP write address Set the OTP address where data is written. The address to be set is OTP address in a halfword (16-bit) unit.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

OTPADRWR register is used to set the write address to OTP.

44.2.5 OTPDATAWR : OTP Write Data Register

Base address: OTP = 0x8102_8000

Offset address: 0x10



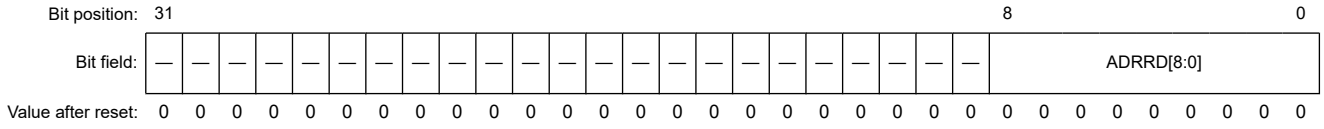
Bit	Symbol	Function	R/W
15:0	DATAWR[15:0]	OTP write data Set the data to be written to the OTP.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

OTPDATAWR register is used to set the write data to OTP.

44.2.6 OTPADRRD : OTP Read Address Register

Base address: OTP = 0x8102_8000

Offset address: 0x14



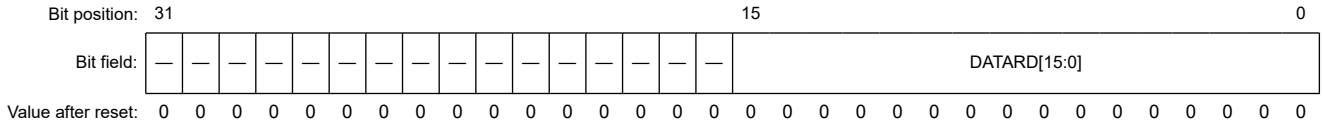
Bit	Symbol	Function	R/W
8:0	ADRRD[8:0]	OTP read address Set the OTP address where data is read. The address to be set is OTP address in a halfword (16-bit) unit. After reading data from the OTP, the address set in this register is automatically incremented. By reading this register, the incremented address can be read. However, if read error (ERR_RP or ERR_RDY_RD in OTPSTR register) occurs, it will not be incremented. Set a different address.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

OTPADRRD register is used to set the read addresses to OTP.

44.2.7 OTPDATARD : OTP Read Data Register

Base address: OTP = 0x8102_8000

Offset address: 0x18



Bit	Symbol	Function	R/W
15:0	DATARD[15:0]	OTP read data OTP data in address specified by the OTPADRRD register can be read.	R
31:16	—	These bits are read as 0.	R

OTPDATARD register stores read data from OTP.

OTP read access is not performed when the OTPDATARD register is read while ACCL bit in OTPPWR register is 0 or read prohibited area is set in the OTPADRRD register. In this case, the ERR_RP bit of the OTPSTR register is set and the read value from this register is 0.

44.3 OTP Memory Map

Data width of OTP is 16-bit, and its address is not memory mapped. Dedicated address (0x000 to 0x1FF) is defined to access OTP. Table 44.2 shows OTP memory map in non-security support product. Various information is stored or can be stored in OTP. Address not listed in Table 44.2 is reserved and do not access reserved area.

In OTP, unwritten bit is 0 and written bit is 1. There are two kinds of address attribution, WORDLOCK applied address and WORDLOCK not-applied address.

- WORDLOCK applied address

Only one time write of 16-bit data including 0 and 1 is permitted. Once writing to the address, not only written bits but also unwritten bits can't be written again. That means the address is read-only. All 16-bit 0 write is also supported. After writing, write to the address is impossible longer.

- WORDLOCK not-applied address

Write 1 to the unwritten bit is possible even if the write address is the same. Write can be divided to multiple times as long as the write bit is unwritten yet. Set 0 to the bit which is not needed to write.

Table 44.2 OTP memory map in non-security support product

Area	Bit width	Start address	End address	WORDLOCK	Initial property
Unique ID	64	0x089	0x08C	—	R
JTAG authentication mode	3	0x091	0x091	No	R/W
JTAG authentication level 1 plaintext ID	128	0x093	0x09A	Yes	W
JTAG authentication level 2 plaintext ID	128	0x09B	0x0A2	Yes	W
SCI/USB boot authentication mode	2	0x18D	0x18D	No	R/W
SCI/USB boot authentication plaintext ID	128	0x0A3	0x0AA	Yes	W
Anti-rollback counter	320	0x159	0x16C	No	R/W
Part number	16	0x1A7	0x1A7	—	R
Product Version	16	0x1A9	0x1A9	—	R
RGMII TX clock delay OSC mode clock count	16	0x1B1	0x1B1	—	R
RGMII RX clock delay OSC mode clock count	16	0x1B3	0x1B3	—	R
SHOSTIF boot mode setting	16 × 4	0x1B5	0x1B8	Yes	R/W
PHOSTIF boot mode setting	16 × 4	0x1B9	0x1BC	Yes	R/W
User area	304	0x1BD	0x1CF	Yes	R/W

44.3.1 Unique ID (UID)

Indicates 64-bit unique ID. This area is read-only.

Address(es): 0x089 to 0x08C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ID															
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
15:0	ID	64-bit unique ID 0x089: Unique ID [15:0] 0x08A: Unique ID [31:16] 0x08B: Unique ID [47:32] 0x08C: Unique ID [63:48]	R

Note 1. Value after reset depends on the product variant.

44.3.2 JATG Authentication Mode (AUTHMODEJ)

Specifies how to authenticate JTAG connection.

Address(es): 0x091

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MODE[2:0]	Specifies JTAG authentication mode 0 0 0: No authentication 0 0 1: Authentication level 1 (Both EL2 and EL1/EL0 access permission) 0 1 x: Authentication level 2 (Only EL1/EL0 access permission) 1 x x: Permanent prohibition of JTAG connection	R/W
15:3	—	Reserved	—

44.3.3 JTAG Authentication Level 1 Plaintext ID (JID1P)

Specifies plaintext ID for JTAG authentication level 1. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x093 to 0x09A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ID	128-bit JTAG authentication level 1 plaintext ID 0x093: ID [15:0] 0x094: ID [31:16] 0x095: ID [47:32] 0x096: ID [63:48] 0x097: ID [79:64] 0x098: ID [95:80] 0x099: ID [111:96] 0x09A: ID [127:112]	W

44.3.4 JTAG Authentication Level 2 Plaintext ID (JID2P)

Specifies plaintext ID for JTAG authentication level 2. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x09B to 0x0A2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ID	128-bit JTAG authentication level 2 plaintext ID 0x09B: ID [15:0] 0x09C: ID [31:16] 0x09D: ID [47:32] 0x09E: ID [63:48] 0x09F: ID [79:64] 0x0A0: ID [95:80] 0x0A1: ID [111:96] 0x0A2: ID [127:112]	W

44.3.5 SCI/USB Boot Authentication Mode (AUTHMODES)

Specifies how to authenticate SCI/USB boot connection.

Address(es): 0x18D

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MODE[1:0]	Specifies SCI/USB boot authentication mode 0 0: No authentication 0 1: Authentication 1 x: Permanent prohibition of SCI/USB boot connection	R/W

Bit	Symbol	Function	R/W
15:2	—	Reserved	—

44.3.6 SCI/USB Boot Authentication Plaintext ID (SIDP)

Specifies plaintext ID for SCI/USB boot authentication. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x0A3 to 0x0AA

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ID	128-bit SCI/USB boot authentication plaintext ID 0x0A3: ID [15:0] 0x0A4: ID [31:16] 0x0A5: ID [47:32] 0x0A6: ID [63:48] 0x0A7: ID [79:64] 0x0A8: ID [95:80] 0x0A9: ID [111:96] 0x0AA: ID [127:112]	W

44.3.7 Anti-rollback Counter (ARBC)

This area is used as anti-rollback counter. User can freely use this area to control version of their application. For example, five 64-bit counter for version control of five program modules at firmware update.

Address(es): 0x159 to 0x16C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BIT15	BIT14	BIT13	BIT12	BIT11	BIT10	BIT9	BIT8	BIT7	BIT6	BIT5	BIT4	BIT3	BIT2	BIT1	BIT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	BIT15 to BIT0	Uses as version control	R/W

44.3.8 Part Number (PN)

Indicates part number of the product. This area is read-only.

Address(es): 0x1A7

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PN															
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
15:0	PN	Part number of the product 0x1000 : R9A07G084M08GBG 0x1001 : R9A07G084M04GBG 0x1100: R9A07G084M08GBA 0x1101: R9A07G084M04GBA	R

Note 1. Depends on part number of the product

44.3.9 Product Version (VER)

Indicates product version. This area is read-only.

Address(es): 0x1A9

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VER															
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
15:0	VER	Product version	R

Note 1. Depends on version of the product

44.3.10 RGMII TX Clock Delay OSC Mode Clock Count (TXFCNT)

Indicates 16-bit clock count measured in OSC mode of RGMII TX clock delay module. This area is read-only.

Address(es): 0x1B1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TXFCNT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TXFCNT	16-bit clock count measured in OSC mode of RGMII TX clock delay module	R

44.3.11 RGMII RX Clock Delay OSC Mode Clock Count (RXFCNT)

Indicates 16-bit clock count measured in OSC mode of RGMII RX clock delay module. This area is read-only.

Address(es): 0x1B3

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXFCNT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RXFCNT	16-bit clock count measured in OSC mode of RGMII RX clock delay module	R

44.3.12 SHOSTIF Boot Mode Setting (SHBMS)

Specifies values set in SHOSTIF registers (CTRLR0 and SHCFG registers) when SHOSTIF boot mode.is selected. Four addresses (0x1B5 to 0x1B8) are available. If VALID bit of either address is 1, setting of the valid address is applied. If VALID bits of multiple addresses are 1, setting of the highest address in the valid addresses is applied. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x1B5 to 0x1B8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VALID	—	—	—	—	—	—	—	—	ADDRESSING	BYTESWAP	SPIMODE[1:0]		—	SCPOL	SCPH
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SCPH	Specifies value of SCPH bit in CTRLR0 register.	R/W
1	SCPOL	Specifies value of SCPOL bit in CTRLR0 register.	R/W
2	—	Reserved	—
4:3	SPIMODE[1:0]	Specifies value of SPIMODE[1:0] bits in SHCFG register.	R/W
5	BYTESWAP	Specifies value of BYTESWAP bit in SHCFG register.	R/W
6	ADDRESSING	Specifies value of ADDRESSING bit in SHCFG register.	R/W
14:7	—	Reserved	—
15	VALID	Valid flag Writes 1 to indicate setting values of this area is valid.	R/W

44.3.13 PHOSTIF Boot Mode Setting (PHBMS)

Specifies values set in PHOSTIF registers (PHCFG and PHACC registers) when PHOSTIF boot mode.is selected. Four addresses (0x1B9 to 0x1BC) are available. If VALID bit of either address is 1, setting of the valid addresses is applied. If VALID bits of multiple addresses are 1, setting of the highest address in the valid addresses is applied. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x1B9 to 0x1BC

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VALID	—	—	—	—	—	—	—	—	—	—	—	MODENO[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	MODENO[3:0]	Specifies the operation mode number of the PHOSTIF. See Table 46.3 Allowable combination of operation mode setting bits for Operation Mode No.	R/W
14:4	—	Reserved	—
15	VALID	Valid flag Writes 1 to indicate setting values of this area is valid.	R/W

44.3.14 User Area (USERAREA)

This area can be used by user freely. Since WORDLOCK is applied for this area, one time write of 16-bit data is needed each address.

Address(es): 0x1BD to 0x1CF

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AREA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	AREA[15:0]	Free area which user can use.	R/W

44.4 Operation

44.4.1 Write procedure

Table 44.3 Write procedure

Steps	What to do
A	It is assumed that OTP is in a power-down state. Confirm completion of the power-down process by checking that the PWR bit in OTPPWR register is 0 and the CMD_RDY bit in OTPSTR register is 0.
B	Set the PWR and ACCL bits in OTPPWR register to 1. Confirm if CMD_RDY bit in OTPSTR register is 1 after setting.
C	Set the write address to the OTPADRWR register.
D	Set the data to be written to the OTPDATAWR register.
E	Set 1 to the STAWR bit in OTPSTAWR register.
F	OTP controller starts the OTP write process. CMD_RDY bit changes from 1 to 0. If setting the write-prohibited area to OTPADRWR register, the STAWR bit is not set to 1 and the CMD_RDY bit keeps 1. In this case, ERR_WP bit in the OTPSTR register is set to 1.
G	OTP controller writes the value of OTPDATAWR register to OTP. Note) The values of OTPADRWR and OTPDATAWR registers must be retained until this procedure is completed.
H	Poll the STAWR bit until changing to 0 in order to detect the completion of the write command acceptance.
I	Poll the CMD_RDY bit until changing to 1 in order to detect the completion of the write.
J	Once detecting the CMD_RDY bit is 1, confirm that the ERR_WR bit in the OTPSTR register is not set to 1. Note) If set to 1, OTP write error occurs.
K	When continuing OTP write, repeat step C) and later. When issuing OTP read, refer to step C) and later of Table 44.4. When completing OTP access, confirm stop of the OTP access (CMD_RDY = 1). Then set PWR and ACCL bits in the OTPPWR registers to 0, and wait until CMD_RDY bit is set to 0. Note) Be sure to power down by this procedure if no more access is needed.

Note: WORDLOCK is applied for some areas. The OTP write to the WORDLOCK applied area cannot be divided to multiple times. Set the data to be written to all the bits of OTPDATAWR register only once.
For written bits, the bits retain 1 no matter whether they are written with 0 or 1 again.
Reset while writing OTP is prohibited. That operation is not guaranteed.

44.4.2 Read procedure

Table 44.4 Read procedure (1 of 2)

Steps	What to do
A	It is assumed that OTP is in a power-down state. Confirm completion of the power-down process by checking that the PWR bit in OTPPWR register is 0 and the CMD_RDY bit in OTPSTR register is 0.
B	Set the PWR and ACCL bits in OTPPWR register to 1. Confirm if CMD_RDY bit in OTPSTR register is 1 after setting.
C	Set the read address to the OTPADRRD register.
D	Read the OTPDATARD register.

Table 44.4 Read procedure (2 of 2)

Steps	What to do
E	OTP controller starts the OTP read process. CMD_RDY bit changes from 1 to 0. If setting the read-prohibited area to OTPADRRD register, OTP read process is not performed and the CMD_RDY bit keeps 1. In this case, ERR_RP bit of the OTPSTR register is set to 1.
F	OTP controller reads the data of address set in the OTPADRRD register from OTP. After completion of the process, CPU can receive read data. CMD_RDY bit changes from 0 to 1. Note) Since CPU is waited until completion of the process, polling of CMD_RDY bit is not needed.
G	When continuing OTP read, repeat step C) and later. ● When reading a continuous address (continuous read), repeat step D) and later. The OTPADRRD register is incremented automatically, so no need to change. ● When reading a different address from a continuous address, repeat step C) and later. When issuing OTP write, refer to step C) and later of Table 44.3. When completing OTP access, confirm stop of the OTP access (CMD_RDY = 1). Then set PWR and ACCL bits in the OTPPWR registers to 0, and wait until CMD_RDY bit is set to 0. Note) Be sure to power down by this procedure if no more access is needed.

Note: Continuous read is valid for readable areas. If the read address is changed to the read-prohibited area, OTP read process is not performed and the CMD_RDY bit keeps 1. ERR_RP bit of the OTPSTR register is set to 1.

45. Serial Host Interface (SHOSTIF)

45.1 Overview

This LSI has a serial host interface to connect an external host CPU (SPI master) with up to eight input/output pins. The serial host interface allows an external SPI master to access the internal resources (mainly System SRAM) of this LSI directly. Additionally, the booting of this LSI from the external SPI master is possible.

Figure 45.1 shows a block diagram of the SHOSTIF and Table 45.1 lists the serial host interface specifications.

Table 45.1 SHOSTIF specifications

Parameter	Description
Number of units	1 unit
Functionality	• Serial communication is possible in slave mode • Supported interface: – Motorola Serial Peripheral Interface (4-wire SPI) – Enhanced SPI modes with Dual, Quad or Octal SPI. • Serial clock polarity switching • Serial clock phase switching • Transfer mode: – Single data transfer (SDR) supported – No DDR, data strobe nor data mask supported • All the SPI transfer consists of Instruction phase, Address phase and Data phase: – Command phase: 8 bits — Support read/write, transfer type, wait cycles and data length – Address phase: 24 bits — Aligned to 32-bit data boundary – Data phase: 32 bits × burst length up to 64 • Hardware protocol state machine for transfer management • 32 bits × 64 stage FIFO transmit and receive buffers • Serial clock (sclk_in): Up to 40 MHz
Interrupt source	Maskable interrupt sources. All sources are combined to one interrupt. External output pin is available: • SPI master error • AHB error • Transmit FIFO Empty • Transmit FIFO Underflow • Receive FIFO Full • Receive FIFO Overflow
Accessible area	• System SRAM • Mailbox and Semaphore registers • Serial Host Interface registers
Module-stop function	Module-stop state can be set to reduce power consumption

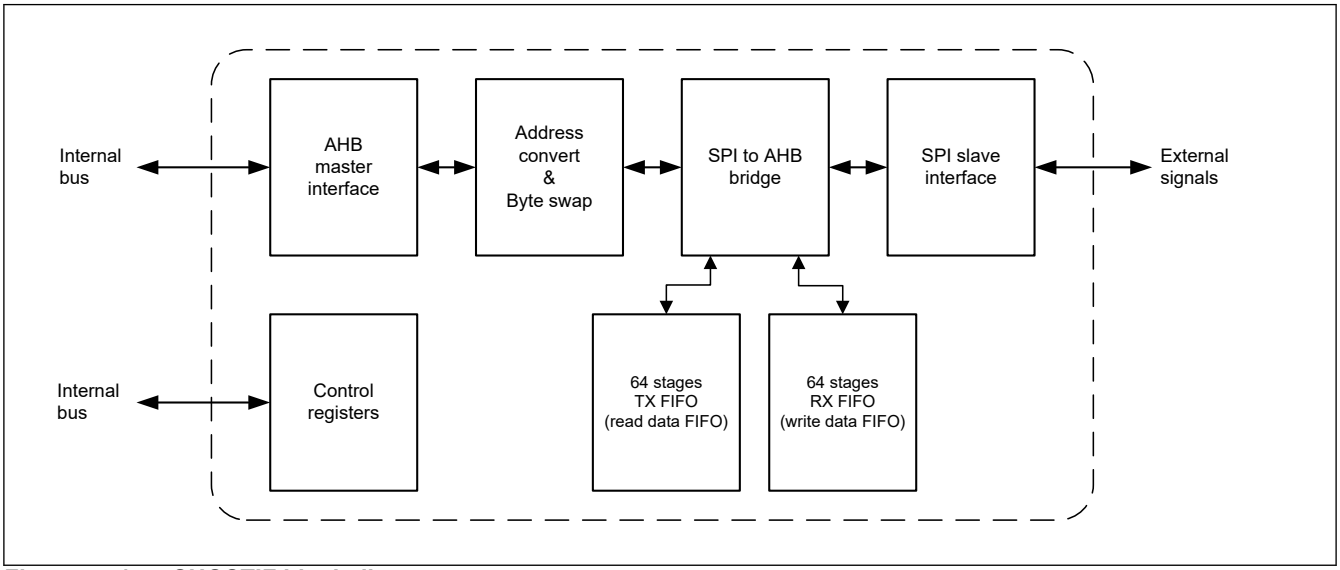


Figure 45.1 SHOSTIF block diagram

Table 45.2 lists the input/output pins of the serial host interface.

Table 45.2 SHOSTIF I/O pins

Name	I/O	Function
HSPI_CK	Input	SHOSTIF Clock input pin
HSPI_CS#	Input	SHOSTIF Chip select input pin
HSPI_IO0	I/O	SHOSTIF Data0 input/output pin
HSPI_IO1	I/O	SHOSTIF Data1 input/output pin
HSPI_IO2	I/O	SHOSTIF Data2 input/output pin
HSPI_IO3	I/O	SHOSTIF Data3 input/output pin
HSPI_IO4	I/O	SHOSTIF Data4 input/output pin
HSPI_IO5	I/O	SHOSTIF Data5 input/output pin
HSPI_IO6	I/O	SHOSTIF Data6 input/output pin
HSPI_IO7	I/O	SHOSTIF Data7 input/output pin
HSPI_INT#	Output	SHOSTIF Interrupt output pin

45.2 Register Descriptions

The register base address is different between external SPI master view and internal memory address view except for SHCFG register.

- External SPI master view (8-bit addressing mode) : SHOSTIF_E08 = 0x18_1000

  Note: When 32-bit addressing mode is used, please shift 8-bit address (base address + offset address) by 2 bits in the right direction.

- Internal memory address view: SHOSTIF = 0x8024_1000
- Internal memory address view for SHCFG: SHOSTIF_CFG = 0x8124_1920

45.2.1 CTRLR0 : Control Register 0

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SCPOL	SCPH	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	SCPH	Serial Clock Phase Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data is captured on the first edge of the serial clock. When SCPH = 1, the serial clock toggles for 1 cycle after the slave select line is activated, and data is captured on the second edge of the serial clock. 0: Serial clock toggles in the middle of the first bit 1: Serial clock toggles at the start of the first bit	R/W

Bit	Symbol	Function	R/W
9	SCPOL	Serial Clock Polarity Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the SPI master is not actively transferring data on the serial bus. 0: Inactive state of the serial clock is low 1: Inactive state of the serial clock is high	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The CTRLR0 register controls the serial data transfer. It is not possible to write to this register when SHOSTIF is enabled (ENR.ENABLE = 1).

45.2.2 ENR : Enable Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ENABLE	SHOSTIF Enable Enables and disables all SHOSTIF operations. When disabled, all serial transfers are halted immediately. Transmit and receive FIFO buffers are cleared when the device is disabled. It is not possible to program some of the SHOSTIF control registers when enabled. When disabled, the SLEEP bit in the SHCFG register is set (after a delay) to inform the system that it is safe to remove the internal clock, thus saving power consumption in the system. 0: Disables SHOSTIF 1: Enables SHOSTIF	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The ENR register enables or disables the serial host interface.

45.2.3 RXFBTR : Receive FIFO Burst Threshold Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RXFBTL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1

Bit	Symbol	Function	R/W
5:0	RXFBTL[5:0]	Receive FIFO Burst Threshold For write operations on SPI slave interface, this register is used to build a burst on AHB master interface. The data is sent in bursts equal to the level specified in this register. If the RXFBTL value is 3 then a burst length of 4 is used for every write transfer. If SHOSTIF receives a burst smaller than the programmed value, then SHOSTIF issues a smaller burst on the AHB interface and completes the transaction. In case of 8-bit addressing mode, do not change from the initial value. In case of 32-bit addressing mode, recommendation value is 0x0F.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The RXFBTR register controls the burst threshold value for AHB interface from RX FIFO.

45.2.4 TXFTLR : Transmit FIFO Threshold Level Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TFT[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TFT[5:0]	Transmit FIFO Threshold Controls the level of entries (or below) at which the transmit FIFO controller triggers an interrupt. The FIFO depth is 64. When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The TXFTLR register controls the threshold value for the transmit FIFO memory.

45.2.5 RXFTLR : Receive FIFO Threshold Level Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x01C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RFT[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	RFT[5:0]	Receive FIFO Threshold Controls the level of entries or above at which the receive FIFO controller triggers an interrupt. The FIFO depth is 64. When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The RXFTLR register controls the threshold value for the received FIFO memory.

45.2.6 SR : Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BUSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUSY	Busy Flag When set, indicates that a serial transfer is in progress. When cleared, indicates that the SHOSTIF is idle or disabled. 0: SHOSTIF is idle or disabled 1: SHOSTIF is actively transferring data	R
31:1	—	These bits are read as 0.	R

The SR register is a read-only register that indicates the current transfer status, FIFO status, and any transmission/reception errors that may have occurred. The Status register may be read at any time. None of the bits in this register request an interrupt.

45.2.7 IMR : Interrupt Mask Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x02C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMEM	AHBEM	TXUIM	—	—	RXFIM	RXOIM	—	—	TXEIM
Value after reset:	0	0	0	0	0	0	1	1	1	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	TXEIM	Transmit FIFO Empty Interrupt Mask 0: txe_intr interrupt is masked 1: txe_intr interrupt is not masked	R/W

Bit	Symbol	Function	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	RXOIM	Receive FIFO Overflow Interrupt Mask 0: rxo_intr interrupt is masked 1: rxo_intr interrupt is not masked	R/W
4	RXFIM	Receive FIFO Full Interrupt Mask 0: rxf_intr interrupt is masked 1: rxf_intr interrupt is not masked	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TXUIM	Transmit FIFO Underflow Mask 0: txu_intr interrupt is masked 1: txu_intr interrupt is not masked	R/W
8	AHBEM	AHB Error Interrupt Mask 0: ahbe_intr interrupt is masked 1: ahbe_intr interrupt is not masked	R/W
9	SPIMEM	SPI Master Error Interrupt Mask 0: spime_intr interrupt is masked 1: spime_intr interrupt is not masked	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The IMR register masks or enables all interrupts generated by the SHOSTIF. Actual interrupt mask is determined by combination with the SHCFG register.

45.2.8 ISR : Interrupt Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMES	AHBES	TXUIS	—	—	RXFIS	RXOIS	—	—	TXEIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1

Bit	Symbol	Function	R/W
0	TXEIS	Transmit FIFO Empty Interrupt Status 0: txe_intr interrupt is not active after masking 1: txe_intr interrupt is active after masking	R
2:1	—	These bits are read as 0.	R
3	RXOIS	Receive FIFO Overflow Interrupt Status 0: rxo_intr interrupt is not active after masking 1: rxo_intr interrupt is active after masking	R
4	RXFIS	Receive FIFO Full Interrupt Status 0: rxf_intr interrupt is not active after masking 1: rxf_intr interrupt is active after masking	R
6:5	—	These bits are read as 0.	R
7	TXUIS	Transmit FIFO Underflow Status 0: txu_intr interrupt is not active after masking 1: txu_intr interrupt is active after masking	R

Bit	Symbol	Function	R/W
8	AHBES	AHB Error Interrupt Status 0: ahbe_intr interrupt is not active after masking 1: ahbe_intr interrupt is active after masking	R
9	SPIMES	SPI Master Error Interrupt Status 0: spime_intr interrupt is not active after masking 1: spime_intr interrupt is active after masking	R
31:10	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of ENR register. The value is 0 when ENR.ENABLE = 0 and 1 when ENR.ENABLE = 1.

The ISR register reports the status of the SHOSTIF interrupts after they are masked.

45.2.9 RISR : Raw Interrupt Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMER	AHBER	TXUIR	—	—	RXFIR	RXOIR	—	—	TXEIR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1

Bit	Symbol	Function	R/W
0	TXEIR	Transmit FIFO Empty Raw Interrupt Status 0: txe_intr interrupt is not active prior to masking 1: txe_intr interrupt is active prior to masking	R
2:1	—	These bits are read as 0.	R
3	RXOIR	Receive FIFO Overflow Raw Interrupt Status 0: rxo_intr interrupt is not active prior to masking 1: rxo_intr interrupt is active prior to masking	R
4	RXFIR	Receive FIFO Full Raw Interrupt Status 0: rxf_intr interrupt is not active prior to masking 1: rxf_intr interrupt is active prior to masking	R
6:5	—	These bits are read as 0.	R
7	TXUIR	Transmit FIFO Underflow Raw Interrupt Status 0: txu_intr interrupt is not active prior to masking 1: txu_intr interrupt is active prior to masking	R
8	AHBER	AHB Error Raw Interrupt Status This bit indicates whether AHB master interface received an error response. This bit is cleared when the status register is read. 0: ahbe_intr interrupt is not active prior to masking 1: ahbe_intr interrupt is active prior to masking	R
9	SPIMER	SPI Master Error Raw Interrupt Status This bit is set to 1 under the following conditions: ● If SPI slave receives a command which does not fall into the command set ● If SPI slave receives an out-of-order read command (for example read data before read request in polling mode) ● If SPI master writes more data than specified in the instruction phase This bit is cleared when the status register is read. 0: spime_intr interrupt is not active prior to masking 1: spime_intr interrupt is active prior to masking	R
31:10	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of the ENR register. The value is 0 when ENR.ENABLE = 0 and 1 when ENR.ENABLE = 1.

The RISR register reports the status of the SHOSTIF interrupts before they are masked.

45.2.10 TXUICR : Transmit FIFO Underflow Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXUICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXUICR	Clear Transmit FIFO Underflow Interrupt This register reflects the status of the interrupt. A read from this register clears the txu_intr interrupt. Writing to this register has no effect. Read value is the same as TXUIS bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The TXUICR register is used to clear the txu_intr interrupts.

45.2.11 RXOICR : Receive FIFO Overflow Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXOICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RXOICR	Clear Receive FIFO Overflow Interrupt This register reflects the status of the interrupt. A read from this register clears the rxo_intr interrupt. Writing has no effect. Read value is the same as RXOIS bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The RXOICR register is used to clear the rxo_intr interrupts.

45.2.12 SPIMECR : SPI Master Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPIMECR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPIMECR	Clear SPI Master Error interrupt This register reflects the status of the interrupt. A read from this register clears the spime_intr interrupt. Writing to this register has no effect. Read value is the same as the SPIMES bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The SPIMECR register is used to clear the spime_intr interrupts.

45.2.13 AHBECR : AHB Error Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AHBECR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AHBECR	Clear AHB Error Interrupt This register reflects the status of the interrupt. A read from this register clears the ahbe_intr interrupt. Writing to this register has no effect. Read value is the same as AHBES bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The AHBECR register is used to clear the ahbe_intr interrupts.

45.2.14 ICR : Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x0018_1000

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ICR	Clear Interrupts This register is set if any of the specified interrupts are active. A read clears the txo_intr, rxu_intr, rxo_intr, ahbe_intr, and the mst_intr interrupts. Writing to this register has no effect. Read value is the same as logical OR of the RXOIS, TXUIS, AHBES, and SPIMES bits in the ISR register.	R
31:1	—	These bits are read as 0.	R

The ICR register is used to clear the txo_intr, rxu_intr, rxo_intr, ahbe_intr, and the mst_intr interrupts.

45.2.15 SHCFG : SHOSTIF Configuration Register

Base address: SHOSTIF_CFG = 0x8128_1920

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	INTMASKE[5:0]						—	—	INTMASKI[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	SLEEP	ADDRESSING	BYTE SWAP	SPIMODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SPIMODE[1:0]	SPI Frame Format Select Indicates the mode in which the SPI transfer occurs. 0 0: Standard SPI mode 0 1: SPI Dual mode 1 0: SPI Quad mode 1 1: SPI Octal mode	R/W
2	BYTESWAP	Byte Swap Mode Swap data by byte order on AHB bus. 0: No byte swap. Use this setting if byte order of data input by SPI master is [31:24], [23:16], [15:8], or [7:0]. 1: Byte swap. Use this setting if byte order of data input by SPI master is [7:0], [15:8], [23:16], or [31:24].	R/W
3	ADDRESSING	Addressing Mode Specifies unit of the address input by SPI master. 0: 32-bit 1: 8-bit	R/W

Bit	Symbol	Function	R/W
4	SLEEP	SHOSTIF Enable Flag Monitor Indicates whether the internal clock can be stopped. Note that when SHOSTIF is reset, this flag does not indicate correct state. 0: Not safe to stop the internal clock 1: Safe to stop the internal clock	R
15:5	—	These bits are read as 0. The write value should be 0.	R/W
21:16	INTMASKI[5:0]	Interrupt Mask Enable for Internal Interrupt (SHOST_INT) Bits correspond to the interrupts: • INTMASKI[0]: Transmit FIFO Empty Interrupt • INTMASKI[1]: Receive FIFO Overflow Interrupt • INTMASKI[2]: Receive FIFO Full Interrupt • INTMASKI[3]: Transmit FIFO underflow Interrupt • INTMASKI[4]: AHB Master interface error Interrupt • INTMASKI[5]: SPI Master interface error Interrupt 0: No masked 1: Masked	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
29:24	INTMASKE[5:0]	Interrupt Mask Enable for External Interrupt (HSPI_INT# signal) Bits correspond to the interrupts: • INTMASKE[0]: Transmit FIFO Empty Interrupt • INTMASKE[1]: Receive FIFO Overflow Interrupt • INTMASKE[2]: Receive FIFO Full Interrupt • INTMASKE[3]: Transmit FIFO Underflow Interrupt • INTMASKE[4]: AHB Master Interface Error Interrupt • INTMASKE[5]: SPI Master Interface Error Interrupt 0: No masked 1: Masked	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The SHCFG register sets the operation mode and monitors the status of SHOSTIF. This register is not accessible from the external SPI master.

45.3 Operations

The SHOSTIF converts all transfers from SPI to AHB transactions. The external SPI master sends address to SHOSTIF. SHOSTIF takes the address and converts it into an AHB transfer. This enables the external master to access the internal memory directly without any CPU intervention. SHOSTIF can be enabled through boot mode on the reset and load boot program from external master.

All SPI transfers have the following phases:

- Instruction
- Address
- Data

45.3.1 Instruction Phase

Each transfer from the SPI master starts with an 8-bit instruction, which determines the transfer type and process for the rest of the transfer. Table 45.3 shows the instruction field decode.

Table 45.3 Instruction field decode (1 of 2)

Bit	Bit name	Description
7	Read/Write	Defines whether the transfer is read or write. 0: Read 1: Write
6:5	Transfer Type	Defines the transfer type. 00: Read/write data 01: Read request 10: Read/write status 11: Read data with dummy

Table 45.3 Instruction field decode (2 of 2)

Bit	Bit name	Description
4:3	Wait Cycles	Defines the wait cycles for read transactions. Selects the number of wait cycles for a read transfer. This field is only applicable for read data transfers. When the transfer type is 00, the field decode is as follows: 00: 0 Wait cycles 01: 1 Wait cycle 10: Reserved 11: Reserved When the transfer type is 11, the field decode is as follows: 00: 8 Wait cycles 01: 16 Wait cycles 10: 24 Wait cycles 11: 32 Wait cycles Note: Wait cycles are not applicable for write data operation.
2:0	Data Length	Defines the data to be transmitted in the current transfer. Unit is 32 bits (4 bytes). 000: 1 001: 4 010: 8 011: 16 100: 32 101: 64 110: Prohibited 111: Prohibited

45.3.2 Address Phase

The address phase determines the address from which the data should be read or written on the AHB master interface. Address could be received in the standard, dual, quad, or octal frame format, which is defined by the SPIMODE[1:0] bits in SHCFG register. AHB interface address width is fixed to 32 bits. SPI interface expects to receive 24-bit address, which is sent to the AHB interface. Because the data is always read/written in frame of 32 bits, the address is always word-aligned. The 32-bit output address on the SPI to AHB bridge is dependent on the setting of addressing mode as shown in Table 45.4. Addressing mode is determined by the ADDRESSING bit in SHCFG register.

Table 45.4 Addressing mode

Addressing mode	Data length	Permitted SPI_ADDR*1	Permitted address granularity	SPI to AHB bridge output address
32-bit*2	1/4/8/16/32/64	0x0, 0x1, 0x2, …, 0xFF_FFFF	0x1	{000000b, {SPI_ADDR}, 00b}
8-bit	1	0x0, 0x4, 0x8, …, 0xFF_FFFC	0x4	{00000000b, {SPI_ADDR}}
	4	0x0, 0x10, 0x20, …, 0xFF_FFF0	0x10	
	8	0x0, 0x20, 0x40, …, 0xFF_FFE0	0x20	
	16	0x0, 0x40, 0x80, …, 0xFF_FFC0	0x40	
	32	0x0, 0x80, 0x100, …, 0xFF_FF80	0x80	
	64	0x0, 0x100, 0x200, …, 0xFF_FF00	0x100	

Note 1. SPI_ADDR = 24 bits address received on SPI Interface.
Note 2. Burst transfer across 1 Kbyte boundary is prohibited.

45.3.2.1 Address Conversion

The SPI master cannot access all the memory area in this LSI because the address size is 24-bit address on SPI frame. In this LSI, System SRAM, Mailbox and Semaphore, and SHOSTIF registers are accessible from the external SPI master. Address conversion circuit converts the SPI to AHB bridge output address to the internal address of System SRAM, Mailbox and Semaphore, and SHOSTIF registers. Table 45.5 shows address mapping between SPI address on SPI frame and internal address. Access to reserved area causes an AHB error interrupt.

Table 45.5 Address mapping

Module	SPI address*1	Internal address	Size
System SRAM0 (SYSRAM0)	0x00_0000 to 0x01_FFFF (32-bit) 0x00_0000 to 0x07_FFFC (8-bit)	0x1000_0000 to 0x1007_FFFC	512 KB
System SRAM1 (SYSRAM1)	0x02_0000 to 0x03_FFFF (32-bit) 0x08_0000 to 0x0F_FFFC (8-bit)	0x1008_0000 to 0x100F_FFFC	512 KB
System SRAM2 (SYSRAM2)	0x04_0000 to 0x05_FFFF (32-bit) 0x10_0000 to 0x17_FFFC (8-bit)	0x1010_0000 to 0x1017_FFFC	512 KB
Mailbox and Semaphore (MBXSEM)	0x06_0000 to 0x06_03FF (32-bit) 0x18_0000 to 0x18_0FFC (8-bit)	0x8024_0000 to 0x8024_0FFC	4 KB
SHOSTIF registers	0x06_0400 to 0x06_07FF (32-bit) 0x18_1000 to 0x18_1FFC (8-bit)	0x8024_1000 to 0x8024_1FFC	4 KB
Reserved	0x06_0800 to 0xFF_FFFC (32-bit) 0x18_2000 to 0xFF_FFFF (8-bit)	Error response	—

Note 1. Depends on the addressing mode.

45.3.3 Data Phase

Data is received or transmitted in frames of 32 bits. The amount of data to be transmitted or received is defined by the Data Length field of Instruction phase.

Data frame is assumed MSB first, which means the byte order is [31:24], [23:16], [15:8], or [7:0]. When the BYTESWAP bit in the SHCFG register is set to 1, the byte order of Data frame can be swapped to [7:0], [15:8], [23:16], or [31:24].

45.3.4 Bridge Operation

The SHOSTIF performs as a bridge between the SPI master and AHB subsystem. The transfers from SPI master are directly converted in AHB read/write operations. The 8-bit instruction defines the characteristics of the transfer and direction of data flow, and SPIMODE[1:0] bits in the SHCFG register define the SPI operating mode. The following sections describe the read and write operations.

45.3.5 Write Operation

45.3.5.1 Write Instruction

The Instruction phase determines the amount of data to be transmitted during write operation. The SPI frame format is derived from SPIMODE[1:0] bits in the SHCFG register. SPI slave supports the instruction opcodes as shown in Table 45.6.

Table 45.6 Instruction set for write data operations

Instruction	Instruction name	Description
0x8i*1 i = 0 to 5	WRITEn n = 1, 4, 8, 16, 32, 64	Write operation
0xC0	WRITESTATUS0	Write Data Status instruction
0xC8	WRITESTATUS1	Write Data Status instruction with 1 wait cycle

Note 1. The lower 3 bits of the instruction determine the amount of data to be fetched by AHB master. For field decode, see Table 45.3.

45.3.5.2 Write Operation

Figure 45.2 shows how SHOSTIF performs write operation.

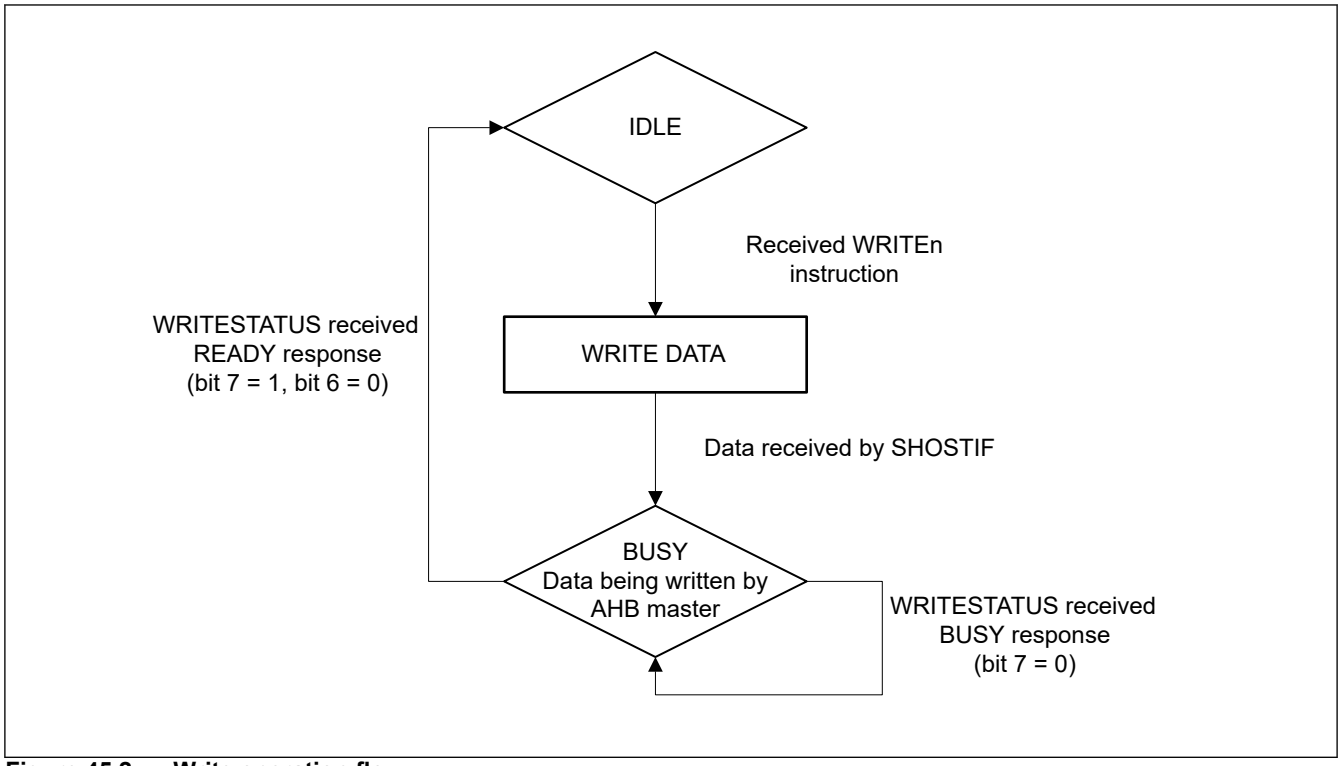

Figure 45.2 Write operation flow

(1) WRITEn (Write Data Instruction)

Data write transaction is always performed in the format specified by SPIMODE[1:0] bits in SHCFG register. The instruction, data, and address phases are sent in single, dual, quad, or octal format. Write operation from the AHB master interface to the internal slave module starts after the data of length specified in the WRITEn instruction is received in the receive FIFO.

Figure 45.3 shows the write data operation using WRITEn instruction.

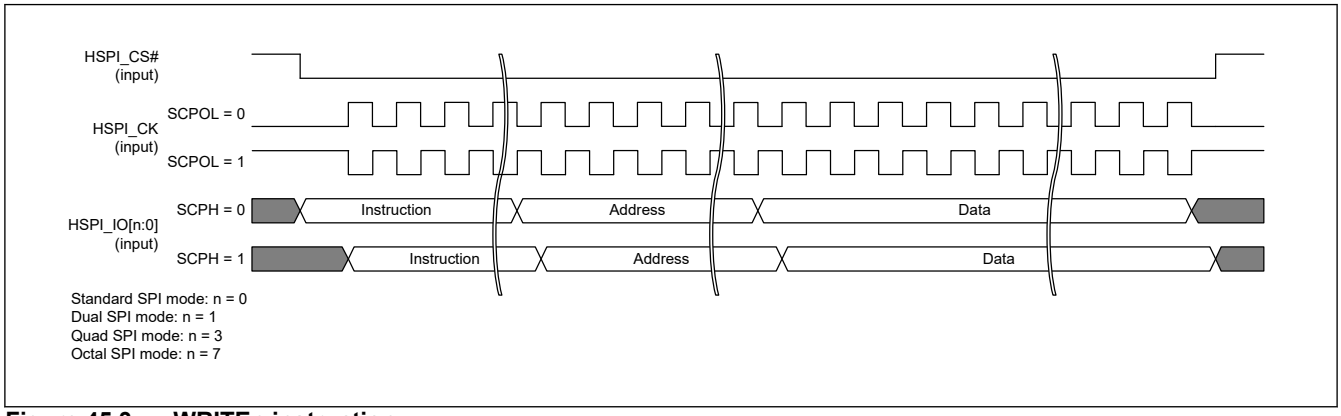

Figure 45.3 WRITEn instruction

(2) WRITESTATUSm (Write Status Instruction)

After the write operation is completed by the master, it should poll for status of the write operation using instruction opcode 0xC0 or 0xC8. Only when the master receives a READY response, it should start a new transfer.

Figure 45.4 shows the write status operation using WRITESTATUSm instruction.

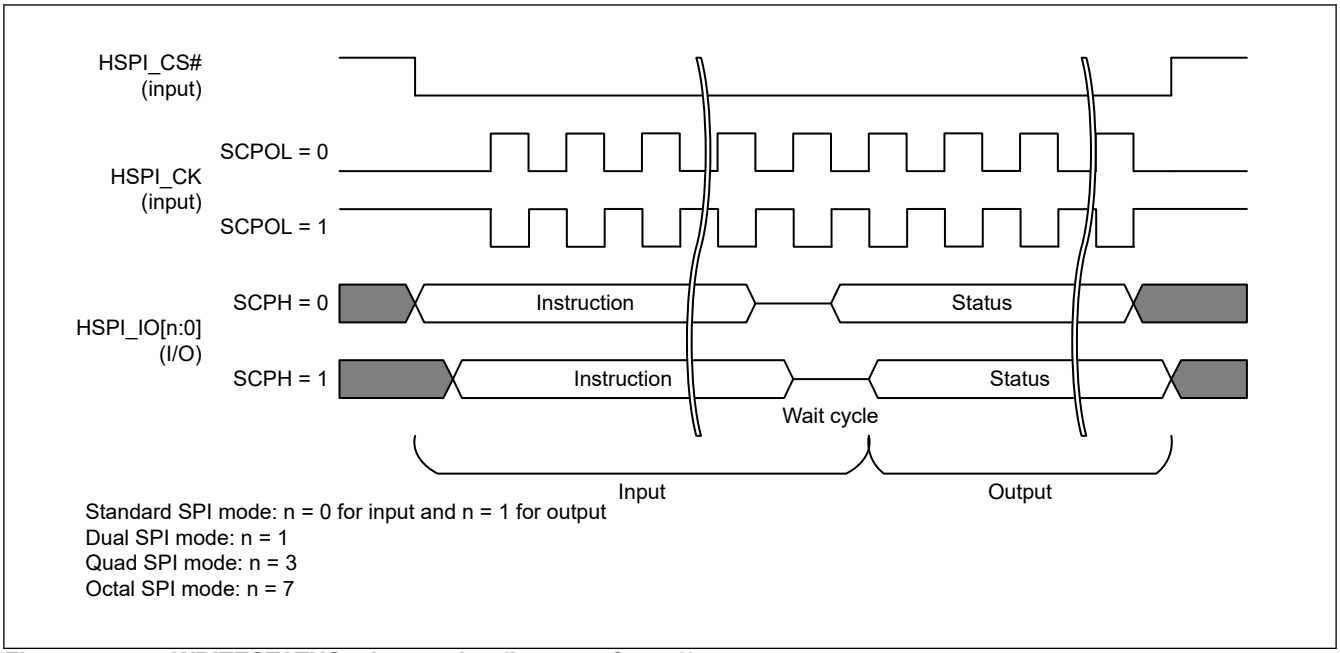

Figure 45.4 WRITESTATUSm instruction (in case of m = 0)

After the SPI master receives a READY response from SHOSTIF, it can move on to the next operation. The AHB interface may get an ERROR response for the write transfer. If the AHB interface gets an ERROR response, the WRITESTATUSm instruction indicates the same by sending a response of 0xC0. The SPI master can then issue a new write transfer or retry the same operation.

Table 45.7 Response field decode

Bit	Name	Description
7	READY	Indicates whether next operation is ready to accept or not. 0: Not ready 1: Ready
6	ERROR	Indicates whether AHB transaction ended with an ERROR response. 0: No error 1: Error
5:0	Reserved	Reserved

45.3.6 Read Operation

45.3.6.1 Read Instruction

In enhanced SPI (Dual/Quad/Octal) modes, all signals are bidirectional. Therefore, the master and slave know when to sample or drive the data on the line. The read instruction set defines the protocol under which the read transactions occur. There are two ways in which the SPI master can read data through SHOSTIF.

(1) Direct Read

In the Direct Read Instruction method, SPI Master initiates a read command and expects the data to be returned in the same command. This way the data is read in the same instruction. Be sure that the data is read on the AHB master interface within the specified cycles (DUMMY cycles).

(2) Read Data in Three Stages (this requires polling)

In some cases, the delay involved during the read operation is such that the read data availability cannot be guaranteed in terms of HSPI_CK cycles due to bus access conflict. To make sure that the data is read in the expected way during the read operation, SHOSTIF provides an alternate approach to divide the read operation into three parts:

- Read request phase
- Wait state

- Read data phase

SPI master requests the read data from SPI slave by sending only the instruction and address during the read request phase. The length of data (1, 4, 8, 16, 32, or 64) to be fetched is also encoded into the instruction. This is converted into an AHB transfer, and data is fetched and stored in the transmit FIFO. After the Read request phase, SPI master checks for availability of data by polling through the READSTATUS instruction. If SPI master receives a positive response for that instruction, then it reads the data using the READn instruction. SHOSTIF then sends all the data received from transmit FIFO to SPI master. Table 45.8 shows all the instructions applicable for read operation.

Table 45.8 Instruction set for read operations

Method	Instruction	Instruction name	Description
Direct Read	0x6i*1 i = 0 to 5	READ8n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 8 wait cycles.
	0x6i*1 i = 8, 9, A, B, C, D	READ16n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 16 wait cycles.
	0x7i*1 i = 0 to 5	READ24n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 24 wait cycles.
	0x7i*1 i = 8, 9, A, B, C, D	READ32n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 32 wait cycles.
3-Stage Read	0x2i*1 i = 0 to 5	READREQn n = 1, 4, 8, 16, 32, 64	Read request.
	0x40	READSTATUS0	Read Data ready instruction without wait cycles.
	0x48	READSTATUS1	Read Data ready instruction with 1 wait cycle.
	0x0i*1 i = 0 to 5	READ0n n = 1, 4, 8, 16, 32, 64	Read Data instruction without wait cycles.
	0x0i*1 i = 8, 9, A, B, C, D	READ1n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 1 wait cycle.

Note 1. The lower 3 bits of the instruction determine the amount of data to be fetched by AHB master. For field decode, see Table 45.3.

45.3.6.2 Direct Read Operation

(1) READmn (Direct Read Data Instruction, m = 8, 16, 24, or 32)

In the direct read approach, only a single instruction is used to fetch the data using AHB interface. After SHOSTIF receives a command with more than or equal to 8 wait cycles (see Table 45.8 for details), SHOSTIF initiates a command on AHB interface to fetch the required amount of data. After data is received from AHB interface, it is transmitted to the SPI interface after the required amount of wait cycles. Figure 45.5 shows the waveform of the direct read transfer.

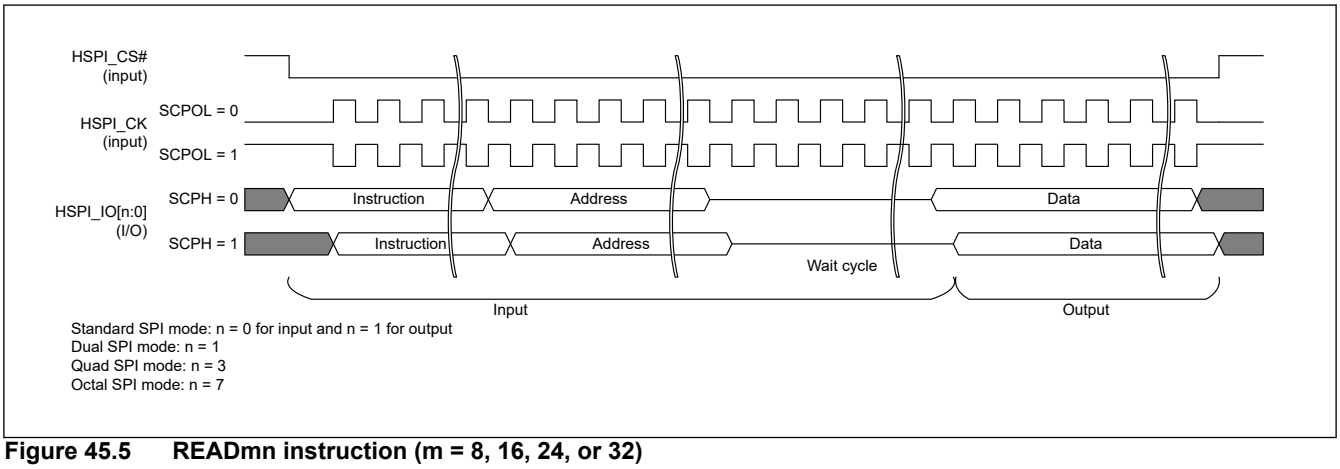

Figure 45.5 READmn instruction (m = 8, 16, 24, or 32)

If SHOSTIF is unable to fetch the data during specific wait cycles, then SHOSTIF indicates this by setting TXE bit in the Status Register (SR) and the Transmit FIFO Underflow Interrupt is asserted.

45.3.6.3 Three Stage Read Operation

When SHOSTIF is idle (the receive/transmit FIFO is empty), and a READREQn instruction is received, it is treated as a read request, and it starts fetching the data from AHB master interface. After the data is available, the READmn instruction returns the read data to SPI master. The SPI master ensures that the data is available before issuing another READmn instruction by polling for data availability. The AHB interface may receive an ERROR response for the read transfer and the READSTATUS instruction indicates this in the response while the SPI master performs the required actions.

Figure 45.6 shows the flow for read operation.

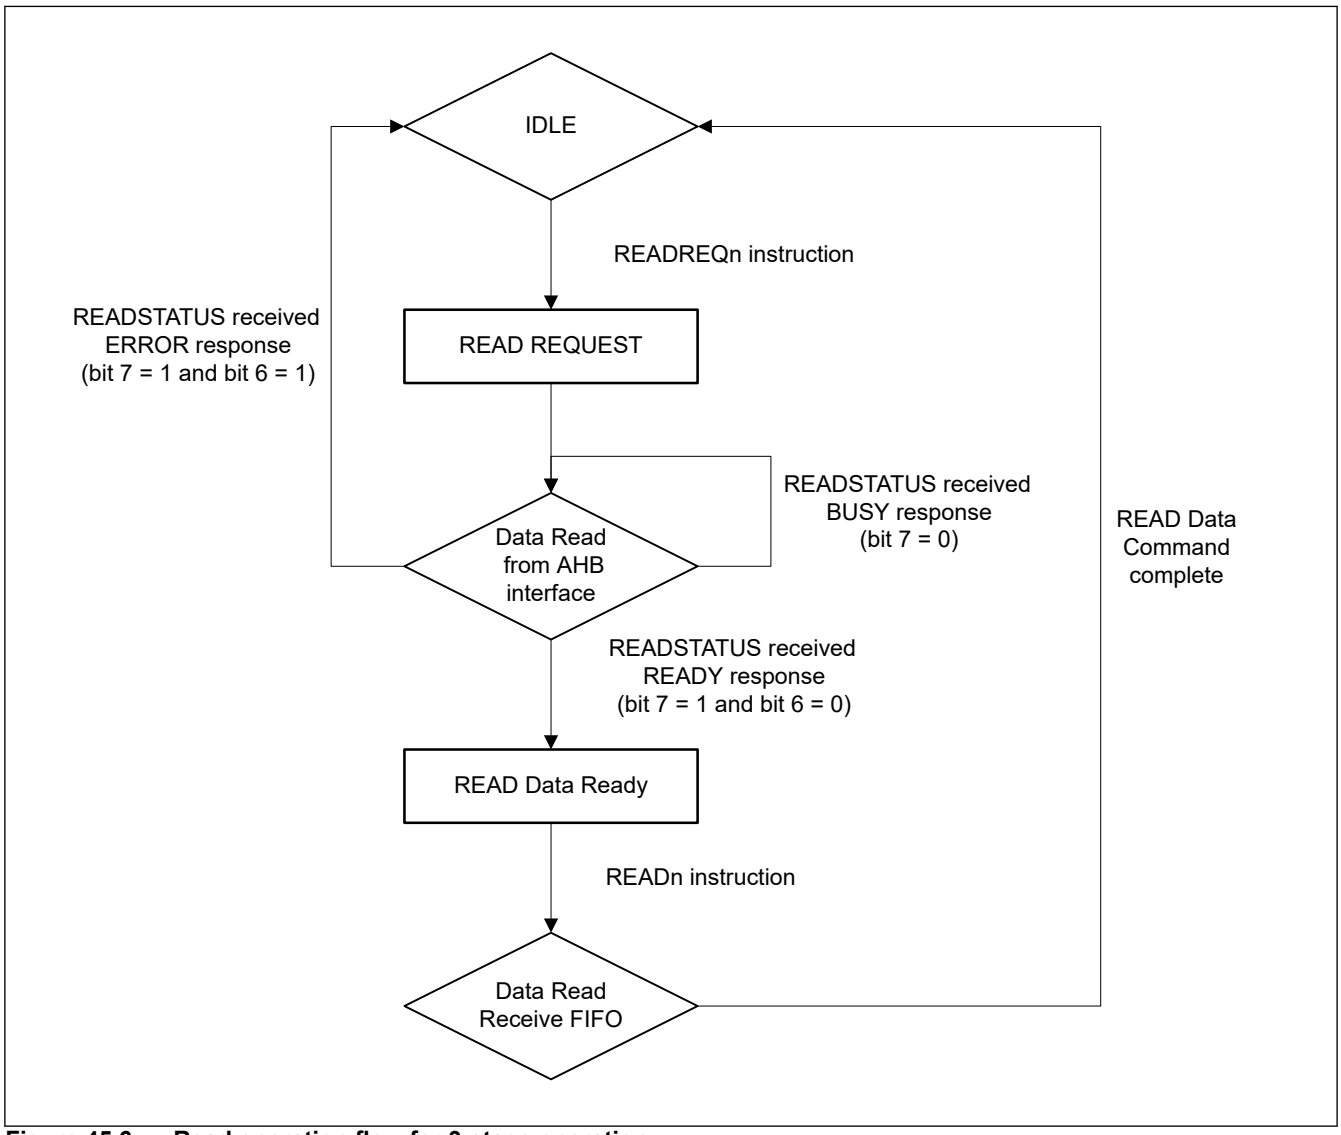

Figure 45.6 Read operation flow for 3-stage operation

(1) READREQn (Read Request Instruction)

Read transaction is always performed in the format specified by SPIMODE[1:0] bits in SHCFG register. This instruction does not require any data transfer and SHOSTIF expects only instruction and address.

Figure 45.7 shows the read request operation using READREQn instruction.

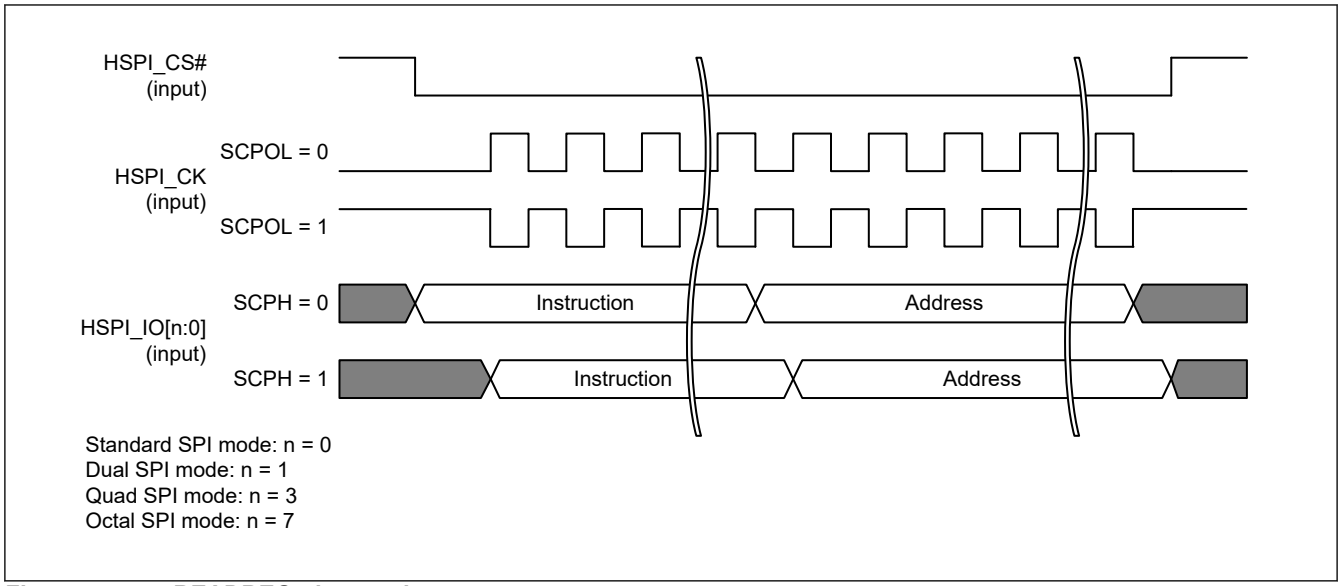

Figure 45.7 READREQn instruction

(2) READSTATUSm (Read Status Instruction, m = 0 or 1)

Read status instruction is used while SHOSTIF fetches the data from AHB interface. The SPI master always polls for data before performing a read data operation, to ensure that data is available for the read operation. SHOSTIF responds to the READSTATUSm command with 8-bit status. The MSB of the status bit indicates whether data is ready or not.

- Response bit 7 = 0 indicates that SHOSTIF is not ready with the data
- Response bit 7 = 1 and bit 6 = 0 indicates that SHOSTIF is ready with the data

Figure 45.8 shows the read status operation using READSTATUSm instruction.

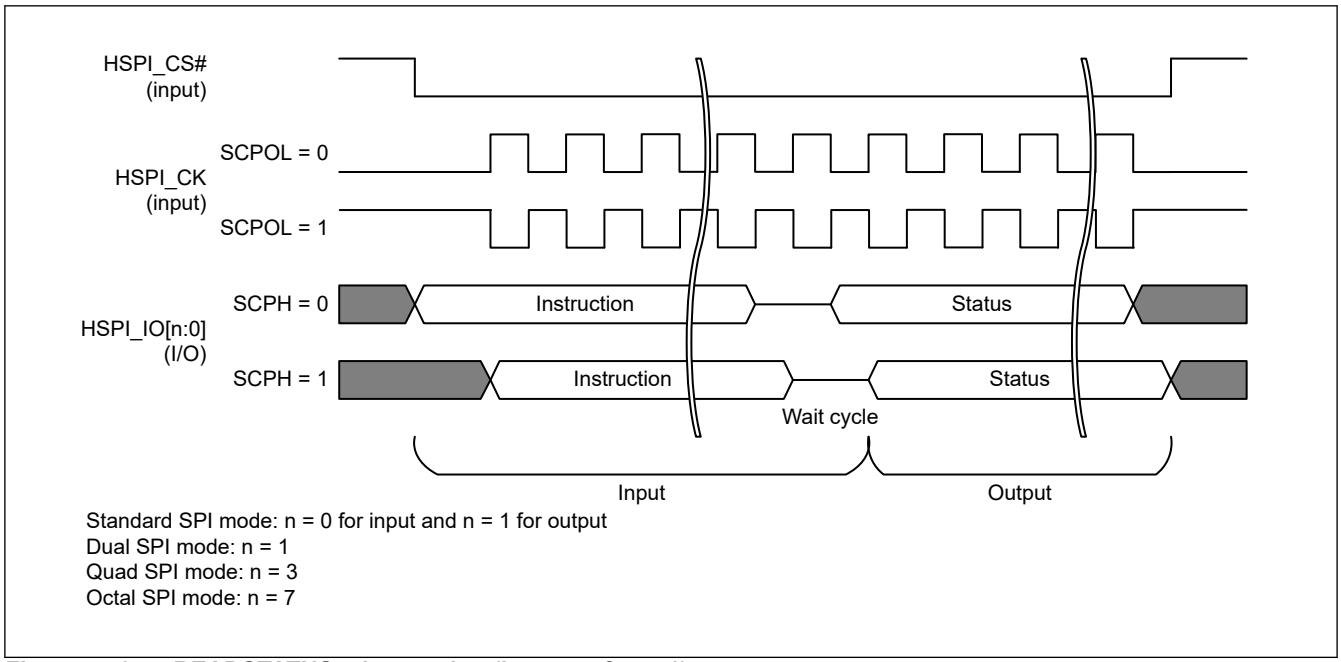

Figure 45.8 READSTATUSm instruction (in case of m = 1)

After the SPI master receives a READY response from SHOSTIF, it performs the read data operation to read the data from SHOSTIF. The AHB interface may get an ERROR response for the read transfer. In that situation, the READSTATUS instruction indicates the same status by sending a response of bit 7 =1 and bit 6 = 1. SPI master can then issue a new read transfer or retry the same operation.

Table 45.9 Response field decode

Bit	Name	Description
7	READY	Indicates whether data is ready to be fetched from SHOSTIF. 0: Not ready 1: Ready
6	ERROR	Indicates whether AHB transaction ended with an ERROR response or not. 0: No error 1: Error
5:0	Reserved	Reserved

(3) READmn (Read Data Instruction, m = 0 or 1)

After the data is available, READmn instruction is used to read back data from SHOSTIF. This time SHOSTIF does not expect any address to be transmitted by the SPI master. After the instruction is received, the inputs/outputs change direction and revert the data after some wait cycles. Wait cycles can be sent by SHOSTIF depending on the instruction (Table 45.3).

Figure 45.9 shows the read data operation using READmn instruction.

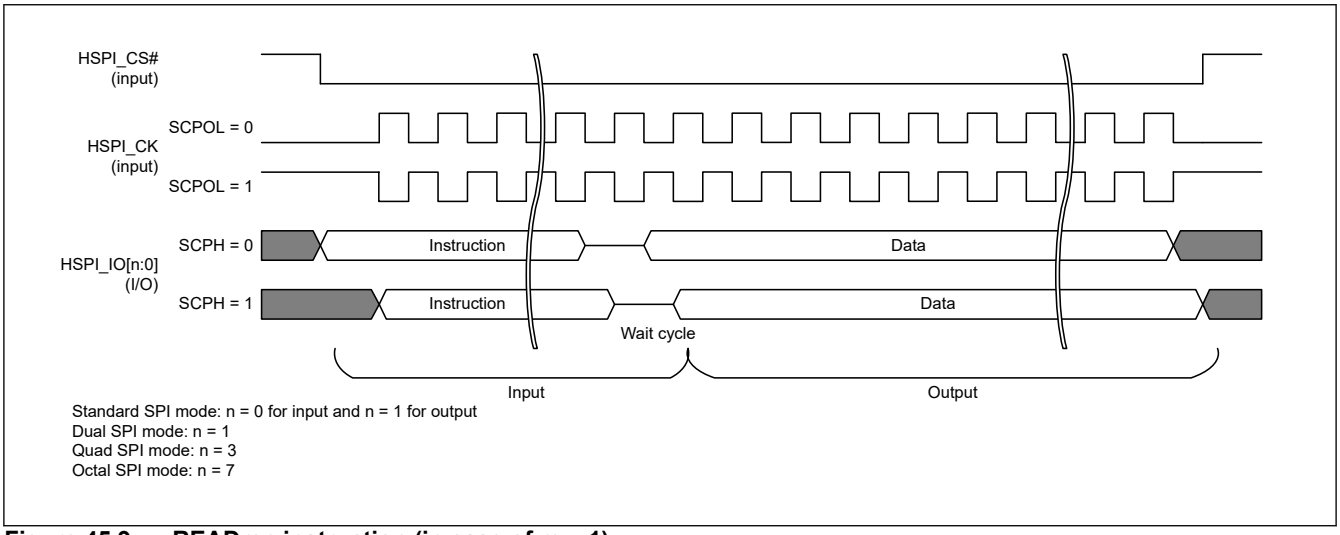

Figure 45.9 READmn instruction (in case of m = 1)

45.3.7 External SPI Master Expectations

The external SPI master must adhere to the flow specified for write and read operations. Any out-of-order operations by SPI master can move SHOSTIF into an undefined state. If SPI master behaves abnormally, then interrupt is sent by SHOSTIF. In such situations, reset SHOSTIF and restart the new transfer.

The following conditions may lead to an error state and the SPIMER bit in RISR register is set for notification.

- SPI master requests for read/write transfer when SHOSTIF is busy with AHB transfer. For example:
  - A read is requested by the SPI master and is followed by a write data transfer while read transfer is still ongoing on the AHB interface.
  - A write transfer is pending on the AHB interface but another read/write data transfer is received by SHOSTIF.
- SPI master reads less amount of data then requested during the Read request phase.
- If the SPI master requested for 16 data frames but it reads only 12 data frames, then the SPIMER bit in RISR register is set and the rest of the data is flushed from the FIFO by performing a soft reset.
- SPI master writes less amount of data than specified in the transfer length.
- If the SPI master requested for 16 data frames but it writes only 12 data frames and deselects the slave early, then the SPIMER bit in the RISR register is set and any of the data left in the FIFO is flushed by performing a soft reset.
- SPI master sends more data for a write, or SPI master read more data then requested.

- If AHB read transfer receives an error response from the slave, then no further transfer is performed for the current request, and data in the FIFO is flushed immediately. If read request transfer receives an error response on AHB interface, SHOSTIF does not expect read data transfer after that because there is no read data available in FIFO. If AHB master still performs a read data transfer, this results in an SPI master error.
- Successful read request transfer is followed by another read request from SPI master.
- A successful read request transfer (which does not receive an error response on the AHB interface) should be followed by read data or read status transfer. If a successful read request transfer is followed by another read request from SPI master, this results in an SPI master error.

45.3.8 AHB Master Interface

The AHB master interface is used as a secondary interface to read or write data for every SPI transfer. The AHB interface address and data width is fixed to 32. The following sections describe how SPI transfers are converted to AHB transactions by SHOSTIF.

45.3.8.1 Write Operation

When SHOSTIF receives a write request (WRITEn command) from SPI master, SHOSTIF saves the address per the rules specified in section 45.3.2. Address Phase. After data is received, it is transmitted as a burst transfer defined by RXFBTR register on AHB interface. This continues until the AHB slave is deselected by the AHB master. If AHB write transfer receives and ERROR response, it is indicated by ahbe_intr interrupt of the ISR and RISR registers. As soon as the error is received on the AHB interface, the rest of the data from SPI interface is discarded and no further transfers are performed for the current operation.

45.3.8.2 Read Operation

When SHOSTIF receives a read request (READmn command) from SPI master, SHOSTIF saves the address per the rules specified in section 45.3.2. Address Phase. SHOSTIF then waits for a burst to complete, and the data to be fully received. The data length is specified in the Data length field of the instruction. For data length of 1, 4, 8, or 16, the corresponding AHB burst type is used to fetch the data. For the burst length of 32 or more, INCR burst type is used to fetch the data.

If any read transfer receives an ERROR response, SHOSTIF aborts the rest of the transfer and indicates the same status in the ISR and RISR registers. When the SPI interface performs a READSTATUS instruction for data ready status, this is indicated to the SPI master with an error response of bit 6 = 1.

45.3.9 Interrupt

Interrupt signal is available in the internal CPU and external host CPU (SPI master). Multiple individual interrupt factors are combined to one signal for internal CPU and external host CPU. Individual interrupt factor can be masked commonly and separately. Figure 45.10 shows a diagram of the interrupt.

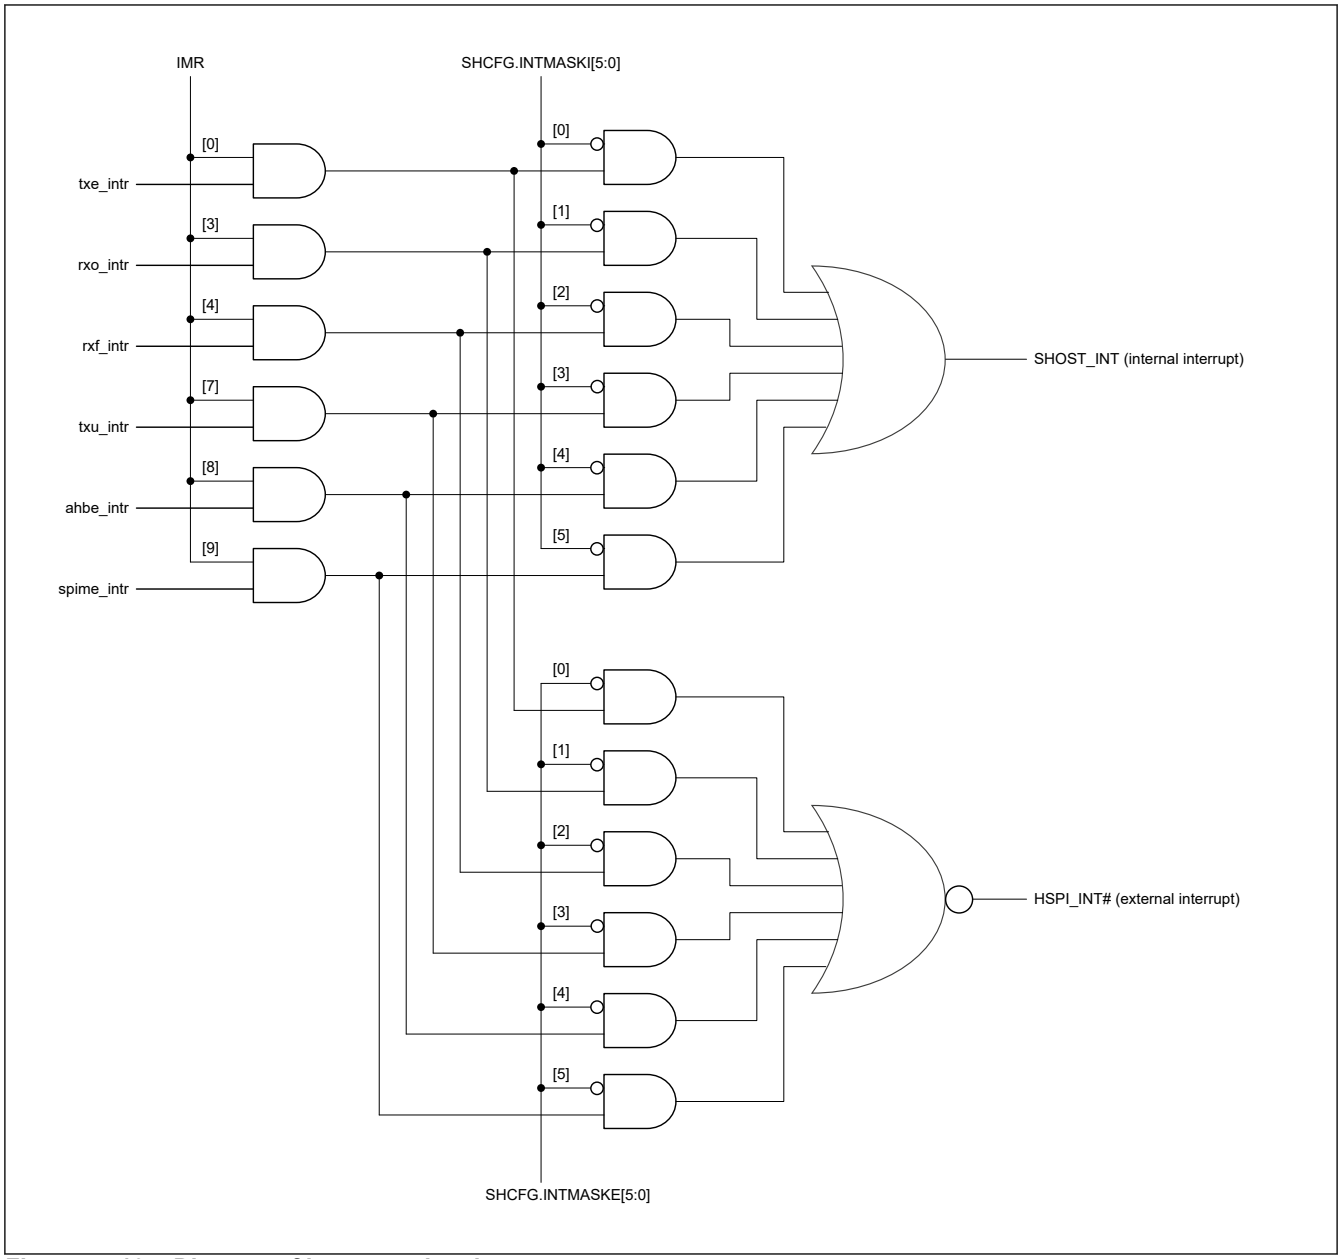

Figure 45.10 Diagram of interrupt signal

Table 45.10 SHOSTIF interrupt source (internal)

Name	Interrupt sources	CPU GIC request	DMAC activation	ELC activation
SHOST_INT	SHOSTIF interrupt (logical OR of all individual interrupts)	Possible	Not possible	Not possible

Table 45.11 SHOSTIF individual interrupt factor (1 of 2)

Factor name	Description	Interrupt clear	Interrupt mask setting		
			Common	Internal CPU	External host CPU
			IMR register	SHCFG register	
				INTMASKI[5:0] bits	INTMASKE[5:0] bits
txe_intr	Transmit FIFO (read data FIFO) Empty interrupt. When the number of transmit FIFO entries is less than or equal to transmit FIFO threshold level, the interrupt is triggered.	Transmit FIFO entries is greater than threshold	b0	b0	b0

Table 45.11 SHOSTIF individual interrupt factor (2 of 2)

Factor name	Description	Interrupt clear	Interrupt mask setting		
			Common	Internal CPU	External host CPU
			IMR register	SHCFG register	
				INTMASKI[5:0] bits	INTMASKE[5:0] bits
rxo_intr	Receive FIFO (write data FIFO) Overflow interrupt. This interrupt is not triggered if module operates normally.	RXOICR or ICR register read	b3	b1	b1
rxf_intr	Receive FIFO (write data FIFO) Full interrupt. When the number of receive FIFO entries is greater than or equal to receive FIFO threshold level + 1, the interrupt is triggered.	Receive FIFO entries is less than threshold	b4	b2	b2
txu_intr	Transmit FIFO (read data FIFO) Underflow interrupt. The interrupt is triggered in any of the following conditions: ● Data length in READmn is greater than that in READREQn in the 3-stage approach ● Transmission of AHB master interface is not completed within wait cycles specified in READmn in direct read approach	TXUICR or ICR register read	b7	b3	b3
ahbe_intr	AHB Master Interface Error interrupt. When AHB master interface receives an error response, the interrupt is triggered.	AHBECR or ICR register read	b8	b4	b4
spime_intr	SPI Master Interface Error interrupt. The interrupt is triggered in any of the following conditions: ● Illegal instruction code ● Next read or write transaction is issued before the previous transfer is completed	SPEMECR or ICR register read	b9	b5	b5

Note: If Transmit FIFO Underflow interrupt (txu_intr) happens, read access from external bus master may be impossible. Set ENR.ENABLE to 0 once.

45.4 Usage Notes

- When changing the SPI data width, disable SHOSTIF first by setting ENR.ENABLE = 0 during no transmission. Then, change SHCFG.SPIMODE. After changing the SPI data width, enable SHOSTIF again and start transmission.
- During ENR.ENABLE = 0, register access from internal CPU is available but access from external SPI master is ignored. No interrupts occur and read data is undefined.
- Do not change Receive FIFO Burst Threshold Register (RXFBTR) from 0x3F (initial value) in case of 8-bit addressing mode. In case of 32-bit addressing mode, recommendation value is 0x0F.

46. Parallel Host Interface (PHOSTIF)

46.1 Overview

This LSI has parallel host interface to connect an external MPU/MCU (Bus master) with 8/16-bit bus. Parallel host interface allows an external bus master to access the internal resources (System SRAM, Mailbox, and PHOSTIF registers) of this LSI directly. Additionally, the booting of this LSI from the external bus master is possible.

Table 46.1 lists the serial host interface specifications and Figure 46.1 shows a block diagram of the PHOSTIF.

Table 46.1 PHOSTIF specifications

Item	Description
Number of units	1 unit
Interface Mode	• Synchronous/Asynchronous SRAM Interface Mode • Synchronous Burst SRAM Type Transfer Mode
Synchronous/Asynchronous SRAM Interface Mode	• Interface system – Asynchronous SRAM with wait control (for reading and writing) – Page ROM reading with wait control • Synchronous relationship – HCKIO synchronous mode (Up to 50 MHz) • Asynchronous mode • Bus width: 16 bits / 8 bits • Transfer data size: 16 bits/8 bits • Write buffer: Eight stages (synchronous mode is selected) or one stage (asynchronous mode is selected) • Read buffer: Read-ahead up to 32 bytes is possible. • Multiplexing of addresses and data – No multiplexing of addresses and data
Synchronous Burst SRAM Type Transfer Mode	• Interface system – Synchronous SRAM single transfer (for reading and writing) – Synchronous SRAM burst transfer (for reading and writing) • Synchronous relations – HCKIO synchronous (up to 50 MHz) • Bus width: 16 bits/8 bits • Transmission data size: 16 bits/8 bits • Write buffer: 8 stages • Read buffer: Advance reading of up to 32 bytes is possible. • Multiplexing of addresses and data – Multiplexing of addresses and data – Separation of addresses and data
Interrupt source	• Error interrupt • External output pin is available
Accessible area	• System SRAM • Semaphore and mailbox registers • Host Interface IP registers
Module-stop function	Module-stop state can be set to reduce power consumption

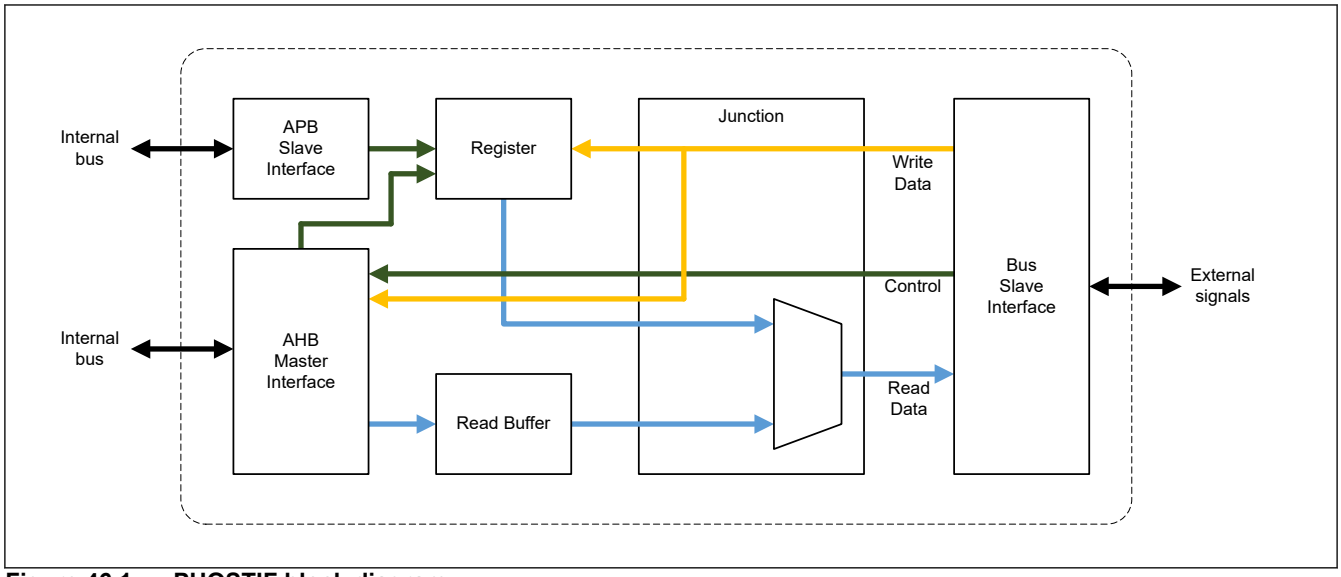

Figure 46.1 PHOSTIF block diagram

Table 46.2 lists the input/output pins of the parallel host interface.

Table 46.2 PHOSTIF I/O pins

Name	I/O	Function
HCKIO	Input	PHOSTIF Bus clock input pin
HA0 to HA20	Input	PHOSTIF Address input pins
HD0 to HD15	I/O	PHOSTIF Data I/O pins
HCS0#	Input	PHOSTIF Chip select input pin supporting burst transfer
HCS1#	Input	PHOSTIF Chip select input pin supporting BSC ADMUX Mode
HRD#	Input	PHOSTIF Strobe input pin indicating a read access
HWAIT#	Output	PHOSTIF Output pin indicating that the bus cycle is in wait state
HWRSTB#	Input	PHOSTIF Strobe input pin indicating a write access
HWR0#	Input	PHOSTIF Write strobe / byte enable input pin to HD7 to HD0
HWR1#	Input	PHOSTIF Write strobe / byte enable input pin to HD15 to HD8
HERROUT#	Output	PHOSTIF Outputs the bus access error interrupt signal
HBS#	Input	PHOSTIF Bus cycle input pin

46.2 Register Descriptions

Register base address is different between external bus master view and internal memory address view except PHCFG and PHACC registers. PHCFG and PHACC registers are different base addresses and accessible from internal CPU only.

- External bus master view: BASE = 0x18_2000
- Internal CPU view: BASE = 0x8024_2000

46.2.1 HIFBCC : HOSTIF Bus Control Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	WRPON	BSTON	—	—	—	RBUFONX	—	—	RBUFON5	RBUFON4	RBUFON3	RBUFON2	RBUFON1	RBUFON0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RBUFON0	Enables or disables the read-ahead function to lower 256 Kbyte of System SRAM0 (0x1000_0000 to 0x1003_FFFC). 0: Read-ahead function disabled 1: Read-ahead function enabled	R/W*1
1	RBUFON1	Enables or disables the read-ahead function to upper 256 Kbyte of System SRAM0 (0x1004_0000 to 0x1007_FFFC). 0: Read-ahead function disabled 1: Read-ahead function disabled	R/W*1
2	RBUFON2	Enables or disables the read-ahead function to lower 256 Kbyte of System SRAM1 (0x1008_0000 to 0x100B_FFFC). 0: Read-ahead function disabled 1: Read-ahead function enabled	R/W*1
3	RBUFON3	Enables or disables the read-ahead function to upper 256 Kbyte of System SRAM1 (0x100C_0000 to 0x100F_FFFC). 0: Read-ahead function disabled 1: Read-ahead function enabled	R/W*1
4	RBUFON4	Enables or disables the read-ahead function to lower 256 Kbyte of System SRAM2 (0x1010_0000 to 0x1013_FFFC). 0: Read-ahead function disabled 1: Read-ahead function disabled	R/W*1
5	RBUFON5	Enables or disables the read-ahead function to upper 256 Kbyte of System SRAM2 (0x1014_0000 to 0x1017_FFFC). 0: Read-ahead function disabled 1: Read-ahead function disabled	R/W*1
7:6	—	These bits are read as 0. The write value should be 0.	R/W*1
8	RBUFONX	Enables or disables the read-ahead function to the area specified in HIFXAL and HIFXAH registers. 0: Read ahead function disabled 1: Read ahead function disabled	R/W*1
11:9	—	These bits are read as 0. The write value should be 0.	R/W*1
12	BSTON	Specifies the method of AHB transfer when performing read-ahead function. 0: Single transfer is used 1: Burst transfer is used	R/W*1
13	WRPON	Selects the burst transfer type. 0: INCR4 1: WRAP4	R/W*1
15:14	—	These bits are read as 0. The write value should be 0.	R/W*1

Note: Clearing of read buffers requires write access to any of the PHOSTIF registers (HIFxxx registers). To prevent erroneous writing to registers, write access to the HIFMON1 register (read-only register) is recommended. Values written to the HIFMON register are ignored.

Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFBCCSEL bit in PHACC register.

HIFBCC register controls the interface operation of the PHOSTIF.

46.2.2 HIFBTC : HOSTIF Timing Control Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RDDTS[1:0]		—	PASTD[2:0]			—	—	RDSTD[1:0]		—	WRSTD[2:0]		
Value after reset:	0	0	1	1	0	1	1	1	0	0	1	1	0	1	1	1

Bit	Symbol	Function	R/W
2:0	WRSTD[2:0]	Specifies the timing for detecting the start of write operation by the HWRSTB# signal. Used to adjust the setup time of address input signals and write data input signals for falling edges of the HWRSTB# signal. 0 0 0: Simultaneous with the detection of the falling edge after synchronization 0 0 1: Delay by 1 clock cycle of PCLKH from the detection of the falling edge after synchronization 0 1 0: Delay by 2 clock cycles of PCLKH from the detection of the falling edge after synchronization 0 1 1: Delay by 3 clock cycles of PCLKH from the detection of the falling edge after synchronization 1 0 0: Delay by 4 clock cycles of PCLKH from the detection of the falling edge after synchronization 1 0 1: Delay by 5 clock cycles of PCLKH from the detection of the falling edge after synchronization 1 1 0: Delay by 6 clock cycles of PCLKH from the detection of the falling edge after synchronization 1 1 1: Delay by 7 clock cycles of PCLKH from the detection of the falling edge after synchronization	R/W*1
3	—	This bit is read as 0. The write value should be 0.	R/W*1
5:4	RDSTD[1:0]	Specifies the timing for detecting the start of read operation by the HRD# signal. Used to adjust the setup time of address input signals for falling edges of the HRD# signal. 0 0: Simultaneous with the detection of the falling edge after synchronization 0 1: Delay by 1 clock cycle of PCLKH from the detection of the falling edge after synchronization 1 0: Delay by 2 clock cycles of PCLKH from the detection of the falling edge after synchronization 1 1: Delay by 3 clock cycles of PCLKH from the detection of the falling edge after synchronization	R/W*1
7:6	—	These bits are read as 0. The write value should be 0.	R/W*1
10:8	PASTD[2:0]	Specifies the waiting time for off-page detection. 0 0 0: No wait 0 0 1: Wait for 1 clock cycle of PCLKH 0 1 0: Wait for 2 clock cycles of PCLKH 0 1 1: Wait for 3 clock cycles of PCLKH 1 0 0: Wait for 4 clock cycles of PCLKH 1 0 1: Wait for 5 clock cycles of PCLKH 1 1 0: Wait for 6 clock cycles of PCLKH 1 1 1: Wait for 7 clock cycles of PCLKH	R/W*1
11	—	This bit is read as 0. The write value should be 0.	R/W*1
13:12	RDDTS[1:0]	Specifies the waiting time from HD[15:0] signal valid to de-assertion of the HWAIT# signal. 0 0: No wait 0 1: Wait for 1 clock cycle of PCLKH 1 0: Wait for 2 clock cycles of PCLKH 1 1: Wait for 3 clock cycles of PCLKH	R/W*1
15:14	—	These bits are read as 0. The write value should be 0.	R/W*1

Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFBTCSEL bit in PHACC register.

HIFBTC register controls the timing of the Bus slave interface.

46.2.3 HIFPRC : HOSTIF Page ROM Control Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x08

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PAGE SZ	—	—	—	PAGE ONX	—	—	PAGE ON5	PAGE ON4	PAGE ON3	PAGE ON2	PAGE ON1	PAGE ON0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PAGEON0	Enables or disables page ROM reading to lower 256 Kbyte of System SRAM0 (0x1000_0000 to 0x1003_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
1	PAGEON1	Enables or disables page ROM reading to upper 256 Kbyte of System SRAM0 (0x1004_0000 to 0x1007_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
2	PAGEON2	Enables or disables page ROM reading to lower 256 Kbyte of System SRAM1 (0x1008_0000 to 0x100B_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
3	PAGEON3	Enables or disables page ROM reading to upper 256 Kbyte of System SRAM1 (0x100C_0000 to 0x100F_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
4	PAGEON4	Enables or disables page ROM reading to lower 256 Kbyte of System SRAM2 (0x1010_0000 to 0x1013_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
5	PAGEON5	Enables or disables page ROM reading to upper 256 Kbyte of System SRAM2 (0x1014_0000 to 0x1017_FFFC). 0: SRAM reading 1: Page ROM reading	R/W*1
7:6	—	These bits are read as 0. The write value should be 0.	R/W*1
8	PAGEONX	Enables or disables page ROM reading to the area specified in HIFXAL and HIFXAH registers. 0: SRAM reading 1: Page ROM reading	R/W*1
11:9	—	These bits are read as 0. The write value should be 0.	R/W*1
12	PAGESZ	Specifies the page size for Page ROM reading.*2 0: 8-byte 1: 16-byte	R/W*1
15:13	—	These bits are read as 0. The write value should be 0.	R/W*1

Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFPRCSEL bit in PHACC register.
Note 2. The page size to be set in the PAGESZ bit must match the page size setting of the external bus master.

HIFPRC register controls the page ROM access operation of Bus slave interface.

46.2.4 HIFIRC : HOSTIF Interrupt Request Control Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERRRSP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERRRSP	This bit is set to 1 on reception of an error response from internal slave modules. This bit is cleared to 0 by writing 0 to it. Writing 1 to this bit has no effect. While this bit is 1, the low level is output to the interrupt signal HERROUT#. 0: No error response 1: Error response	R/W*1
15:1	—	These bits are read as 0. The write value should be 0.	R/W*1

Note: While the ERRRSP bit is 1, the HOSTIF error source registers (HIFECR0, HIFECR1) are not updated even if a new error response was generated. The first error information is held in HIFECR0 and HIFECR1 registers.
Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFIRCSEL bit in PHACC register.

HIFIRC register controls the interrupt requests to the external MCU.

46.2.5 HIFECR0 : HOSTIF Error Source Register 0

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x10
0x10 (from external bus master for HIFECR0.ERRADDR[15:0])
0x12 (from external bus master for HIFECR0.ERRADDR[31:16])

Bit position:	31																												0
Bit field:	ERRADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ERRADDR[31:0]	These bits hold the address (32-bit address) at which an error occurred.	R

Note: When two or more errors occur, the transfer information where the first error occurred is stored.
When ERRRSP bit in HIFIRC register is 0, the value stored in this register is invalid.
Clearing the ERRRSP bit in the HIFIRC register leads to updating this register in response to the detection of the next error response. In interrupt processing, this register must be referenced before clearing the ERRRSP bit.

HIFECR0 register stores the address at which an error occurred when an error response is returned from an internal slave module at the time of access by the external bus master.

46.2.6 HIFECR1 : HOSTIF Error Source Register 1

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x14

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	ERRWR	ERRSZ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ERRSZ[2:0]	The transfer size (access width) when the error occurred is stored. 0 0 0: 8-bit 0 0 1: 16-bit 0 1 0: 32-bit Others: Setting prohibited	R
3	ERRWR	The information on whether an error was caused by reading or writing is stored. 0: Reading 1: Writing	R
15:4	—	These bits are read as 0.	R

Note: When two or more errors occur, the transfer information where the first error occurred is stored.
When ERRRSP bit in HIFIRC register is 0, the value stored in this register is invalid.
Clearing the ERRRSP bit in the HIFIRC register leads to updating this register in response to the detection of the next error response. In interrupt processing, this register must be referenced before clearing the ERRRSP bit.

HIFECR1 register stores the transfer information at which an error occurred when an error response is returned from an internal slave module at the time of access by the external bus master.

46.2.7 HIFMON1 : HOSTIF Monitor Register 1

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x20

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	HIFSYNC	—	BUSSEL	HIFRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HIFRDY	Indicates the internal initialization state of HOSTIF. 0: Internal initializing 1: Internal initialization complete	R/W*1
1	BUSSEL	Indicates bus width. 0: 8-bit bus width 1: 16-bit bus width	R
2	—	This bit is read as 0. The write value should be 0.	R/W
3	HIFSYNC	Indicate synchronous or asynchronous mode. 0: Asynchronous mode 1: Synchronous mode	R
15:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: During internal initialization (when HIFRDY bit is 0), accesses other than reading from HOSTIF register area are prohibited. HIFRDY bit is set to 0 at the start of reset, and it changes to 1 when the internal initialization process is completed after the reset is released. Poll HIFRDY bit from the external bus master and wait for the completion of the initialization process inside HOSTIF.

Note 1. Read and write is available from internal CPU. External bus master is read only.

HIFMON1 register indicates the operation mode and internal status of PHOSTIF.

Writing to the HIF register from the external MCU port is prohibited until initialization of the MCU slave port is completed. Invalid values are read from the bits other than HIFRDY bits of HIFMON1 register.

46.2.8 HIFMON2 : HOSTIF Monitor Register 2

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x24

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	HIFXAH	HIFXAL	HIFIRC	HIFPRC	HIFBTC	HIFBCC
Value after reset:	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
0	HIFBCC	Indicates the property of HIFBCC register from the Bus slave interface. 0: Read only 1: Read and Write	R
1	HIFBTC	Indicates the property of HIFBTC register from the Bus slave interface. 0: Read only 1: Read and Write	R
2	HIFPRC	Indicates the property of HIFPRC register from the Bus slave interface. 0: Read only 1: Read and Write	R
3	HIFIRC	Indicates the property of HIFIRC register from the Bus slave interface. 0: Read only 1: Read and Write	R

Bit	Symbol	Function	R/W
4	HIFXAL	Indicates the property of HIFXAL register from the Bus slave interface. 0: Read only 1: Read and Write	R
5	HIFXAH	Indicates the property of HIFXAH register from the Bus slave interface. 0: Read only 1: Read and Write	R
15:6	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of PHACC register.

HIFMON2 register indicates the property of register access from external bus master.

46.2.9 HIFMON3 : HOSTIF Monitor Register 3

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x28

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HIFEXT1	HIFEXT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1

Bit	Symbol	Function	R/W
0	HIFEXT0	Indicates the property of HIFEXT0 register from the Bus slave interface. 0: Read only 1: Read and Write	R
1	HIFEXT1	Indicates the property of HIFEXT1 register from the Bus slave interface. 0: Read only 1: Read and Write	R
15:2	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of PHACC register.

HIFMON3 register indicates the property of register access from external bus master.

46.2.10 HIFXAL : HOSTIF Specified Area Lower-limit Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x30

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	XADDRL[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	XADDRL[8:0]	Specifies the lower-limit address of the specified area to be set in the external bus address space. The lower-limit address to be set is HA[20:0] = {XADDRL[8:0], 0x000}.	R/W*1
15:9	—	These bits are read as 0. The write value should be 0.	R/W*1

Note: Before setting this register, set the RBUFONX bit in HIFBCC register to 0.
The range from HA[20:0] = {XADDRL[8:0], 0x000} to {XADDRH[8:0], 0xFFF} is the specified area.
If the values of XADDRL[8:0] and XADDRH[8:0] are equal, the specified 4-Kbyte area is selected.
If the value of XADDRL[8:0] is greater than the value of XADDRH[8:0], any existing specified area is lost and a new specified area is not secured.

Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFXALSEL bit in PHACC register.

HIFXAL register specifies the lower limit address of the specified area to be set in the external bus address space. Set the specified area by combining HOSTIF Specified Area Lower-limit Register (HIFXAL) and HOSTIF Specified Area Upper-limit Register (HIFXAH).

46.2.11 HIFXAH : HOSTIF Specified Area Upper-limit Register

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x34

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	XADDRH[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	XADDRH[8:0]	Specifies the upper-limit address of the specified area to be set in the external bus address space. The upper-limit address to be set is HA[20:0] = {XADDRH[8:0], 0xFFF}.	R/W*1
15:9	—	These bits are read as 0. The write value should be 0.	R/W*1

Note: Before setting this register, set the RBUFONX bit in HIFBCC register to 0.
The range from HA[20:0] = {XADDRL[8:0], 0x000} to {XADDRH[8:0], 0xFFF} is the specified area.
If the values of XADDRL[8:0] and XADDRH[8:0] are equal, the specified 4-Kbyte area is selected.
If the value of XADDRL[8:0] is greater than the value of XADDRH[8:0], any existing specified area is lost and a new specified area is not secured.

Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFXAHSEL bit in PHACC register.

HIFXAH register specifies the upper limit address of the specified area to be set in the external bus address space. Set the specified area by combining HOSTIF Specified Area Lower-limit Register (HIFXAL) and HOSTIF Specified Area Upper-limit Register (HIFXAH).

46.2.12 HIFEXT0 : HOSTIF Synchronous Burst Transfer Control Register 0

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x80

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MODTRN	—	—	—	—	—	CNDWEO	—	—	—	KESWTO	KESDTO	KESAVI	KESDTI	—	KESSBI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	KESSBI	Effective edge selection for strobe signal input (HRD#, HWRSTB#) 0: Rising edge 1: Falling edge	R/W*1
1	—	This bit is read as 0. The write value should be 0.	R/W*1
2	KESDTI	Effective edge selection for data input 0: Rising edge 1: Falling edge	R/W*1
3	KESAVI	Effective edge selection for address input 0: Rising edge 1: Falling edge	R/W*1
4	KESDTO	Effective edge selection for data output 0: Rising edge 1: Falling edge	R/W*1

Bit	Symbol	Function	R/W
5	KESWTO	Effective edge selection for HWAIT# output 0: Rising edge 1: Falling edge	R/W*1
8:6	—	These bits are read as 0. The write value should be 0.	R/W*1
9	CNDWEO	WAIT release timing selection 0: Simultaneous with data 1: Precedes the data by one clock cycle.	R/W*1
14:10	—	These bits are read as 0. The write value should be 0.	R/W*1
15	MODTRN	Transfer mode selection 0: Single transfer only 1: Burst transfer is supported.	R/W*1

Note: This register can be accessed only when MEMCSEL bit in the PHCFG register is set to 1.
Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFEXT0SEL bit in PHACC register.

HIFEXT0 register specifies operation for burst transfer to and from external bus master.

46.2.13 HIFEXT1 : HOSTIF Synchronous Burst Transfer Control Register 1

Base address: PHOSTIF = 0x8024_2000
PHOSTIF_E = 0x0018_2000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	DLYRA[3:0]				—	—	—	—	DLYWA[3:0]

Note: This register can be accessed only when MEMCSEL bit in the PHCFG register is set to 1.
Note 1. Read and write is available from internal CPU. Access from external bus master depends on HIFEXT1SEL bit in PHACC register.

HIFEXT1 register specifies operation for burst transfer to and from external bus master.

46.2.14 PHCFG : PHOSTIF Configureation Register

Note: ✓: Available
—: Not available
Note 1. Both CS can be swapped by CSSWAP bit.
Note 2. Only single transfer is available.

46.3 Address Conversion

External bus master cannot access all the memory area in this LSI because address size is 21-bit. In this LSI, System SRAM, Mailbox and PHOSTIF registers are accessible from external bus master. Address conversion circuit converts external bus address to the internal address of System SRAM, Mailbox, and PHOSTIF registers. Table 46.5 shows address mapping between external bus address and internal address. Access to reserved area causes error response.

Table 46.5 Address mapping (1 of 2)

Module	External bus address	Internal address	Size
System SRAM0 (SYSRAM0)	0x00_0000 to 0x07_FFFC	0x1000_0000 to 0x1007_FFFC	512 KB
System SRAM1 (SYSRAM1)	0x08_0000 to 0x0F_FFFC	0x1008_0000 to 0x100F_FFFC	512 KB
System SRAM2 (SYSRAM2)	0x10_0000 to 0x17_FFFC	0x1010_0000 to 0x1017_FFFC	512 KB

Table 46.5 Address mapping (2 of 2)

Module	External bus address	Internal address	Size
Mailbox	0x18_0000 to 0x18_0FFC	0x8024_0000 to 0x8024_0FFC	4 KB
Reserved	0x18_1000 to 0x18_1FFC	Error response	4 KB
PHOSTIF registers	0x18_2000 to 0x18_2FFC	0x8024_2000 to 0x8024_2FFC	4 KB
Reserved	0x18_3000 to 0x1F_FFFF	Error response	—

46.4 Synchronous/Asynchronous SRAM Interface Mode

The external bus interface supports the synchronous SRAM supported MCU connection mode and asynchronous SRAM supported MCU connection mode. When the HIFSYNC bit in PHCFG register is 1, it is a synchronous SRAM interface, and when HIFSYNC bit in PHCFG register is 0, it is an asynchronous SRAM interface.

Two modes are used when the MEMIFSEL bit in PHCFG register is 1 and the MEMCSEL bit in PHCFG register is 0.

When changing these bits in PHCFG register, set PHOSTIF to the module reset state. After setting bits, release the module reset. Dynamic switching is not supported during operation.

46.4.1 Operation

46.4.1.1 Supported Transfer Method

Table 46.6 Supported transfer method

PHCFG register setting			Supported transfer method	
MEMIFSEL	HIFSYNC	BUSSEL	Page access permitted area	Page access prohibited area
0	—	—	Not accessible	Not accessible
1	0 (Asynchronous Mode)	0 (8-bit)	SRAM reading SRAM writing Page ROM reading	SRAM reading SRAM writing
		1 (16-bit)		
	1 (Synchronous Mode)	0 (8-bit)		
		1 (16-bit)		

Note: Page ROM reading can only be used for the area permitted by the HIFBCC and HIFPRC registers.

46.4.1.2 Register Settings in each Area and Supported Access Methods

Table 46.7 Register settings and access method for each area

Area	Register setting		Access method		
	HIFPRC.PAGEONn	HIFBCC.RBUFONn	Page ROM	SRAM	
			R	W	R
No Buffer Target	—	—	Prohibited	OK	OK
Buffer Target	0	0	Prohibited	OK	OK
		1	Prohibited	OK	OK
	1	0	Prohibited	OK	OK
		1	OK	OK	OK

46.4.1.3 Bus Sizing

The bus size for internal access is in accordance with the external bus width.

Table 46.8 Bus sizing

HWRZSEL	BUSSEL	Access area	R/W	Targets for access through internal bus
0	0 (8-bit)	Register area	R	All byte lanes (32-bit)
			W	Specified byte lanes only*1
		System SRAM to be buffered	R	All byte lanes (32-bit)*2
			W	Specified byte lanes only*1
		System SRAM not to be buffered	R	Specified byte lanes only
			W	Specified byte lanes only*1
	1 (16-bit)	Register area	R	All byte lanes (32-bit)
			W	Specified byte lanes only*1
		System SRAM to be buffered	R	All byte lanes (32-bit)*2
			W	Specified byte lanes only*1
		System SRAM not to be buffered	R	Specified byte lanes only
			W	Specified byte lanes only*1
1	0 (8-bit)	Register area	R	All byte lanes (32-bit)
			W	Specified byte lanes only*1
		System SRAM to be buffered	R	All byte lanes (32-bit)*2
			W	Specified byte lanes only*1
		System SRAM not to be buffered	R	1st, 2nd, 3rd or 4th 8-bit*3
			W	Specified byte lanes only*1
	1 (16-bit)	Register area	R	All byte lanes (32-bit)
			W	Specified byte lanes only*1
		System SRAM to be buffered	R	All byte lanes (32-bit)*2
			W	Specified byte lanes only*1
		System SRAM not to be buffered	R	Lower 16-bit or upper 16-bit*3
			W	Specified byte lanes only*1

Note 1. Only the specified byte lanes are to be written. AHB write data in the not specified byte lanes is not changed.
Note 2. The AHB area being buffered is always read in 32-bit units.
Note 3. When HWRZSEL = 1, the AHB area not being buffered is read with the external bus width.

46.4.1.4 Synchronous Mode and Asynchronous Mode

The synchronous SRAM supported MCU connection mode or asynchronous SRAM supported MCU connection mode is selectable by the setting of the HIFSYNC bit in PHCFG register.

The synchronous relationship of each interface signal is shown in Table 46.9.

Table 46.9 Synchronous relationship of PHOSTIF signals (1 of 2)

Signal name	I/O	Synchronous (HIFSYNC = 1)		Asynchronous (HIFSYNC = 0)
		Write	Read	Write and Read
HCS0#	I	HCKIO synchronous	Asynchronous	Asynchronous
HCS1#	I	HCKIO synchronous	Asynchronous	Asynchronous
HA20-HA1	I	HCKIO synchronous	Asynchronous	Asynchronous
HRD#	I	—	Asynchronous	Asynchronous
HWRSTB#	I	HCKIO synchronous	—	Asynchronous
HWR1#-HWR0#	I	HCKIO synchronous	—	Asynchronous

Table 46.9 Synchronous relationship of PHOSTIF signals (2 of 2)

Signal name	I/O	Synchronous (HIFSYNC = 1)		Asynchronous (HIFSYNC = 0)
		Write	Read	Write and Read
HD15-HD0 (input)	I	HCKIO synchronous	—	Asynchronous
HD15-HD0 (output)	O	—	Asynchronous	Asynchronous
HWAIT#	O	HCKIO synchronous	HCKIO synchronous	Asynchronous
HERROUT#	O	Asynchronous	Asynchronous	Asynchronous

46.4.1.5 Buffer Reading

Buffer reading can be used for System SRAM area. Buffer reading is enabled when the RBUFONn bit in the HIFBCC register is set to 1. When buffer reading is enabled, up to 32 bytes are read in advance from each address read by the external bus interface and stored in the buffer. The next time the address accessed by the external bus interface matches the original address of the data stored in the read-ahead buffer, the target data is read from the buffer. This improves throughput because data can be read from the read-ahead buffer at high speed.

Data at addresses for read-ahead are always read in the ascending order of addresses.

46.4.1.6 Page ROM Reading

In addition to buffer reading, page ROM reading can be used for System SRAM area.

To enable page ROM reading, set the RBUFONn bit in HIFBCC register and the PAGEONn bit in the HIFPRC register to 1.

In reading from page ROM, the wait state is released (the HWAIT# signal output is at the High level) once all data in a page has been prepared for off-page reading. This improves throughput because on-page reading following off-page reading does not require wait processing.

Table 46.10 Page size and On-page ratio

Page Size setting HIFPRC.PAGESZ	Address for use in page judgment	On-Page ratio (TYP)	
		BUSSEL	Ratio
0 (8-byte)	HA[20:3]	0 (8-bit)	7/8
		1 (16-bit)	3/4
1 (16-byte)	HA[20:4]	0 (8-bit)	15/16
		1 (16-bit)	7/8

Note: Page ROM access to the area where page ROM reading is disabled is prohibited. Attempted page ROM access to an area where page ROM reading is disabled may lead to a deadlock.
Areas, where page ROM reading is enabled, can be read in the same way as normal SRAM. However, since the chip is placed in the wait state until all data on a page have been provided, the latency increases in comparison with the case where page ROM reading is disabled.
In Page ROM reading, access across 16-byte boundaries is prohibited. Start page ROM reading from the start of 16-byte boundaries such as 0xXX00 and 0xXX40.
The page size is not affected by the bus width. Large page size will increase the on-page ratio and transfer rate. Selecting 16 bytes as the page size is recommended unless this creates a problem for the system.

46.4.1.7 Initialization

PHOSTIF is reset state after power-on. Either internal CPU or external bus master can initialize PHOSTIF registers (HIFxxx register only) dependent on HIFRDYSEL bit in PHACC register. Even initialization by external bus master, internal CPU must set PHCFG and PHACC registers first and then release module reset. After releasing module reset, PHCFG and PHACC registers cannot be changed dynamically during operation. Initialization flow is shown in Table 46.11.

Table 46.11 Initialization flow (1 of 2)

Step	Initialization by internal CPU (HIFRDYSEL = 0)	Initialization by external bus master (HIFRDYSEL = 1)
1	Internal CPU sets PHCFG and PHACC registers.	
2	Internal CPU releases module reset of PHOSTIF.	
3	HW initialization starts.	

Table 46.11 Initialization flow (2 of 2)

Step	Initialization by internal CPU (HIFRDYSEL = 0)	Initialization by external bus master (HIFRDYSEL = 1)
4	Internal CPU sets HIFBCC, HIFBTC, and HIFPRC registers.	External bus master polls HIFRDY bit in HIFMON1 register. The other bits except HIFRDY bit are invalid while HIFRDY bit is 0. After reading HIFRDY = 1, external bus master reads HIFMON1 and HIFMON2 registers to confirm operation mode.
5	Internal CPU sets HIFRDY bit in HIFMON1 register to 1.	External bus master sets HIFBCC, HIFBTC, and HIFPRC registers if corresponding bit in HIFMON2 register is set.
6	External bus master can access SYSRAM and Mailbox area.	External bus master can access SYSRAM and Mailbox area.

Note: Do not change PHOSTIF register from internal CPU to avoid conflict of the write access with external bus master after initialization process.

46.4.2 Basic Operation Timing

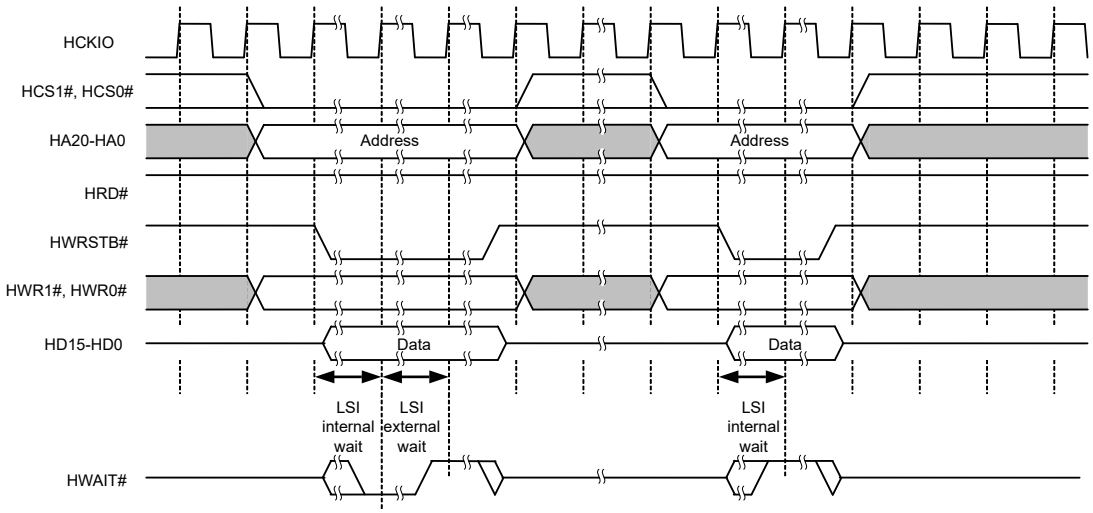

Figure 46.2 Write access timing (SRAM writing)

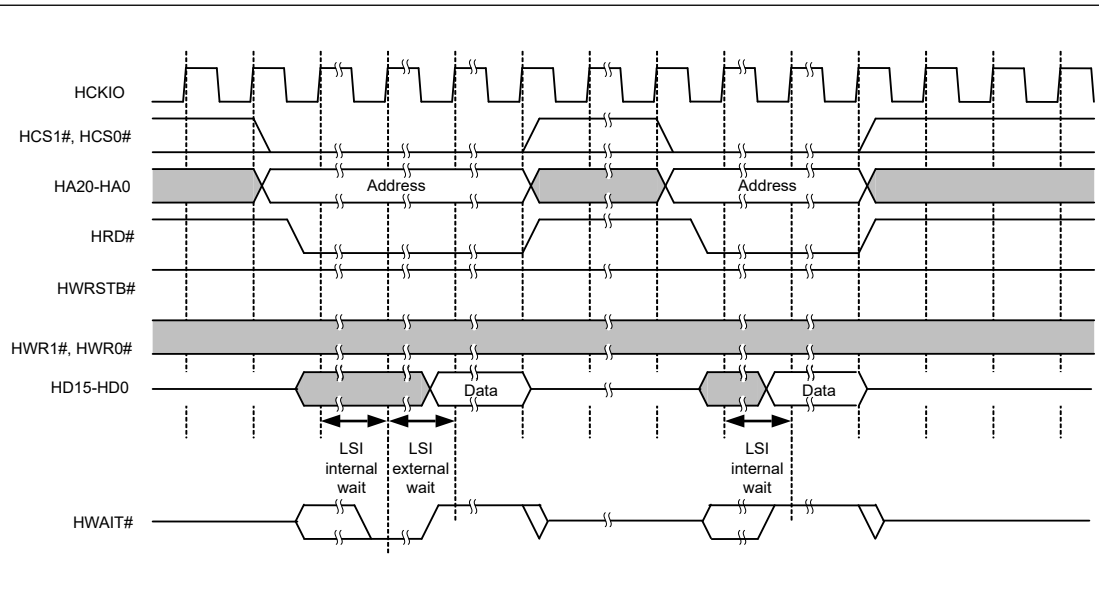

Figure 46.3 Read access timing (SRAM reading)

46.4.3 Asynchronous Connection Timing Adjustment of the External Bus Slave Interface

46.4.3.1 Outline of Asynchronous Connection Timing Adjustment

Adjustment of asynchronous connection timing is provided to adjust for variations in the relative timing between the external bus slave interface and external bus master in asynchronous connection (HIFSYNC = 0).

Table 46.12 Asynchronous connection timing adjustment of the external bus slave interface

Transfer method	Asynchronous connection timing adjustment				Target areas for adjustment	
	Adjustment timing		Setting register		PHOSTIF registers	System SRAM Mailbox
	Target signal	Relativity signal	Register name	Bits name		
SRAM writing	HCS0# HCS1# HA20–HA0 HWR0# HWR1# HD15–HD0	HWRSTB#	HIFBTC	WRSTD2–0	✓	✓
SRAM reading	HCS0# HCS1# HA20–HA0	HRD#	HIFBTC	RDSTD1–0	—	✓
	HD15–HD0	HWAIT#	HIFBTC	RDDTS1–0	—	✓
Page ROM reading	HCS0# HCS1# HA20–HA0	HA20–HA0	HIFBTC	RDSTD1–0	—	✓
	HA20–HA0	HA20–HA0	HIFBTC	PASTD2–0	—	✓
	HD15–HD0	HWAIT#	HIFBTC	RDDTS1–0	—	✓

Note: ✓: Available
—: Not available
Note: Timing adjustment does not apply to reading from the PHOSTIF registers area.
Timing adjustment affects access latency.

46.4.3.2 Asynchronous Connection Timing Adjustment of SRAM Writing

Writing to internal resources starts in response to the detection of a falling edge of the write strobe signal (HWRSTB#). The write strobe signal is selected in Table 46.13 under the condition of input by the HWRZSEL bit or the BUSSEL bit.

When externally writing to internal resources of this LSI, stable addresses and data are required. When falling edge of write strobe signal is detected, other signals may not be stable dependent on output start timing of other signals and transmission delay. This LSI has a function to adjust the timing for the sampling of addresses and data. Sampling timing adjustment can be handled by the WRSTD[2:0] bits in HIFBTC register. Sampling timing is selectable from delay by 0 to 7 clock cycles of PCLKH from the detection of the falling edge of write strobe signal.

Table 46.13 Write Strobe signal

HWRZSEL	BUSSEL	Write Strobe signal (Active Low)
0	—	HWRSTB#
1	0	HWR0#
	1	HWR1# & HWR0#

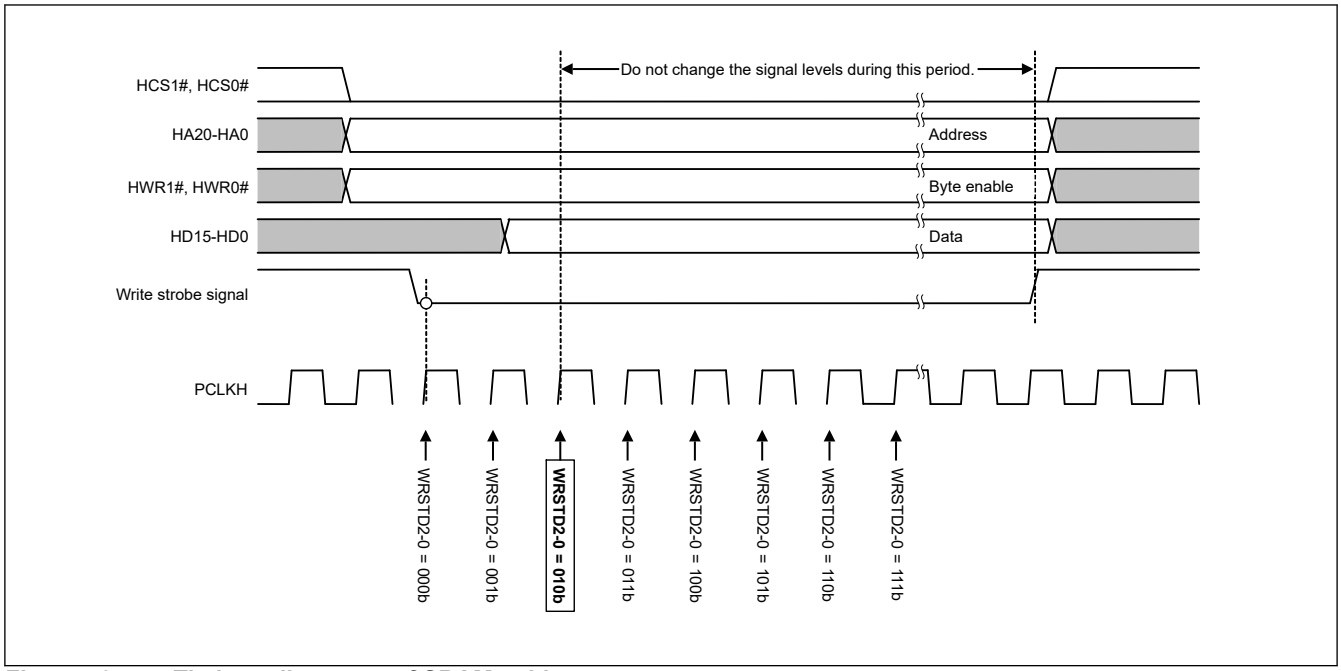

Figure 46.4 Timing adjustment of SRAM writing

46.4.3.3 Asynchronous Connection Timing Adjustment of SRAM Reading and Page ROM Reading

Reading from internal resources starts in response to detection of a falling edge of the read strobe signal (HRD#).

To ensure successful reading, the address and the HCS0#/HCS1# signal must be fixed before detection of the falling edge of the HRD# signal. The timing for starting sampling can be adjusted by using the RDSTD[1:0] bits in the HIFBTC register. Sampling timing is selectable from delay by 0 to 3 clock cycles of PCLKH from the detection of the falling edge of read strobe signal.

Furthermore, the time from fixing of the data (HD15 to HD0) to output of the High level as the HWAIT# signal can also be set. The time difference is set up by using the RDDTS1[1:0] bits in the HIFBTC register. It is selectable from delay by 0 to 3 clock cycles of PCLKH from the fixing of the data.

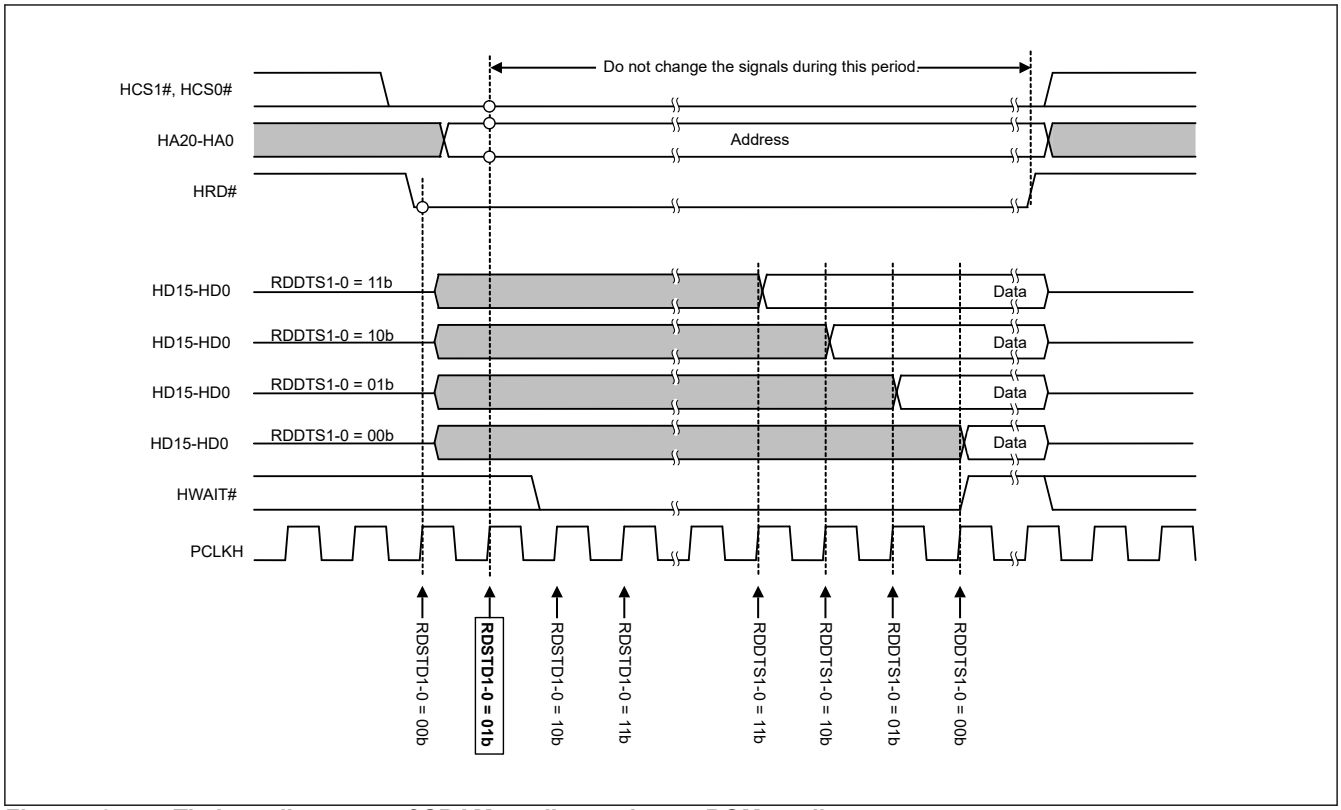

Figure 46.5 Timing adjustment of SRAM reading and page ROM reading

Note: In SRAM reading, input stable address signals during bus cycles after the start of sampling. Input of unstable address signals may create a possibility of incorrect data being read and completion of the bus cycle not being possible without the HWAIT# signal de-asserted.

46.4.3.4 Asynchronous Connection Timing Adjustment of Page ROM Reading

Reading of a new page starts in response to detection of changes in the page address while reading the page ROM.

To ensure successful read, stable address information is required. Timing adjustment is provided to sample stable addresses. The timing is adjusted by using the PASTD[2:0] bits in the HIFBTC register. It is selectable from 1 to 8 clock cycles of PCLKH. Address signals are expected not to change in this period.

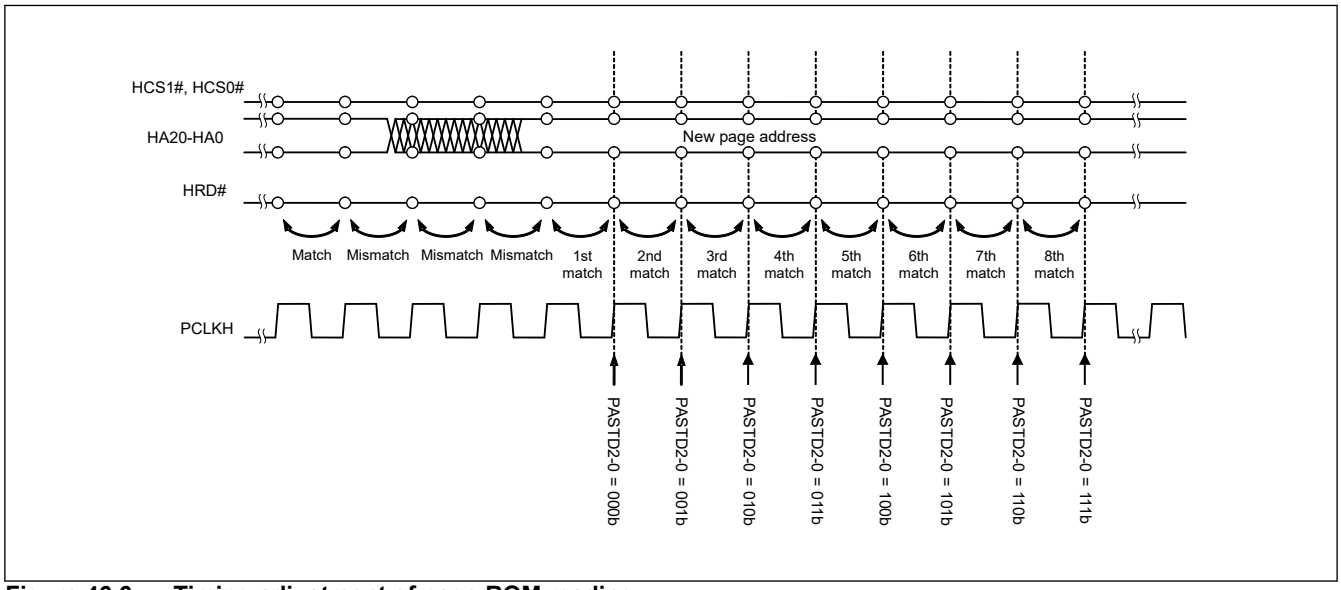

Figure 46.6 Timing adjustment of page ROM reading

46.5 Synchronous Burst SRAM Type Transfer Mode

The external bus interface supports the synchronous burst SRAM type transfer mode when the MEMIFSEL bit in PHCFG register is 1 and the MEMCSEL bit in PHCFG register is 1. In this mode, clocked single transfer and burst transfer are supported.

When changing these bits in PHCFG register, set PHOSTIF to the module reset state. After setting bits, release the module reset. Dynamic switching is not supported during operation.

Note: In synchronous burst SRAM type transfer mode, the internal reset state cannot be checked by reading a register because the external bus slave interface cannot be accessed until the internal reset signal is de-asserted.

In this section, the HWDATA and HRDATA are aliases for the HD.

HWDATA: HD output signals of the external bus master

HRDATA: HD input signal of the external bus master

46.5.1 Operation

46.5.1.1 Supported Transfer Method

Table 46.14 Supported transfer method

PHCFG register setting				Operating mode	Byte address [20:0] acquisition Destination (MSB, …, LSB)
MEMIF SEL	BUS SEL	HIF SYNC	ADMUX MODE		
0	—	—	—	Not accessible	—
1	0	0	0	Setting Prohibited	—
			1	8-bit Address/Data multiplexing (byte address)	{HA[20:8], HWDATA[7:0]}
		1	0	8-bit Address/Data separation	{HA[20:0]}
			1	8-bit Address/Data multiplexing (byte address)	{HA[20:8], HWDATA[7:0]}
	1	0	0	Setting Prohibited	—
			1	16-bit Address/Data multiplexing (byte address)	{HA[20:16], HWDATA[15:0]}
		1	0	16-bit Address/Data separation	{HA[20:1], 0b}
			1	16-bit Address/Data multiplexing (word address)	{HA[20:17], HWDATA[15:0], 0b}

46.5.1.2 Register Settings for each Area and Available Access Methods

Table 46.15 Register settings for each area selected by the level on the HCS0# pin and method of access

Area	Register setting			Access method				Remark
				Burst transfer		Single transfer		
	HIFEXT0. MODTRN	HIFPRC. PAGEONn	HIFBCC. RBUFONn	Write	Read	Write	Read	
No Buffer Target	—	—	—	Prohibited	Prohibited	OK	OK	Single area
Buffer Target	0	—	—	Prohibited	Prohibited	OK	OK	Single setting
	1	0	0	Prohibited	Prohibited	Prohibited	Prohibited	
			1	Prohibited	Prohibited	Prohibited	Prohibited	
		1	0	Prohibited	Prohibited	Prohibited	Prohibited	
			1	OK	OK	Prohibited	Prohibited	

Note: In case of burst transfer, set HIFEXT0.MODTRN = 1, HIFPRC.PAGEONn = 1, and HIFBCC.RBUFONn = 1.

Table 46.16 Register settings for each area selected by the level on the HCS1# pin and method of access

Area	Register setting			Access method				Remark
	HIFEXT0. MODTRN	HIFPRC. PAGEONn	HIFBCC. RBUFONn	Burst transfer		Single transfer		
				Write	Read	Write	Read	
All areas	—	—	—	Prohibited	Prohibited	OK	OK	Single area

46.5.1.3 Write Status Mode and Write Strobe Mode

There are two types of write operations in synchronous burst SRAM type transfer mode: write status mode and write strobe mode. Either of these two operating modes is selected every bus cycle by the level on the HWRSTB# pin to be sampled while the Low level is input on the HBS# pin.

When the HWRSTB# pin is at the Low level while the Low level is input on the HBS# pin, write status mode is entered. In write status mode, the current bus cycle ends (the High level is sampled from the HCS0# or HCS1# signal) or the write bus cycle continues until the next bus cycle starts (the Low level is sampled from the HBS# pin).

When the HWRSTB# pin is at the High level while the Low level is input on the HBS# pin and then the HWRSTB# pin turns Low level, write strobe mode is entered. In write strobe mode, the write bus cycle continues until the current bus cycle ends (the High level is sampled from the HWRSTB# pin).

46.5.1.4 BSC ADMUX Mode

It is possible to connect with MPX I/O Interface of Renesas Bus State Controller (BSC) which is implemented in a part of Renesas MPU/MCU like RZ/T2, by setting BSCADMUX bit in PHACC register. Since AH# signal of BSC outputs High level at start of address phase, PHOSTIF internally inverts HBS# signal to receive AH# signal in this mode. In reading, byte enable signals, HWRZ[1:0], are not used and access is always bus width. Supported CS is HCS1# only.

Table 46.17 shows connection between PHOSTIF signals and BSC signals. Necessary BSC setting is shown in Table 46.18.

Table 46.17 Connection between PHOSTIF signals and BSC signals

PHOSTIF signals	BSC signals	Remark
HCKIO	CKIO	
HCS0#	— (No connect)	
HCS1#	CS5#	In case of CSSWAP = 0
HA[20:16]	A[20:16]	Address is not shifted. (HIFSYNC = 0)
HRD#	RD#	
HWRSTB#	RD/WR#	
HWR1#, HWR0#	WE1#, WE0#	
HD[15:0]	D[15:0]	
HWAIT#	WAIT#	
HBS#	AH#	

Table 46.18 BSC MPX-I/O interface setting

Register	Bits	Value	Remark
CS5BCR	BSZ[1:0]	01b or 10b	8-bit or 16-bit only
	TYPE[2:0]	010b	MPX-I/O
CS5WCR	MPXW/BAS	1b	1 wait cycle inserted in address cycle.
	SW[1:0]	00b	0.5 cycles from the end of the address cycle to RD# and WEn# active.
	WM	0b	External wait input is valid.
	HW[1:0]	00b	0.5 cycles from RD# and WEn# inactive to CS5# inactive.

46.5.1.5 Initialization

PHOSTIF is reset state after power-on. Either internal CPU or external bus master can initialize PHOSTIF registers (HIFxxx register only) dependent on HIFRDYSEL bit in PHACC register. Even initialization by external bus master, internal CPU must set PHCFG and PHACC registers first and then release module reset. After releasing module reset, PHCFG and PHACC registers cannot be changed dynamically during operation. Initialization flow is shown in Table 46.19.

Table 46.19 Initialization flow

Step	Initialization by internal CPU (HIFRDYSEL = 0)	Initialization by external bus master (HIFRDYSEL = 1)
1	Internal CPU sets PHCFG and PHACC registers.	
2	Internal CPU releases module reset of PHOSTIF.	
3	HW initialization starts.	
4	Internal CPU sets HIFBCC, HIFBTC and HIFPRC registers.	External bus master polls HIFRDY bit in HIFMON1 register. The other bits except HIFRDY bit are invalid while HIFRDY bit is 0. After reading HIFRDY = 1, external bus master reads HIFMON1 to HIFMON3 registers to confirm operation mode.
5	Internal CPU sets HIFEXT0 and HIFEXT1 registers.	External bus master sets HIFEXT0 and HIFEXT1 registers if corresponding bit in HIFMON3 register is set.
5	Internal CPU sets HIFRDY bit in HIFMON1 register to 1.	External bus master sets HIFBCC, HIFBTC, and HIFPRC registers if corresponding bit in HIFMON2 register is set.
6	External bus master can access SYSRAM and Mailbox area.	External bus master can access SYSRAM and Mailbox area.

Note: Do not change PHOSTIF register from internal CPU to avoid conflict of the write access with external bus master after initialization process.

46.5.3 Usage Notice

46.5.3.1 Prohibition of Burst Transfer that Spans Boundaries of Spaces and the Advance Reading Area

Burst transfer that spans boundaries of the register space, external bus space, or internal bus space, or the boundaries of the area set for read-ahead, is prohibited. Stop burst transfer before it crosses the boundaries of these spaces and the area.

46.5.3.2 Timing for Starting the Internal Bus Cycle for Writing

In bus cycles for writing in synchronous burst SRAM type transfer mode, data for writing are sampled in synchronization with HCKIO and an access request is issued to the AHB control block on the next rising edge of HCKIO.

Accordingly, if the connected external bus master only supplies the clock signal to the HCKIO pin during the bus cycle periods, actual writing to the target internal resource is put on hold until the next bus cycle for supplying the clock signal to the HCKIO pin starts.

If immediate completion of actual writing to the target internal resource is essential, add some bus cycles over which the clock signal is supplied to the HCKIO pin after the number of bus cycles that would otherwise be required for writing.

46.5.3.3 Confirming Reading from a Control Register

When reading from a given control register, this LSI does not wait for prior writing to the control register to be completed. Accordingly, if a control register is read after writing to it but before its value is actually changed, the value before writing will be read.

To change the setting of a control register, confirm completion of the change to the setting by polling the register until the same value as was written is read.

46.5.3.4 De-asserting the Reset Signal

The internal reset signal output by the reset synchronization circuit is de-asserted in synchronization with HCKIO supplied by the external bus master. Accordingly, if the external bus master only supplies HCKIO during bus cycles of this LSI, the internal reset signal is not de-asserted at the point at which the first bus cycle of this LSI starts, so that bus cycle is not recognizable.

47. Mailbox and Semaphore (MBXSEM)

47.1 Overview

Mailbox and semaphore are available for controlling exclusive access between internal CPU (Cortex-R52) and external host CPU. Table 47.1 shows specification of mailbox and semaphore registers. These registers are accessible from external host CPU via either SHOSTIF or PHOSTIF as well as internal CPU. Concurrent use from both host interface modules is not supported.

Table 47.1 Specification of MBXSEM

Semaphore/ Mailbox	Function	Bit size	Number of register	Interrupt generation		Access property		
				Cortex-R52	Host CPU	Cortex-R52	Host CPU	Access size
Semaphore	Semaphore	1	8	No	No	R(C)/W	R(C)/W	8, 16, 32
	Read clear enable*1	8	1	No	No	R/W	R/W	8, 16, 32
Mailbox (External Host CPU to Cortex-R52)	Mailbox	32	4	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1	Yes (each bit)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	4	1	Cleared (each bit)	No	R/W	R	8, 16, 32
Mailbox (Cortex-R52 to External Host CPU)	Mailbox	32	4	No	No	R/W	R	8, 16, 32
	Interrupt Set*2 *3	4	1	No	Yes (combined)	R/W	R	8, 16, 32
	Interrupt Clear*2 *4	4	1	No	Cleared (when all bits become 0)	R	R/W	8, 16, 32

Note 1. Each bit corresponds to each semaphore register.
Note 2. Each bit represents the interrupt status. When read, same interrupt status can be read through interrupt set and clear registers.
Note 3. When 1 is written to a bit, the corresponding bit is set.
Note 4. When 1 is written to a bit, the corresponding bit is cleared.

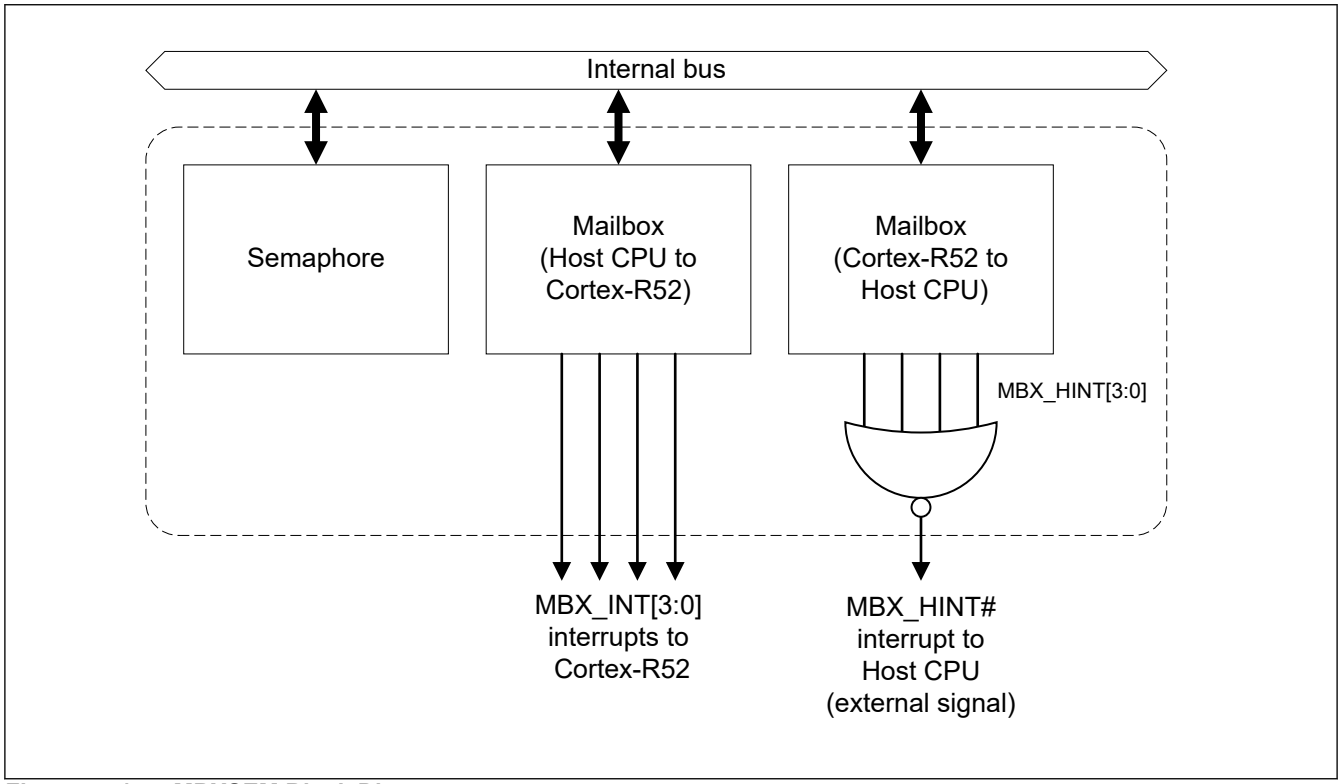

Figure 47.1 MBXSEM Block Diagram

Table 47.2 lists the output pin of the MBXSEM.

Table 47.2 MBXSEM I/O pin

Name	I/O	Function
MBX_HINT#	Output	Mailbox (Cortex-R52 to Host CPU) interrupt output pin

47.2 Register Descriptions

Register base address is different between external Host CPU view and internal memory address view except.

- External host CPU view : BASE = 0x18_0000

  Note: When 32-bit addressing mode in SHOSTIF is used, please shift the address (base address + offset address) by 2 bits in the right direction.

- Internal CPU view: BASE = 0x8024_0000

Register offset address is described in byte address. Convert it to word address by dividing by 4 if 32-bit addressing mode is used in SHOSTIF.

47.2.1 SEMn : Semaphore Register n (n = 0 to 7)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x00 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEM	Semaphore bit 0: Resource being used 1: Resource not being used	R/W*1
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When read clear function is disabled (SEMRCEN.SEMRCENn = 0), register value is retained after reading the register. When read clear function is enabled (SEMRCEN.SEMRCENn = 1), register is cleared to 0 after reading the register.

SEMn register is used to perform semaphore for synchronization and exclusive control between internal CPU (Cortex-R52) and external host CPU. Resource status can be controlled when the resource is shared between CPUs. Semaphore bit can be cleared when reading this register if SEMRCEN register is enabled.

47.2.2 SEMRCEN : Semaphore Read Clear Enable Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SEMRCEN7	SEMRCEN6	SEMRCEN5	SEMRCEN4	SEMRCEN3	SEMRCEN2	SEMRCEN1	SEMRCEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEMRCEN0	Enables or disables SEM0 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
1	SEMRCEN1	Enables or disables SEM1 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
2	SEMRCEN2	Enables or disables SEM2 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
3	SEMRCEN3	Enables or disables SEM3 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
4	SEMRCEN4	Enables or disables SEM4 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
5	SEMRCEN5	Enables or disables SEM5 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
6	SEMRCEN6	Enables or disables SEM6 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
7	SEMRCEN7	Enables or disables SEM7 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

SEMRCEN register enables and disables read clear function of SEMn register.

47.2.3 MBXH2Cn : Host to CR52 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x40 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from external host CPU to internal Cortex-R52	R

Note: Only read is available from internal Cortex-R52, and read and write are available from external host CPU.

MBXH2Cn register is used as mailbox from external host CPU to internal Cortex-R52.

47.2.4 MBXISETH2C : Host to CR52 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INT3S	MBX_INT2S	MBX_INT1S	MBX_INT0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INT0S	Generates or indicates MBX_INT0 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from external host CPU: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_INT0 interrupt is asserted. Read: Indicates MBX_INT0 interrupt status	R
1	MBX_INT1S	Generates or indicates MBX_INT1 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from external host CPU: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_INT1 interrupt is asserted. Read: Indicates MBX_INT1 interrupt status	R
2	MBX_INT2S	Generates or indicates MBX_INT2 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from external host CPU: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_INT2 interrupt is asserted. Read: Indicates MBX_INT2 interrupt status	R
3	MBX_INT3S	Generates or indicates MBX_INT3 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from external host CPU: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_INT3 interrupt is asserted. Read: Indicates MBX_INT3 interrupt status	R
31:4	—	These bits are read as 0.	R

Note: Only read is available from internal Cortex-R52, and read and write are available from external host CPU.

MBXISETH2C register is used to generate mailbox interrupt from external host CPU to internal Cortex-R52. Maximum 4 interrupts can be generated.

47.2.5 MBXICLRH2C : Host to CR52 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x54

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INT3C	MBX_INT2C	MBX_INT1C	MBX_INT0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INT0C	Clears or indicates MBX_INT0 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from internal Cortex-R52: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_INT0 interrupt is cleared. Read: Indicates MBX_INT0 interrupt status	R/W
1	MBX_INT1C	Clears or indicates MBX_INT1 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from internal Cortex-R52: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_INT1 interrupt is cleared. Read: Indicates MBX_INT1 interrupt status	R/W
2	MBX_INT2C	Clears or indicates MBX_INT2 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from internal Cortex-R52: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_INT2 interrupt is cleared. Read: Indicates MBX_INT2 interrupt status	R/W
3	MBX_INT3C	Clears or indicates MBX_INT3 interrupt of mailbox from external host CPU to internal Cortex-R52. Write from internal Cortex-R52: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_INT3 interrupt is cleared. Read: Indicates MBX_INT3 interrupt status	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: Read and write are available from internal Cortex-R52, and only read is available from external host CPU.

MBXICLRH2C register is used to clear mailbox interrupt from external host CPU to internal Cortex-R52.

47.2.6 MBXC2Hn : CR52 to Host Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x80 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from internal Cortex-R52 to external host CPU	R/W

Note: Read and write are available from internal Cortex-R52, and only read is available from external host CPU.

MBXC2Hn register is used as mailbox from internal Cortex-R52 to external host CPU.

47.2.7 MBXISETC2H : CR52 to Host Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_HINT3S	MBX_HINT2S	MBX_HINT1S	MBX_HINT0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_HINT0S	Generates or indicates MBX_HINT0 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from internal Cortex-R52: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_HINT0 interrupt is asserted. Read: Indicates MBX_HINT0 interrupt status	R/W
1	MBX_HINT1S	Generates or indicates MBX_HINT1 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from internal Cortex-R52: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_HINT1 interrupt is asserted. Read: Indicates MBX_HINT1 interrupt status	R/W
2	MBX_HINT2S	Generates or indicates MBX_HINT2 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from internal Cortex-R52: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_HINT2 interrupt is asserted. Read: Indicates MBX_HINT2 interrupt status	R/W
3	MBX_HINT3S	Generates or indicates MBX_HINT3 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from internal Cortex-R52: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_HINT3 interrupt is asserted. Read: Indicates MBX_HINT3 interrupt status	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: Read and write are available from internal Cortex-R52, and only read is available from external host CPU.

MBXISETC2H register is used to generate mailbox interrupt from internal Cortex-R52 to external host CPU. Maximum 4 interrupts can be generated but all the interrupts are combined to one output interrupt signal (MBX_HINT#) by logical NOR.

47.2.8 MBXICLRC2H : CR52 to Host Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_HINT3C	MBX_HINT2C	MBX_HINT1C	MBX_HINT0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_HINT0C	Clears or indicates MBX_HINT0 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT0 interrupt status is not changed. 1: MBX_HINT0 interrupt is cleared. Read: Indicates MBX_HINT0 interrupt status	R
1	MBX_HINT1C	Clears or indicates MBX_HINT1 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT1 interrupt status is not changed. 1: MBX_HINT1 interrupt is cleared. Read: Indicates MBX_HINT1 interrupt status	R
2	MBX_HINT2C	Clears or indicates MBX_HINT2 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT2 interrupt status is not changed. 1: MBX_HINT2 interrupt is cleared. Read: Indicates MBX_HINT2 interrupt status	R
3	MBX_HINT3C	Clears or indicates MBX_HINT3 interrupt of mailbox from internal Cortex-R52 to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT3 interrupt status is not changed. 1: MBX_HINT3 interrupt is cleared. Read: Indicates MBX_HINT3 interrupt status	R
31:4	—	These bits are read as 0.	R

Note: Only read is available from internal Cortex-R52, and read and write are available from external host CPU.

MBXICLRC2H register is used to clear mailbox interrupt from internal Cortex-R52 to external host CPU.

47.3 Operation

47.3.1 Semaphore

SEMn registers are used to perform up to 8 semaphores for synchronization and exclusive control between internal CPU (Cortex-R52) and external host CPU.

SEM bit in SEMn register is used to set the status of the resource shared between CPUs to indicate whether the resource is being used or not. Writing 1 to this bit maintains its value. When the read clear function is enabled (SEMRCEN.SEMRCENn bit = 1), reading SEM bit of corresponding SEM register clears its value to 0.

When the SEM0 register is used for semaphore control for a resource A, for example, the following procedure takes place, where CPU0 is Cortex-R52 and CPU1 is external host CPU or vice versa:

1. Use the initialization routine of CPU0 to set the SEMRCEN.SEMRCEN0 bit to 1 (this enables the read clear function for SEM0 register).
2. Set the SEM bit to 1 (resource not being used) in the SEM0 register.
3. For example, when CPU1 attempts to use the resource A, CPU1 reads the SEM0 register repeatedly until 1 is read.
4. When SEM0.SEM = 1 is read, CPU1 confirms that the resource is not being used.
   This operation clears the SEM0.SEM bit to 0.
5. Then CPU1 uses the resource A.
   If CPU0 attempts to use the resource A while CPU1 is using it, 0 is read from the SEM0.SEM bit (resource A being used by CPU1). CPU0 repeats read operation and waits until the resource is released.
6. When CPU1 completes its use of the resource A, 1 is written in the SEM0.SEM bit to indicate that the resource A is released.
7. If CPU0 attempts to use the resource A after the above step (6), it confirms whether the resource is used or not by reading the SEM0.SEM bit. When the SEM0.SEM bit is 1, CPU0 starts to use the resource A. This operation clears the SEM0.SEM bit to 0.

47.3.2 Mailbox

MBXH2Cn and MBXC2Hn register are used to perform up to 4 32-bit mailboxes for communication between internal CPU (Cortex-R52) and external host CPU. MBXH2Cn registers are mailboxes from external host CPU to Coretex-R52 and MBXC2Hn registers are vice versa.

47.3.3 Interrupt

Interrupt signals are available to internal CPU and external host CPU. One CPU can generate up to 4 interrupts to the other CPU each other. They can be related to 4 mailboxes and be used independent of mailbox. MBXISETH2C and MBXISETC2H registers are used to generate interrupt by writing 1 to corresponding bit. Writing 0 to corresponding bit is to retain the current interrupt status of the bit. MBXICLRH2C and MBXICLRC2H registers are used to clear interrupt by writing 1 to corresponding bit. Current interrupt status can be confirmed by reading these registers.

Table 47.3 MBXSEM interrupt source (to Cortex-R52)

Name	Interrupt sources	CPU GIC request	DMAC activation	ELC activation
MBX_INT0	Mailbox (Host CPU to Cortex-R52) interrupt 0	Possible	Possible	Possible
MBX_INT1	Mailbox (Host CPU to Cortex-R52) interrupt 1	Possible	Possible	Possible
MBX_INT2	Mailbox (Host CPU to Cortex-R52) interrupt 2	Possible	Possible	Possible
MBX_INT3	Mailbox (Host CPU to Cortex-R52) interrupt 3	Possible	Possible	Possible

Table 47.4 MBXSEM interrupt source (to external Host CPU)

Name	Interrupt sources	CPU GIC request	DMAC activation	ELC activation
MBX_HINT0	Mailbox (Cortex-R52 to Host CPU) interrupt 0	Not Possible	Not Possible	Not Possible
MBX_HINT1	Mailbox (Cortex-R52 to Host CPU) interrupt 1	Not Possible	Not Possible	Not Possible
MBX_HINT2	Mailbox (Cortex-R52 to Host CPU) interrupt 2	Not Possible	Not Possible	Not Possible
MBX_HINT3	Mailbox (Cortex-R52 to Host CPU) interrupt 3	Not Possible	Not Possible	Not Possible

Note: MBX_HINT[3:0] are combined to one output interrupt signal (MBX_HINT#) by logical NOR.

48. Electrical Characteristics

Electrical characteristics of this LSI is defined with the following conditions unless otherwise described.

Conditions:

VDD = 1.05 to 1.15 V

VCC18 = VCC1833_n (1.8-V mode) = VCC18_PLL0 = VCC18_PLL1 = VCC18_USB = AVCC18_USB = VCC18_ADC0 = VCC18_ADC1 = AVCC18_TSU = VREFH0 = VREFH1= 1.70 to 1.95 V

VCC33 = VCC1833_n (3.3-V mode) = VCC33_USB = 3.135 to 3.465 V

VSS = VSS_USB = 0 V

Tj = −40 to 125ºC

48.1 Absolute Maximum Ratings

Table 48.1 Absolute maximum ratings

Parameter	Symbol	Value	Unit
Power supply voltage (3.3-V mode)	VCC33, VCC1833_0, VCC1833_1, VCC1833_2, VCC1833_3, VCC1833_4	−0.3 to +3.8	V
Power supply voltage (1.8-V mode)	(VCC18) VCC1833_0 VCC1833_1, VCC1833_2, VCC1833_3, VCC1833_4	−0.3 to +2.5	V
Power supply voltage	VDD	−0.3 to +1.5	V
Input voltage	Vin (3.3-V logic)	−0.3 to VCC33 + 0.3	V
Input voltage	Vin (1.8-V logic)	−0.3 to VCC18 + 0.3	V
Analog power supply voltage	VCC18_PLL0, VCC18_PLL1, VCC18_USB, AVCC18_USB, VCC18_ADC0, VCC18_ADC1, AVCC18_TSU*1	−0.3 to smaller value of VCC18*2 + 0.3 or 2.5	V
	VCC33_USB	−0.3 to smaller value of VCC33 + 0.3 or 3.8	V
Voltage difference between power supply pins	VCC33-VCC18	-2.5 to + 2.1	V
Analog input voltage	VAN	−0.3 to smaller value of VCC18_ADC0/1 + 0.3 or 2.5	V
Reference voltage	VREFH0, VREFH1	−0.3 to smaller value of VCC18_ADC0/1 + 0.3 or 2.5	V
Crystal oscillator pins input voltage	XTAL, EXTAL	−0.3 to +1.5	V
Operating temperature (Junction temperature)	T_j	−40 to +125	ºC
Storage temperature	T_{stg}	−55 to +125	ºC

Note 1. Connect Analog power supply pins to VCC18 when Analog block(s) are not used. Do not leave these pins open.
Note 2. For convention, "VCC18" virtually represents any 1.8-V power supplies of the chip such as VCC1833_n in 1.8-V mode.

Caution: Permanent damage to the LSI might result if absolute maximum ratings are exceeded.

48.2 Power Supply

Table 48.2 Power supply

Parameter	Symbol	Value	Min.	Typ.	Max.	Unit
Power supply voltages	VCC33		3.135	—	3.465	V
	VDD		1.05	1.1	1.15	V
	VSS		—	0	—	V
Power supply voltages supporting multi voltage mode	VCC1833_0, VCC1833_1, VCC1833_2, VCC1833_3, VCC1833_4	3.3-V mode	3.135	3.3	3.465	V
		1.8-V mode (VCC18)	1.70	1.8	1.95	V
Analog power supply voltages	VCC18_PLL0		—	VCC18	—	V
	VCC18_PLL1		—	VCC18	—	V
	VCC33_USB		—	VCC33	—	V
	VCC18_USB		—	VCC18	—	V
	AVCC18_USB		—	VCC18	—	V
	VCC18_ADC0		—	VCC18	—	V
	VCC18_ADC1		—	VCC18	—	V
	AVCC18_TSU		—	VCC18	—	V
	VSS_USB		—	0	—	V

48.3 Power On/Off Sequence

Power on/off sequence and timing are shown in the figure and table below.

For power-up, 1.1-V and 1.8-V power (i.e. VDD, VCC18, and AVCC) must be supplied first, then 3.3-V power (i.e. VCC33) must be supplied. The power-up sequence must be completed within 100 ms. Reset signal (i.e. RES#) must be held to Low level during the power-up.

For Power-down, 3.3-V power (i.e. VCC33) must go down first and then 1.1-V and 1.8-V power (i.e. VDD, VCC18, and AVCC). The power-down sequence must be completed within 100 ms.

Rise and fall time of each power supply for the power-up and the power-down must be larger than 10 µs.

Power supply voltages and reset signal must be applied with monotonic increase.

Do not apply a negative voltage to power supply voltages.

Stable clock must be supplied to EXTAL/XTAL or EXTCLKIN pin when reset signal (i.e. RES#) is driven high.

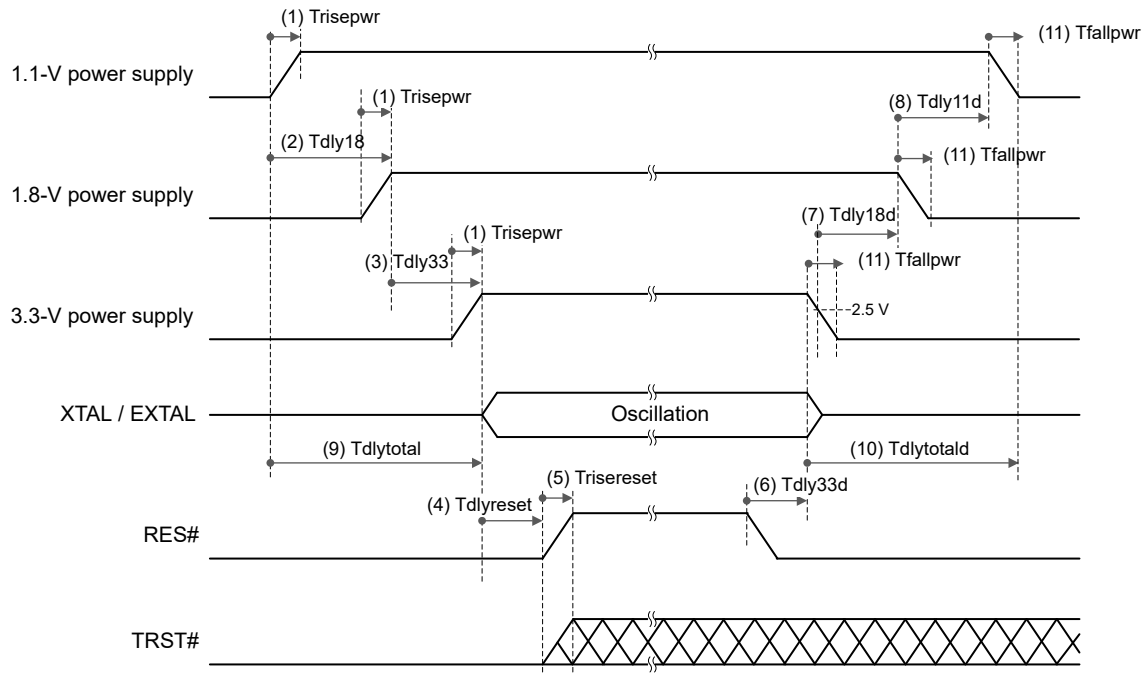

Figure 48.1 Power on/off sequence

Table 48.3 Power on/off sequence timing

No.	Symbol	Description	Value		
			Min.	Typ.	Max.
(1)	Trisepwr	Rising time of the power supply voltage	10 µs	—	30 ms
(2)	Tdly18	Delay time from start of rising of the 1.1-V power supply voltage to completion of rising of the 1.8-V power supply voltage	0	—	100 ms
(3)	Tdly33	Delay time from completion of rising of the 1.8-V power supply voltage to completion of rising of the 3.3-V power supply voltage	0	—	100 ms
(4)	Tdlyreset	Delay time from completion of rising of the 3.3-V power supply voltage to start of rising of RES# when XTAL/EXTAL is used.	10 ms	—	—
		Delay time from completion of rising of the 3.3-V power supply voltage to start of rising of RES# when EXTCLKIN is used.	1 ms	—	—
(5)	Trisereset	Rising time of RES#	—	—	150 µs
(6)	Tdly33d	Delay time from start of falling of RES# to start of falling of the 3.3-V power supply voltage	10 µs	—	—
(7)	Tdly18d	Delay time from start of falling time of the 3.3-V power supply voltage to start of falling of the 1.8-V power supply voltage	0	—	100 ms
(8)	Tdly11d	Delay time from start of falling of the 1.8-V power supply voltage to start of falling of the 1.1-V power supply voltage	0	—	100 ms
(9)	Tdlytotal	Startup time of all power supply voltage	—	—	100 ms
(10)	Tdlytotald	Shut down time of all power supply voltage	—	—	100 ms
(11)	Tfallpwr	Falling time of the power supply voltage	10 µs	—	30 ms

48.4 DC Characteristics

Table 48.4 DC Characteristics (3.3-V mode)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input High-level voltage	V_{IH33}	3.3-V mode, Schmitt Trigger Control Disabled, Except P07_4 pin	2.0	—	VCC33 + 0.3	V
Input Low-level voltage	V_{IL33}		−0.3	—	0.8	V
Positive trigger voltage	V_{T33+}	3.3-V mode, Schmitt Trigger Control Enabled, Except P07_4 pin	0.9	—	2.1	V
Negative trigger voltage	V_{T33-}		0.7	—	1.9	V
Hysteresis voltage	ΔV_{T33}		0.2	—	—	V
Input High-level voltage 2	V_{IH33_2}	3.3-V mode, Schmitt Trigger Control Disabled, P07_4 pin ONLY	VCC33 × 0.7	—	VCC33 + 0.3	V
Input Low-level voltage 2	V_{IL33_2}		-0.3	—	VCC33 × 0.3	V
Positive trigger voltage 2	V_{T33+_2}	3.3-V mode, Schmitt Trigger Control Enabled, P07_4 pin ONLY	—	—	VCC33 × 0.72	V
Negative trigger voltage 2	V_{T33-_2}		VCC33 × 0.3	—	—	V
Hysteresis voltage 2	ΔV_{T33_2}		VCC33 × 0.1	—	—	V
Output High-level voltage	V_{OH33}	Low, IOH = −2 mA	VCC33 − 0.4	—	—	V
	V_{OH33}	Middle, IOH = −4 mA	VCC33 − 0.4	—	—	V
	V_{OH33}	High, IOH = −8 mA	VCC33 − 0.4	—	—	V
	V_{OH33}	Ultra High, IOH = −12 mA	VCC33 − 0.4	—	—	V
Output Low-level voltage	V_{OL33}	Low, IOL = 2 mA	—	—	0.4	V
	V_{OL33}	Middle, IOL = 4 mA	—	—	0.4	V
	V_{OL33}	High, IOL = 8 mA	—	—	0.4	V
	V_{OL33}	Ultra High, IOL = 12 mA	—	—	0.4	V
Input leakage current	|Iin|	Vin = 0 V, Vin = VCC33	—	—	10	µA
Three-State leakage current (off state)	$\|I_{TSI}\|$	Vin = 0 V, Vin = VCC33	—	—	10	µA
Input Pull-up resistors resistance	Rpu	Vin = 0 V	15	—	300	kΩ
Input Pull-up resistors current	Ipu	Vin = 0 V	-220	—	-11	µA
Input Pull-down resistors resistance	Rpd	Vin = VCC33	15	—	300	kΩ
Input Pull-down resistors current	Ipd	Vin = VCC33	11	—	220	µA
Input Capacitance	Cin	All input/output and input pins	—	—	10	pF

Table 48.5 DC Characteristics (1.8-V mode) (1 of 2)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input High-level voltage	V_{IH18}	1.8-V mode, Schmitt Trigger Control Disabled	VCC18 × 0.65	—	VCC18 + 0.3	V
Input Low-level voltage	V_{IL18}		−0.3	—	VCC18 × 0.35	V
Positive trigger voltage	V_{T18+}	1.8-V mode, Schmitt Trigger Control Enabled	VCC18 × 0.4	—	VCC18 × 0.7	V
Negative trigger voltage	V_{T18-}		VCC18 × 0.3	—	VCC18 × 0.6	V
Hysteresis voltage	ΔV_{T18}		VCC18 × 0.1	—	—	V
Output High-level voltage	V_{OH18}	Low, IOH = −2 mA	VCC18 − 0.45	—	—	V
	V_{OH18}	Middle, IOH = −4 mA	VCC18 − 0.45	—	—	V
	V_{OH18}	High, IOH = −8 mA	VCC18 − 0.45	—	—	V
	V_{OH18}	Ultra High, IOH = −12 mA	VCC18 − 0.45	—	—	V

Table 48.5 DC Characteristics (1.8-V mode) (2 of 2)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Output Low-level voltage	V_{OL18}	Low, IOL = 2 mA	—	—	0.45	V
	V_{OL18}	Middle, IOL = 4 mA	—	—	0.45	V
	V_{OL18}	High, IOL = 8 mA	—	—	0.45	V
	V_{OL18}	Ultra High, IOL = 12 mA	—	—	0.45	V
Input leakage current	|Iin|	Vin = 0 V, Vin = VCC18	—	—	10	µA
Three-State leakage current (off state)	$\|I_{TSI}\|$	Vin = 0 V, Vin = VCC18	—	—	10	µA
Input Pull-up resistors resistance	Rpu	Vin = 0 V	15	—	300	kΩ
Input Pull-up resistors current	Ipu	Vin = 0 V	-120	—	-6	µA
Input Pull-down resistors resistance	Rpd	Vin = VCC18	15	—	300	kΩ
Input Pull-down resistors current	Ipd	Vin = VCC18	6	—	120	µA
Input Capacitance	Cin	All input/output and input pins	—	—	10	pF

Table 48.6 USB2.0 USB_RREF Pin

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Reference resistor*1	R_{REF}	—	1.8 (±1%)			kΩ

Note 1. The reference resistor connected to the USB_RREF pin is for external connection to this LSI.

Table 48.7 USB2.0 Pull-Up/Pull-Down Resistors

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
USB_DP pull-up resistor (when the function controller is selected)	R_{PU}	Idle	0.900	—	1.575	kΩ
		Transmission/reception	1.425	—	3.090	kΩ
USB_DP/USB_DM pull-down resistors (when the host controller is selected)	R_{PD}	—	14.25	—	24.80	kΩ

Table 48.8 USB2.0 Host/Function-Related Pins (Low/Full Speed)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input high level voltage	V_{FSIH}	—	2.0	—	—	V
Input low level voltage	V_{FSIL}	—	—	—	0.8	V
Differential input sensitivity	V_{FSDI}	|(USB_DP) − (USB_DM)|	0.2	—	—	V
Differential common mode range	V_{FSCM}	—	0.8	—	2.5	V
Output low level voltage	V_{FSOL}	IFSOL = 2 mA	0.0	—	0.3	V
Output high level voltage	V_{FSOH}	IFSOH = −200 µA	2.8	—	3.6	V
Output signal crossover voltage	V_{FSCRS}	—	1.3	—	2.0	V

	$I_{VCC1833_0}$	*1	—	9	—	mA
	$I_{VCC1833_1}$	*1	—	9	—	mA
	$I_{VCC1833_2}$	*1	—	9	—	mA
	$I_{VCC1833_3}$	*1	—	9	—	mA
	$I_{VCC1833_4}$	*1	—	9	—	mA
	I_{VCC18_PLL0}	—	—	—	6	mA
	I_{VCC18_PLL1}	—	—	—	6	mA
	I_{VCC18_USB}	—	—	—	39	mA
	I_{VCC18_ADC0}	—	—	—	3	mA
	I_{VCC18_ADC1}	—	—	—	3	mA
	I_{VCC18_TSU}		—	—	2	mA
	I_{VCC33_USB}	—	—	—	6	mA
Low power consumption mode*2	I_{vdd}	All modules inactive	—	6	—	mA
	I_{VCC33}	—	—	6	—	mA
	$I_{VCC1833_0}$	—	—	2	—	mA
	$I_{VCC1833_1}$	—	—	2	—	mA
	$I_{VCC1833_2}$	—	—	2	—	mA
	$I_{VCC1833_3}$	—	—	2	—	mA
	$I_{VCC1833_4}$	—	—	2	—	mA
	I_{VCC18_PLL0}	—	—	3.5	—	mA
	I_{VCC18_PLL1}	—	—	0.1	—	mA
	I_{VCC18_USB}	—	—	0.5	—	mA
	I_{VCC18_ADC0}	—	—	0.2	—	mA
	I_{VCC18_ADC1}	—	—	0.2	—	mA
	I_{VCC18_TSU}	—	—	0.1	—	mA
	I_{VCC33_USB}	—	—	0.3	—	mA

Note: These values are reference values. The actual operating current greatly depends on the system (such as unsharpened waveforms due to I/O load and toggle frequency). Be sure to measure these current values in the system.

Note 1. IO supply current (I_{VCC33}, $I_{VCC1833_n\ (n = 0\ to\ 4)}$) should be 80 mA or less. (ΣIOH in Table 48.11)

Note 2. All applicable modules are stopped or standby mode with the lowest clock frequency setting, no pull-up/down or operation for all I/O ports, and room temperature.

Table 48.11 Permissible Output Currents

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Permissible output low current (max. value per pin)	IOL	All output pins	—	—	12	mA
Permissible output low current (total)	ΣIOL	Sum of all output pins	—	—	80	mA
Permissible output high current (max. value per pin)	IOH	All output pins	—	—	-12	mA
Permissible output high current (total)	ΣIOH	Sum of all output pins	—	—	-80	mA

Note: All output current values shall be within the values in this table to ensure the reliability of this LSI.

Table 48.12 Thermal Resistance value (Reference)

Item	Symbol	Package	Max.	Unit
Thermal Resistance	Θja	225 pin FBGA 13 × 13 mm, 0.8-mm pitch	30.1	°C/W
		121 pin FBGA 10 × 10 mm, 0.8-mm pitch	30.5	°C/W
	Ψjt	225 pin FBGA 13 × 13 mm, 0.8-mm pitch	0.42	°C/W
		121 pin FBGA 10 × 10 mm, 0.8-mm pitch	0.42	°C/W

Note: Package thermal resistance values above are based on EIA/JESD51-9 (2s2p) condition and reference only.

48.5 AC Characteristics

Table 48.13 Operating frequency

Parameter		Symbol	Min.	Max.	Unit
Operating frequency	CPU clock (CPU0CLK)	f	150 200	300 400	MHz
	System clock (ICLK)		150	200	
	Peripheral module clock H (PCLKH)		150	200	
	Peripheral module clock M (PCLKM)		75	100	
	Peripheral module clock L (PCLKL)		37.5	50	
	Peripheral module clock for ADC (PCLKADC)		18.75	25	
	Peripheral module clock for SCIn (PCLKSCIn, n = 0 to 5)		75	100	
	Peripheral module clock for SPIn (PCLKSPIn, n = 0 to 3)		75	100	
	External bus clock output (CKIO)		18.75	100	
	Ethernet PHY reference clock (ETHn_REFCLK, n = 0 to 2)		25		
	Ethernet PHY reference clock (RMIIn_REFCLK, n = 0 to 2)		50		

AC Characteristics are defined in condition of the IO setting (DRCTLm register setting) show in Table 48.14.

Table 48.14 IO setting (DRCTLm register setting) condition (1 of 2)

Module	Signal		IO type	Voltage	DRCTLm register		
					DRVn	SRn	SMTn
Bus	CKIO	SDRAM and High drive	—	3.3 V	High	Fast	—
		Other than the above	—	3.3 V	Middle	Fast	—
	Other than the above		Type A	3.3 V	Middle	Slow	Disable
			Type B	3.3 V	Low	Slow	Disable
DMAC, MTU3, IIC, CANFD, DSMIF	All signals		Type A	3.3 V	Middle	Slow	Disable
			Type B	3.3 V	Low	Slow	Disable

Table 48.14 IO setting (DRCTLm register setting) condition (2 of 2)

Module	Signal	IO type	Voltage	DRCTLm register		
				DRVn	SRn	SMTn
GPT (n = 0 to 17) (m = 0, 1)	GTIOCnA, GTIOCnB	Type A	3.3 V	Middle	Slow	Disable
		Type B	3.3 V	Low	Slow	Disable
	GTADSMLm, GTADSMPm	—	3.3 V	Low	Slow	Disable
SCI, SPI	All signals	—	3.3 V	High	Fast	Disable
xSPI (n = 0, 1; m = 0, 1)	XSPIn_CKP, XSPIn_CKN, XSPIn_IO[7:0], XSPIn_CSm#, XSPIn_DS	—	1.8 V	High	Fast	Disable
		—	3.3 V	High	Fast	Enable
	Other than the above	—	—	Low	Slow	Disable
Ethernet Interface (n = 0 to 2)	ETHn_TXCLK, ETHn_TXD[3:0]	—	1.8 V/3.3 V	High	Fast	Disable
	ETHn_TXER	—	3.3 V	Middle	Fast	—
	ETHn_RXCLK, ETHn_RXD[3:0]	—	1.8 V/3.3 V	—	—	Disable
	ETHn_RXER, ETHn_COL, ETHn_CRS	—	3.3 V	—	—	Disable
	ETHn_REFCLK, RMIIn_REFCLK	—	3.3 V	High	Fast	—
	Other than the above	—	—	Low	Slow	Disable
SHOSTIF	HSPI_CK, HSPI_CS#, HSPI_IO[7:0]	—	1.8 V/3.3 V	High	Fast	Disable
	HSPI_INT#	—	1.8 V/3.3 V	Low	Slow	Disable
PHOSTIF	All signals	Type A	3.3 V	Middle	Slow	Disable
		Type B	3.3 V	Low	Slow	Disable
Debug Interface	TRACECLK, TRACECTL, TRACEDATA[7:0], TDO, TMS	—	3.3 V	High	Fast	Disable
	Other than the above	—	—	Low	Slow	Disable
Other than the above		—	—	Low	Slow	Disable

48.5.1 Clock Timing

48.5.1.1 CKIO Pin Output Timing

Table 48.15 CKIO pin output timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
CKIO pin output cycle time	t_{CKcyc}	Figure 48.2	10	—	53.4	ns
CKIO pin output high level pulse width	t_{CKH}		t_{CKcyc} / 2 − t_{CKr}	—	—	ns
CKIO pin output low level pulse width	t_{CKL}		t_{CKcyc} / 2 − t_{CKf}	—	—	ns
CKIO pin output rising time 1	t_{CKr}	CKIO: High drive output Setting	—	—	3.8	ns
CKIO pin output falling time 1	t_{CKf}		—	—	3.8	ns
CKIO pin output rising time 2	t_{CKr}	CKIO: Normal output setting	—	—	9	ns
CKIO pin output falling time 2	t_{CKf}		—	—	9	ns

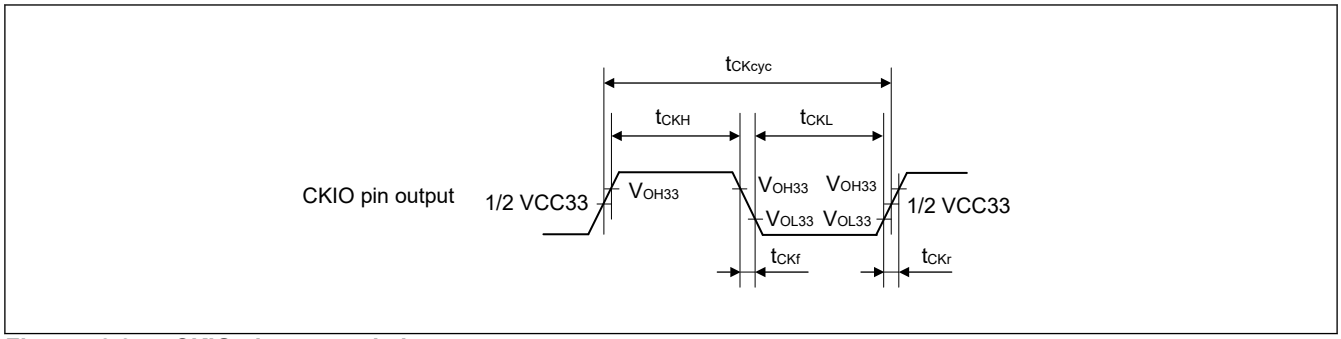

Figure 48.2 CKIO pin output timing

48.5.1.2 Ethernet PHY Reference Clock Output Timing

Conditions:

C = 30 pF (ETHn_REFCLK)

C = 20 pF (RMIIn_REFCLK)

Table 48.16 Ethernet PHY reference clock output timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
ETHn_REFCLK cycle time	t_{CK}	Figure 48.3	40	—	—	ns
ETHn_REFCLK frequency	—		25.00 ± 50 ppm			MHz
ETHn_REFCLK duty	—		45	—	55	%
ETHn_REFCLK rising/falling time	t_{CKr} / t_{CKf}		0.5	—	4.0	ns
RMIIn_REFCLK cycle time	t_{CK}		20	—	—	ns
RMIIn_REFCLK frequency	—		50.00 ± 50 ppm			MHz
RMIIn_REFCLK duty	—		45	—	55	%
RMIIn_REFCLK rising/falling time	t_{CKr} / t_{CKf}		0.5	—	3.5	ns

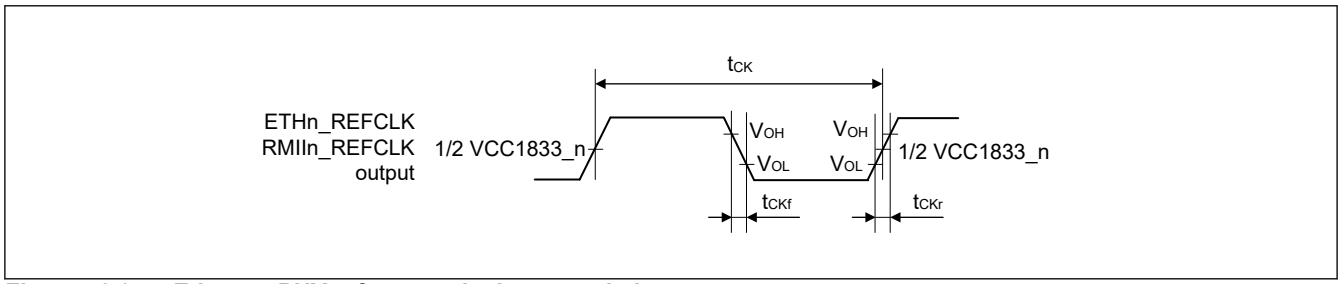

Figure 48.3 Ethernet PHY reference clock output timing

48.5.1.3 EXTCLKIN External Clock Input

Table 48.17 EXTCLKIN clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
EXTCLKIN external clock frequency	$f_{EXTCLKIN}$	—	25.00 ± 50 ppm			MHz
		EtherCAT in use	25.00 ± 25 ppm			MHz
EXTCLKIN duty	$r_{EXTCLKIN}$	—	±5%			—
EXTCLKIN rising time	$t_{rEXTCLKIN}$	—	0	—	5	ns
EXTCLKIN falling time	$t_{fEXTCLKIN}$	—	0	—	5	ns

Note: When using crystal resonator (i.e. EXTA/XTAL clock is used), EXTCLKIN should be driven low.

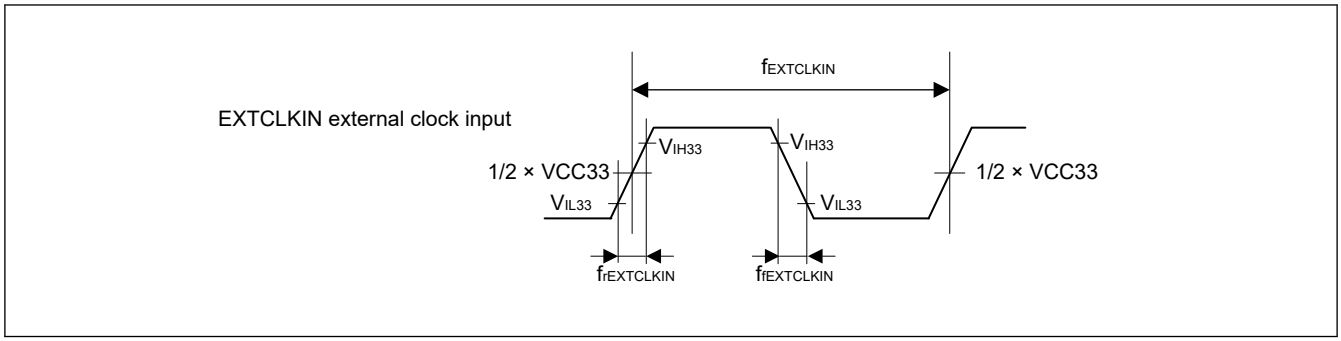

Figure 48.4 EXTCLKIN external clock input timing

48.5.1.4 EXTAL/XTAL Clock Timing

Table 48.18 EXTAL/XTAL clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
EXTAL/XTAL clock frequency*1	f_{XTAL}	—	25.00 ± 50 ppm			MHz
		EtherCAT in use	25.00 ± 25 ppm			MHz

Note: When using an external oscillator, be sure to leave XTAL open-circuit and make sure that EXTAL is driven low.
Note 1. When using the EXTAL/XTAL clock (i.e. crystal resonator), ask the oscillator manufacturer to evaluate oscillation of the oscillator. For the oscillation stabilization time, see the evaluation result provided by the oscillator manufacturer.

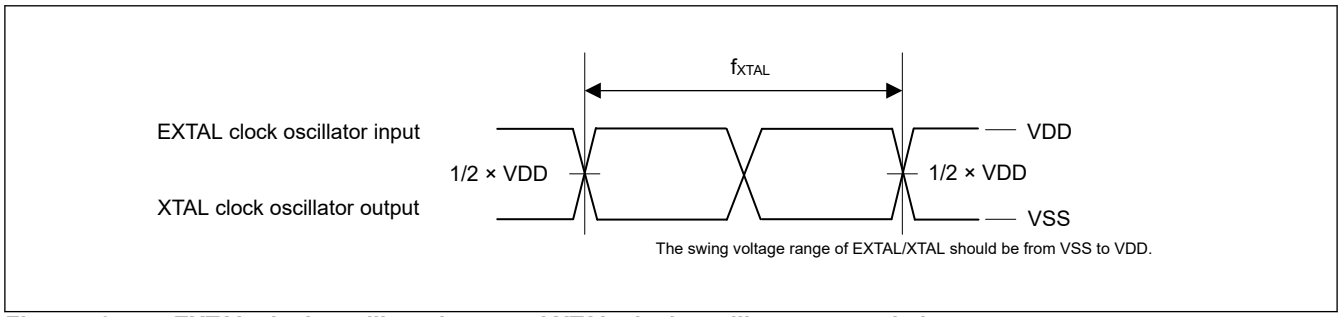

Figure 48.5 EXTAL clock oscillator input and XTAL clock oscillator output timing

48.5.1.5 LOCO Clock Timing

Table 48.19 LOCO clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
LOCO clock cycle time	t_{Lcyc}	—	4.62	4.17	3.79	µs
LOCO clock oscillation frequency	t_{LOCO}	—	216	240	264	kHz
LOCO clock oscillation stabilization wait time	t_{LOCOWT}	—	—	—	40	µs

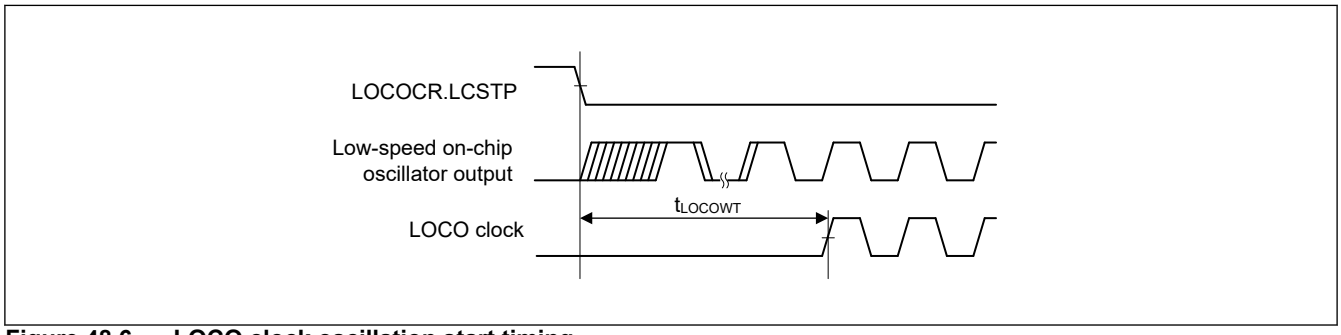

Figure 48.6 LOCO clock oscillation start timing

48.5.2 Reset, Interrtup, and Mode Timing

Table 48.20 Reset, interrupt, and mode timing

Parameter		Symbol	Conditions	Min.*1	Typ.	Max.	Unit
RES# pulse width	At power on	$t_{dlyreset}$	Figure 48.7	10	—	—	ms
	Other than above	$t_{dlyreset2}$		1	—	—	ms
RES# rising time		$t_{risereset}$		—	—	150	µs
TRST# pulse width	At power on	$t_{dlyreset}$		10	—	—	ms
	Other than above	$t_{dlyreset2}$		1	—	—	ms
TRST# rising time		$t_{risereset}$		—	—	150	µs
NMI pulse width		t_{NMIW}	Figure 48.8	t_{Icyc} × 2	—	—	ns
IRQ pulse width		t_{IRQW}	Figure 48.9	t_{Icyc} × 2	—	—	ns
Mode hold time (to RES#)	At power on	t_{MDH}	Figure 48.10	250	—	—	ns

Note 1. t_{Icyc}: ICLK cycle

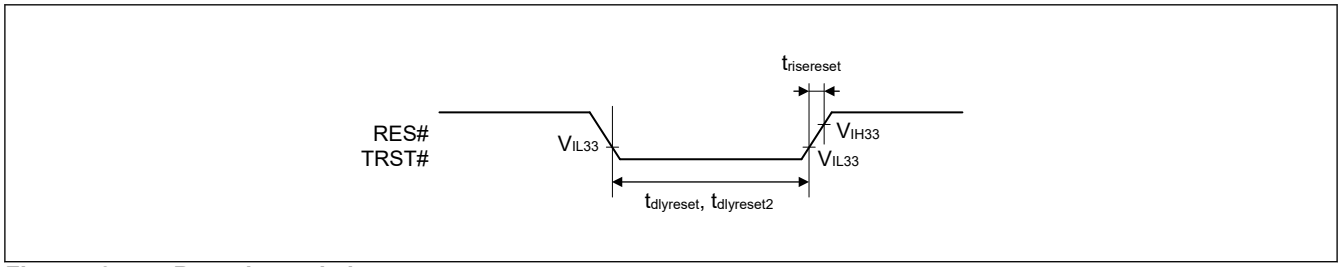

Figure 48.7 Reset input timing

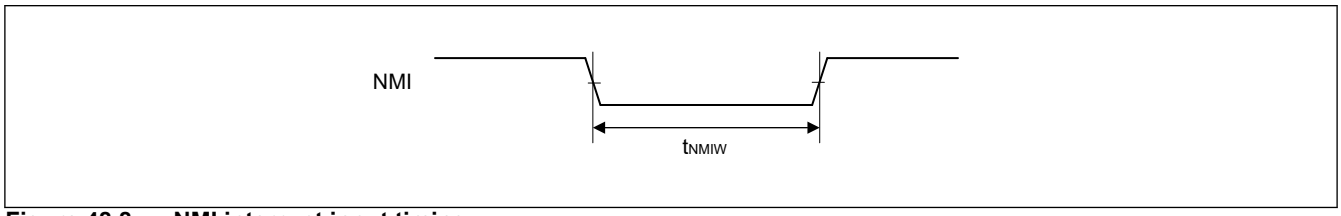

Figure 48.8 NMI interrupt input timing

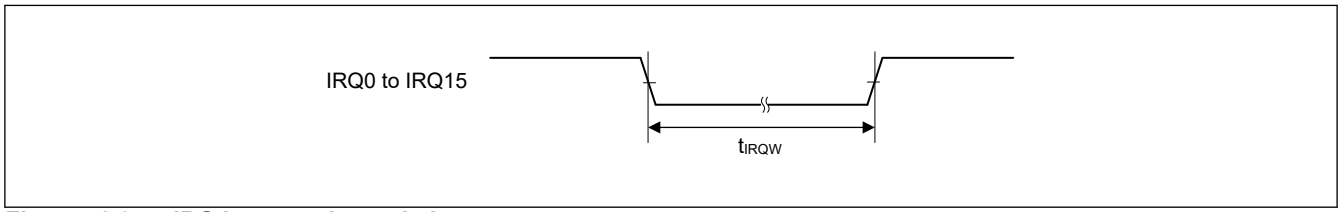

Figure 48.9 IRQ interrupt input timing

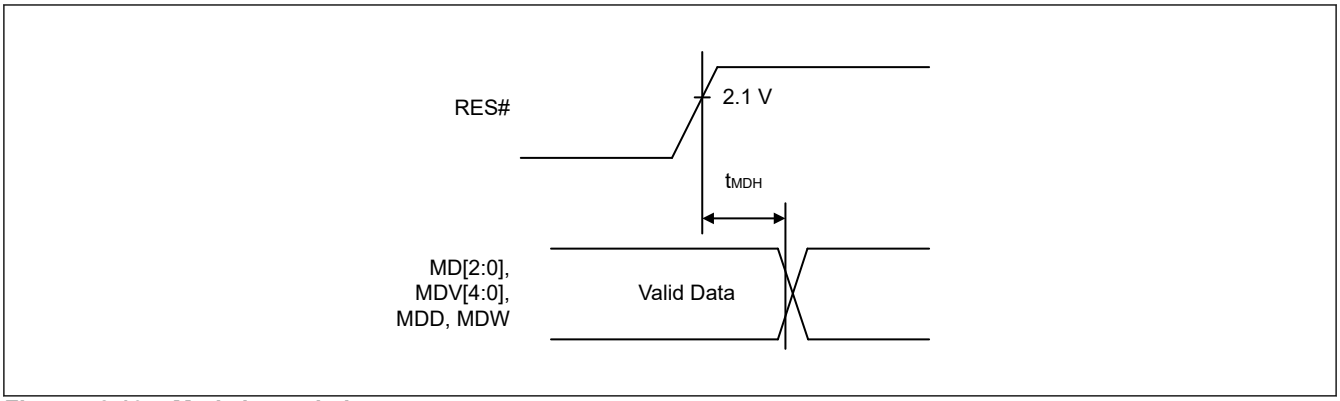

Figure 48.10 Mode input timing

48.5.3 Bus Timing

Table 48.21 Bus timing (1 of 2)

Conditions: V_{OH} = VCC33 × 0.5, V_{OL} = VCC33 × 0.5, C = 15 pF (CKIO), 30 pF (others), $T_j$min = -40°C

Parameter		Symbol	CKIO = $1/t_{CKcyc}$ *1 (Max 66 MHz)		Unit	Reference Figure
			Min.	Max.		
Address delay time 1	SDRAM*2	t_{AD1}	2	11	ns	Figure 48.11 to Figure 48.35

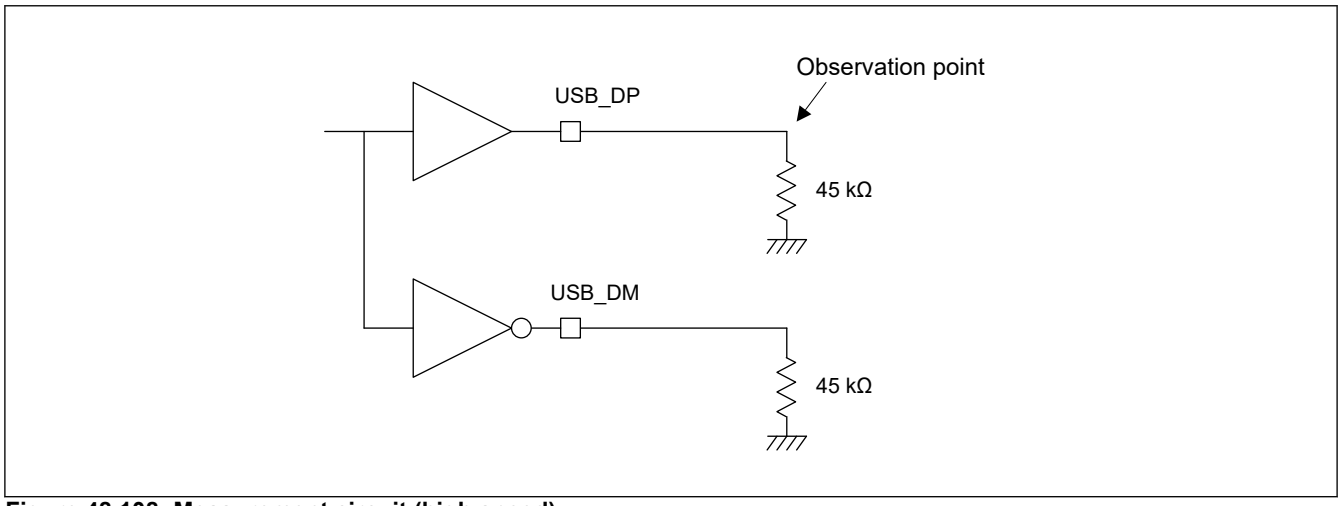

Figure 48.108 Measurement circuit (high speed)

48.7 A/D Conversion Characteristics

Table 48.48 12-Bit A/D (unit 0) conversion characteristics

Parameter		Min.	Typ.	Max.	Unit	Reference figure
Resolution		12			bits	—
Analog input capacitance		—	—	13	pF	—
Channel-dedicated sample-and-hold circuits in use (AN000 to AN002)	Conversion time*1 Permissible signal source impedance Max. = 1.0 kΩ	1.52	—	—	µs	—
	Offset error	—	—	±13	LSB	—
	Full-scale error	—	—	±13	LSB	—
	Quantization error	—	±0.5	—	LSB	—
	Absolute accuracy	—	—	±14	LSB	—
	DNL differential non-linearity error	—	—	±3	LSB	—
	INL integral non-linearity error	—	—	±4	LSB	—
	Holding characteristics of sample-and-hold circuits	—	—	2.67	µs	—
	Dynamic range	0.15	—	VREFH0 - 0.15	V	—
Channel-dedicated sample-and-hold circuits not in use (AN000 to AN007)	Conversion time*1 Permissible signal source impedance Max. = 1.0 kΩ	0.84	—	—	µs	—
	Offset error	—	—	±11	LSB	—
	Full-scale error	—	—	±11	LSB	—
	Quantization error	—	±0.5	—	LSB	—
	Absolute accuracy	—	—	±12	LSB	—
	DNL differential non-linearity error	—	—	±3	LSB	—
	INL integral non-linearity error	—	—	±4	LSB	—

Note: The specified values in the table apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the specified ranges.

Note 1. The conversion time is the total of the sampling time and the comparison time.

Table 48.49 12-Bit A/D (unit 1) conversion characteristics

Parameter		Min.	Typ.	Max.	Unit	Reference figure
Resolution		12			bits	—
Conversion time*1	Permissible signal source impedance Max = 1.0 kΩ	0.84	—	—	µs	—
Analog input capacitance		—	—	13	pF	—
Offset error		—	—	±11	LSB	—
Full-scale error		—	—	±11	LSB	—
Quantization error		—	±0.5	—	LSB	—
Absolute accuracy		—	—	±12	LSB	—
DNL differential non-linearity error		—	—	±3	LSB	—
INL integral non-linearity error		—	—	±4	LSB	—

Note: The specified values in the table apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the specified ranges.

Note 1. The conversion time is the total of the sampling time and the comparison time.

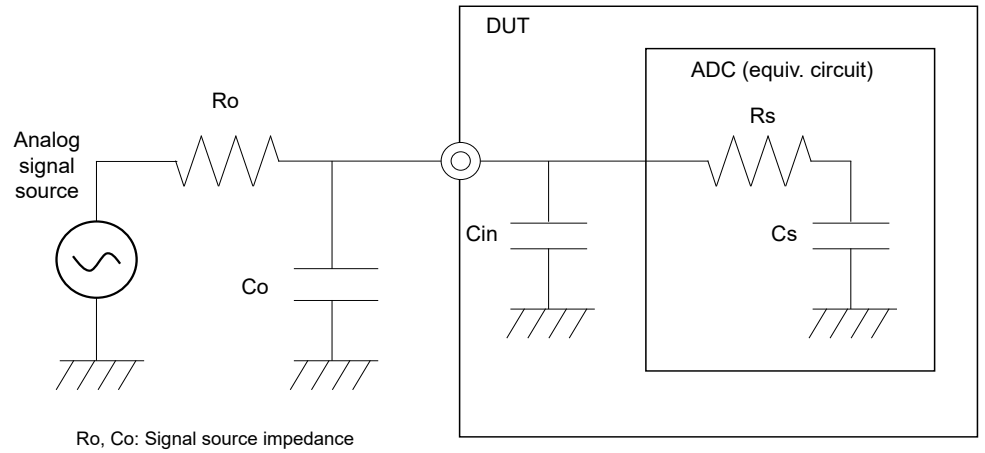

Figure 48.109 A/D converter equivalent circuit and peripheral configuration diagram

48.8 Temperature Sensor Characteristics

Table 48.50 Temperature sensor characteristics

Parameter	Min.	Typ.	Max.	Unit	Test Conditions
Relative accuracy	—	±1	—	°C	*1
Temperature slope	—	0.0625	—	°C/LSB	—
Output code (at 25°C)	—	1545 (decimal)	—	—	TSUSAD register

Note 1. 2-point calibration (Tj = 25℃ and Tj = 85℃) and 8 times averaging. For details of 2-point calibration, see section 41.3.6.1. Preparation for Using the Temperature Sensor.

48.9 Debug Interface Timing

Condition: V_{OH} = VCC33 × 0.5, V_{OL} = VCC33 × 0.5

Table 48.51 Debug interface timing (1 of 2)

Parameter		Symbol	Min.	Max.	Unit	Reference figure
TCK cycle time	With an ICE connected	t_{TCKcyc}	30*1	—	ns	Figure 48.110
	For use in BSCAN		80	—		
TCK high pulse width		t_{TCKH}	0.4	0.6	t_{TCKcyc}	
TCK low pulse width		t_{TCKL}	0.4	0.6	t_{TCKcyc}	
TDI setup time		t_{TDIS}	5	—	ns	Figure 48.111 Output load: 30 pF
TDI hold time		t_{TDIH}	5	—	ns	
TMS/SWDIO setup time		t_{TMSS}	5	—	ns	
TMS/SWDIO hold time		t_{TMSH}	5	—	ns	
SWDIO delay time		t_{SWDO}	—	15	ns	
TDO delay time	With an ICE connected	t_{TDOD}	—	15	ns	
	For use in BSCAN		—	22		

Table 48.51 Debug interface timing (2 of 2)

Parameter		Symbol	Min.	Max.	Unit	Reference figure
Capture register setup time		t_{CAPTS}	5	—	ns	Figure 48.112
Capture register hold time		t_{CAPTH}	5	—	ns	
Update register delay time		$t_{UPDATED}$	—	15	ns	
Trace clock cycle		t_{TCYC}	20	—	ns	Figure 48.113 Output load: 15 pF
Trace data delay time	Trace clock: P18_6	t_{TDT}	-2.9	3.2	ns	
	Trace clock: P17_4		-2.8	3.3		
	Trace clock: P22_2		-2.2*2	4.0		

Note 1. This value is the minimum cycle time for the normal operation of internal circuits.
The actual cycle time should be determined in consideration of the TCK capture edge timing and cable length of the connected ICE.
Note 2. If P22_1 is not used as trace control, this value is -1.8 ns.

Appendix 1. Peripheral I/O Registers

This appendix describes pheripheral I/O register addresses, access type, and reset values by function.

1.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual.

Table 1.1 shows the name, description, and the base address of each peripheral.

Table 1.1 Peripheral base address (1 of 3)

Name	Description	Base address
GPT7	General PWM Timer 7	0x80000000
GPT8	General PWM Timer 8	0x80000100
GPT9	General PWM Timer 9	0x80000200
GPT10	General PWM Timer 10	0x80000300
GPT11	General PWM Timer 11	0x80000400
GPT12	General PWM Timer 12	0x80000500
GPT13	General PWM Timer 13	0x80000600
SCI0	Serial Communication Interface 0	0x80001000
SCI1	Serial Communication Interface 1	0x80001400
SCI2	Serial Communication Interface 2	0x80001800
SCI3	Serial Communication Interface 3	0x80001C00
SCI4	Serial Communication Interface 4	0x80002000
SPI0	Serial Peripheral Interface 0	0x80003000
SPI1	Serial Peripheral Interface 1	0x80003400
SPI2	Serial Peripheral Interface 2	0x80003800
CRC0	CRC Unit 0	0x80004000
CANFD	CAN-FD	0x80020000
CMTC	Compare Match Timer Control	0x80040000
CMT0	Compare Match Timer 0	0x80040002
CMT1	Compare Match Timer 1	0x80040008
CMT2	Compare Match Timer 2	0x80040402
CMT3	Compare Match Timer 3	0x80040408
CMT4	Compare Match Timer 4	0x80040802
CMT5	Compare Match Timer 5	0x80040808
CMTW0	Compare Match Timer W	0x80041000
CMTW1	Compare Match Timer W	0x80041400

Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

1.2 Register Descriptions

This section provides information associated with registers described in this manual.

Table 1.2 shows a list of registers including address offsets, address sizes, access rights, and reset values.

Table 1.2 Register description (1 of 51)

Peripheral name	Dim	Dim inc.	Dim index	Register name	Description	Address offset	Size	R/W	Reset value	Reset mask
GPT7-13	—	—	—	GTWP	General PWM Timer Write-Protection Register	0x00	32	R/W	0x00000000	0xFFFFFFFF
GPT7-13	—	—	—	GTSTR	General PWM Timer Software Start Register	0x04	32	R/W	0x00000000	0xFFFFFFFF
GPT7-13	—	—	—	GTSTP	General PWM Timer Software Stop Register	0x08	32	R/W	0xFFFFFFFF	0xFFFFFFFF
GPT7-13	—	—	—	GTCLR	General PWM Timer Software Clear Register	0x0C	32	W	0x00000000	0xFFFFFFFF
GPT7-13	—	—	—	GTSSR	General PWM Timer Start Source Select Register	0x10	32	R/W	0x00000000	0xFFFFFFFF
GPT7-13	—	—	—	GTPSR	General PWM Timer Stop Source Select Register	0x14	32	R/W	0x00000000	0xFFFFFFFF
GPT7-13	—	—	—	GTCSR	General PWM Timer Clear Source Select Register	0x18	32	R/W	0x00000000	0xFFFFFFFF

Table 1.2 Register description (19 of 51)

Peripheral name	Dim	Dim inc.	Dim index	Register name	Description	Address offset	Size	R/W	Reset value	Reset mask
ETHSW	—	—	—	TSM_IRQ_STAT_ACK	Interrupt Status/Acknowledge Register	0x508	32	R/W	0x00000000	0x000F3337
ETHSW	—	—	—	PTP_DOMAIN	Domain Number of PTP Frame	0x50C	32	R/W	0x00000000	0x0000FFFF
ETHSW	4	0x10	0-3	PEERDELAY_P%s_T0	Port %s Peer Delay Value for Timer 0 (n = 0 to 3)	0x540	32	R/W	0x00000000	0x3FFFFFFF
ETHSW	4	0x10	0-3	PEERDELAY_P%s_T1	Port %s Peer Delay Value for Timer 1 (n = 0 to 3)	0x544	32	R/W	0x00000000	0x3FFFFFFF
ETHSW	—	—	—	TS_FIFO_STATUS	Transmit Timestamp FIFO Status Register	0x5C0	32	R/W	0x00000000	0x000F000F
ETHSW	—	—	—	TS_FIFO_READ_CTRL	Transmit Timestamp FIFO Read Control Register	0x5C4	32	R/W	0x00000000	0x00007F5F
ETHSW	—	—	—	TS_FIFO_READ_TIMESTAMP	32-bit Timestamp Value Read from FIFO	0x5C8	32	R	0x00000000	0xFFFFFFFF
ETHSW	—	—	—	INT_CONFIG	Interrupt Enable Configuration Register	0x600	32	R/W	0x00000000	0xF80707FB
ETHSW	—	—	—	INT_STAT_ACK	Interrupt Status/ACK Register	0x604	32	R/W	0x00000000	0xF80707FB
ETHSW	2	0x20	0-1	ATIME_CTRL%s	Timer %s Control Register (n = 0, 1)	0x680	32	R/W	0x00000000	0x00001A37
ETHSW	2	0x20	0-1	ATIME%s	Timer %s Count Register (n = 0, 1)	0x684	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	2	0x20	0-1	ATIME_OFFSET%s	Timer %s Offset Register (n = 0, 1)	0x688	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	2	0x20	0-1	ATIME_EVT_PERIOD%s	Timer %s Periodic Event Register (n = 0, 1)	0x68C	32	R/W	0x3B9ACA00	0xFFFFFFFF
ETHSW	2	0x20	0-1	ATIME_CORR%s	Timer %s Correction Period Register (n = 0, 1)	0x690	32	R/W	0x00000000	0x7FFFFFFF
ETHSW	2	0x20	0-1	ATIME_INC%s	Timer %s Increment Register (n = 0, 1)	0x694	32	R/W	0x00000000	0x007F7F7F
ETHSW	2	0x20	0-1	ATIME_SEC%s	Timer %s Seconds Time Register (n = 0, 1)	0x698	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	2	0x20	0-1	ATIME_OFFS_CORR%s	Timer %s Offset Correction Counter Register (n = 0, 1)	0x69C	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	—	—	—	MDIO_CFG_STATUS	MDIO Configuration and Status Register	0x700	32	R/W	0x00001400	0x0000FFFF
ETHSW	—	—	—	MDIO_COMMAND	MDIO PHY Command Register	0x704	32	R/W	0x00000000	0x000083FF
ETHSW	—	—	—	MDIO_DATA	MDIO Data Register	0x708	32	R/W	0x00000000	0x0000FFFF
ETHSW	4	0x400	0-3	REV_P%s	Port %s MAC Core Revision (n = 0 to 3)	0x800	32	R	0x00010002	0xFFFFFFFA
ETHSW	4	0x400	0-3	COMMAND_CONFIG_P%s	Port %s Command Configuration Register (n = 0 to 3)	0x808	32	R/W	0x01000813	0x4F803FFF
ETHSW	3	0x400	0-2	MAC_ADDR_0_P%s	Port %s MAC Address Register 0 (n = 0 to 2)	0x80C	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	3	0x400	0-2	MAC_ADDR_1_P%s	Port %s MAC Address Register 1 (n = 0 to 2)	0x810	32	R/W	0x00000000	0x0000FFFF
ETHSW	4	0x400	0-3	FRM_LENGTH_P%s	Port %s Maximum Frame Length Register (n = 0 to 3)	0x814	32	R/W	0x000005FE	0x00003FFF
ETHSW	4	0x400	0-3	PAUSE_QUANT_P%s	Port %s MAC Pause Quanta (n = 0 to 3)	0x818	32	R	0x0000FFFF	0x0000FFFF
ETHSW	3	0x400	0-2	MAC_LINK_QTRIG_P%s	Port %s Trigger Event Configuration Register (n = 0 to 2)	0x81C	32	R/W	0x00000000	0xF0FF000F
ETHSW	3	0x400	0-2	PTPCLOCKIDENTITY1_P%s	Port %s PTP Clock Identity 1 Register (n = 0 to 2)	0x830	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	3	0x400	0-2	PTPCLOCKIDENTITY2_P%s	Port %s PTP Clock Identity 2 Register (n = 0 to 2)	0x834	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	3	0x400	0-2	PTPAUTORESPONSE_P%s	Port %s PTP Auto Response Register (n = 0 to 2)	0x838	32	R/W	0x00000000	0xFFFF0003
ETHSW	4	0x400	0-3	STATUS_P%s	Port %s Status Register	0x840	32	R/W	0x00000008	0x000001FC
ETHSW	4	0x400	0-3	TX_IPG_LENGTH_P%s	Port %s Transmit IPG Length Register (n = 0 to 3)	0x844	32	R/W	0x0000000C	0x0011001F
ETHSW	3	0x400	0-2	EEE_CTL_STAT_P%s	Port %s MAC EEE Functions Control and Status (n = 0 to 2)	0x848	32	R/W	0x00000000	0x00171F07
ETHSW	3	0x400	0-2	EEE_IDLE_TIME_P%s	Port %s EEE Idle Time Register (n = 0 to 2)	0x84C	32	R/W	0x00000000	0xFFFFFFFF

Table 1.2 Register description (20 of 51)

Peripheral name	Dim	Dim inc.	Dim index	Register name	Description	Address offset	Size	R/W	Reset value	Reset mask
ETHSW	3	0x400	0-2	EEE_TWSYS_TIME_P%s	Port %s EEE Wake Up Time Register (n = 0 to 2)	0x850	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	—	—	—	IDLE_SLOPE_Pn	Port n MAC Traffic Shaper Bandwidth Control (n = 0 to 3)	0x854	32	R/W	0x00000000	0x000007FF
ETHSW	—	—	—	CT_DELAY_Pn	Port n Cut-Through Delay Indication Register (n = 0 to 2)	0x858	32	R/W	0x00000000	0x000001FF
ETHSW	3	0x400	0-2	BR_CONTROL_P%s	Port %s 802.3br Frame Configuration Register	0x85C	32	R/W	0x00000A00	0x001F7F37
ETHSW	4	0x400	0-3	AFRAMESTRANSMITTEDOK_P%s	Port %s MAC Transmitted Valid Frame Count Register (n = 0 to 3)	0x868	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AFRAMESRECEIVEDOK_P%s	Port %s MAC Received Valid Frame Count Register (n = 0 to 3)	0x86C	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AFRAMECHECKSEQUENCEERRORS_P%s	Port %s MAC FCS Error Frame Count Register (n = 0 to 3)	0x870	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AALIGNMENTERRORS_P%s	Port %s MAC Alignment Error Frame Count Register (n = 0 to 3)	0x874	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AOCTETSTRANSMITTEDOK_P%s	Port %s MAC Transmitted Valid Frame Octets Register (n = 0 to 3)	0x878	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AOCTETSRECEIVEDOK_P%s	Port %s MAC Received Valid Frame Octets Register (n = 0 to 3)	0x87C	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ATXPAUSEMACCTRLFRAMES_P%s	Port %s MAC Transmitted Pause Frame Count Register (n = 0 to 3)	0x880	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ARXPAUSEMACCTRLFRAMES_P%s	Port %s MAC Received Pause Frame Count Register (n = 0 to 3)	0x884	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFINERRORS_P%s	Port %s MAC Input Error Count Register (n = 0 to 3)	0x888	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFOUTERRORS_P%s	Port %s MAC Output Error Count Register (n = 0 to 3)	0x88C	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFINUCASTPKTS_P%s	Port %s MAC Received Unicast Frame Count Register (n = 0 to 3)	0x890	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFINMULTICASTPKTS_P%s	Port %s MAC Received Multicast Frame Count Register (n = 0 to 3)	0x894	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFINBROADCASTPKTS_P%s	Port %s MAC Received Broadcast Frame Count Register (n = 0 to 3)	0x898	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFOUTDISCARDS_P%s	Port %s MAC Discarded Outbound Frame Count Register (n = 0 to 3)	0x89C	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFOUTUCASTPKTS_P%s	Port %s MAC Transmitted Unicast Frame Count Register (n = 0 to 3)	0x8A0	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFOUTMULTICASTPKTS_P%s	Port %s MAC Transmitted Multicast Frame Count Register (n = 0 to 3)	0x8A4	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	IFOUTBROADCASTPKTS_P%s	Port %s MAC Transmitted Broadcast Frame Count Register (n = 0 to 3)	0x8A8	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSDROPEVENTS_P%s	Port %s MAC Dropped Frame Count Register (n = 0 to 3)	0x8AC	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSOCTETS_P%s	Port %s MAC All Frame Octets Register (n = 0 to 3)	0x8B0	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS_P%s	Port %s MAC All Frame Count Register (n = 0 to 3)	0x8B4	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSUNDERSIZEPKTS_P%s	Port %s MAC Too Short Frame Count Register (n = 0 to 3)	0x8B8	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSOVERSIZEPKTS_P%s	Port %s MAC Too Long Frame Count Register (n = 0 to 3)	0x8BC	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS64OCTETS_P%s	Port %s MAC 64 Octets Frame Count Register (n = 0 to 3)	0x8C0	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS65TO127OCTETS_P%s	Port %s MAC 65 to 127 Octets Frame Count Register (n = 0 to 3)	0x8C4	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS128TO255OCTETS_P%s	Port %s MAC 128 to 255 Octets Frame Count Register (n = 0 to 3)	0x8C8	32	R	0x00000000	0xFFFFFFFF

Table 1.2 Register description (21 of 51)

Peripheral name	Dim	Dim inc.	Dim index	Register name	Description	Address offset	Size	R/W	Reset value	Reset mask
ETHSW	4	0x400	0-3	ETHERSTATSPKTS256TO511OCTETS_P%s	Port %s MAC 256 to 511 Octets Frame Count Register (n = 0 to 3)	0x8CC	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS512TO1023OCTETS_P%s	Port %s MAC 512 to 1023 Octets Frame Count Register (n = 0 to 3)	0x8D0	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS1024TO1518OCTETS_P%s	Port %s MAC 1024 to 1518 Octets Frame Count Register (n = 0 to 3)	0x8D4	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSPKTS1519TOXOCTETS_P%s	Port %s MAC Over 1519 Octets Frame Count Register (n = 0 to 3)	0x8D8	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSJABBERS_P%s	Port %s MAC Jabbers Frame Count Register (n = 0 to 3)	0x8DC	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ETHERSTATSFRAGMENTS_P%s	Port %s MAC Fragment Frame Count Register (n = 0 to 3)	0x8E0	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	VLANRECEIVEDOK_P%s	Port %s MAC Received VLAN Tagged Frame Count Register (n = 0 to 3)	0x8E8	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	VLANTRANSMITTEDOK_P%s	Port %s MAC Transmitted VLAN Tagged Frame Count Register (n = 0 to 3)	0x8F4	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	FRAMESRETRANSMITTED_P%s	Port %s MAC Retransmitted Frame Count Register (n = 0 to 3)	0x8F8	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	STATS_HIWORD_P%s	Port %s MAC Statistics Counter High Word Register (n = 0 to 3)	0x900	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	STATS_CTRL_P%s	Port %s MAC Statistics Control Register (n = 0 to 3)	0x904	32	R/W	0x00000000	0x00000003
ETHSW	4	0x400	0-3	STATS_CLEAR_VALUELO_P%s	Port %s MAC Statistics Clear Value Lower Register (n = 0 to 3)	0x908	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	STATS_CLEAR_VALUEHI_P%s	Port %s MAC Statistics Clear Value Higher Register (n = 0 to 3)	0x90C	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ADEFERRED_P%s	Port %s MAC Deferred Count Register (n = 0 to 3)	0x910	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AMULTIPLECOLLISIONS_P%s	Port %s MAC Multiple Collision Count Register (n = 0 to 3)	0x914	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ASINGLECOLLISIONS_P%s	Port %s MAC Single Collision Count Register (n = 0 to 3)	0x918	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ALATECOLLISIONS_P%s	Port %s MAC Late Collision Count Register (n = 0 to 3)	0x91C	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	AEXCESSIVECOLLISIONS_P%s	Port %s MAC Excessive Collision Count Register (n = 0 to 3)	0x920	32	R	0x00000000	0xFFFFFFFF
ETHSW	4	0x400	0-3	ACARRIERSENSEERRORS_P%s	Port %s MAC Carrier Sense Error Count Register (n = 0 to 3)	0x924	32	R	0x00000000	0xFFFFFFFF
ETHSW	8	0x028	0-7	P0_QSTMACU%s	Qci Stream Filter Table MAC Address Upper Part	0x2000	32	R/W	0x00000000	0x0001FFFF
ETHSW	8	0x028	0-7	P0_QSTMACD%s	Qci Stream Filter Table MAC Address Downer Part	0x2004	32	R/W	0x00000000	0xFFFFFFFF
ETHSW	8	0x028	0-7	P0_QSTMAMU%s	Qci Stream Filter Table MAC Address Mask Upper Part	0x2008	32	R/W	0x00000000	0x0000FFFF

Table 1.2 Register description (51 of 51)

Peripheral name	Dim	Dim inc.	Dim index	Register name	Description	Address offset	Size	R/W	Reset value	Reset mask
GSC	—	—	—	CNTFID0	Global System Counter Base Frequency ID Register	0x20	32	R/W	0x00000000	0xFFFFFFFF

Note: Peripheral name = Name of peripheral
Dim = Number of elements in an array of registers
Dim inc. = Address increment between two simultaneous registers of a register array in the address map
Dim index = Sub string that replaces the %s placeholder within the register name
Register name = Name of register
Description = Register description
Address offset = Address of the register relative to the base address defined by the peripheral of the register
Size = Bit width of the register
Reset value = Default reset value of a register
Reset mask = Identifies which register bits have a defined reset value

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in "Packages" on the Renesas Electronics Corporation website.

Revision History

Revision 1.00 — June 10, 2022

- Initial release

Revision 1.10 — July 29, 2022

28. Ethernet Switch (ETHSW):

- Changed the register symbol from MEM_WDATAn to ASI_MEM_WDATAn.
- Changed the register symbol from MEM_ADDR to ASI_MEM_ADDR.
- Changed the register symbol from MEM_RDATAn to ASI_MEM_RDATAn.

48. Electrical Characteristics:

- Corrected Table 48.21 Bus timing [Conditions: V_{OH} = VCC33 × 0.5, V_{OL} = VCC33 × 0.5, C = 15 pF (CKIO), 30 pF (others), $T_j$min = -40℃].
- Corrected Table 48.22 Bus timing [Conditions: V_{OH} = VCC33 × 0.5, V_{OL} = VCC33 × 0.5, C = 12 pF (CKIO), 12 pF (others), $T_j$min = -20℃].
